

TPS61256xC チップ・スケール・パッケージの3.5MHz、高効率の昇圧コンバータ

1 特長

- 3.5MHz動作時に93%の効率
- 通常動作時の静止電流: 37 μ A
- 2.3V~5.5Vの広い V_{IN} 範囲
- $V_{IN} \geq V_{OUT}$ の動作をサポート
- 合計DC電圧精度: $\pm 2\%$
- 軽負荷時のPFMモード
- ENをLOWにしてパススルー・モードを選択
- サーマル・シャットダウンおよび過負荷保護機能
- 3つの表面実装の外付け部品のみで動作
- 合計ソリューション・サイズ < 25mm²
- 9ピンの NanoFree™(CSP)パッケージ

2 アプリケーション

- NFC PA電源
- 携帯電話、スマートフォン
- モノラルおよびステレオAPAアプリケーション
- USB充電ポート

3 概要

TPS61256xCデバイスは、バッテリー駆動の携帯アプリケーション用の電源ソリューションです。TPS61256xCは低消費電力のアプリケーションを対象としており、バッテリーが最低2.65Vまで放電されても、800mAまでの負荷電流をサポートし、低コストのチップ・インダクタとコンデンサを使用できます。

このデバイスは2.3V~5.5Vの広い入力電圧範囲で動作するため、拡張電圧範囲でリチウムイオン・バッテリーにより動作するアプリケーションをサポートしています。3.15Vから5.0Vまで、各種の固定電圧出力バージョンが用意されています。

TPS61256xCは、レギュレートされた3.5MHzのスイッチング周波数で動作し、負荷電流が小さいときはパワー・セーブ・モードに移行して、負荷電流の範囲全体にわたって高い効率を維持します。PFMモードでは、軽負荷動作時の静止電流が37 μ A (標準値)に低下し、バッテリー駆動時間が延長されます。

さらに、TPS61256xCデバイスは、ENをLOWにすることで、パススルー・モードもサポートできます。このモードでは、出力電圧が入力電圧に追従し、インダクタおよびハイサイドFETの抵抗分だけ電圧降下が発生します。

TPS61256xCは、最小限の外付け部品で、非常に小型のソリューションを実現できます。小さなインダクタと入力コンデンサを使用できるため、ソリューションが小型化します。

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
EN	B3	I	EN = high, the device works in the boost mode. EN = low, the device is in pass-through mode. This pin must not be left floating and must be terminated.
GND	C1, C2, C3		Ground pin.
SW	B1, B2	I/O	This is the switch pin of the converter and is connected to the drain of the internal Power MOSFETs.
VIN	A3	I	Power supply input.
VOUT	A1, A2	O	Boost converter output.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Input voltage	Voltage at VIN ⁽²⁾ , VOUT ⁽²⁾ , SW ⁽²⁾ , EN ⁽²⁾	-0.3	7	V
Input current	Continuous average current into SW ⁽³⁾	1.8		A
	Peak current into SW ⁽⁴⁾	3.5		
Power dissipation		Internally limited		
Temperature	Operating, T _A ⁽⁵⁾	-40	85	°C
	Operating virtual junction, T _J	-40	150	
	Storage, T _{stg}	-65	150	

- Stresses beyond those listed under *absolute maximum ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *recommended operating conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- All voltages are with respect to network ground terminal.
- Limit the junction temperature to 105°C for continuous operation at maximum output power.
- Limit the junction temperature to 125°C for 5% duty cycle operation.
- In applications where high power dissipation and/or poor package thermal resistance is present, the maximum ambient temperature may have to be derated. Maximum ambient temperature (T_{A(max)}) is dependent on the maximum operating junction temperature (T_{J(max)}), the maximum power dissipation of the device in the application (P_{D(max)}), and the junction-to-ambient thermal resistance of the part/package in the application (θ_{JA}), as given by the following equation: T_{A(max)} = T_{J(max)} - (θ_{JA} × P_{D(max)}). To achieve optimum performance, it is recommended to operate the device with a maximum junction temperature of 105°C.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1000	
	Machine model (MM)	±200	

- JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 500-V HBM is possible with the necessary precautions.
- JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 250-V CDM is possible with the necessary precautions.

7.3 Recommended Operating Conditions

			MIN	NOM	MAX	UNIT

9 Detailed Description

9.1 Overview

The TPS61256xC synchronous step-up converter typically operates at a quasi-constant 3.5-MHz frequency pulse width modulation (PWM) at moderate to heavy load currents. At light load currents, the TPS61256xC converter operates in power-save mode with pulse frequency modulation (PFM).

