

BQ25123 ウェアラブル向け、700nA 低静止電流、高集積、バッテリー充電管理ソリューション

1 特長

- 1 回の充電あたりのシステム動作時間を増加
 - 構成可能な 300mA 降圧レギュレータ
 - 降圧コンバータがイネーブルの状態 (無負荷) での I_q : 700nA (代表値)
 - 負荷スイッチまたは 100mA LDO 出力を設定可能
 - 最大 300mA の充電電流による高速充電
 - 精度 0.5% のバッテリー電圧レギュレーション (3.6V ~ 4.65V を 10mV 刻みで設定可能)
 - 終端電流を最小 500 μ A に設定可能
 - シンプルな電圧ベースのバッテリー監視
- 占有面積が小さい高集積ソリューション
 - 2.5mm × 2.5mm の WCSP パッケージと 6 個の外付け部品により、最小のソリューションを構築可能
 - 押しボタンによる可変タイマ付きウェイクアップおよびリセット
 - システム電源およびバッテリー充電用の電力パス管理
 - 電力パス管理により 50nA 未満のシップ・モードのバッテリー静止電流を実現し、保管寿命を延長
 - バッテリー充電器は 3.4V ~ 5.5V_{IN} で動作 (5.5V OVP / 20V 耐圧)
 - 入力電流制限、充電電流、終端電流、ステータス出力用の専用ピン
- I²C 通信制御
 - 充電電圧および電流
 - 終端スレッシュホールド
 - 入力電流制限
 - VINDPM スレッシュホールド
 - タイマ・オプション
 - 負荷スイッチ制御
 - フォルトとステータスのための割り込みの制御
 - システム出力電圧の調整
 - LDO 出力電圧を調整可能

2 アプリケーション

- スマートウォッチ、その他のウェアラブル・デバイス
- フィットネス用アクセサリ
- 健康管理用医療アクセサリ
- 充電式玩具

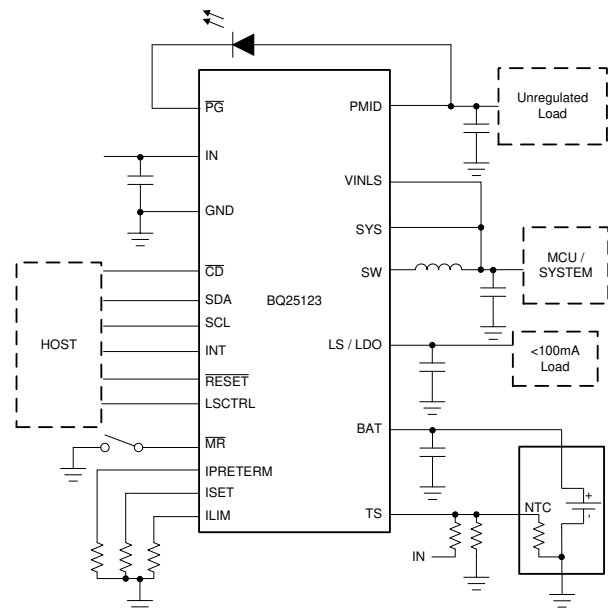

3 概要

BQ25123 は、ウェアラブル・デバイスの最も一般的な機能を統合した高集積バッテリー充電管理 IC です。リニア充電器、レギュレート出力、負荷スイッチ、タイマ付き手動リセット、バッテリー電圧モニタなどが組み込まれています。内蔵の降圧コンバータは高効率の低 I_Q スイッチャーで、DCS 制御を使用して、軽負荷時の効率を最小 10 μ A の負荷電流まで拡張します。動作時およびシャットダウン時の静止電流が小さいため、最大のバッテリー駆動時間が得られます。このデバイスは、5mA ~ 300mA の充電電流をサポートします。入力電流制限、充電電流、降圧コンバータの出力電圧、LDO 出力電圧、その他のパラメータは、I²C インターフェイスからプログラム可能です。

5 Description (continued)

The battery is charged using a standard Li-Ion charge profile with three phases: precharge, constant current and constant voltage. A voltage-based JEITA compatible battery pack thermistor monitoring input (TS) is included that monitors battery temperature and automatically changes charge parameters to prevent the battery from charging outside of its safe temperature range. The charger is optimized for 5-V USB input, with 20-V tolerance to withstand line transients. The buck converter is run from the input or battery. When in battery only mode, the device can run from a battery up to 4.65 V.

A configurable load switch allows system optimization by disconnecting infrequently used devices. The manual reset with timer allows multiple different configuration options for wake are reset optimization. A simple voltage based monitor provides battery level information to the host in 2% increments from 60% to 100% of the programmed $V_{(BATREG)}$.

6 Device Comparison Table

PART NUMBER	VINDPM	DEFAULT SYS OUTPUT	DEFAULT LDO OUTPUT	DEFAULT VBERG	DEFAULT CHARGE CURRENT	DEFAULT TERMINATION CURRENT
BQ25123	Enabled	1.25 V	3 V	4.2 V	10 mA	2 mA

7 Pin Configuration and Functions

图 7-1. YFP Package 25-Pin (DSBGA) Top View

表 7-1. Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
BAT	B1, B2	I/O	Battery Connection. Connect to the positive terminal of the battery. Bypass BAT to GND with at least 1 μF of ceramic capacitance.
$\overline{\text{CD}}$	E2	I	Chip Disable. Drive $\overline{\text{CD}}$ low to place the part in High-Z mode with battery only present, or enable charging when V_{IN} is valid. Drive $\overline{\text{CD}}$ high for Active Battery mode when battery only is present, and disable charge when V_{IN} is present. $\overline{\text{CD}}$ is pulled low internally with 900 k Ω .
GND	A1, D5	-	Ground connection. Connect to the ground plane of the circuit.
ILIM	C2	I	Adjustable Input Current Limit Programming. Connect a resistor from ILIM to GND to program the input current limit. The input current includes the system load and the battery charge current. Connect ILIM to GND to set the input current limit to the internal default threshold. ILIM can also be updated through I ² C.
IN	A2	I	DC Input Power Supply. IN is connected to the external DC supply. Bypass IN to GND with at least 1 μF of capacitance using a ceramic capacitor.
INT	D2	O	Status Output. INT is an open-drain output that signals charging status and fault interrupts. INT pulls low during charging. INT is high impedance when charging is complete, disabled, or the charger is in high impedance mode. When a fault occurs, a 128 μs pulse is sent out as an interrupt for the host. INT charge indicator function is enabled/disabled using the EN_INT bit in the control register. Connect INT to a logic rail using an LED for visual indication of charge status or through a 100k Ω resistor to communicate with the host processor.
IPRETERM	D1	I	Termination current programming input. Connect a 0- Ω to 10-k Ω resistor from IPRETERM to GND to program the termination current between 5% and 20% of the charge current. The pre-charge current is the same as the termination current setting. Connect IPRETERM to GND to set the termination current to the internal default threshold. IPRETERM can also be updated through I ² C.

表 7-1. Pin Functions (continued)

PIN		I/O	DESCRIPTION
NAME	NO.		
ISET	C1	I	Fast-Charge Current Programming Input. Connect a resistor from ISET to GND to program the fast-charge current level. Connect a resistor from ISET to GND to set the charge current to the internal default. ISET can also be updated through I ² C. While charging, the voltage at ISET reflects the actual charging current and can be used to monitor charge current if an ISET resistor is present and the device is not in host mode.
LS/LDO	C5	O	Load Switch or LDO output. Connect 1 μF of effective ceramic capacitance to this pin to assure stability. Be sure to account for capacitance bias voltage derating when selecting the capacitor.
LSCTRL	E3	I	Load Switch and LDO Control Input. Pull high to enable the LS/LDO output, pull low to disable the LS/LDO output.
MR	E1	I	Manual Reset Input. MR is a push-button input that must be held low for greater than t _{RESET} to assert the reset output. If MR is pressed for a shorter period, there are two programmable timer events, t _{WAKE1} and t _{WAKE2} , that trigger an interrupt to the host. The MR input can also be used to bring the device out of Ship mode.
PG	D4	O	Open-drain Power Good status indication output. PG pulls to GND when V _{IN} is above V _(BAT) + V _{SLP} and less than V _{OVP} . PG is high-impedance when the input power is not within specified limits. Connect PG to the desired logic voltage rail using a 1kΩ to 100kΩ resistor, or use with an LED for visual indication. PG can also be configured as a push-button voltage shifted output (MRS) in the registers, where the output of the PG pin reflects the status of the MR input, but pulled up to the desired logic voltage rail using a 1kΩ to 100kΩ resistor.
PGND	A5	-	Power ground connection. Connect to the ground plane of the circuit. Connect the output filter cap from the buck converter to this ground as shown in the layout example.
PMID	A3, B3	I/O	High Side Bypass Connection. Connect at least 3μF of ceramic capacitance with DC bias derating from PMID to GND as close to the PMID and GND pins as possible. When entering Ship Mode, PMID is discharged by a 20-kΩ internal discharge resistor.
RESET	D3	O	Reset Output. RESET is an open drain active low output that goes low when MR is held low for longer than t _{RESET} , which is configurable by the MRRESET registers. RESET is deasserted after the t _{RESET_D} , typically 400ms.
SCL	E5	I	I ² C Interface Clock. Connect SCL to the logic rail through a 10-kΩ resistor.
SDA	E4	I/O	I ² C Interface Data. Connect SDA to the logic rail through a 10-kΩ resistor.
SW	A4	O	Inductor Connection. Connect to the switched side of the external inductor.
SYS	B5	I	System Voltage Sense Connection. Connect SYS to the system output at the output bulk capacitors. Bypass SYS locally with at least 4.7 μF of effective ceramic capacitance.
TS	C3	I	Battery Pack NTC Monitor. Connect TS to the center tap of a resistor divider from VIN to GND. The NTC is connected from TS to GND. The TS function provides four thresholds for JEITA compatibility. TS faults are reported by the I ² C interface during charge mode.
VINLS	B4, C4	I	Input to the Load Switch / LDO output. Connect 1 μF of effective ceramic capacitance from this pin to GND.

