

OPA164x-Q1 SoundPlus™ JFET入力、車載グレード、オーディオ・オペアンプ

1 特長

- 車載アプリケーションに対応
- 下記内容でAEC-Q100認定済み：
 - デバイス温度グレード 1: 動作時周囲温度 $-40^{\circ}\text{C} \sim +125^{\circ}\text{C}$
 - デバイスHBM ESD分類レベル2
 - デバイスCDM ESD分類レベルC6
- 低ノイズ: 1kHz時に $5.1\text{nV}/\sqrt{\text{Hz}}$
- 非常に低い歪み: 1kHz時に0.00005%
- 高いスルー・レート: $20\text{V}/\mu\text{s}$
- ユニティ・ゲイン安定
- 位相反転なし
- 低い静止電流:
チャンネルごとに1.8mA
- レール・ツー・レール出力
- 広い電源電圧範囲: $\pm 2.25\text{V} \sim \pm 18\text{V}$
- シングル、デュアル、クワッドのバージョンを利用可能

2 アプリケーション

- 車載用
- HEVおよびEVのパワートレイン
- 先進運転支援システム(ADAS)
- インフォテインメント・システム
- 車室内マイク

3 概要

OPA1641-Q1 (シングル)およびOPA1642-Q1 (デュアル)シリーズは、JFET入力、非常に低い歪み、低ノイズのオペアンプであり、オーディオ・アプリケーション向けに完全に規定されています。

レール・ツー・レール出力によりヘッドルームが増大するため、これらのデバイスはあらゆるオーディオ回路での使用に理想的です。特長として、 $5.1\text{nV}/\sqrt{\text{Hz}}$ のノイズ、低い全高調波歪み+ノイズ(THD+N) (0.00005%)、低い入力バイアス電流(2pA)、低い静止電流(チャンネルごとに1.8mA)が挙げられます。

これらのデバイスは $\pm 2.25\text{V} \sim \pm 18\text{V}$ の非常に広い電源電圧範囲で動作します。OPA164x-Q1シリーズのオペアンプはユニティ・ゲイン安定で、広い範囲の負荷条件にわたって非常に優れた動的特性を示します。

デュアル・バージョンは完全に独立した回路を使用しているため、クロストークが非常に低く、オーバードライブや過負荷時でもチャンネル間の干渉が発生しません。

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
V _S	Supply voltage		40	V
V _{IN}	Input voltage ⁽²⁾	(V ₋) - 0.5	(V ₊) + 0.5	V
I _{IN}	Input current ⁽²⁾		±10	mA
V _{IN(DIFF)}	Differential input voltage		±V _S	V
I _O	Output short-circuit ⁽³⁾		Continuous	
T _A	Operating temperature	-55	125	°C
T _J	Junction temperature	-65	150	°C
T _{stg}	Storage temperature	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Input pins are diode-clamped to the power-supply rails. Input signals that can swing more than 0.5 V beyond the supply rails must be current-limited to 10 mA or less. The input voltage and output negative-voltage ratings can be exceeded if the input and output current ratings are followed.
- (3) Short-circuit to V_S / 2 (ground in symmetrical dual-supply setups), one amplifier per package.

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per AEC Q100-002 ⁽¹⁾	±3000
		Charged-device model (CDM), per AEC Q100-011	±1000

- (1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
Supply voltage (V ₊ , V ₋)	Single supply	4.5		36	V
	Dual supply	±2.25		±18	
Specified temperature		-40		125	°C

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾	OPA1641-Q1, OPA1642-Q1		UNIT	
	D (SOIC)	DGK (VSSOP)		
	8 PINS	8 PINS

7 Detailed Description

7.1 Overview

The OPA164x-Q1 family of operational amplifiers combine an ultra-low noise JFET input stage with a rail-to-rail output stage to provide high overall performance in audio applications. The internal topology is selected specifically to deliver extremely low distortion, consume limited power, and accommodate small packages. These amplifiers are well-suited for analog signal processing applications such as active filter circuits, pre-amplifiers, and tone controls. The unique input stage design and semiconductor processes used in this device deliver extremely high performance even in applications with high source impedance and wide common-mode voltage swings.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Phase Reversal Protection

The OPA164x-Q1 family has internal phase-reversal protection. Many op amps exhibit phase reversal when the input is driven beyond the linear common-mode range. This condition is most often encountered in noninverting circuits when the input is driven beyond the specified common-mode voltage range, causing the output to reverse into the opposite rail. The input of the OPA164x-Q1 prevents phase reversal with excessive common-mode voltage. Instead, the appropriate rail limits the output voltage. This performance is shown in [Figure 29](#).