During PWM operation, the converter uses a novel quasi-constant on-time valley current mode control scheme to achieve excellent line/load regulation and allows the use of a small ceramic inductor and capacitors. Based on the V_{IN}/V_{OUT} ratio, a simple circuit predicts the required on-time.

At the beginning of the switching cycle, the low-side N-MOS switch is turned-on and the inductor current ramps up to a peak current that is defined by the on-time and the inductance. In the second phase, once the on-timer has expired, the rectifier is turned-on and the inductor current decays to a preset valley current threshold. Finally, the switching cycle repeats by setting the on timer again and activating the low-side N-MOS switch.

In general, a dc/dc step-up converter can only operate in "true" boost mode, i.e. the output "boosted" by a certain amount above the input voltage. The TPS61256xC device operates differently as it can smoothly transition in and out of zero duty cycle operation. Therefore the output can be kept as close as possible to its regulation limits even though the converter is subject to an input voltage that tends to be excessive. In this operation mode, the output current capability of the regulator is limited to 500 mA (min.). Refer to [Figure 3](#) for further details.

The current mode architecture with adaptive slope compensation provides excellent transient load response, requiring minimal output filtering. Internal soft-start and loop compensation simplifies the design process while minimizing the number of external components.

9.3 Feature Description

9.3.1 Current Limit Operation

The TPS61256xC device employs a valley current limit sensing scheme. Current limit detection occurs during the off-time by sensing of the voltage drop across the synchronous rectifier.

The output voltage is reduced as the power stage of the device operates in a constant current mode. The maximum continuous output current ($I_{OUT(CL)}$), before entering current limit (CL) operation, can be defined by Equation 1.

$$I_{OUT(CL)} = (1 - D) \cdot (I_{VALLEY} + \frac{1}{2} \Delta I_L) \tag{1}$$

The duty cycle (D) can be estimated by Equation 2

$$D = 1 - \frac{V_{IN} \cdot \eta}{V_{OUT}} \tag{2}$$

and the peak-to-peak current ripple (ΔI_L) is calculated by Equation 3

$$\Delta I_L = \frac{V_{IN}}{L} \cdot \frac{D}{f} \tag{3}$$

The output current, $I_{OUT(DC)}$, is the average of the rectifier ripple current waveform. When the load current is increased such that the lower peak is above the current limit threshold, the off-time is increased to allow the current to decrease to this threshold before the next on-time begins (so called frequency fold-back mechanism). When the current limit is reached the output voltage decreases during further load increase.

Figure 8 illustrates the inductor and rectifier current waveforms during current limit operation.

Figure 8. Inductor/Rectifier Currents in Current Limit Operation

9.3.2 Enable

The TPS61256xC device starts operation when EN is set high and starts up with the soft-start sequence. For proper operation, the EN pin must be terminated and must not be left floating.

Pulling the EN low and V_{in} above UVLO, the device is in the forced pass-through mode and the output voltage follows the input voltage (with a voltage drop of the inductor DCR and R_{dson} of HS FET).

9.3.3 Softstart

The TPS61256xC device has an internal softstart circuit that limits the inrush current during start-up. The first step in the start-up cycle is the pre-charge phase. During pre-charge, the rectifying switch is turned on until the output capacitor is charged to a value close to the input voltage. The rectifying switch is current limited (500 mA min.) during this phase. This mechanism is used to limit the output current under short-circuit condition.

Feature Description (continued)

Once the output capacitor has been biased to the input voltage, the converter starts switching. The soft-start system progressively increases the on-time as a function of the input-to-output voltage ratio. As soon as the output voltage is reached, the regulation loop takes control and full current operation is permitted.

The TPS61256xC works in the pass-through mode when EN is low and V_{IN} above UVLO, the device enters into the boost switching phase directly when EN becomes high.

9.3.4 Undervoltage Lockout

The under voltage lockout circuit prevents the device from malfunctioning at low input voltages and the battery from excessive discharge. It disables the output stage of the converter once the falling V_{IN} trips the under-voltage lockout threshold V_{UVLO} which is typically 2.0V. The device starts operation once the rising V_{IN} trips V_{UVLO} threshold plus its hysteresis of 100 mV at typically 2.1 V.