8 Specifications

8.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) ⁽¹⁾

			MIN	MAX	UNIT
Input voltage	IN	wrt GND	-0.3	20	V
	PMID, VINLS	wrt GND	-0.3	7.7	V
	CD, SDA, SCL, ILIM, ISET, IPRETERM, LSCTRL, INT, RESET, TS	wrt GND	-0.3	5.5	V
Output voltage	SYS		3.6	V	
Input current	IN		400	mA	
Sink current	INT		10	mA	
Sink/Source current	RESET		10	mA	
Output voltage continuous	SW		-0.7	7.7	V
Output current continuous	SW		400	mA	
	SYS, BAT		300	mA	
Current	LS/LDO		150	mA	
BAT operating voltage	VBAT, MR		6.6	V	
Junction temperature, T _J			-40	125	°C
Storage temperature, T _{stg}				300	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

8.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

8.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{IN}	IN voltage	3.4	5	20	V
	IN operating voltage range, recommended	3.4	5	5.5	
V _(BAT)	V _(BAT) operating voltage			5.5 ⁽¹⁾	V
V _(VINLS)	VINLS voltage range for Load Switch	0.8		5.5 ⁽²⁾	V
V _(VINLS)	VINLS voltage range for LDO	2.2		5.5	V
I _{IN}	Input Current, IN input			400	mA
I _(SW)	Output Current from SW, DC			300	mA
I _(PMID)	Output Current from PMID, DC			300	mA
I _{LS/LDO}	Output Current from LS/LDO			100	mA
I _(BAT) , I _(SYS)	Charging and discharging using internal battery FET			300	mA
T _J	Operating junction temperature	-40		125	°C

- (1) Any voltage greater than shown should be a transient event.

(2) These inputs will support 6.6 V for less than 10% of the lifetime at $V_{(BAT)}$ or V_{IN} , with reduced current and/or performance.

8.4 Thermal Information

THERMAL METRIC ⁽¹⁾		BQ25123	UNIT
		YFP (DSBGA)	
		25 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	60	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	0.3	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	12	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	1.2	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	12	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	N/A	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

8.5 Electrical Characteristics

Circuit of [Figure 8-1](#), $V_{(UVLO)} < V_{IN} < V_{(OVP)}$ and $V_{IN} > V_{(BAT)} + V_{(SLP)}$, $T_J = -40$ to $+85^\circ\text{C}$ and $T_J = 25^\circ\text{C}$ for typical values (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT

9 Detailed Description

9.1 Overview

The following sections describe in detail the functions provided by the BQ25123. These include linear charger, PWM output, configurable LS/LDO output, Push-button input, reset timer, functional modes, battery monitor, I²C configurability and functions, and safety features.

9.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

9.3 Feature Description

9.3.1 Ship Mode

Ship Mode is the lowest quiescent current state for the device. Ship Mode latches off the device and BAT FET until $V_{IN} > V_{BAT} + V_{SLP}$ or the \overline{MR} button is depressed for t_{WAKE1} and released. The following list shows the events that are active during Ship Mode:

1. VIN_UV Comparator
2. \overline{MR} Input (No clock or delay in this mode for lowest power consumption)
3. PMID active pull down

9.3.1.1 Ship Mode Entry and Exit

The device may only enter Ship Mode when there is not a valid VIN supply present ($V_{IN} < V_{UVLO}$). Once the IN supply is removed there are two ways for the device to enter Ship Mode: through I²C command using the EN_SHIPMODE bit and by doing a long button press when MRREC bit is set to 0. If the EN_SHIPMODE bit is set while the IN supply is present, the device will enter Ship Mode upon removal of the supply. The EN_SHIPMODE bit can be cleared using the I²C interface as well while the IN input is valid.

In addition to $V_{IN} < V_{UVLO}$, \overline{CD} and \overline{MR} must be high. Once all of these conditions are met the device will begin the transition to Ship Mode. All three conditions must remain unchanged for a period of t_{QUIET} to ensure proper operation. [Figure 9-1](#) and [Figure 9-2](#) show the correct sequencing to ensure proper entry into the Ship Mode through I²C command and \overline{MR} button press respectively.

Figure 9-1. \overline{CD} , \overline{MR} and VIN Sequencing for Ship Mode Entry Through I²C Command

图 9-2. \overline{CD} , \overline{MR} and V_{IN} Sequencing for Ship Mode Entry Through Long MR button press

The end user can enable the device (exit Ship Mode) by connecting an adapter to IN ($V_{IN} > V_{BAT} + V_{SLP}$) or by toggling the \overline{MR} button. Note that in the case where an adapter is connected while the \overline{MR} is still held low and immediately after the RESET timer has expired (\overline{MR} low for t_{RESET}), the device will not enter Ship Mode, but may enter it upon adapter removal (Same behavior as setting the EN_SHIPMODE bit when the adapter is present). This will not be the case if \overline{MR} has gone high when the adapter is connected or \overline{MR} continues to be held low for a period longer than t_{WAKE1} after the adapter is connected.

To exit Ship Mode through and \overline{MR} press the battery voltage must be above the maximum programmable BUVLO threshold when V_{IN} is not present. Once \overline{MR} goes low, the device will start to exit Ship Mode, powering PMID. The device will not complete the transition from Ship Mode until \overline{MR} has been held low for at least t_{WAKE1} . Only after the transition is complete may the host start I²C communication if the device has not entered High Impedance Mode.

9.3.2 High Impedance Mode

High Impedance mode is the lowest quiescent current state while operating from the battery. During Hi-Z mode the SYS output is powered by BAT, the \overline{MR} input is active, and the LSCTRL input is active. All other circuits are in a low power or sleep state. The LS/LDO output can be enabled in Hi-Z mode with the LSCTRL input. If the LS/LDO output has been enabled through I²C prior to entering Hi-Z mode, it will stay enabled. The \overline{CD} pin is used to put the device in a high-impedance mode when battery is present and $V_{IN} < V_{UVLO}$. Drive \overline{CD} high to enable the device and enter active battery operation when V_{IN} is not valid. When the HZ_MODE bit is written by the host, the I²C interface is disabled if only battery is present. To resume I²C, the \overline{CD} pin must be toggled. If the supply for the \overline{CD} pull up glitches or experiences a brownout condition, it is recommended to toggle the \overline{CD} pin to resume I²C communication. The functionality of the pin is shown in 表 9-1.

表 9-1. \overline{CD} , State Table

CD, STATE	$V_{IN} < V_{UVLO}$	$V_{IN} > V_{UVLO}$
L	Hi-Z	Charge Enabled
H	Active Battery	Charge Disabled

9.3.3 Active Battery Only Connected

When the battery above $V_{BATUVLO}$ is connected with no input source, the battery discharge FET is turned on. After the battery rises above $V_{BATUVLO}$ and the deglitch time is reached, the SYS output starts to rise. The current from PMID and SYS is not regulated, but is protected by a short circuit current limit. If the short circuit limit is reached for the deglitch time (t_{DGL_SC}), the battery discharge FET is turned off for the recovery time (t_{REC_SC}). After the recovery time, the battery FET is turned on to test if the short has been removed. If it has not, the FET turns off and the process repeats until the short is removed. This process protects the internal FET from over current. During this event PMID will likely droop and cause SYS to go out of regulation.