Figure 29. Output Waveform Devoid of Phase Reversal During an Input Overdrive Condition

7.3.2 Output Current Limit

The output current of the OPA164x-Q1 series is limited by internal circuitry to 36 mA and –30 mA (sourcing and sinking), to protect the device if the output is accidentally shorted. This short-circuit current depends on temperature; see [Figure 26](#).

Although uncommon for most modern audio applications to require 600-Ω load drive capability, many audio operational amplifier applications continue to specify the total harmonic distortion (THD+N) at 600-Ω load for comparative purposes. [Figure 7](#) and [Figure 8](#) provide typical THD+N measurement curves for the OPA164x-Q1 series, where the output drives a 3-V_{RMS} signal into a 600-Ω load. However, correct device operation cannot be ensured when driving 600-Ω loads at full supply. Depending on supply voltage and temperature, this operating condition can possibly trigger the output current limit circuitry of the device.

7.3.3 EMI Rejection Ratio (EMIRR)

The electromagnetic interference (EMI) rejection ratio, or EMIRR, describes the EMI immunity of operational amplifiers. An adverse effect that is common to many operational amplifiers is a change in the offset voltage as a result of RF signal rectification. An operational amplifier that is more efficient at rejecting this change in offset as a result of EMI has a higher EMIRR and is quantified by a decibel value. Measuring EMIRR can be performed in many ways, but this document provides the EMIRR IN+, which specifically describes the EMIRR performance when the RF signal is applied to the noninverting input pin of the operational amplifier. In general, only the noninverting input is tested for EMIRR for the following three reasons:

- Operational amplifier input pins are known to be the most sensitive to EMI, and typically rectify RF signals better than the supply or output pins.
- The noninverting and inverting operational amplifier inputs have symmetrical physical layouts and exhibit nearly matching EMIRR performance.
- EMIRR is easier to measure on noninverting pins than on other pins because the noninverting input pin can be isolated on a printed-circuit-board (PCB). This isolation allows the RF signal to be applied directly to the noninverting input pin with no complex interactions from other components or connecting PCB traces.

A more formal discussion of the EMIRR IN+ definition and test method is provided in application report [EMI Rejection Ratio of Operational Amplifiers](#), available for download at www.ti.com.

Feature Description (continued)

The EMIRR IN+ of the OPA164x-Q1 is plotted versus frequency in [Figure 30](#). If available, any dual and quad operational amplifier device versions have nearly identical EMIRR IN+ performance. The OPA164x-Q1 unity-gain bandwidth is 11 MHz. EMIRR performance below this frequency denotes interfering signals that fall within the operational amplifier bandwidth.

Figure 30. OPA164x-Q1 EMIRR vs Frequency

[Table 1](#) lists the EMIRR IN+ values for the OPA164x-Q1 at particular frequencies commonly encountered in real-world applications. Applications listed in [Table 1](#) can be centered on or operated near the particular frequency shown. This information can be of special interest to designers working with these types of applications, or working in other fields likely to encounter RF interference from broad sources, such as the industrial, scientific, and medical (ISM) radio band.

Table 1. OPA164x-Q1 EMIRR IN+ for Frequencies of Interest

FREQUENCY	APPLICATION AND ALLOCATION	EMIRR IN+
400 MHz	Mobile radio, mobile satellite, space operation, weather, radar, UHF	53.1 dB
900 MHz	GSM, radio communication and navigation, GPS (to 1.6 GHz), ISM, aeronautical mobile, UHF	72.2 dB
1.8 GHz	GSM, mobile personal comm. broadband, satellite, L-band	80.7 dB
2.4 GHz	802.11b/g/n, Bluetooth™, mobile personal comm., ISM, amateur radio and satellite, S-band	86.8 dB
3.6 GHz	Radiolocation, aero comm./nav., satellite, mobile, S-band	91.7 dB
5 GHz	802.11a/n, aero communication and navigation, mobile communication, space and satellite operation, C-band	96.6 dB