9.3.5 Thermal Regulation

The TPS61256xC device contains a thermal regulation loop that monitors the die temperature during the pre-charge phase. If the die temperature rises to high values of about 110 °C, the device automatically reduces the current to prevent the die temperature from increasing further. Once the die temperature drops about 10 °C below the threshold, the device automatically increases the current to the target value. This function also reduces the current during a short-circuit condition.

9.3.6 Thermal Shutdown

As soon as the junction temperature, T_J , exceeds 140°C (typ.) the device goes into thermal shutdown. In this mode, the high-side and low-side MOSFETs are turned-off. When the junction temperature falls below the thermal shutdown minus its hysteresis, the device continues the operation.

9.4 Device Functional Modes

9.4.1 Power Save Mode

The TPS61256xC integrates a power save mode to improve efficiency at light load. In power save mode the converter only operates when the output voltage trips below a set threshold voltage.

The TPS61256xC ramps up the output voltage with several pulses and goes into power save mode once the output voltage exceeds the set threshold voltage.

The PFM mode is exited and PWM mode entered when the output current can no longer be supported in PFM mode.

Figure 9. Power Save

Device Functional Modes (continued)

9.4.2 Pass-Through Mode

When EN is pulled to low and V_{in} above UVLO, the device works in the pass-through mode and the output voltage of TPS61256xC follows the input voltage level. In so called pass-through mode, the synchronous rectifier is current limited to 500 mA (min.). The output voltage is slightly reduced due to voltage drop across the rectifier MOSFET and the inductor DC resistance.

10 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

With a wide input voltage range of 2.3 V to 5.5 V, the TPS61256xC supports applications powered by Li-Ion batteries with extended voltage range. Intended for low-power applications, it supports up to 800-mA load current from a battery discharged as low as 2.65 V and allows the use of low cost chip inductor and capacitors. Different fixed voltage output versions are available from 3.15 V to 5.0 V. The TPS61256xC offers a very small solution size due to minimum amount of external components. The TPS6125xC allows the use of small inductors and input capacitors to achieve a small solution size. During the pass-through mode, the output voltage is biased to the input voltage.

10.2 Typical Application

This section details an application with TPS61256xC to output fixed 5.0 V.

Figure 10. Smallest Solution Size Application

10.2.1 Design Requirements

In this example, TPS61256xC is used to design a 5-V power supply with up to 800-mA output current capability. The TPS61256xC can be powered by one-cell Li-ion battery, and in this example the input voltage range is from 2.65 V to 4.85 V.

(2) Inductor used to characterize TPS61256xCYFF device.

10.2.2.1 Inductor Selection

A boost converter normally requires two main passive components for storing energy during the conversion, an inductor and an output capacitor. TI advises selecting an inductor with a saturation current rating higher than the possible peak current flowing through the power switches.

The inductor peak current varies as a function of the load, the input and output voltages and can be estimated using [Equation 4](#).

$$I_{L(\text{PEAK})} = \frac{V_{\text{IN}} \cdot D}{2 \cdot f \cdot L} + \frac{I_{\text{OUT}}}{(1-D) \cdot \eta} \quad \text{with} \quad D = 1 - \frac{V_{\text{IN}} \cdot \eta}{V_{\text{OUT}}} \quad (4)$$

Selecting an inductor with insufficient saturation performance can lead to excessive peak current in the converter. This could eventually harm the device and reduce its reliability.

When selecting the inductor, as well as the inductance, parameters of importance are: maximum current rating, series resistance, and operating temperature. The inductor DC current rating should be greater (by some margin) than the maximum input average current, refer to [Equation 5](#) and [Current Limit Operation](#) section for more details.

$$I_{L(DC)} = \frac{V_{OUT}}{V_{IN}} \cdot \frac{1}{\eta} \cdot I_{OUT} \quad (5)$$

The TPS61256xC series of step-up converters have been optimized to operate with a effective inductance in the range of 0.7 μ H to 2.9 μ H and with output capacitors in the range of 10 μ F to 47 μ F. The internal compensation is optimized for an output filter of $L = 1 \mu$ H and $C_O = 10 \mu$ F. Larger or smaller inductor values can be used to optimize the performance of the device for specific operating conditions. For more details, see the [Checking Loop Stability](#) section.

In high-frequency converter applications, the efficiency is essentially affected by the inductor AC resistance (i.e. quality factor) and to a smaller extent by the inductor DCR value. To achieve high efficiency operation, care should be taken in selecting inductors featuring a quality factor above 25 at the switching frequency. Increasing the inductor value produces lower RMS currents, but degrades transient response. For a given physical inductor size, increased inductance usually results in an inductor with lower saturation current.

