LP2980-ADJ 16V、50mA、低消費電力、可変低ドロップアウト・レギュレータ

1 特長

- V_{IN} 範囲:
  - 従来のチップ:2.2V～16V
  - 新しいチップ:2.5V～16V
- V_{OUT} 範囲:
  - 従来のチップ:1.23V～15.0V
  - 新しいチップ:1.2V～15.0V
- V_{OUT} (標準値) 精度:
  - 従来のチップ:±1%
  - 新しいチップ:±0.5%
- 負荷および温度範囲にわたる出力精度:
  - 従来のチップ:±3.5%
  - 新しいチップ:±1%
- 出力電流:最大 50mA
- 静止電流、低い I_Q (新チップ):
  - 55µA (I_{LOAD} = 0mA の場合)
  - 350µA (I_{LOAD} = 50mA の場合)
- シャットダウン電流と温度との関係:
  - 従来のチップ:1µA 未満
  - 新しいチップ:0.8µA 以下
- 出力電流制限および過熱保護
- 2.2µF のセラミック・コンデンサで安定動作 (新チップ)
- 高 PSRR (新チップ):
  - 1kHz で 70dB、1MHz で 42dB
- 動作時接合部温度:-40℃～+125℃
- パッケージ:5 ピン SOT-23 (DBV)

2 アプリケーション

- 住宅用ブレーカ
- ソリッド・ステート・ドライブ (SSD)
- 電気メーター
- 電化製品
- ビル・オートメーション

3 概要

LP2980-ADJ は、可変出力で入力範囲の広い低ドロップアウトの電圧レギュレータで、最大 16V の入力電圧範囲、最大 50mA の負荷電流に対応します。LP2980-ADJ は、1.2V～15.0V (新チップ) および 1.23V～15.0V (従来のチップ) の出力範囲をサポートしています。

さらに、LP2980-ADJ (新チップ) は、負荷および温度の全範囲にわたって 1% の出力精度を備えており、低電圧マイクロコントローラ (MCU) およびプロセッサのニーズを満たすことができます。

新チップの広帯域の PSRR 特性は、1kHz で 70dB、1MHz で 45dB を超え、上流の DC/DC コンバータのスイッチング周波数を減衰して、レギュレータ後のフィルタ処理を最小化できます。

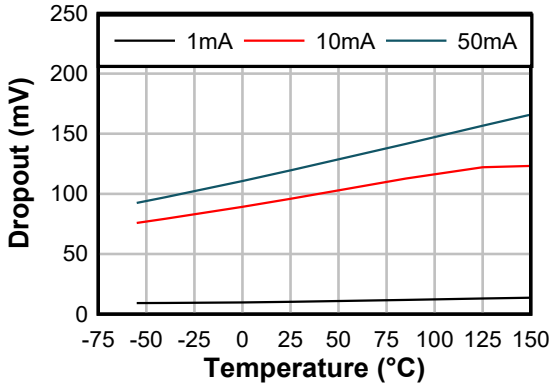
内部ソフトスタート時間および電流制限保護により、スタートアップ時の突入電流が減少し、入力静電容量を最小化しました。過電流および過熱保護などの一般的な保護機能を備えています。

LP2980-ADJ は、5 ピン、2.9mm × 1.6mm の SOT-23 (DBV) パッケージで供給されます。

パッケージ情報

部品番号	パッケージ(1)	パッケージ・サイズ(2)
LP2980-ADJ	DBV (SOT-23、5)	2.9mm × 2.8mm

(1) 利用可能なすべてのパッケージについては、データシートの末尾にある注文情報を参照してください。
(2) パッケージ・サイズ (長さ × 幅) は公称値であり、該当する場合はピンも含まれます。



新チップのドロップアウト電圧と温度との関係

5 Pin Configuration and Functions

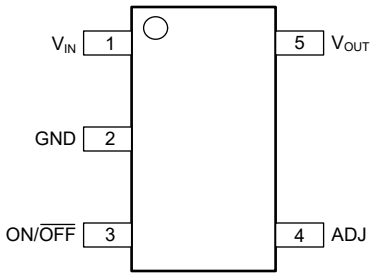

図 5-1. DBV Package, 5-Pin SOT-23 (Top View)

表 5-1. Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
ADJ	4	I/O	Feedback pin to set the output voltage with help of the feedback divider. See the *Recommended Operating Conditions* section for more information.
GND	2	—	Ground
ON/$\overline{\text{OFF}}$	3	I	Enable pin for the LDO. Driving the ON/$\overline{\text{OFF}}$ pin high enables the device. Driving this pin low disables the device. High and low thresholds are listed in the *Electrical Characteristics* table. Tie this pin to V_{IN} if unused.
V_{IN}	1	I	Input supply pin. Use a capacitor with a value of 1 µF or larger from this pin to ground. See the *Input and Output Capacitor Requirements* section for more information.
V_{OUT}	5	O	Output of the regulator. Use a capacitor with a value of 4.7 µF (for legacy chip) and 2.2 µF (for new chip) or larger from this pin to ground.(1) See the *Input and Output Capacitor Requirements* section for more information.