7.3.3.1 EMIRR IN+ Test Configuration

Figure 31 shows the circuit configuration for testing the EMIRR IN+. An RF source is connected to the operational amplifier noninverting input pin using a transmission line. The operational amplifier is configured in a unity-gain buffer topology with the output connected to a low-pass filter (LPF) and a digital multimeter (DMM). A large impedance mismatch at the operational amplifier input causes a voltage reflection; however, this effect is characterized and accounted for when determining the EMIRR IN+. The resulting dc offset voltage is sampled and measured by the multimeter. The LPF isolates the multimeter from residual RF signals that can interfere with multimeter accuracy. See [EMI Rejection Ratio of Operational Amplifiers](#) for more details.

Figure 31. EMIRR IN+ Test Configuration Schematic

7.4 Device Functional Modes

7.4.1 Operating Voltage

The OPA164x-Q1 series of operational amplifiers can be used with single or dual supplies from an operating range of $V_S = 4.5 \text{ V}$ ($\pm 2.25 \text{ V}$) and up to $V_S = 36 \text{ V}$ ($\pm 18 \text{ V}$). These devices do not require symmetrical supplies; only a minimum supply voltage of 4.5 V ($\pm 2.25 \text{ V}$) is required. For V_S less than $\pm 3.5 \text{ V}$, the common-mode input range does not include midsupply. Supply voltages higher than 40 V can permanently damage the device; see [Absolute Maximum Ratings](#) for more information. Key parameters are specified over the operating temperature range, $T_A = -40^\circ\text{C}$ to $+85^\circ\text{C}$. Key parameters that vary over the supply voltage or temperature range are shown in [Typical Characteristics](#).

8 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The OPA164x-Q1 amplifiers are unity-gain stable, audio operational amplifiers with very low noise, input bias current, and input offset voltage. Applications with noisy or high-impedance power supplies require decoupling capacitors placed close to the device pins. In most cases, 0.1- μ F capacitors are adequate.  32 shows a simplified schematic of the OPA1641-Q1.

Copyright © 2017 Texas Instruments Inc.

 32. Simplified Internal Schematic

Application Information (continued)

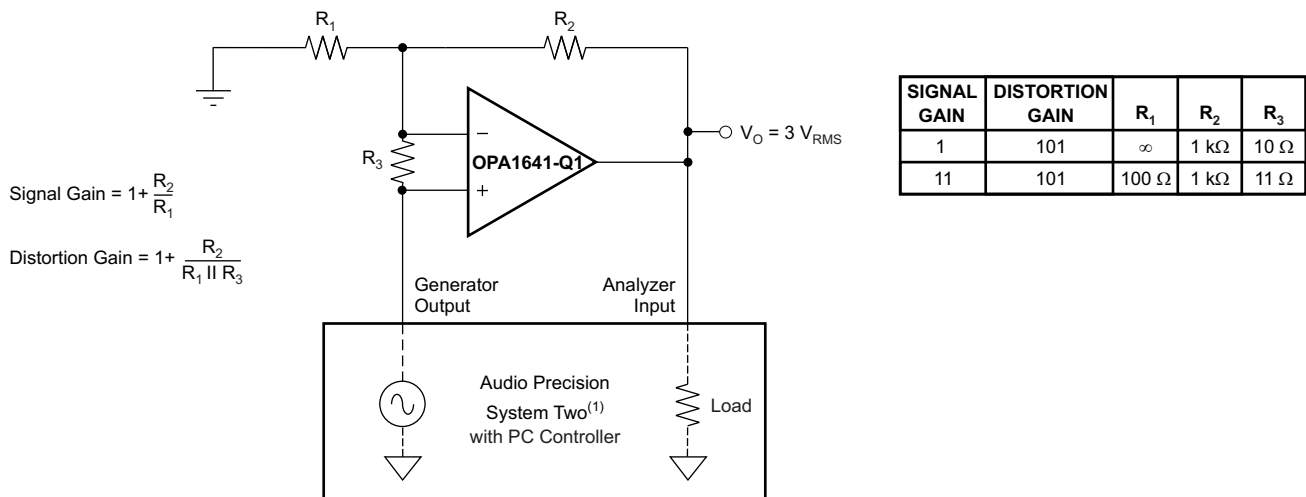

8.1.1 Total Harmonic Distortion Measurements

The OPA164x-Q1 series operational amplifiers have excellent distortion characteristics. THD + noise is below 0.00005% ($G = 1$, $V_O = 3 V_{RMS}$, $BW = 80 \text{ kHz}$) throughout the audio frequency range, 20 Hz to 20 kHz, with a 2-k Ω load (see [Figure 7](#)).