The total losses of the coil consist of both the losses in the DC resistance, $R_{(DC)}$, and the following frequency-dependent components:

- The losses in the core material (magnetic hysteresis loss, especially at high switching frequencies)
- Additional losses in the conductor from the skin effect (current displacement at high frequencies)
- Magnetic field losses of the neighboring windings (proximity effect)
- Radiation losses

The following inductor series from different suppliers have been used with the TPS61256xC converters.

Table 2. List of Inductors

MANUFACTURER ⁽¹⁾	SERIES	DIMENSIONS (in mm)
HITACHI METALS	KSLI-322512BL1-1R0	3.2 x 2.5 x 1.2 max. height

	MDT2012-CLR1R0AM	2.0 x 1.2 x 0.58 max height

(1) See [Third-Party Products Disclaimer](#)

10.2.2.2 Output Capacitor

For the output capacitor, TI recommends using small ceramic capacitors placed as close as possible to the V_{OUT} and GND pins of the IC. If, for any reason, the application requires the use of large capacitors which can not be placed close to the IC, using a smaller ceramic capacitor in parallel to the large one is highly recommended. This small capacitor should be placed as close as possible to the V_{OUT} and GND pins of the IC. To get an estimate of the recommended minimum output capacitance, [Equation 6](#) can be used.

$$C_{MIN} = \frac{I_{OUT} \cdot (V_{OUT} - V_{IN})}{f \cdot \Delta V \cdot V_{OUT}} \quad (6)$$

Where f is the switching frequency which is 3.5 MHz (typ.) and ΔV is the maximum allowed output ripple.

With a chosen ripple voltage of 20mV, a minimum effective capacitance of 9 μ F is needed. The total ripple is larger due to the ESR of the output capacitor. This additional component of the ripple can be calculated using [Equation 7](#)

$$V_{ESR} = I_{OUT} \cdot R_{ESR} \quad (7)$$

An MLCC capacitor with twice the value of the calculated minimum should be used due to DC bias effects. This is required to maintain control loop stability. The output capacitor requires either an X7R or X5R dielectric. Y5V and Z5U dielectric capacitors, aside from their wide variation in capacitance over temperature, become resistive at high frequencies. There are no additional requirements regarding minimum ESR. Larger capacitors cause lower output voltage ripple as well as lower output voltage drop during load transients but the total output capacitance value should not exceed ca. 50 μ F.

DC bias effect: high cap. ceramic capacitors exhibit DC bias effects, which have a strong influence on the device's effective capacitance. Therefore the right capacitor value has to be chosen very carefully. Package size and voltage rating in combination with material are responsible for differences between the rated capacitor value and its effective capacitance. For instance, a 10- μ F X5R 6.3-V 0603 MLCC capacitor would typically show an effective capacitance of less than 4 μ F (under 5 V bias condition, high temperature).

In applications featuring high pulsed load currents, it is recommended to run the converter with a reasonable amount of effective output capacitance, for instance x2 10- μ F X5R 6.3-V 0603 MLCC capacitors connected in parallel.

10.2.2.3 Input Capacitor

Multilayer ceramic capacitors are an excellent choice for input decoupling of the step-up converter as they have extremely low ESR and are available in small footprints. Input capacitors should be located as close as possible to the device. While a 4.7- μ F input capacitor is sufficient for most applications, larger values may be used to reduce input current ripple without limitations.

Take care when using only ceramic input capacitors. When a ceramic capacitor is used at the input and the power is being supplied through long wires, such as from a wall adapter, a load step at the output can induce ringing at the VIN pin. This ringing can couple to the output and be mistaken as loop instability or could even damage the part. Additional "bulk" capacitance (electrolytic or tantalum) should in this circumstance be placed between C_I and the power source lead to reduce ringing that can occur between the inductance of the power source leads and C_I.

10.2.2.4 Checking Loop Stability

The first step of circuit and stability evaluation is to look from a steady-state perspective at the following signals:

- Switching node, SW
- Inductor current, I_L
- Output ripple voltage, V_{OUT(AC)}

These are the basic signals that need to be measured when evaluating a switching converter. When the switching waveform shows large duty cycle jitter or the output voltage or inductor current shows oscillations, the regulation loop may be unstable. This is often a result of board layout and/or L-C combination.