(1) The nominal output capacitance must be greater than 1 µF (for the new chip) and 2.2 µF (for the legacy chip). Throughout this document, the nominal derating on these capacitors is 50%. Make sure that the effective capacitance at the pin is greater than 1 µF (for the new chip) and 2.2 µF (for the legacy chip).

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1) (2)

		MIN	MAX	UNIT
V_{IN}	Continuous input voltage range (for legacy chip)	–0.3	16	V
	Continuous input voltage range (for new chip)	–0.3	18	
V_{OUT}	Output voltage range (for legacy chip)	–0.3	16	
	Output voltage range (for new chip)	–0.3	V_{IN} + 0.3 or 18 (whichever is smaller)	
V_{ADJ}	ADJ pin voltage range (for new chip)	–0.3	3	
$V_{IN} – V_{OUT}$ (3)	Input – Output voltage (for legacy chip)	–0.3	16	
$V_{ON/\overline{OFF}}$	ON/$\overline{OFF}$ pin voltage range (for legacy chip)	–0.3	16	
	ON/$\overline{OFF}$ pin voltage range (for new chip)	–0.3	18	
Current	Maximum output	Internally limited		A
Temperature	Operating junction, T_J	–55	150	°C
	Storage, T_{stg}	–65	150	

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) All voltages with respect to GND.
(3) In legacy chip, the output PNP structure contains a diode between the V_{IN} and V_{OUT} terminals that is normally reverse-biased. Reversing the polarity from V_{IN} to V_{OUT} will turn on this diode

6.2 ESD Ratings

			VALUE (Legacy Chip)	VALUE (New Chip)	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001(1)	±2000	±3000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101(2)	NA	±1000	

(1) JEDEC document JEP155 states that 2-kV HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 500-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

		MIN	NOM	MAX	UNIT
V_{IN}	Supply input voltage (for legacy chip)	2.2		16	V
	Supply input voltage (for new chip)	2.5		16	
V_{OUT}	Output voltage (for legacy chip)	1.225		15.0	
	Output voltage (for new chip)	1.2		15.0	
V_{ADJ}	ADJ voltage (for legacy chip)		1.225		
	ADJ voltage (for new chip)		1.2		
$V_{ON/\overline{OFF}}$	Enable voltage (for legacy chip)	0		V_{IN}	
	Enable voltage (for new chip)	0		16	
I_{OUT}	Output current	0		50	mA
C_{IN} (3)	Input capacitor		1		µF
C_{OUT}	Output capacitor (for legacy chip) (2)	2.2	4.7		
	Output capacitance (for new chip) (1)	1	2.2	200	
C_{FF} (4)	Feed-forward capacitor (for legacy chip)		7		pF
	Feed-forward capacitor (for new chip)		10		
T_J	Operating junction temperature	–40		125	°C

(1) For new chip, all capacitor values are assumed to derate to 50% of the nominal capacitor value. Maintain an effective output capacitance of 1 µF minimum for stability.
(2) For legacy chip, minimum output capacitance of 2.2 µF is required with ESR range suggested in the *Recommended Capacitor Types* section
(3) For legacy chip, an input capacitor of value ≥1 µF is required. It must be located not more than 0.5″ from the input pin and returned to a clean analog ground.
(4) Regarding the requirement of feed-forward capacitor (C_{FF}), see the *Feed-Forward Capacitor* section.

6.4 Thermal Information

THERMAL METRIC (2) (1)		Legacy Chip DBV (SOT23-5) 5 PINS	New Chip DBV (SOT23-5) 5 PINS	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	205.4	178.6	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	78.8	77.9	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	46.7	47.2	°C/W
ψ_{JT}	Junction-to-top characterization parameter	8.3	15.9	°C/W
ψ_{JB}	Junction-to-board characterization parameter	46.3	46.9	°C/W

(1) For more information about traditional and new thermal metrics, see the Semiconductor and IC Package Thermal Metrics application note.
(2) Thermal performance results are based on the JEDEC standard of 2s2p PCB configuration. These thermal metric parameters can be further improved by 35-55% based on thermally optimized PCB layout designs. See the analysis of the Impact of board layout on LDO thermal performance application report.

