NSF4V does not support the following features:

- Edge Enhancement
- YUV formats
- Module bypass (it is implemented at top subsystem level)

##### 7.7.3.4.2 NSF4V Overview

The advanced noise filter NSF4v decomposes the input image into low-frequency, mid-frequency, and high-frequency bands first and then filter out the noise in frequency domain. NSF4v can adapt its noise filtering strength to local image intensity according to the user programmable noise threshold registers. NSF4 is also able to adjust its strength according to the amount of previously applied lens shading correction gains with a user programmable approximate radial model.

##### 7.7.3.4.2.1 Decomposition Kernel Representation

With combination of just level 1, levels 1+2, and levels 1+2+3, horizontally and vertically, the result feature detection filter kernels are shown in [Figure 7-48](#). Note that all coefficients are powers of 2, and therefore do not require multiplication.

$$\begin{aligned}
 F1 &= \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix} /4 \\
 F2 &= \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix} /4 \\
 F3 &= \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} /4 \\
 F4 &= \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \end{bmatrix} /16 \\
 F5 &= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix} /16 \\
 F6 &= \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ -1 & -1 & 1 & 1 \\ -1 & -1 & 1 & 1 \end{bmatrix} /16 \\
 F7 &= \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \end{bmatrix} /64 \\
 F8 &= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \end{bmatrix} /64 \\
 F9 &= \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \end{bmatrix} /64
 \end{aligned}$$

nsf4v-002

**Figure 7-48. NSF4V Kernel Representation for Decomposition Filters**

G1...9 are the counter-part reconstruction kernels. Each of G1...9 is a row-wise and column-wise mirror of the counterpart F function.

The kernel representation in [Figure 7-49](#) illustrates a filter alignment.

nsf4v-003

**Figure 7-49. NSF4V Kernel Representation Filter Alignment**

Figure 7-49 is showing an academic 8x8 pixel image frame which has been border extended on all 4 edges. Superposed onto this border extended frame (shown in dotted lines) is the kernel alignment for all 3 different kernel sizes for each of the three levels:

- Level 1: 2x2 kernel
- Level 2: 4x4 kernel
- Level 3: 8x8 kernel

For each of the 9 different kernels, a matrix of (width + 7) x (height + 7) decomposition values result. All of these result matrixes are exactly aligned.

nsf4v-004

**Figure 7-50. NSF4V Example F1 Kernel Result**

The kernel alignment is top-left aligned for the first pixel. Which translates in the recursive approach as a X-Y shift. In order to be mathematically aligned in the Recursive approach, the Level 1 output needs to be shifted 6 positions in both the X and Y direction relative to the Level 3 output. Additionally, the Level 2 output needs to be shifted 4 positions in both the X and Y direction relative to the Level 3 output. These shifts are critical such that Level 1, 2, and 3 values are cycle aligned when presented to the thresholding circuit.

One can reach the same conclusion by looking at the figure and thinking about which line delay or which horizontal pipelined pixel position is used in order for the kernels to output their results in the same pipeline cycle.

#### 7.7.3.4.3 NSF4V Lens Shading Correction Compensation

The Lens Shading Correction (LSC) is implemented prior to NSF. This is not an optimal order of operation and therefore an adjustment factor is implemented to compensate for the order of operations. The LSCC (Lens Shading Correction Compensation) first approximates the gain of LSC and calculates both that gain and it's inverse. Within the T<sub>n</sub> calculation, the inverse gain is applied to the LL2 average, then the T<sub>n</sub> is calculated. Last, the result is multiplied by the gain. In this way, the LSC is approximately reversed temporarily in order that T<sub>n</sub> is calculated properly.

LSCC calculates the radius (distance) from the center of the image, then uses a programmable curve to look up the gain value.

While calculating the radius, the center on the frame is programmable. Also a correction gain (kh and kv) separately for X and Y are programmable which allows for elliptical shaped lenses. Because the SQRT is such an expensive function, the resulting radius is used in the SQR form and as such has a very large dynamic range. A programmable shift value effectively selects which portion of this dynamic range is to use for the curve lookup.

The curve lookup is a 16 segment curve. The SQR(Radius) is lookup on the X axis and the resulting gain is supplied on the Y axis.

#### 7.7.3.4.4 NSF4V Noise Threshold Adaptation to Local Image Intensity

Figure 7-51 shows the local image intensity to noise threshold  $T_n$  mapping via the 12-segment interpolated lookup. Twelve sets of  $(X, Y, S)$ ,  $S$  = slope, are provided per curve, one set per color plane, with the first  $X$  coordinate fixed at zero.