To provide designers the most flexibility in optimizing their system, an adjustable BATUVLO is provided. When the voltage drops below the $V_{BATUVLO}$ threshold, the battery discharge FET is turned off. Deeper discharge of the battery enables longer times between charging, but may shorten the battery life. The BATUVLO is adjustable with a fixed 150-mV hysteresis.

If a valid V_{IN} is connected during active battery mode, $V_{IN} > V_{UVLO}$, the supplement and battery discharge FET is turned on when the battery voltage is above the minimum $V_{BATUVLO}$.

Drive \overline{CD} high or write the CE register to disable charge when $V_{IN} > V_{UVLO}$ is present. \overline{CD} is internally pulled down. When exiting this mode, charging resumes if V_{IN} is present, \overline{CD} is low and charging is enabled.

All HOST interfaces (\overline{CD} , SDA/SCL, INT, \overline{RESET} and LSCTRL) are active no later than 5 ms after SYS reaches the programmed level.

9.3.4 Voltage Based Battery Monitor

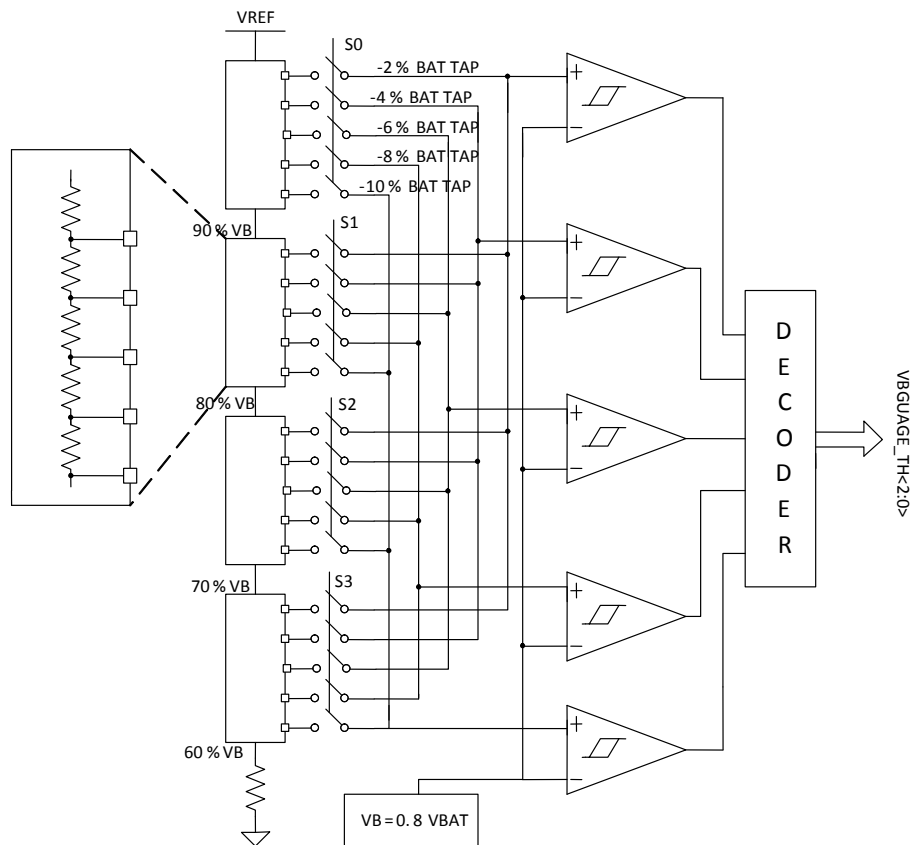

The device implements a simple voltage battery monitor which can be used to determine the depth of discharge. Prior to entering High-Z mode, the device will initiate a VBMON reading. The host can read the latched value for the no-load battery voltage, or initiate a reading using VBMON_READ to see the battery voltage under a known load. The register will be updated and can be read 2 ms after a read is initiated. The VBMON voltage threshold is readable with 2% increments with $\pm 1.5\%$ accuracy between 60% and 100% of VBATREG using the VBMON_TH registers. Reading the value during charge is possible, but for the most accurate battery voltage indication, it is recommended to disable charge, initiate a read, and then re-enable charge.

A typical discharge profile for a Li-Ion battery is shown in 表 9-2. The specific battery to be used in the application should be fully characterized to determine the thresholds that will indicate the appropriate battery status to the user. Two typical examples are shown below, assuming the VBMON reading is taken with no load on the battery.

This function enables a simple 5-bar status indicator with the following typical performance with different VBATREG settings:

表 9-2. Discharge Profile for a Li-Ion Battery

VBATREG	BATTERY FULL	95% to 65% REMAINING CAPACITY	65% to 35% REMAINING CAPACITY	35% to 5% REMAINING CAPACITY	BATTERY EMPTY
4.35 V	VBMON > 90%	VBMON = 88%	VBMON = 86%	VBMON = 84%	VBMON < 82%
4.2 V	VBMON > 98%	VBMON = 94% or 96%	VBMON = 90% or 92%	VBMON = 86% or 88%	VBMON < 84%

9-3. Voltage Battery Monitor

9.3.5 Sleep Mode

The device enters the low-power sleep mode if the voltage V_{IN} falls below the sleep-mode entry threshold and V_{IN} is higher than the undervoltage lockout threshold. In sleep mode, the input is isolated from the connected battery. This feature prevents draining the battery during the absence of V_{IN} . When $V_{IN} < V_{(BAT)} + V_{SLP}$, the device turns the battery discharge FET on, sends a 128- μ s pulse on the INT output, and the FAULT bits of the register are updated over I²C. Once $V_{IN} > V_{(BAT)} + V_{SLP}$, the device initiates a new charge cycle. The FAULT bits are not cleared until they are read over I²C and the sleep condition no longer exists. It is not recommended to do a battery connection or plug in when $V_{UVLO} < V_{IN} < V_{BAT} + V_{SLP}$ as it may cause higher quiescent current to be drained from the battery.

9.3.6 Input Voltage Based Dynamic Power Management ($V_{IN(DPM)}$)

During the normal charging process, if the input power source is not able to support the programmed or default charging current and System load, the supply voltage decreases. Once the supply approaches $V_{IN(DPM)}$, the input DPM current and voltage loops will reduce the input current through the blocking FETs, to prevent the further drop of the supply. The $V_{IN(DPM)}$ threshold is programmable through the I²C register from 4.2 V to 4.9 V in 100-mV steps. It can be disabled completely as well. When the device enters this mode, the charge current may be lower than the set value and the VINDPM_STAT bit is set. If the 2X timer is set, the safety timer is extended while $V_{IN(DPM)}$ is active. Additionally, termination is disabled. Note that in a condition where the battery is connected while $V_{UVLO} < V_{IN} < V_{IN(DPM)}$, the VINDPM loop will prevent the battery from being charged and PMID will be powered from BAT.

9.3.7 Input Overvoltage Protection and Undervoltage Status Indication

The input overvoltage protection protects the device and downstream components connected to PMID, SYS, and BAT against damage from overvoltage on the input supply. When $V_{IN} > V_{OVP}$ an OVP fault is determined to exist. During the OVP fault, the device turns the battery discharge FET on, sends a single 128- μ s pulse on INT,

and the FAULT bits are updated over I²C. Once the OVP fault is removed, after the deglitch time, t_{DGL_OVP} , STAT and FAULT bits are cleared and the device returns to normal operation. The FAULT bits are not cleared until they are read in from I²C after the OVP condition no longer exists. The OVP threshold for the device is set to operate from standard USB sources.

The input under-voltage status indication is used to notify the host or other device when the input voltage falls below a desired threshold. When $V_{IN} < V_{UVLO}$, after the deglitch time t_{DGL_UVLO} , a UVLO fault is determined to exist. During the V_{IN} UVLO fault, the device sends a single 128- μ s pulse on INT, and the STAT and FAULT bits are updated over I²C. The FAULT bits are not cleared until they are read in from I²C after the UVLO condition no longer exists.

9.3.8 Battery Charging Process and Charge Profile

When a valid input source is connected ($V_{IN} > V_{UVLO}$ and $V_{(BAT)} + V_{SLP} < V_{IN} < V_{OVP}$ and $V_{IN} > V_{IN(DPM)}$), the \overline{CE} bit in the control register determines whether a charge cycle is initiated. When the \overline{CE} bit is 1 and a valid input source is connected, the battery discharge FET is turned off, and the output at SYS is regulated depending on the output configuration. A charge cycle is initiated when the \overline{CE} bit is written to a 0. Alternatively, the \overline{CD} input can be used to enable and disable charge.