6.5 Electrical Characteristics

specified at T_J = 25°C, V_{IN} = $V_{OUT(nom)}$ + 1.0 V or VIN = 2.5 V (whichever is greater), I_{OUT} = 1 mA, $V_{ON/OFF}$ = 2 V, C_{IN} = 1.0 µF, and C_{OUT} = 2.2 µF (unless otherwise noted)

PARAMETER			TEST CONDITIONS	MIN	TYP	MAX	UNIT

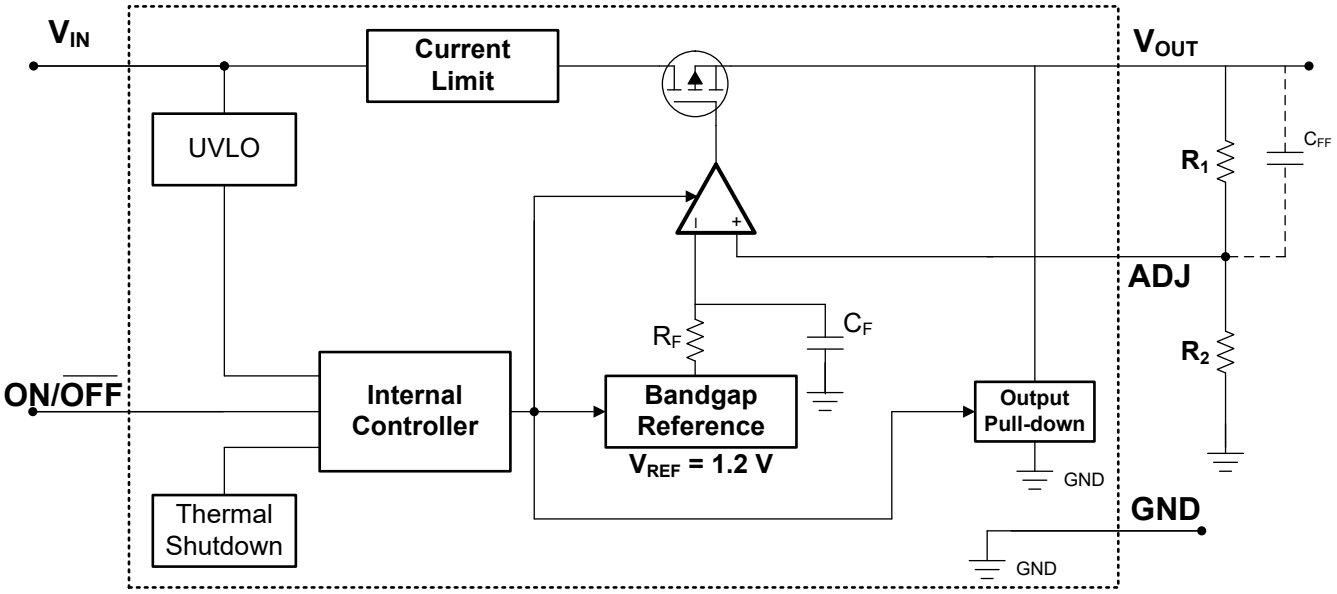
7 Detailed Description

7.1 Overview

The LP2980-ADJ is an adjustable-output, low-dropout regulator that offers exceptional, cost-effective performance for both portable and nonportable applications. The LP2980-ADJ has an output tolerance of 1% across line, load, and temperature variation (for the new chip) and is capable of delivering 50 mA of continuous load current.

This device features integrated overcurrent protection, thermal shutdown, output enable, and internal output pulldown and has a built-in soft-start mechanism for controlled inrush current. This device delivers excellent line and load transient performance. The operating ambient temperature range of the device is –40°C to +125°C.

7.2 Functional Block Diagram



7.3 Feature Description

7.3.1 Output Enable

The ON/$\overline{\text{OFF}}$ pin for the device is an active-high pin. The output voltage is enabled when the voltage of the ON/$\overline{\text{OFF}}$ pin is greater than the high-level input voltage of the ON/$\overline{\text{OFF}}$ pin and disabled when the ON/$\overline{\text{OFF}}$ pin voltage is less than the low-level input voltage of the ON/$\overline{\text{OFF}}$ pin. If independent control of the output voltage is not needed, connect the ON/$\overline{\text{OFF}}$ pin to the input of the device.

For the new chip, the device has an internal pulldown circuit that activates when the device is disabled by pulling the ON/$\overline{\text{OFF}}$ pin voltage lower than the low-level input voltage of the ON/$\overline{\text{OFF}}$ pin, to actively discharge the output voltage.

7.3.2 Dropout Voltage

Dropout voltage (V_{DO}) is defined as the input voltage minus the output voltage ($V_{IN} – V_{OUT}$) at the rated output current (I_{RATED}), where the pass transistor is fully on. I_{RATED} is the maximum I_{OUT} listed in the *Recommended Operating Conditions* table. The pass transistor is in the ohmic or triode region of operation, and acts as a switch. The dropout voltage indirectly specifies a minimum input voltage greater than the nominal programmed output voltage at which the output voltage is expected to stay in regulation. If the input voltage falls to less than the nominal output regulation, then the output voltage falls as well.

For a CMOS regulator, the dropout voltage is determined by the drain-source on-state resistance ($R_{DS(ON)}$) of the pass transistor. Therefore, if the linear regulator operates at less than the rated current, the dropout voltage for that current scales accordingly. The following equation calculates the $R_{DS(ON)}$ of the device.

$$R_{DS(ON)} = \frac{V_{DO}}{I_{RATED}} \quad (1)$$

7.3.3 Current Limit

The device has an internal current limit circuit that protects the regulator during transient high-load current faults or shorting events. The current limit is a brick-wall scheme. In a high-load current fault, the brick-wall scheme limits the output current to the current limit (I_{CL}). I_{CL} is listed in the *Electrical Characteristics* table.