The distortion produced by the OPA164x-Q1 series op amps is below the measurement limit of many commercially available distortion analyzers. However, a special test circuit (such as shown in [Figure 33](#)) can be used to extend the measurement capabilities.

Operational amplifier distortion can be considered an internal error source that can be referred to the input. [Figure 33](#) shows a circuit that causes the operational amplifier distortion to be 101 times (or approximately 40 dB) greater than that normally produced by the op amp. The addition of R_3 to the otherwise standard noninverting amplifier configuration alters the feedback factor or noise gain of the circuit. The closed-loop gain is unchanged, but the feedback available for error correction is reduced by a factor of 101, extending the resolution by 101. The input signal and load applied to the op amp are the same as with conventional feedback without R_3 . Keep the value of R_3 small to minimize any effect on distortion measurements.

The validity of this technique can be verified by duplicating measurements at high gain or high frequency where the distortion is within the measurement capability of the test equipment. Measurements for this document were made with an audio precision system two distortion and noise analyzer that greatly simplifies repetitive measurements. However, the measurement technique can be performed with manual distortion measurement instruments.

Figure 33. Distortion Test Circuit

8.1.2 Source Impedance and Distortion

In traditional JFET-input op amps, the impedance applied to the positive and negative inputs in noninverting applications must be matched for lowest distortion. Legacy methods for fabricating the JFETs in the FET input stage exhibit a varying input capacitance with applied common-mode input voltage. In inverting configurations, the input does not vary with input voltage because the inverting input is held at virtual ground. However, in noninverting applications, the inputs do vary, and the gate-to-source voltage is not constant. This effect produces increased distortion resulting from the varying capacitance for unmatched source impedances. However, the OPA164x-Q1 family of amplifiers is designed to maintain a constant input capacitance with varying common-mode voltage to prevent this mechanism of distortion. The variation of input capacitance with common-mode voltage for a traditional amplifier is compared to the OPA164x-Q1 family in [Figure 34](#).

Figure 34. Input Capacitance of the OPA164x-Q1 Family of Amplifiers Compared to Traditional JFET-input Amplifiers

By stabilizing the input capacitance, the distortion performance of the amplifier is greatly improved for noninverting configurations with high source impedances. The measured performance of an OPA164x-Q1 amplifier is compared to a traditional JFET-input amplifier in Figure 35. The unity-gain configuration, high source impedance, and large-signal amplitude produce additional distortion in the traditional amplifier.

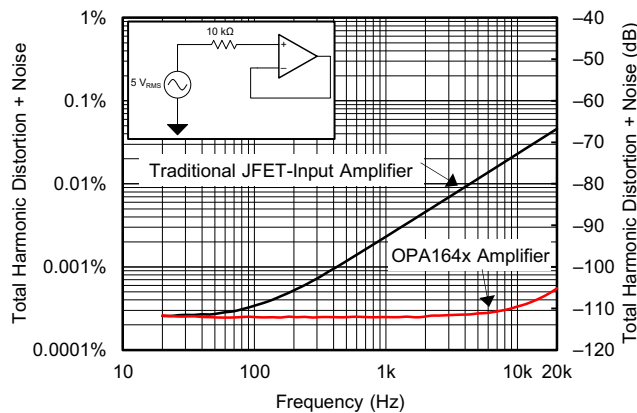

Figure 35. Measured THD+N of the OPA164x-Q1 Family of Amplifiers Compared to Traditional JFET-input Amplifiers

8.1.3 Capacitive Load and Stability

The dynamic characteristics of the OPA164x-Q1 are optimized for commonly encountered gains, loads, and operating conditions. The combination of low closed-loop gain and high capacitive loads decreases the phase margin of the amplifier and can lead to gain peaking or oscillations. As a result, heavier capacitive loads must be isolated from the output. The simplest way to achieve this isolation is to add a small resistor (R_{OUT} equal to 50 Ω, for example) in series with the output.