The device supports multiple battery chemistries for single-cell applications. Charging is done through the internal battery MOSFET. There are several loops that influence the charge current: constant current loop (CC), constant voltage loop (CV), input current limit, V_{DPPM} , and $V_{IN(DPM)}$. During the charging process, all loops are enabled and the one that is dominant takes control.

The charge current is regulated to I_{CHARGE} until the voltage between BAT and GND reaches the regulation voltage. The voltage between BAT and GND is regulated to V_{BATREG} (CV Mode) while the charge current naturally tapers down. When termination is enabled, the device monitors the charging current during the CV mode, and once the charge current tapers down to the termination threshold, I_{TERM} , and the battery voltage is above the recharge threshold, the device terminates charge, and turns off the battery charging FET. Termination is disabled when any loop is active other than CV.

9.3.9 Dynamic Power Path Management Mode

With a valid input source connected, the power-path management circuitry monitors the input voltage and current continuously. The current into IN is shared at PMID between charging the battery and powering the system load at PMID, SYS, and LS/LDO. If the sum of the charging and load currents exceeds the current that the VIN can support, the input DPM loop (V_{INDPM}) reduces the current going into PMID through the input blocking FETs. This will cause a drop on the PMID voltage if the system demands more current. If PMID drops below the DPPM voltage threshold (V_{DPPM}), the charging current is reduced by the DPPM loop through the BATFET in order to stabilize PMID. If PMID continues to drop after BATFET charging current is reduced to zero, the part enters supplement mode when PMID falls below the supplement mode threshold. Battery termination is disabled while in DPPM mode. In order to charge the battery, the voltage at PMID has to be greater than $V_{BATREG} + V_{DPPM}$ threshold.

9.3.10 Battery Supplement Mode

While in DPPM mode, if the charging current falls to zero and the system load current increases beyond the programmed input current limit, the voltage at PMID reduces further. When the PMID voltage drops below the battery voltage by $V_{(BSUP1)}$, the battery supplements the system load. The battery stops supplementing the system load when the voltage on the PMID pin rises above the battery voltage by $V_{(BSUP2)}$. During supplement mode, the battery supplement current is not regulated, however, the short-circuit protection circuit is active. Battery termination is disabled while in supplement mode.

9.3.11 Default Mode

The default mode is used when there is no host, or I²C communication is not available. If the externally programmable pins, ILIM, ISET, and ITERM have resistors connected, that is considered the default mode. If any one of these resistors is tied to GND, the default register settings are used. The default mode can be entered by connecting a valid power source to V_{IN} or the RESET bit is written. Default mode is exited by writing to the I²C interface.

9.3.12 Termination and Pre-Charge Current Programming by External Components (IPRETERM)

The termination current threshold is user programmable through an external resistor or through registers over I²C. Set the termination current using the IPRETERM pin by connecting a resistor from IPRETERM to GND. The termination can be set between 5% and 20% of the programmed output current set by ISET, using 表 9-3 for guidance:

表 9-3. IPRETERM Resistor Settings

IPRE_CHARGE and ITERM			KKIPRETERM			RIPRETERM (STANDARD 1% VALUES)	UNIT
MIN	TYP (% of ISET)	MAX	MIN	TYP	MAX	RECOMMENDED RIPRETERM	
	5		180	200	220	15000	Ω
	10		180	200	220	4990	Ω
	15		180	200	220	1650	Ω
	20		180	200	220	549	Ω

Using the I²C register, the termination current can be programmed with a minimum of 500 μA and a maximum of 37 mA.

The pre-charge current is not independently programmable through the external resistor, and is set at the termination current. The pre-charge and termination currents are programmable using the IPRETERM registers. If no IPRETERM resistor is connected and the pin is tied to GND, the default values in the IPRETERM registers are used. The external value can be used in host mode by configuring the IPRETERM registers. If the external ICHG setting will be used after being in Host mode, the IPRETERM registers should be set to match the desired external threshold for the highest ICHG accuracy.

Termination is disabled when any loop other than CV is active.

9.3.13 Input Current Limit Programming by External Components (ILIM)

The input current limit threshold is user programmable through an external resistor or through registers over I²C. Set the input current limit using the ILIM pin by connecting a resistor from ILIM to GND using 表 9-4 for guidance. If no ILIM resistor is connected and the pin is tied to GND, the default ILIM register value is used. The external value is not valid once the device enters host mode.

表 9-4. ILIM Resistor Settings

ILIM			KILIM			RILIM (STANDARD 1% VALUES)	UNIT
MIN	TYP	MAX	MIN	TYP	MAX		
0.048469388	0.051020408	0.053571429	190	200	210	3920	Ω
0.09047619	0.095238095	0.1	190	200	210	2100	Ω
0.146153846	0.153846154	0.161538462	190	200	210	1300	Ω
0.19	0.2	0.21	190	200	210	1000	Ω
0.285714286	0.30075188	0.315789474	190	200	210	665	Ω
0.380761523	0.400801603	0.420841683	190	200	210	499	Ω

The device has register programmable input current limits from 50 mA to 400 mA in 50-mA steps. The device is USB-IF compliant for inrush current testing, assuming that the input capacitance to the device is selected to be small enough to prevent a violation (<10 μF), as this current is not limited.

9.3.14 Charge Current Programming by External Components (ISET)

The fast charge current is user programmable through an external resistor or through registers over I²C. Set the fast charge current by connecting a resistor from ISET to GND. If no ISET resistor is connected and the pin is tied to GND, the default ISET register value is used. While charging, if the charge current is using the externally programmed value, the voltage at ISET reflects the actual charging current and can be used to monitor charge current. The current out of ISET is 1/100 (±10%) of the charge current. The charge current can be calculated by using 表 9-5 for guidance:

表 9-5. ISET Resistor Settings

ISET			KISET			RISET (STANDARD 1% VALUES)	UNIT
MIN	TYP	MAX	MIN	TYP	MAX		
0.285714286	0.30075188	0.315789474	190	200	210	665	Ω

9.3.15 Safety Timer and Watchdog Timer

At the beginning of the charge cycle, the device starts the safety timer. If charging has not terminated before the programmed safety time, t_{MAXCHG} , expires, the device enters idle mode and charging is disabled. The pre-charge safety time, t_{PRECHG} , is 10% of t_{MAXCHG} . When a safety timer fault occurs, a single 128 μs pulse is sent on the INT pin and the STAT and FAULT bits of the status registers are updated over I²C. The \overline{CD} pin or power

must be toggled in order to clear the safety timer fault. The safety timer duration is programmable using the TMR bits. When the safety timer is active, changing the safety timer duration resets the safety timer. The device also contains a 2X_TIMER bit that enables the 2X timer function to prevent premature safety timer expiration when the charge current is reduced by a load on PMID, SYS, LS/LDO or a NTC condition. When t_{2X_TIMER} function is enabled, the timer is allowed to run at half speed when any loop is active other than CC or CV.

In addition to the safety timer, the device contains a 50-second watchdog timer that monitors the host through the I²C interface. Only after an I²C transaction is performed on the I²C interface, will the watchdog timer start. In the case where the device is set to operate in High Impedance Mode, the watchdog timer is automatically disabled and can only be re-started after the device exits the High Impedance Mode and a subsequent I²C transaction is performed. The watchdog timer is reset by any transaction by the host using the I²C interface. If the watchdog timer expires without a reset from the I²C interface, all registers except MRRESET_VIN and MRREC are reset to the default values.

9.3.16 External NTC Monitoring (TS)

The I²C interface allows the user to easily implement the JEITA standard for systems where the battery pack thermistor is monitored by the host. Additionally, the device provides a flexible voltage based TS input for monitoring the battery pack NTC thermistor. The voltage at TS is monitored to determine that the battery is at a safe temperature during charging.

To satisfy the JEITA requirements, four temperature thresholds are monitored: the cold battery threshold, the cool battery threshold, the warm battery threshold, and the hot battery threshold. These temperatures correspond to the V_(COLD), V_(COOL), V_(WARM), and V_(HOT) threshold in the [セクション 8.5](#). Charging and timers are suspended when V_(TS) < V_(HOT) or > V_(COLD). When V_(COOL) < V_(TS) < V_(COLD), the charging current is reduced to half of the programmed charge current. When V_(HOT) < V_(TS) < V_(WARM), the battery regulation voltage is reduced by 140 mV (minimum V_{BATREG} under this condition is 3.6 V).