The output voltage is not regulated when the device is in current limit. When a current limit event occurs, the device begins to heat up because of the increase in power dissipation. When the device is in brick-wall current limit, the pass transistor dissipates power [(V_{IN} – V_{OUT}) × I_{CL}]. If thermal shutdown is triggered, the device turns off. After the device cools down, the internal thermal shutdown circuit turns the device back on. If the output current fault condition continues, the device cycles between current limit and thermal shutdown. For more information on current limits, see the *Know Your Limits* application note.

図 7-1 shows a diagram of the current limit.

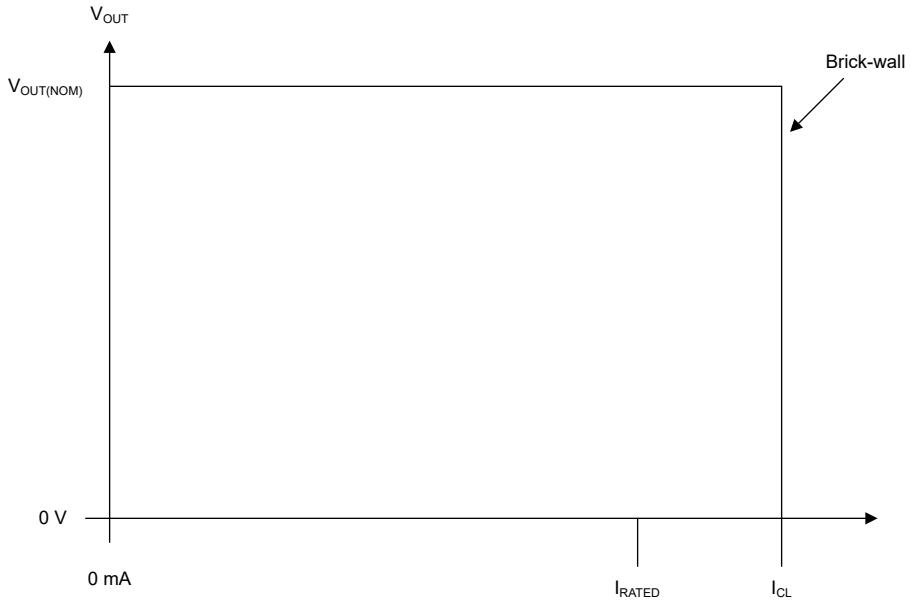


図 7-1. Current Limit

7.3.4 Undervoltage Lockout (UVLO)

For the new chip, the device has an independent undervoltage lockout (UVLO) circuit that monitors the input voltage, allowing a controlled and consistent turn on and off of the output voltage. To prevent the device from turning off if the input drops during turn on, the UVLO has hysteresis as specified in the *Electrical Characteristics* table.

7.3.5 Output Pulldown

The new chip has an output pulldown circuit. The output pulldown activates in the following conditions:

- When the device is disabled ($V_{ON/\overline{OFF}} < V_{ON/\overline{OFF}(LOW)}$)
- If 1.0 V < V_{IN} < V_{UVLO}

Do not rely on the output pulldown circuit for discharging a large amount of output capacitance after the input supply has collapsed because reverse current can flow from the output to the input. This reverse current flow can cause damage to the device. See the *Reverse Current* section for more details.

7.3.6 Thermal Shutdown

The device contains a thermal shutdown protection circuit to disable the device when the junction temperature (T_J) of the pass transistor rises to $T_{SD(shutdown)}$ (typical). Thermal shutdown hysteresis assures that the device resets (turns on) when the temperature falls to $T_{SD(reset)}$ (typical).

The thermal time-constant of the semiconductor die is fairly short, thus the device can cycle on and off when thermal shutdown is reached until power dissipation is reduced. Power dissipation during start up can be high from large V_{IN} – V_{OUT} voltage drops across the device or from high inrush currents charging large output capacitors. Under some conditions, the thermal shutdown protection disables the device before start-up completes.

For reliable operation, limit the junction temperature to the maximum listed in the *Recommended Operating Conditions* table. Operation above this maximum temperature causes the device to exceed operational specifications. Although the internal protection circuitry of the device is designed to protect against thermal overall conditions, this circuitry is not intended to replace proper heat sinking. Continuously running the device into thermal shutdown or above the maximum recommended junction temperature reduces long-term reliability.

7.4 Device Functional Modes

7.4.1 Device Functional Mode Comparison

表 7-1 shows the conditions that lead to the different modes of operation. See the *Electrical Characteristics* table for parameter values.