Figure 19 and Figure 20 illustrate graphs of *Small-Signal Overshoot vs Capacitive Load* for several values of R_{OUT} . For details of analysis techniques and application circuits, see [Feedback Plots Define Op Amp AC Performance](#) available for download at www.ti.com

8.1.4 Power Dissipation and Thermal Protection

The OPA164x-Q1 op amps are capable of driving 2-k Ω loads with power-supply voltages of up to ± 18 V over the specified temperature range. In a single-supply configuration, where the load is connected to the negative supply voltage, the minimum load resistance is 2.8 k Ω at a supply voltage of 36 V. For lower supply voltages (either single-supply or symmetrical supplies), a lower load resistance can be used, as long as the output current does not exceed 13 mA; otherwise, the device short-circuit current-protection circuit can activate.

Internal power dissipation increases when operating at high supply voltages. Copper leadframe construction used in the OPA164x-Q1 series of devices improves heat dissipation compared to conventional materials. PCB layout can help reduce a possible increase in junction temperature. Wide copper traces help dissipate the heat by functioning as an additional heat sink. Temperature rise can be further minimized by soldering the devices directly to the PCB rather than using a socket.

Although the output current is limited by internal protection circuitry, accidental shorting one or more output channels of a device can result in excessive heating. For instance, when an output is shorted to midsupply, the typical short-circuit current of 36 mA leads to an internal power dissipation of over 600 mW at a supply of ± 18 V. In case of a dual OPA1642-Q1 in an VSSOP-8 package (thermal resistance $R_{\theta JA} = 180^{\circ}\text{C}/\text{W}$), such a power dissipation results in the die temperature to be 220 $^{\circ}\text{C}$ above ambient temperature, when both channels are shorted. This temperature increase destroys the device.

To prevent such excessive heating that can destroy the device, the OPA164x-Q1 series has an internal thermal shutdown circuit that shuts down the device if the die temperature exceeds approximately 180 $^{\circ}\text{C}$. When this thermal shutdown circuit activates, a built-in hysteresis of 15 $^{\circ}\text{C}$ ensures that the die temperature must drop to approximately 165 $^{\circ}\text{C}$ before the device switches on again.

8.1.5 Electrical Overstress

Designers often ask questions about the capability of an operational amplifier to withstand electrical overstress. These questions tend to focus on the device inputs, but can involve the supply voltage pins or even the output pin. Each of these different pin functions have electrical stress limits determined by the voltage breakdown characteristics of the particular semiconductor fabrication process and specific circuits connected to the pin. Additionally, internal electrostatic discharge (ESD) protection is built into these circuits to protect them from accidental ESD events both before and during product assembly.

Having a good understanding of this basic ESD circuitry and the relevance to an electrical overstress event is helpful.  36 illustrates the ESD circuits contained in the OPA164x-Q1 series (indicated by the dashed line area). The ESD protection circuitry involves several current-steering diodes connected from the input and output pins and routed back to the internal power-supply lines where an internal absorption device is connected. This protection circuitry is intended to remain inactive during normal circuit operation.

An ESD event produces a short-duration, high-voltage pulse that is transformed into a short-duration, high-current pulse when discharging through a semiconductor device. The ESD protection circuits are designed to provide a current path around the operational amplifier core to prevent damage. The energy absorbed by the protection circuitry is then dissipated as heat.

When an ESD voltage develops across two or more of the amplifier device pins, current flows through one or more of the steering diodes. Depending on the path that the current takes, the absorption device can activate. The absorption device has a trigger (or threshold voltage) that is above the normal operating voltage of the OPA164x-Q1 but below the device breakdown voltage level. When this threshold is exceeded, the absorption device quickly activates and clamps the voltage across the supply rails to a safe level.