The TS function is voltage based for maximum flexibility. Connect a resistor divider from V_{IN} to GND with TS connected to the center tap to set the threshold. The connections are shown in [図 9-4](#). The resistor values are calculated using [式 1](#) and [式 2](#). To disable the TS function, pull TS above TS_{OFF} threshold.

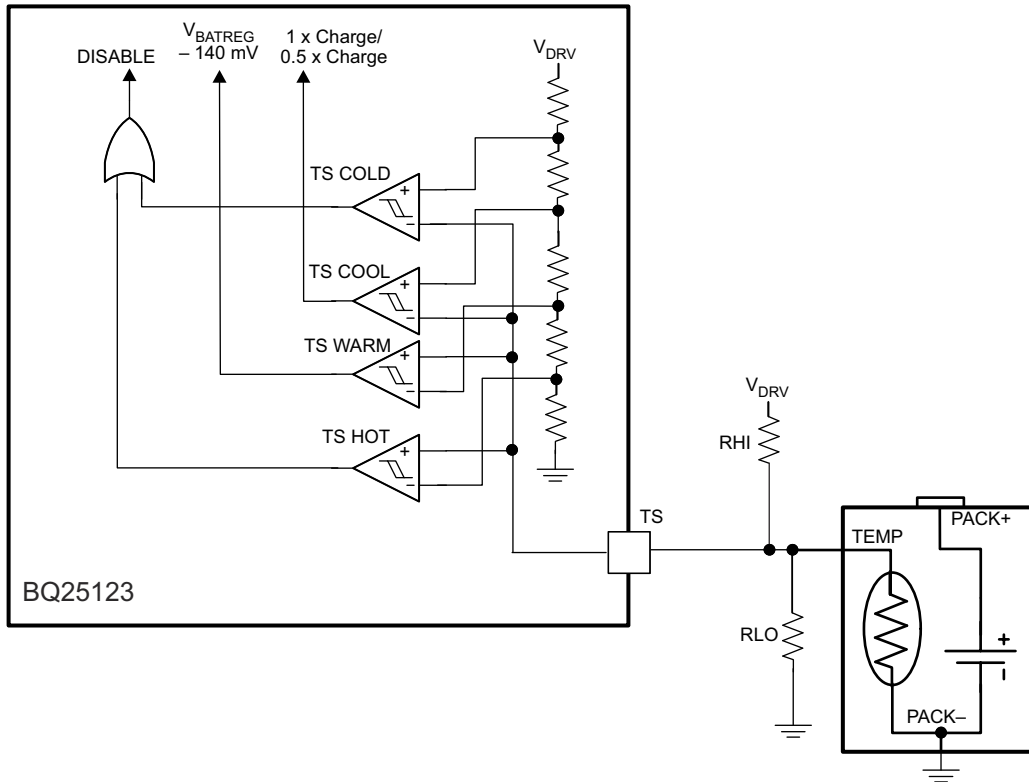

Figure 9-4. TS Circuit

$$R_{(LO)} = \frac{V_{IN} \times R_{(COLD)} \times R_{(HOT)} \times \left(\frac{1}{V_{(COLD)}} - \frac{1}{V_{(HOT)}} \right)}{R_{(HOT)} \times \left(\frac{V_{IN}}{V_{(HOT)}} - 1 \right) - R_{(COLD)} \times \left(\frac{V_{IN}}{V_{(COLD)}} - 1 \right)} \quad (1)$$

$$R_{(HI)} = \frac{\left(\frac{V_{IN}}{V_{(COLD)}} - 1 \right)}{\left(\frac{1}{R_{(LO)}} + \frac{1}{R_{(COLD)}} \right)} \quad (2)$$

Where

- $R_{(HOT)}$ = the NTC resistance at the hot temperature
- $R_{(COLD)}$ = the NTC resistance at the cold temperature

The warm and cool thresholds are not independently programmable. The cool and warm NTC resistances for a selected resistor divider are calculated using 式 3 and 式 4.

$$R_{(COOL)} = \frac{R_{(LO)} \times R_{(HI)} \times V_{(COOL\%)}}{R_{(LO)} - \left(\left(R_{(LO)} \times V_{(COOL\%)} \right) - \left(R_{(HI)} \times V_{(COOL\%)} \right) \right)} \quad (3)$$

$$R_{(WARM)} = \frac{R_{(LO)} \times R_{(HI)} \times V_{(WARM\%)}}{R_{(LO)} - \left(\left(R_{(LO)} \times V_{(WARM\%)} \right) - \left(R_{(HI)} \times V_{(WARM\%)} \right) \right)} \quad (4)$$

9.3.17 Thermal Protection

During the charging process, to prevent overheating in the device, the junction temperature of the die, T_J , is monitored. When T_J reaches $T_{(SHUTDOWN)}$ the device stops charging, disables the PMID output, disables the SYS output, and disables the LS/LDO output. During the time that $T_{(SHUTDOWN)}$ is exceeded, the safety timer is reset and the watchdog timer continues to operate if in host mode. The charge cycle resumes when T_J falls below $T_{(SHUTDOWN)}$ by $T_{(HYS)}$.

To avoid reaching thermal shutdown, ensure that the system power dissipation is under the limits of the device. The power dissipated by the device can be calculated using 式 5.

$$P_{DISS} = P_{(BLOCK)} + P_{(SYS)} + P_{(LS/LDO)} + P_{(BAT)} \quad (5)$$

Where

- $P_{(BLOCK)} = (V_{IN} - V_{(PMID)}) \times I_{IN}$
- $P_{(SYS)} = I_{SYS}^2 \times R_{DS(ON_HS)}$
- $P_{(LS/LDO)} = (V_{(INLS)} - V_{(LS/LDO)}) \times I_{(LS/LDO)}$
- $P_{(BAT)} = (V_{(PMID)} - V_{(BAT)}) \times I_{(BAT)}$

9.3.18 Typical Application Power Dissipation

The die junction temperature, T_J , can be estimated based on the expected board performance using 式 6.

$$T_J = T_A + R_{\theta JA} \times P_{DISS} \quad (6)$$

The $R_{\theta JA}$ is largely driven by the board layout. For more information about traditional and new thermal metrics, see the IC Package Thermal Metrics application report [SPRA953](#). Under typical conditions, the time spent in this state is short.

9.3.19 Status Indicators (\overline{PG} and INT)

The device contains two open-drain outputs that signal its status and are valid only after the device has completed start-up into a valid state. If the part starts into a fault, interrupts will not be sent. The \overline{PG} output signals when a valid input source is connected. \overline{PG} pulls to GND when $V_{IN} > V_{UVLO}$, $V_{IN} > V_{BAT} + V_{SLP}$ and $V_{IN} < V_{OVP}$. \overline{PG} is high-impedance when the input power is not within specified limits. Connect \overline{PG} to the desired logic voltage rail using a 1-k Ω to 100-k Ω resistor, or use with an LED for visual indication.

The \overline{PG} pin can be configured as a \overline{MR} shifted (MRS) output when the PGB_MRS bit is set to 1. \overline{PG} is high-impedance when the \overline{MR} input is not low, and \overline{PG} pulls to GND when the \overline{MR} input is below $V_{OL(TH_MRS)}$. Connect \overline{PG} to the desired logic voltage rail using a 1-k Ω to 100-k Ω resistor.

The INT pin is pulled low during charging when the EN_INT bit is set to 1 and interrupts are pulled high. When EN_INT is set to 0, charging status is not indicated on the INT pin. When charge is complete or disabled, INT is high impedance. The charge status is valid whether it is the first charge or recharge. When a fault occurs, a 128 μ s pulse (interrupt) is sent on INT to notify the host.

9.3.20 Chip Disable (\overline{CD})

The device contains a \overline{CD} input that is used to disable the device and place it into a high impedance mode when only battery is present. In this case, when \overline{CD} is low, PMID and SYS remain active, and the battery discharge FET is turned on. If the LS/LDO output has been enabled prior to pulling \overline{CD} low, it will stay on. The LSCTRL pin can also enable/disable the LS/LDO output when the \overline{CD} pin is pulled low. The \overline{CD} pin has an internal pull-down.

If V_{IN} is present and the \overline{CD} input is pulled low, charge is enabled and all other functions remain active. If V_{IN} is present and the \overline{CD} input is pulled high, charge is disabled.