表 7-1. Device Functional Mode Comparison

OPERATING MODE	PARAMETER			
	V_{IN}	$V_{ON/\overline{OFF}}$	I_{OUT}	T_J
Normal operation	$V_{IN} > V_{OUT(nom)} + V_{DO}$ and $V_{IN} > V_{IN(min)}$	$V_{ON/\overline{OFF}} > V_{ON/\overline{OFF}(HI)}$	$I_{OUT} < I_{OUT(max)}$	$T_J < T_{SD(shutdown)}$
Dropout operation	$V_{IN(min)} < V_{IN} < V_{OUT(nom)} + V_{DO}$	$V_{ON/\overline{OFF}} > V_{ON/\overline{OFF}(HI)}$	$I_{OUT} < I_{OUT(max)}$	$T_J < T_{SD(shutdown)}$
Disabled (any true condition disables the device)	$V_{IN} < V_{UVLO}$	$V_{ON/\overline{OFF}} < V_{ON/\overline{OFF}(LOW)}$	Not applicable	$T_J > T_{SD(shutdown)}$

7.4.2 Normal Operation

The device regulates to the nominal output voltage when the following conditions are met:

- The input voltage is greater than the nominal output voltage plus the dropout voltage ($V_{OUT(nom)} + V_{DO}$)
- The output voltage is set by using ADJ pin (see *External Feedback Resistors*)
- The output current is less than the current limit ($I_{OUT} < I_{CL}$)
- The device junction temperature is less than the thermal shutdown temperature ($T_J < T_{SD}$)
- The ON/$\overline{OFF}$ voltage has previously exceeded the ON/$\overline{OFF}$ rising threshold voltage and has not yet decreased to less than the enable falling threshold

7.4.3 Dropout Operation

If the input voltage is lower than the nominal output voltage plus the specified dropout voltage, but all other conditions are met for normal operation, the device operates in dropout mode. In this mode, the output voltage tracks the input voltage. During this mode, the transient performance of the device becomes significantly degraded because the pass transistor is in the ohmic or triode region, and acts as a switch. Line or load transients in dropout can result in large output-voltage deviations.

When the device is in a steady dropout state (defined as when the device is in dropout, $V_{IN} < V_{OUT(NOM)} + V_{DO}$, directly after being in a normal regulation state, but *not* during start up), the pass transistor is driven into the ohmic or triode region. When the input voltage returns to a value greater than or equal to the nominal output voltage plus the dropout voltage ($V_{OUT(NOM)} + V_{DO}$), the output voltage can overshoot for a short period of time while the device pulls the pass transistor back into the linear region.

7.4.4 Disabled

The output of the device can be shutdown by forcing the voltage of the ON/$\overline{\text{OFF}}$ pin to less than the maximum ON/$\overline{\text{OFF}}$ pin low-level input voltage (see the *Electrical Characteristics* table). When disabled, the pass transistor is turned off, internal circuits are shutdown, and the output voltage is actively discharged to ground by an internal discharge circuit from the output to ground.

8 Application and Implementation

注

以下のアプリケーション情報は、TI の製品仕様に含まれるものではなく、TI ではその正確性または完全性を保証いたしません。個々の目的に対する製品の適合性については、お客様の責任で判断していただくことになります。お客様は自身の設計実装を検証しテストすることで、システムの機能を確認する必要があります。

8.1 Application Information

8.1.1 External Feedback Resistors

The output voltage is set using the ADJ pin with help of the external feedback resistors, R_1 and R_2 (see 図 8-2), according to the following equation:

$$V_{OUT} = V_{ADJ} \times \left(1 + R_1 / R_2\right) \quad (2)$$

For the legacy chip, use a resistor from the ADJ pin to ground with a value of 51.1 kΩ.

For the new chip, to ignore the ADJ pin current error term in the V_{OUT} equation, set the feedback divider current to 100 times the ADJ pin current listed in the *Electrical Characteristics* table. This setting provides the maximum feedback divider series resistance, as shown in the following equation:

$$R_1 + R_2 \leq V_{OUT} / \left(I_{ADJ} \times 100\right) \quad (3)$$

8.1.2 Recommended Capacitor Types

This section describes the recommended capacitors for both the new chip and the legacy chip.

8.1.2.1 Recommended Capacitors for the New Chip

The new chip is designed to be stable using low equivalent series resistance (ESR) ceramic capacitors at the input and output. Multilayer ceramic capacitors have become the industry standard for these types of applications and are recommended, but must be used with good judgment. Ceramic capacitors that employ X7R-, X5R-, and C0G-rated dielectric materials provide relatively good capacitive stability across temperature, whereas the use of Y5V-rated capacitors is discouraged because of large variations in capacitance.

Regardless of the ceramic capacitor type selected, the effective capacitance varies with operating voltage and temperature. Generally, expect the effective capacitance to decrease by as much as 50%. The input and output capacitors listed in the *Recommended Operating Conditions* table account for an effective capacitance of approximately 50% of the nominal value.