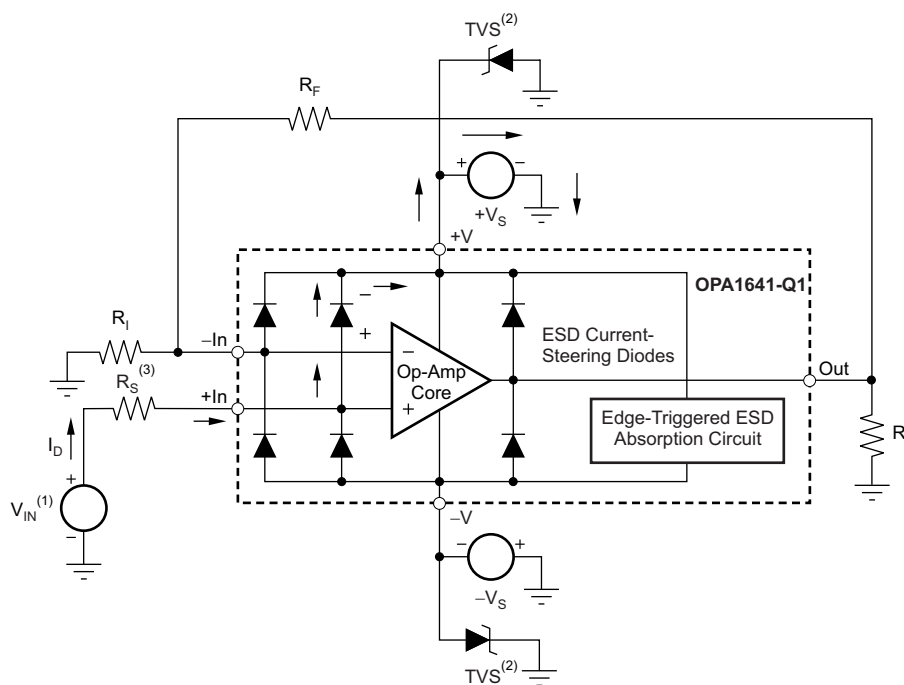

When the operational amplifier connects into a circuit as shown in  36, the ESD protection components are intended to remain inactive and not become involved in the application circuit operation. However, circumstances can arise where an applied voltage exceeds the operating voltage range of a given pin. If this condition occurs, some of the internal ESD protection circuits can be biased on and conduct current. Any such current flow occurs through steering diode paths and rarely involves the absorption device.

 36 depicts a specific example where the input voltage (V_{IN}) exceeds the positive supply voltage ($+V_S$) by 500 mV or more. Much of what happens in the circuit depends on the supply characteristics. If $+V_S$ can sink the current, one of the upper input steering diodes conducts and directs current to $+V_S$. Excessively high current levels can flow with increasingly higher V_{IN} . As a result, the data sheet specifications recommend that applications limit the input current to 10 mA.

If the supply is not capable of sinking the current, V_{IN} can begin sourcing current to the operational amplifier, and then take over as the source of positive supply voltage. The danger in this case is that the voltage can rise to levels that exceed the operational amplifier absolute maximum ratings.

Another common question involves what happens to the amplifier if an input signal is applied to the input when the power supplies $+V_S$ and $-V_S$ are at 0 V. The amplifier behavior depends on the supply characteristic when at 0 V, or at a level below the input signal amplitude. If the supplies appear as high impedance, then the operational amplifier supply current can be supplied by the input source through the current steering diodes. This state is not a normal bias condition; the amplifier most likely does not operate normally. If the supplies are low impedance, then the current through the steering diodes can become quite high. The current level depends on the ability of the input source to deliver current and any resistance in the input path.

If there is an uncertainty about the ability of the supply to absorb this current, external Zener diodes can be added to the supply pins, as shown in [Figure 36](#). The Zener voltage must be selected so the diode does not turn on during normal operation. However, the Zener voltage must be low enough so that the Zener diode conducts if the supply pin begins to rise above the safe operating supply voltage level.

Copyright © 2016, Texas Instruments Incorporated

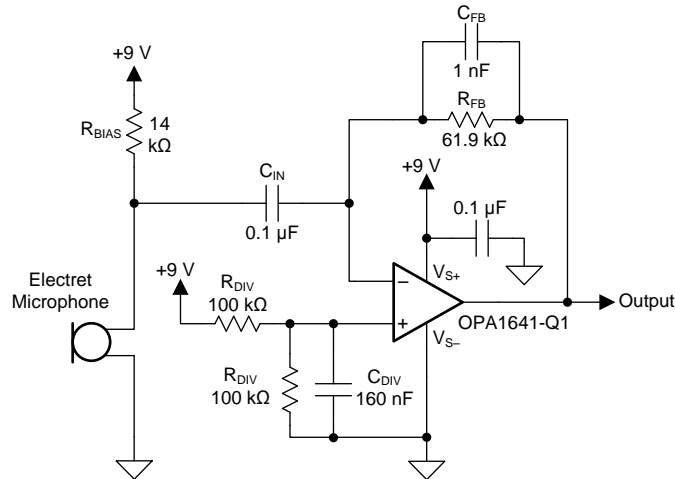

- (1) $V_{IN} = +V_S + 500 \text{ mV}$.
- (2) TVS: $+V_{S(max)} > V_{TVSBR (Min)} > +V_S$
- (3) Suggested value is approximately 1 k Ω .