9.3.21 Buck (PWM) Output

The device integrates a low quiescent current switching regulator with DCS control allowing high efficiency down to 10- μ A load currents. DCS control combines the advantages of hysteretic and voltage mode control. The internally compensated regulation network achieves fast and stable operation with small external components

and low ESR capacitors. During PWM mode, it operates in continuous conduction mode, with a frequency up to 2 MHz. If the load current decreases, the converter enters a power save mode to maintain high efficiency down to light loads. In this mode, the device generates a single switching pulse to ramp up the inductor current and recharge the output capacitor, followed by a sleep period where most of the internal circuits are shut down to achieve a low quiescent current. The duration of the sleep period depends on the load current and the inductor peak current. For optimal operation and maximum power delivery allow $V_{PMID} > V_{SYS} + 0.7 V$.

The output voltage is programmable using the SYS_SEL and SYS_VOUT bits in the SYS VOUT control register.

The SW output is enabled using the EN_SYS_OUT bit in the register. This bit is for testing and debug only and not intended to be used in the final system. When the device is enabled, the internal reference is powered up and the device enters softstart, starts switching, and ramps up the output voltage. When SW is disabled, the output is in shutdown mode in a low quiescent state. The device provides automatic output voltage discharge so the output voltage will ramp up from zero once the device is enabled again. Once SYS has been disabled, either V_{IN} needs to be connected or the MR button must be held low for the t_{RESET} duration to re-enable SYS.

The output is optimized for operation with a 2.2- μ H inductor and 10- μ F output capacitor. 表 9-6 shows the recommended LC output filter combinations.

表 9-6. Recommended Output Filter

INDUCTOR VALUE (μ H)	OUTPUT CAPACITOR VALUE (μ F)		
	4.7	10	22
2.2	Possible	Recommended	Possible

The inductor value affects the peak-to-peak ripple current, the PWM-to-PFM transition point where the part enters and exits Pulse Frequency Modulation to lower the power consumed at low loads, the output voltage ripple and the efficiency. The selected inductor must be selected for its DC resistance and saturation current. The inductor ripple current (ΔI_L) can be estimated according to 式 7.

$$\Delta I_L = V_{SYS} \times (1 - (V_{SYS}/V_{PMID})) / (L \times f) \quad (7)$$

Use 式 8 to calculate the maximum inductor current under static load conditions. The saturation current of the inductor should be rated higher than the maximum inductor current. As the size of the inductor decreases, the saturation “knee” must be carefully considered to ensure that the inductance does not decrease during higher load condition or transient. This is recommended because during a heavy load transient the inductor current rises above the calculated value. A more conservative way is to select the inductor saturation current above the high-side MOSFET switch current.

$$I_L(\max) = I_{SYS}(\max) + \Delta I_L / 2 \quad (8)$$

Where

- F = Switching Frequency
- L = Inductor Value
- ΔI_L = Peak-to-Peak Inductor Ripple Current
- $I_L(\max)$ = Maximum Inductor Current

In DC/DC converter applications, the efficiency is affected by the inductor AC resistance and by the inductor DCR value.

表 9-7 shows recommended inductor series from different suppliers.

表 9-7. Inductor Series

INDUCTANCE (μ H)	DCR (Ω)	DIMENSIONS (mm^3)	INDUCTOR TYPE	SUPPLIER (1)	COMMENT
2.2	0.300	1.6 x 0.8 x 0.8	MDT1608CH2R2N	TOKO	Smallest size, 75mA max
2.2	0.170	1.6 x 0.8 x 0.8	GLFR1608T2R2M	TDK	Smallest size, 150mA max
2.2	0.245	2.0 x 1.2 x 1.0	MDT2012CH2R2N	TOKO	Small size, high efficiency

If the output of the LDO is less than the programmed $V_{(SYS)}$ voltage, connect VINLS to SYS. If the output of the LDO is greater than the programmed V_{SYS} voltage, connect VINLS to PMID.

The current capability of the LDO depends on the VINLS input voltage and the programmed output voltage. The full 100-mA output current for 0.8-V output voltage can be achieved when $V_{(VINLS)} > 3.25$ V. The full 100-mA output current for 3.3-V output voltage can be achieved when $V_{(VINLS)} > 3.6$ V.

When the LSLDO output is disabled with LSCTRL or through the register, an internal pull-down discharges the output.

9.3.23 Manual Reset Timer and Reset Output (\overline{MR} and \overline{RESET})

The \overline{MR} input has an internal pull-up to BAT, and \overline{MR} is functional only when BAT is present or when VIN is valid, stable, and charge is enabled. If \overline{MR} input is asserted during a transient condition while VIN ramps up the IC may incorrectly turn off the SYS buck output, therefore \overline{MR} should not be asserted during this condition in order to avoid unwanted shutdown of SYS output rail. The input conditions can be adjusted by using MRWAKE bits for the wake conditions and MRRESET bits for the reset conditions. When a wake condition is met, a 128- μ s pulse is sent on INT to notify the host, and the WAKE1 and/or WAKE2 bits are updated on I²C. The MR_WAKE bits and RESET FAULT bits are not cleared until the Push-button Control Register is read from I²C.

When a \overline{MR} reset condition is met, a 128- μ s pulse is sent on INT to notify the host and a \overline{RESET} signal is asserted. A reset pulse occurs with duration of t_{RESET_D} only one time after each valid MRRESET condition. The \overline{MR} pin must be released (go high) and then driven low for the MRWAKE period before \overline{RESET} asserts again. After \overline{RESET} is asserted with battery only present, the device enters either Ship Mode or Hi-Z mode depending on MRREC register settings. For details on how to properly enter Ship Mode through MR, refer to the [セクション 9.3.1.1](#). After \overline{RESET} is asserted with a valid V_{IN} present, the device resumes operation prior to the \overline{MR} button press. If SYS was disabled prior to \overline{RESET} , the SYS output is re-enabled if recovering into Hi-Z or Active Battery.

The MRRESET_VIN register can be configured to have \overline{RESET} asserted by a button press only, or by a button press and V_{IN} present ($V_{UVLO} + V_{SLP} < V_{IN} < V_{OVP}$).

To avoid I²C hang-ups, a timer ($t_{I2CRESET}$) runs during I²C transactions. If the SDA line is held low longer than $t_{I2CRESET}$, any additional commands are ignored and the I²C engine is reset. The timeout is reset with START and repeated START conditions and stops when a valid STOP condition is sent.

9.5.2 F/S Mode Protocol

The master initiates data transfer by generating a start condition. The start condition is when a high-to-low transition occurs on the SDA line while SCL is high, as shown in [Figure 9-7](#). All I²C-compatible devices should recognize a start condition.

Figure 9-7. Start Stop Condition

The master then generates the SCL pulses, and transmits the address and the read/write direction bit R/W on the SDA line. During all transmissions, the master ensures that data is valid. A valid data condition requires the SDA line to be stable during the entire high period of the clock pulse (see [Figure 9-8](#)). All devices recognize the address sent by the master and compare it to their internal fixed addresses. Only the slave device with a matching address generates and acknowledge (see [Figure 9-9](#)) by pulling the SDA line low during the entire high period of the ninth SCL cycle. Upon detecting the acknowledge, the master knows that communication link with a slave has been established.

Figure 9-8. Bit Transfer on the Serial Interface

Figure 9-9. Acknowledge on the I²C Bus

The master generates further SCL cycles to either transmit data to the slave (R/W bit 0) or receive data from the slave (R/W bit 1). In either case, the receiver needs to acknowledge the data sent by the transmitter. An acknowledge signal can either be generated by the master or by the slave, depending on which one is the receiver. The 9-bit valid data sequences consisting of 8-bit data and 1-bit acknowledge can continue as long as necessary. To signal the end of the data transfer, the master generates a stop condition by pulling the SDA line from low to high while the SCL line is high (see [Figure 9-10](#)). This releases the bus and stops the communication link with the addressed slave. All I²C compatible devices must recognize the STOP condition. Upon the receipt of a STOP condition, all devices know that the bus is released, and wait for a START condition followed by a matching address. If a transaction is terminated prematurely, the master needs to send a STOP condition to prevent the slave I²C logic from remaining in an incorrect state. Attempting to read data from register addresses not listed in this section results in 0xFFh being read out.