8.1.2.2 Recommended Capacitors for the Legacy Chip

The ESR of a good-quality tantalum capacitor is almost directly centered in the middle of the *stable* range of the ESR curve (approximately 0.5 Ω–1 Ω). The temperature stability of tantalum capacitors is typically very good, with a total variation of only approximately 2:1 over the temperature range of –40°C to +125°C (ESR increases at colder temperatures). Avoid off-brand capacitors because some poor-quality tantalum capacitors are available with ESR values greater than 10 Ω, which usually causes oscillation problems. One caution regarding tantalum capacitors is that if used on the input, the ESR is low enough to be destroyed by a surge current if the capacitor is powered up from a low impedance source (such as a battery) that has no limit on inrush current. In this case, use a ceramic input capacitor that does not have this problem.

Ceramic capacitors are generally larger and more costly than tantalum capacitors for a given amount of capacitance. These capacitors also have a very low ESR that is quite stable with temperature. However, the ESR of a ceramic capacitor is typically low enough to make an LDO oscillate. A 2.2-µF ceramic demonstrated an ESR of approximately 15 mΩ when tested. If used as an output capacitor, this ESR can cause instability (see the ESR curves in the *Typical Characteristics* section). If a ceramic capacitor is used on the output of an LDO, place a small resistor (approximately 1 Ω) in series with the capacitor. If used as an input capacitor, no resistor is needed because there is no requirement for ESR on capacitors used on the input.

8.1.3 Input and Output Capacitor Requirements

For the legacy chip, an input capacitor (C_{IN}) ≥1 µF is required (the amount of capacitance can be increased without limit). Any good-quality tantalum or ceramic capacitor can be used. The capacitor must be located no more than half an inch from the input pin and returned to a clean analog ground.

For the new chip, although an input capacitor is not required for stability, good analog design practice is to connect a capacitor from IN to GND. This capacitor counteracts reactive input sources and improves transient response, input ripple, and PSRR. Use an input capacitor if the source impedance is more than 0.5 Ω. A higher value capacitor can be necessary if large, fast rise-time load or line transients are anticipated or if the device is located several inches from the input power source.

Dynamic performance of the device is improved with the use of an output capacitor. Use an output capacitor within the range specified in the *Recommended Operating Conditions* table for stability.

8.1.4 Feed-Forward Capacitor (C_{FF})

A feed-forward capacitor (C_{FF}) can be connected from the V_{OUT} pin to the ADJ pin. C_{FF} improves transient, noise, and PSRR performance, but is not required for regulator stability. Recommended C_{FF} values are listed in the *Recommended Operating Conditions* table. A higher capacitance C_{FF} can be used; however, the start-up time increases. For a detailed description of C_{FF} tradeoffs, see the *Pros and Cons of Using a Feedforward Capacitor with a Low-Dropout Regulator* application note.

C_{FF} and R_1 form a zero in the loop gain at frequency f_Z, whereas C_{FF}, R_1, and R_2 form a pole in the loop gain at frequency f_P. C_{FF} zero and pole frequencies can be calculated from the following equations:

$$f_Z = 1 / (2 \times \pi \times C_{FF} \times R_1) \quad (4)$$

$$f_P = 1 / (2 \times \pi \times C_{FF} \times (R_1 \parallel R_2)) \quad (5)$$

For the legacy chip, a feed-forward capacitor (C_{FF}) of 7 pF is required, because this capacitor provides the lead compensation necessary for loop stability. Use a temperature-stable ceramic capacitor (NPO or COG type).

For the new chip, a C_{FF} ≥ 10 pF is required for stability only if the feedback divider current is less than 5 µA. The following equation calculates the feedback divider current.

$$I_{FB\_Divider} = V_{OUT} / (R_1 + R_2) \quad (6)$$

To avoid start-up time increases from C_{FF}, limit the product $C_{FF} \times R_1 < 50$ µs.

For an output voltage of 1.2 V with the ADJ pin tied to the V_{OUT} pin, no C_{FF} is used.

8.1.5 Reverse Current

Excessive reverse current can damage this device. Reverse current flows through the intrinsic body diode of the pass transistor instead of the normal conducting channel. At high magnitudes, this current flow degrades the long-term reliability of the device.

Conditions where reverse current can occur are outlined in this section, all of which can exceed the absolute maximum rating of $V_{OUT} \le V_{IN} + 0.3$ V.

- If the device has a large C_{OUT} and the input supply collapses with little or no load current
- The output is biased when the input supply is not established
- The output is biased above the input supply

If reverse current flow is expected in the application, use external protection to protect the device. Reverse current is not limited in the device, so external limiting is required if extended reverse voltage operation is anticipated.

図 8-1 shows one approach for protecting the device.