Figure 36. Equivalent Internal ESD Circuitry and the Relation to a Typical Circuit Application

8.2 Typical Application

8.2.1 Single-Supply Electret Microphone Preamp for Speech

Electret microphones are commonly used in automotive hands-free phone systems because of their small size, low cost, and relatively good signal-to-noise ratio (SNR). The low noise and distortion of the OPA1641-Q1 makes the device a good choice for preamplifier circuits for electret microphones. The circuit shown in [Figure 37](#) is a single-supply preamplifier circuit for electret microphones with a bandwidth from 100 Hz to 3 kHz for capturing speech.

Copyright © 2016, Texas Instruments Incorporated

Figure 37. Preamplifier Circuit for Electret Microphones Using a Single Power Supply Voltage

8.2.1.1 Design Requirements

- 9-V single supply
- 1- V_{RMS} output for 100-dB_{SPL} input
- Approximately 100-Hz to 3-kHz, –3-dB Bandwidth
- Microphone sensitivity: 8 $\mu A / Pa$
- Microphone operating voltage: 2 V to 10 V
- Microphone bias current: 500 μA

8.2.1.2 Detailed Design Procedure

In this circuit, the op amp is configured as a transimpedance amplifier which converts the signal current of the microphone into an output voltage. The bandwidth of this circuit is limited to the vocal range as is common in telephony systems. The gain of the circuit is determined by the feedback resistor (R_{FB}), which must be calculated according to the microphone sensitivity. For this design, a microphone output current of 8 μA per Pascal (Pa) of air pressure was selected. Using this value, the output current for a sound pressure level of 100 dB_{SPL}, or 2 Pa air pressure, is calculated in [Equation 1](#).

$$i_{mic} = \frac{8 \mu A}{1 Pa} \times 2 Pa = 16 \mu A \quad (1)$$

R_{FB} is then calculated from this current to produce 1- V_{RMS} output for a 100-dB_{SPL} input signal in [Equation 2](#).

$$R_{FB} = \frac{V_O}{i_{mic}} = \frac{1 V_{RMS}}{16 \mu A} = 62500 \rightarrow 61.9 k\Omega \quad (2)$$

The feedback capacitor (C_{FB}) is calculated to limit the bandwidth of the amplifier to 3 kHz in [Equation 3](#).

$$C_{FB} = \frac{1}{2 \cdot \pi \cdot R_{FB} \cdot f_H} = \frac{1}{2 \cdot \pi \cdot (61.9 k\Omega) \cdot (3 kHz)} = 857 \times 10^{-12} \rightarrow 1 nF \quad (3)$$

Typical Application (continued)

R_{BIAS} is necessary to divert the microphone signal current through capacitor C_{IN} rather than flowing from the power supply (V_{CC}). Larger values of R_{BIAS} allow for a smaller capacitor to be used for C_{IN} and reduces the overall noise of the circuit. However, the maximum value for R_{BIAS} is limited by the microphone bias current and minimum operating voltage.

The value of R_{BIAS} is calculated in 式 4.

$$R_{BIAS} = \frac{V_{CC} - V_{MIC}}{I_{BIAS}} = \frac{9\text{ V} - 2\text{ V}}{500\text{ }\mu\text{A}} = 14\text{ k}\Omega \quad (4)$$

Input capacitor C_{IN} forms a high-pass filter in combination with resistor R_{BIAS} . The filter corner frequency calculation is shown in 式 5 to place the high-pass corner frequency at 100 Hz.

$$C_{IN} = \frac{1}{2 \cdot \pi \cdot R_{BIAS} \cdot f_L} = \frac{1}{2 \cdot \pi \cdot (14\text{ k}\Omega) \cdot (100\text{ Hz})} = 113.7 \times 10^{-9} \rightarrow 100\text{ nF} \quad (5)$$