Figure 9-10. Bus Protocol

B1		R	x	N/A
B0 (LSB)		R	x	N/A

表 9-23. Voltage Based Battery Monitor Register, Memory Location 1010 (continued)

Bit	Field	Type	Reset	Description
<p>The VBMON registers are used to determine the battery voltage. Before entering a low power state, the device will determine the voltage level by starting at VBMON_RANGE 11 (90% to 100%), and if VBMON_TH of 000 is read, then it will move to VBMON_RANGE 10 (80% to 90%) and continue until a non 000 value of VBMON_TH is found. If this does not happen, then VBMON_RANGE and VBMON_TH will be written with 00 000. The VBMON_READ bit can be used to initiate a new reading by writing a 1 to it. Example: A reading of 10 011 indicated a VBAT voltage of between 84% and 86% of the VBATREG setting.</p>				

9.6.12 VIN_DPM and Timers Register

Memory location 0x0Bh, Reset State: 0100 0010

图 9-22. VIN_DPM and Timers Register

7 (MSB)	6	5	4	3	2	1	0 (LSB)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

表 9-24. VIN_DPM and Timers Register

Bit	Field	Type	Reset	Description
B7 (MSB)	VINDPM_ON	R/W	0	0 – enable VINDPM 1 – disable VINDPM
B6	VINDPM_2	R/W	1	Input $V_{(IN_DPM)}$ voltage: 400 mV
B5	VINDPM_1	R/W	0	Input $V_{(IN_DPM)}$ voltage: 200 mV
B4	VINDPM_0	R/W	0	Input $V_{(IN_DPM)}$ voltage: 100 mV
B3	2XTMR_EN	R/W	0	0 – Timer is not slowed at any time 1 – Timer is slowed by 2x when in any control other than CC or CV
B2	TMR_1	R/W	0	Safety Timer Time Limit 00 – 30 minute fast charge 01 – 3 hour fast charge 10 – 9 hour fast charge 11 – Disable safety timers
B1	TMR_0	R/W	1	
B0 (LSB)			0	

The VINDPM threshold is set using the following equation: $VINDPM = 4.2 + VINDPM_CODE \times 100 \text{ mV}$

10 Application and Implementation

注

以下のアプリケーション情報は、TI の製品仕様に含まれるものではなく、TI ではその正確性または完全性を保証いたしません。個々の目的に対する製品の適合性については、お客様の責任で判断していただくことになります。お客様は自身の設計実装を検証しテストすることで、システムの機能を確認する必要があります。

10.1 Application Information

A typical design is shown in [図 10-1](#). This design uses the BQ25123 with external resistors for ILIM, IPRETERM, and ISET. These are not needed if these values are set with a host controller through I²C commands. This design also shows the TS resistors, which is also optional.

When powering up in default mode the battery voltage is the default for the part (4.2 V), the SYS output is the default (1.8 V). External resistors set the charge current to 40 mA, the termination current to 10% (4 mA), and the input limit to 100 mA. If the I²C interface is used the part goes to the internal default settings until changed by the host.

10.2 Typical Application

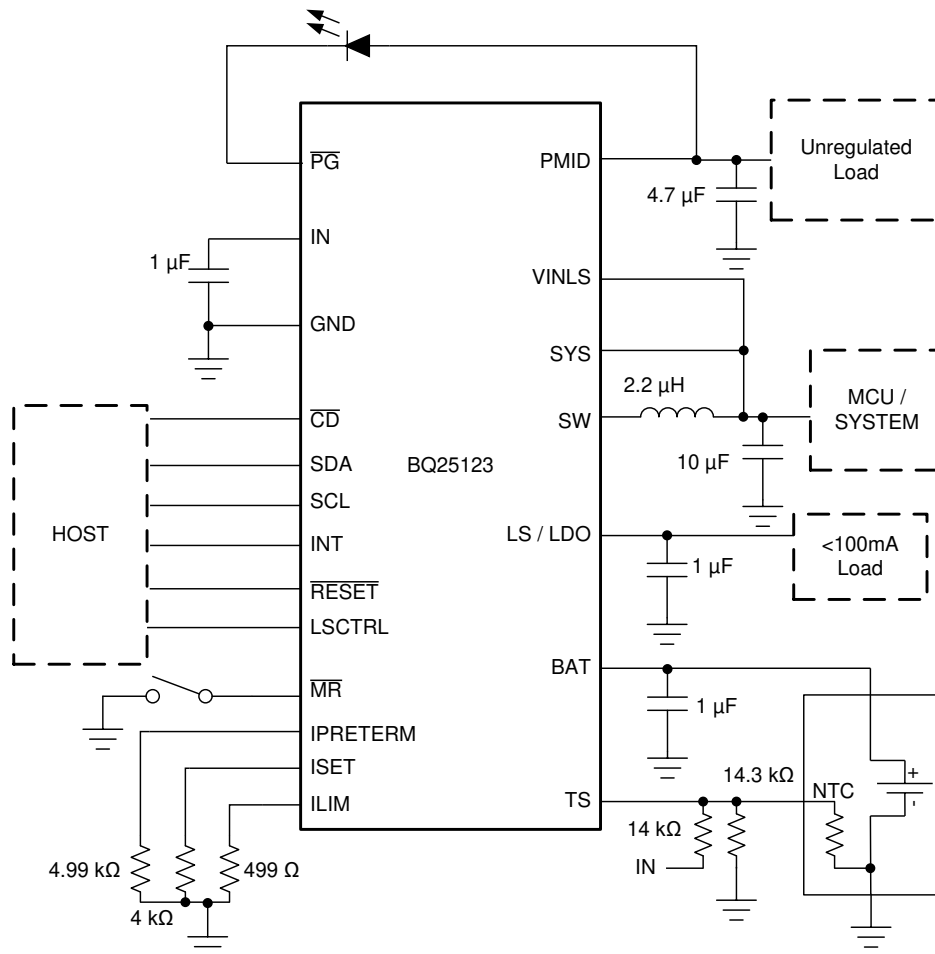

図 10-1. Typical Application Circuit

10.2.1 Design Requirements

This application is for a low power system that has varying loads from less than 10 mA up to 300 mA. It must work with a valid adaptor or USB power input. Below are some of the key components that are needed in normal operation. For this example, the fast charge current is 50 mA, input current limit is 400 mA and the pre-charge and termination current is 10% of the fast charge current.

- Supply voltage = 3.4 V to 20 V
- Fast charge current is default to 10 mA with ISET pin shorted to ground. To program the fast charge current, connect an external resistor from ISET to ground.
- Input current limit is default to 100 mA with ILIM pin shorted to ground. To program the input current limit, connect an external resistor from ILIM to ground.
- Termination current threshold is default to 2 mA with IPRETERM pin shorted to ground. To program the input current limit, connect an external resistor from IPRETERM to ground.
- A 2.2- μ H inductor is needed between SW pin and SYS pin for PWM output.
- TS- Battery temperature sense needs a NTC connected on TS pin.

10.2.2 Detailed Design Procedure

See [Figure 10-1](#) for an example of the application diagram.

10.2.2.1 Default Settings

- Connect ISET, ILIM and IPRETERM pins to ground to program fast charge current to 10 mA, input current limit to 100 mA and pre-charge/termination current to 2 mA.
- BAT_UVLO = 3 V
- VSYS = 1.8 V
- LS/LDO is LS
- VBREG = 4.2 V
- VIN_DPM is enabled and VIN_DPM Threshold = 4.6 V
- Safety Timer = 3 hr
- If the function is not needed, connect TS to the center tab of the resistor divider between V_{IN} and the ground. (pull up resistor = 14 k Ω , pull down resistor = 14.3 k Ω)

10.2.2.2 Choose the Correct Inductance and Capacitance

Refer to the [Section 9.3.21](#) for the detailed procedure to determine the optimal inductance and capacitance for the buck output.

10.2.2.3 Calculations

10.2.2.3.1 Program the Fast Charge Current (ISET)

$$R_{ISET} = K_{ISET}/I_{CHG} \quad (10)$$

$K_{ISET} = 200 \text{ A}\Omega$ from the [Section 8](#) table

$$R_{ISET} = 200 \text{ A}\Omega / 0.05\text{A} = 4 \text{ k}\Omega \quad (11)$$

Select the closest standard value, which in this case is 4.99 k Ω . Connect this resistor between ISET pin and GND.

10.2.2.3.2 Program the Input Current Limit (ILIM)

$$R_{ILIM} = K_{ILIM}/I_{I_MAX} \quad (12)$$

$K_{ILIM} = 200 \text{ A}\Omega$ from the [Section 8](#) table

$$R_{ILIM} = 200 \text{ A}\Omega / 0.4\text{A} = 500 \Omega \quad (13)$$

Select the closest standard value, which in this case is 499 Ω . Connect this resistor between ILIM pin and GND.

10.2.2.3.3 Program the Pre-Charge/Termination Threshold (IPRETERM)

According to [表 9-3](#), the RIPRETERM is 4990 Ω for 10% termination threshold. Therefore, connect a 4.99-k Ω resistor between IPRETERM pin and GND.