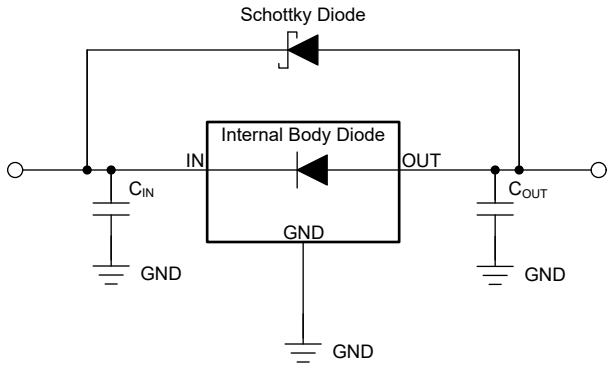

図 8-1. Example Circuit for Reverse Current Protection Using a Schottky Diode

8.1.6 Power Dissipation (P_D)

Circuit reliability requires consideration of the device power dissipation, location of the circuit on the printed circuit board (PCB), and correct sizing of the thermal plane. The PCB area around the regulator must have few or no other heat-generating devices that cause added thermal stress.

To first-order approximation, power dissipation in the regulator depends on the input-to-output voltage difference and load conditions. The following equation calculates power dissipation (P_D).

$$P_D = (V_{IN} – V_{OUT}) \times I_{OUT} \quad (7)$$

注

Power dissipation can be minimized, and therefore greater efficiency can be achieved, by correct selection of the system voltage rails. For the lowest power dissipation use the minimum input voltage required for correct output regulation.

For devices with a thermal pad, the primary heat conduction path for the device package is through the thermal pad to the PCB. Solder the thermal pad to a copper pad area under the device. This pad area must contain an array of plated vias that conduct heat to additional copper planes for increased heat dissipation.

The maximum power dissipation determines the maximum allowable ambient temperature (T_A) for the device. According to the following equation, power dissipation and junction temperature are most often related by the junction-to-ambient thermal resistance ($R_{\theta JA}$) of the combined PCB and device package and the temperature of the ambient air (T_A).

$$T_J = T_A + (R_{\theta JA} \times P_D) \quad (8)$$

Thermal resistance ($R_{\theta JA}$) is highly dependent on the heat-spreading capability built into the particular PCB design, and therefore varies according to the total copper area, copper weight, and location of the planes. The junction-to-ambient thermal resistance listed in the *Thermal Information* table is determined by the JEDEC standard PCB and copper-spreading area, and is used as a relative measure of package thermal performance. As mentioned in the *An empirical analysis of the impact of board layout on LDO thermal performance* application note, $R_{\theta JA}$ can be improved by 35% to 55% compared to the *Thermal Information* table value with the PCB board layout optimization.

8.1.7 Estimating Junction Temperature

The JEDEC standard now recommends the use of psi (Ψ) thermal metrics to estimate the junction temperatures of the linear regulator when in-circuit on a typical PCB board application. These metrics are not thermal resistance parameters and instead offer a practical and relative way to estimate junction temperature. These psi metrics are determined to be significantly independent of the copper area available for heat-spreading. The *Thermal Information* table lists the primary thermal metrics, which are the junction-to-top characterization parameter (ψ_{JT}) and junction-to-board characterization parameter (ψ_{JB}). These parameters provide two methods for calculating the junction temperature (T_J), as described in the following equations. Use the junction-to-top characterization parameter (ψ_{JT}) with the temperature at the center-top of device package (T_T) to calculate the junction temperature. Use the junction-to-board characterization parameter (ψ_{JB}) with the PCB surface temperature 1 mm from the device package (T_B) to calculate the junction temperature.

$$T_J = T_T + \psi_{JT} \times P_D \tag{9}$$

where:

- P_D is the dissipated power
- T_T is the temperature at the center-top of the device package

$$T_J = T_B + \psi_{JB} \times P_D \tag{10}$$

where:

- T_B is the PCB surface temperature measured 1 mm from the device package and centered on the package edge

For detailed information on the thermal metrics and how to use them, see the *Semiconductor and IC Package Thermal Metrics* application note.

8.2 Typical Application

図 8-2 shows the standard usage of the LP2980-ADJ as a low-dropout regulator.

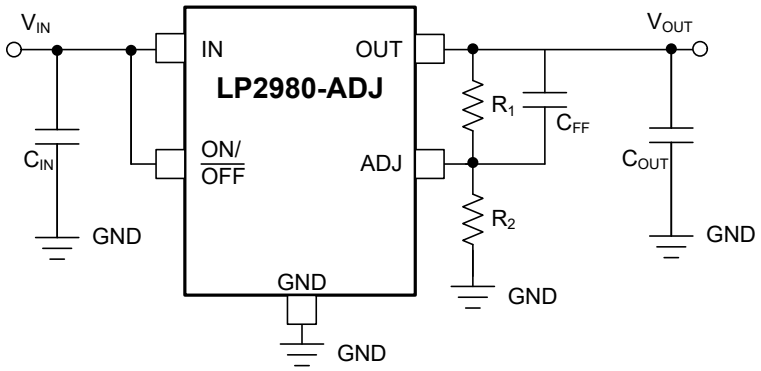

図 8-2. LP2980-ADJ Typical Application

8.2.1 Design Requirements

For this design, use the minimum C_{OUT} value for stability (which can be increased without limit for improved stability and transient response). The ON/$\overline{OFF}$ pin must be actively terminated. Connect this pin to V_{IN} if the shutdown feature is not used. Set the output voltage using a feedback divider between the V_{OUT} pin and the ADJ pin. Use an optional C_{FF} capacitor for improved transient, noise, and PSRR performance.