As a next step in the evaluation of the regulation loop, the load transient response is tested. The time between the application of the load transient and the turn on of the P-channel MOSFET, the output capacitor must supply all of the current required by the load. V_{OUT} immediately shifts by an amount equal to $\Delta I_{(LOAD)} \times ESR$, where ESR is the effective series resistance of C_{OUT}. $\Delta I_{(LOAD)}$ begins to charge or discharge C_{OUT} generating a feedback error signal used by the regulator to return V_{OUT} to its steady-state value. The results are most easily interpreted when the device operates in PWM mode.

During this recovery time, V_{OUT} can be monitored for settling time, overshoot or ringing that helps judge the converter's stability. Without any ringing, the loop has usually more than 45° of phase margin. Because the damping factor of the circuitry is directly related to several resistive parameters (e.g., MOSFET r_{DS(on)}) that are temperature dependant, the loop stability analysis has to be done over the input voltage range, load current range, and temperature range.

11 Power Supply Recommendations

The power supply can be three-cell alkaline, NiCd or NiMH, or one-cell Li-Ion or Li-Polymer battery. The input supply should be well regulated with the rating of TPS61256xC. If the input supply is located more than a few inches from the device, additional bulk capacitance may be required in addition to the ceramic bypass capacitors. An electrolytic or tantalum capacitor with a value of 47 μF is a typical choice.

12 Layout

12.1 Layout Guidelines

For all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator could show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground tracks. The input capacitor, output capacitor, and the inductor should be placed as close as possible to the IC. Use a common ground node for power ground and a different one for control ground to minimize the effects of ground noise. Connect these ground nodes at any place close to the ground pins of the IC.

12.2 Layout Example

Figure 20. Suggested Layout (Top View)

12.3 Thermal Considerations

Implementation of integrated circuits in low-profile and fine-pitch surface-mount packages typically requires special attention to power dissipation. Many system-dependent issues such as thermal coupling, airflow, added heat sinks and convection surfaces, and the presence of other heat-generating components affect the power-dissipation limits of a given component.

Three basic approaches for enhancing thermal performance are listed below:

- Improving the power dissipation capability of the PCB design
- Improving the thermal coupling of the component to the PCB
- Introducing airflow in the system

As power demand in portable designs is more and more important, designers must figure the best trade-off between efficiency, power dissipation and solution size. Due to integration and miniaturization, junction temperature can increase significantly which could lead to bad application behaviors (i.e. premature thermal shutdown or worst case reduce device reliability).

Junction-to-ambient thermal resistance is highly application and board-layout dependent. In applications where the high maximum power dissipation exists, special care must be paid to thermal dissipation issues in board design. The device operating junction temperature (T_J) should be kept below 125°C.

13 デバイスおよびドキュメントのサポート

13.1 デバイス・サポート

13.1.1 デベロッパー・ネットワークの製品に関する免責事項

デベロッパー・ネットワークの製品またはサービスに関するTIの出版物は、単独またはTIの製品、サービスと一緒に提供される場合に関係なく、デベロッパー・ネットワークの製品またはサービスの適合性に関する是認、デベロッパー・ネットワークの製品またはサービスの是認の表明を意味するものではありません。

13.2 ドキュメントの更新通知を受け取る方法

ドキュメントの更新についての通知を受け取るには、ti.comのデバイス製品フォルダを開いてください。右上の隅にある「通知を受け取る」をクリックして登録すると、変更されたすべての製品情報に関するダイジェストを毎週受け取れます。変更の詳細については、修正されたドキュメントに含まれている改訂履歴をご覧ください。

13.3 コミュニティ・リソース

The following links connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

TI E2E™オンライン・コミュニティ *TIのE2E (Engineer-to-Engineer)* コミュニティ。エンジニア間の共同作業を促進するために開設されたものです。e2e.ti.comでは、他のエンジニアに質問し、知識を共有し、アイデアを検討して、問題解決に役立てることができます。

設計サポート *TIの設計サポート* 役に立つE2Eフォーラムや、設計サポート・ツールをすばやく見つけることができます。技術サポート用の連絡先情報も参照できます。

TPS612564CYFFT	PREVIEW	DSBGA	YFF	9	250	Green (RoHS and no Sb/Br)	SNAGCU	Level-1-260C-UNLIM	-40 to 85	16I

- (1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PRE_PROD Unannounced device, not in production, not available for mass market, nor on the web, samples not available.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.
- (2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.
TBD: The Pb-Free/Green conversion plan has not been defined.
Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)
- (3) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
- (4) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (5) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device
- (6) Multiple Device markings will be inside parentheses. Only on Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