10.2.2.3.4 TS Resistors (TS)

The voltage at TS is monitored to determine that the battery is at a safe temperature during charging. This device uses JEITA temperature profile which has four temperature thresholds. Refer to [セクション 8](#) for the detailed thresholds number.

The TS circuit is shown in [図 9-4](#). The resistor values can be calculated using [式 1](#) and [式 2](#).

Power Supply Recommendations

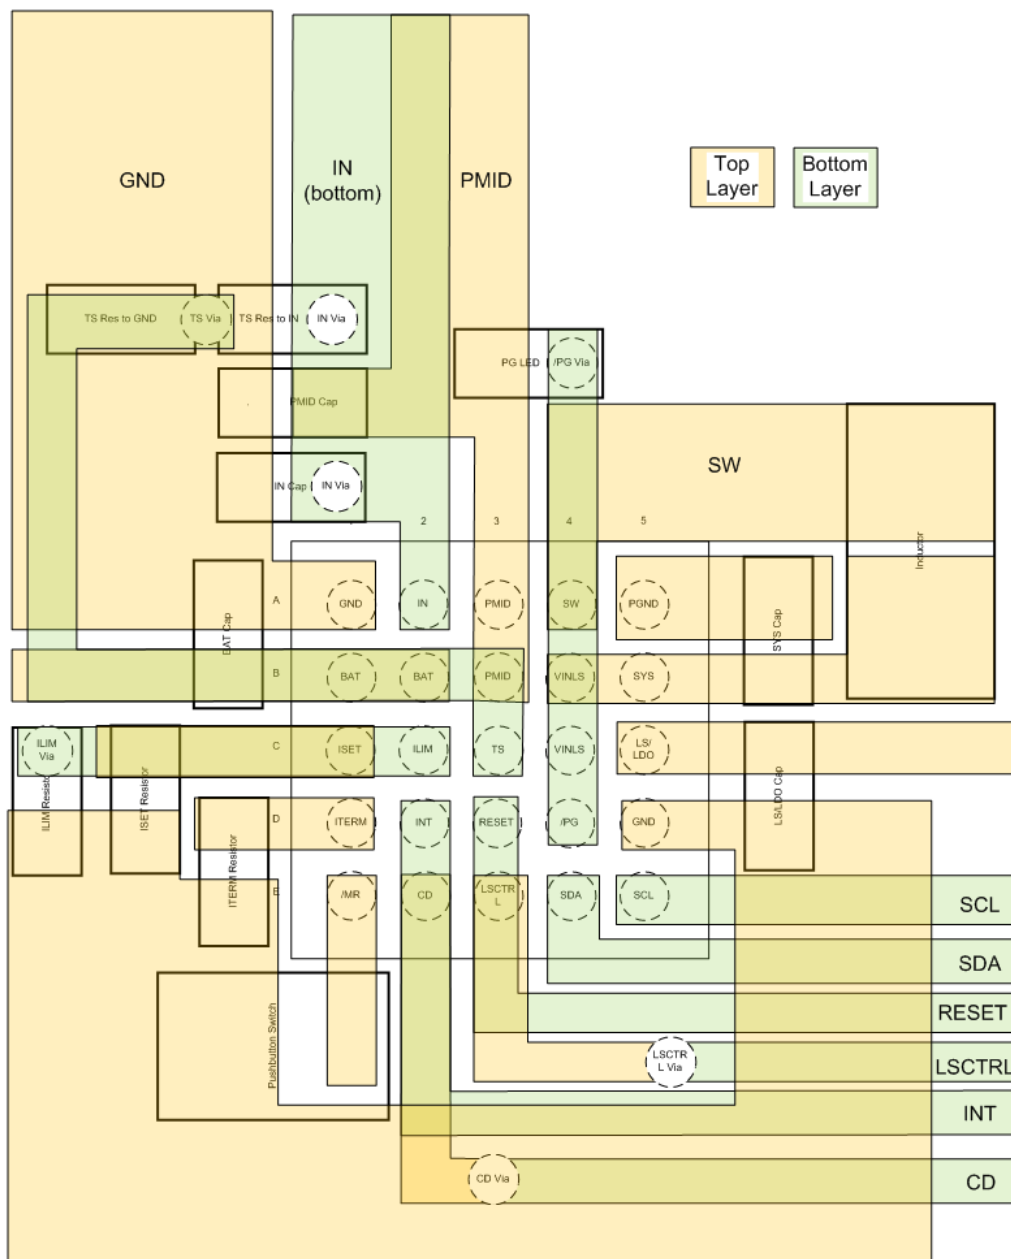

It is recommended to use a power supply that is capable of delivering 5 V at the input current limit set by the BQ25123.

11 Layout

11.1 Layout Guidelines

- Keep the core components of the system close to each other and the device.
- Keep the PMID, IN, and SYS caps as close to their respective pins as possible. Place the bypass caps for PMID, SYS, and LSLDO close to the pins.
- Place the GNDs of the PMID and IN caps close to each other.
- Do not route so the power planes are interrupted.

12.5 静電気放電に関する注意事項

この IC は、ESD によって破損する可能性があります。テキサス・インスツルメンツは、IC を取り扱う際には常に適切な注意を払うことを推奨します。正しい取り扱いおよび設置手順に従わない場合、デバイスを破損するおそれがあります。

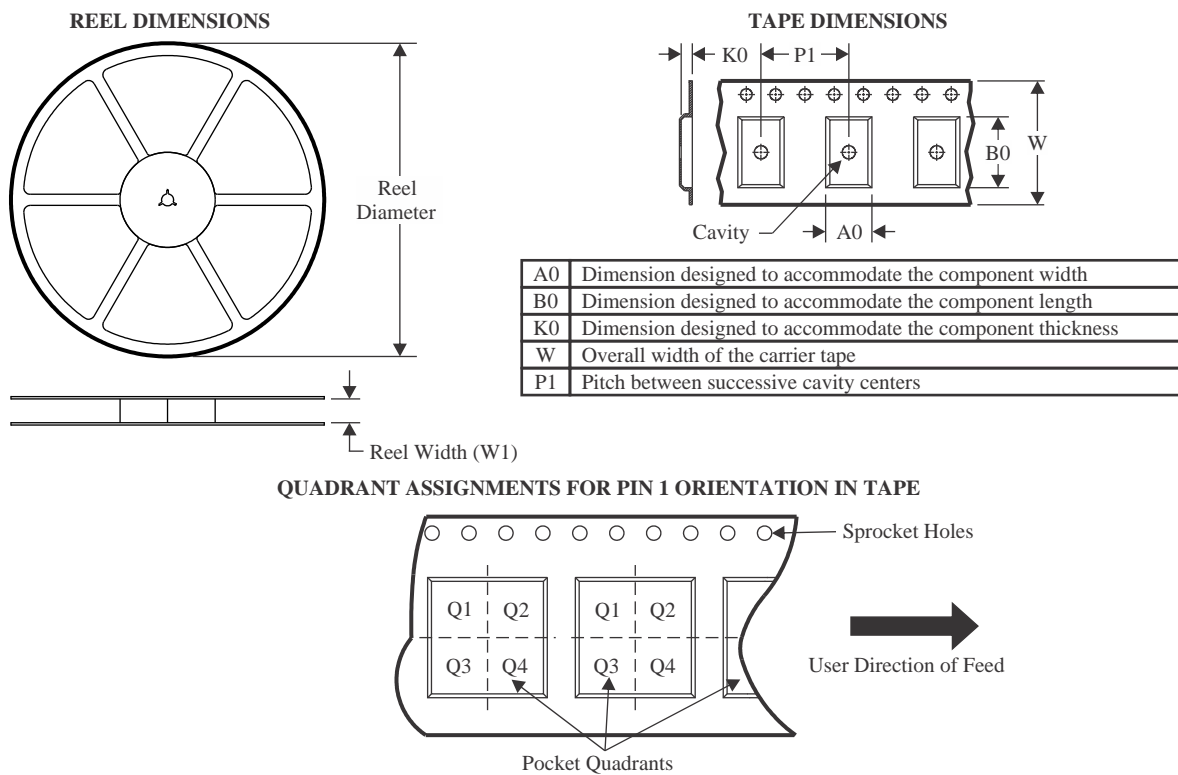

ESD による破損は、わずかな性能低下からデバイスの完全な故障まで多岐にわたります。精密な IC の場合、パラメータがわずかに変化するだけで公表されている仕様から外れる可能性があるため、破損が発生しやすくなっています。