For the new chip, 表 8-1 summarizes the design requirements for 図 8-2.

表 8-1. Design Parameters

PARAMETER	DESIGN REQUIREMENT
Input voltage	12 V
Output voltage	2.5 V
Output current	50 mA
R_1 (feedback resistance)	108.33 kΩ
R_2 (feedback resistance)	100.00 kΩ

8.2.2 Detailed Design Procedure

8.2.2.1 Setting V_{OUT} For the LP2980-ADJ LDO

As illustrated in 図 8-2, the LP2980-ADJ uses the feedback divider to set the output voltage. The output voltage operating range is 1.2 V to 15 V, and is calculated using:

$$V_{OUT} = V_{ADJ} \times \left(1 + R_1/R_2\right) \quad (11)$$

where:

- V_{REF} = 1.2 V (typical)

Choose resistors R1 and R2 as suggested in the *External Feedback Resistors* section.

図 8-2 depicts this configuration.

8.2.2.2 ON/OFF Input Operation

The LP2980-ADJ is shut off by driving the ON/OFF input low, and turned on by pulling the ON/OFF input high. If this feature is not used, the ON/OFF input must be tied to V_{IN} to keep the regulator output on at all times (the ON/OFF input must not be left floating).

To ensure proper operation, the signal source used to drive the ON/OFF input must be able to swing above and below the specified turn-on/turn-off voltage thresholds that specify an ON or OFF state (see the *Electrical Characteristics* table).

For the legacy chip, the turn-on (and turn-off) voltage signals applied to the ON/OFF input must have a slew rate which is greater than 40 mV/µs.

For the new chip, there is no restriction on the slew rate of the voltage signals applied to the ON/OFF input. Both fast and slow ramping voltage signals can be used to drive the ON/OFF pin.

注

For the legacy chip only, the ON/OFF function does not operate correctly if a slow-moving signal is used to drive the ON/OFF input.

8.2.3 Application Curves

at operating temperature T_J = 25°C, V_{IN} = $V_{OUT(NOM)}$ + 1.0 V or 2.5 V (whichever is greater), I_{OUT} = 1 mA, ON/$\overline{OFF}$ pin tied to V_{IN}, C_{IN} = 1.0 µF, and C_{OUT} = 4.7 µF (unless otherwise noted)

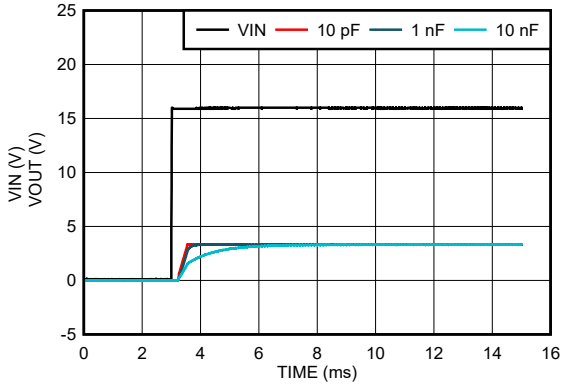
図 8-6. Line Transient Response for New Chip



V_{OUT} = 3.3 V, dV/dt = 1 V/µs

図 8-7. Start-Up vs C_{FF} for New Chip

8.3 Power Supply Recommendations

A power supply can be used at the input voltage within the ranges given in the *Recommended Operating Conditions* table. Use bypass capacitors as described in the *Layout Guidelines* section.

8.4 Layout

8.4.1 Layout Guidelines

- Bypass the input pin to ground with a bypass capacitor.
- The optimum placement of the bypass capacitor is closest to the V_{IN} of the device and GND of the system. Care must be taken to minimize the loop area formed by the bypass capacitor connection, the V_{IN} pin, and the GND pin of the system.
- For operation at full-rated load, use wide trace lengths to eliminate IR drop and heat dissipation.

8.4.2 Layout Example

10 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
LP2980IM5-ADJ/NOM3	ACTIVE	SOT-23	DBV	5	3000	RoHS & Green	SN	Level-1-260C-UNLIM	-40 to 125	L06B	Samples
LP2980IM5-ADJ/NOPB	ACTIVE	SOT-23	DBV	5	3000	RoHS & Green	SN	Level-1-260C-UNLIM	-40 to 125	L06B	Samples
LP2980IM5X-ADJ/NOPB	ACTIVE	SOT-23	DBV	5	3000	RoHS & Green	SN	Level-1-260C-UNLIM	-40 to 125	L06B	Samples

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