The voltage divider network at the op amp noninverting input is used to bias the op amp output to the midsupply point ($V_{CC} / 2$) to maximize the output voltage range of the circuit. This result is easily achieved by selecting the same value for both resistors in the divider. The absolute value of those resistors is limited by the acceptable power-supply current drawn by the voltage divider. Choosing 50 μA as an acceptable limit of supply current gives a value of 100 k Ω for the resistors in the divider, as 式 6 shows.

$$R_{DIV} \geq \frac{V_{CC}}{2 \cdot I_{DIV}} \geq \frac{9\text{ V}}{2 \cdot 50\text{ }\mu\text{A}} \geq 90\text{ k}\Omega \rightarrow 100\text{ k}\Omega \quad (6)$$

Finally, to minimize the additional noise contribution from the voltage divider, a capacitor is placed at the op amp noninverting input. This capacitor forms a low-pass filter with the parallel combination of the voltage divider resistors. Selecting a filter corner frequency of 20 Hz minimizes the noise contribution of the voltage divider inside the amplifier passband; see 式 7.

$$C_{DIV} = \frac{1}{2 \cdot \pi \cdot \left(\frac{R_{DIV}}{2}\right) \cdot f_L} = \frac{1}{2 \cdot \pi \cdot \left(\frac{100\text{ k}\Omega}{2}\right) \cdot (20\text{ Hz})} = 1.592 \times 10^{-7} \rightarrow 160\text{ nF} \quad (7)$$

Typical Application (continued)

8.2.1.3 Application Curve

The transfer function of the microphone preamplifier circuit is shown in [Figure 38](#). The nominal gain of the circuit is 95.46 dB, or 59,292.5 V per amp of input current. The –3-dB bandwidth limits of the circuit are 105.7 Hz and 2.77 kHz.

Figure 38. Microphone Preamplifier Transfer Function

9 Power Supply Recommendations

The OPA164x-Q1 devices are specified for operation from 4.5 V to 36 V (± 2.25 V to ± 18 V); many specifications apply from -40°C to $+125^{\circ}\text{C}$. Parameters that can exhibit significant variance with regard to operating voltage or temperature are presented in [Typical Characteristics](#).

10 Layout

10.1 Layout Guidelines

For best operational performance of the device, use good PCB layout practices, including:

- Noise can propagate into analog circuitry through the power pins of the circuit as a whole and of the op amp itself. Bypass capacitors reduce the coupled noise by providing low-impedance power sources local to the analog circuitry.
 - Connect low-ESR, 0.1- μ F ceramic bypass capacitors between each supply pin and ground, placed as close as possible to the device. A single bypass capacitor from V+ to ground is applicable for single-supply applications.
- Separate grounding for analog and digital portions of circuitry is one of the simplest and most-effective methods of noise suppression. One or more layers on multilayer PCBs are usually devoted to ground planes. A ground plane helps distribute heat and reduces EMI noise pickup. Take care to physically separate digital and analog grounds, paying attention to the flow of the ground current.
- To reduce parasitic coupling, run the input traces as far away as possible from the supply or output traces. If these traces cannot be kept separate, crossing the sensitive trace perpendicular is much better as opposed to in parallel with the noisy trace.
- Place the external components as close as possible to the device. As shown in [Figure 39](#), keeping RF and RG close to the inverting input minimizes parasitic capacitance.
- Keep the length of input traces as short as possible. Always remember that the input traces are the most sensitive part of the circuit.
- Consider a driven, low-impedance guard ring around the critical traces. A guard ring can significantly reduce leakage currents from nearby traces that are at different potentials.
- TI recommends cleaning the PCB following board assembly for best performance.
- Any precision integrated circuit can experience performance shifts resulting from moisture ingress into the plastic package. Following any aqueous PCB cleaning process, TI recommends baking the PCB assembly to remove moisture introduced into the device packaging during the cleaning process. A low temperature, post-cleaning bake at 85°C for 30 minutes is sufficient for most circumstances.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
OPA1641AQDGKRQ1	ACTIVE	VSSOP	DGK	8	2500	RoHS & Green	NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	1641	Samples
OPA1642AQDGKRQ1	ACTIVE	VSSOP	DGK	8	2500	RoHS & Green	NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	1642	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