**Figure 7-51. NSF4V Local Image Intensity to Noise Threshold Piece-wise Linear Function**

The slopes should be implemented with signed value, as some image sensors might require higher noise threshold at the low intensity range than high intensity range.

### 7.7.3.5 VISS Global/Local Brightness and Contrast Enhancement (GLBCE) Module

#### 7.7.3.5.1 GLBCE Overview

The Global Local Brightness Contrast Enhancement module performs dynamic range compression or tone mapping of an input image based on a model of the human visual system. It is used to produce most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations.

#### 7.7.3.5.2 GLBCE Interface

Data flow control of GLBCE module is done by PCLK. GLBCE processes the image cycle by cycle, and output the data after certain cycles of latency.

#### 7.7.3.5.3 GLBCE Core

The GLBCE Core is an iridix® core which performs "dynamic range compression" or "tone mapping" on an input image based on a model of the human visual system. It is used in a camera pipeline to produce the most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The purpose of the transform is to map the image content from an input source such that it remains fully visible on an output display without loss of content. Note that iridix is specifically designed to preserve color, sharpness and boost contrast of the source image.

The iridix core is based on space-variant or pixel-by-pixel processing algorithms which construct a family of transforms based on the analysis of image content. The algorithms inside iridix are adaptive, meaning that a single set of parameters can be set to process any source image or any video sequence under different lighting conditions.

Iridix generates effective tone curves by analyzing the regions surrounding each pixel. The tone curves generated by iridix are based on an asymmetry curve which is then shaped and controlled by a number of parameters that control the gain limitation weighting towards shadows, mid tones and highlights.

##### 7.7.3.5.3.1 GLBCE Core Key Parameters

[Table 7-103](#) shows the key parameters within the iridix core. It is recommended that all parameters be set statically to their recommended values other than the iridix strength parameter, which should be controlled dynamically with scene content. The calculation of iridix strength is explained in [Section 7.7.3.5.3.2](#).

**Table 7-103. GLBCE Core Key Parameters**

Parameter	Description
iridix strength	This register sets iridix processing strength.
	0x00: Video data will not be processed at all, and will pass to the output unchanged.
	0xFF: Maximum processing strength.
Variance space	This register affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to small areas is maximized (i.e. the transform becomes more local). When this parameter is set to 0xF, the transform deemphasizes small local details, and the transform becomes more global
Variance intensity	For a high-contrast image with shadows and highlights, a small value will cause iridix to adjust shadows and highlights almost independently. A large variance causes iridix to become progressively more global, meaning that the presence of highlights affects the processing of shadows and vice-versa.
Slope min limit	This register is used to restrict the slope of the tone curve generated by iridix. When this parameter is set to 0x00, the tone curve slope generated by iridix is not limited.
	When this value is set to 0xFF, iridix will not generate a tone curve with a slope less than 3/4. Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-128
Slope max limit	This register is used to restrict the slope of the tone-curve generated by iridix. When this parameter is set to 0xFF, the tone curve slope generated by iridix is not limited.
	When this value is set to 0x00, iridix will not generate a tone-curve with slope greater than 16/15 (48°). Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-160. For noisy images, lower values should be used.

**Table 7-103. GLBCE Core Key Parameters (continued)**

Parameter	Description
Black level	The value stored in this register will be used as the zero level for iridix processing in all data channels. Data below this value will not be processed and remain unchanged.
White level	The value stored in this register will be used as the white level for iridix processing in all data channels. Data above this value will not be processed and remain unchanged.
Asymmetry LUT	This look-up-table is 33 words, each of which is 16-bits. The asymmetry function is used to balance the iridix effect between the dark and bright regions of the image.
Forward perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is presented to the core, this look-up-table must be used to map the linear data to the perceptual space so that iridix can perform its perceptual functions.
Reverse perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is required from the output of the core, this look-up-table must be used to map the data from the perceptual space back to linear space for further processing in the pipeline.

### 7.7.3.5.3.2 GLBCE Iridix Strength Calculation

This section describes how the dynamic parameter, iridix strength, is calculated.

#### Note

Dynamic range of a digital camera can be described as the ratio of maximum light intensity measurable (at pixel saturation), to minimum light intensity measurable (but above read-out noise). This is a very important concept to consider when computing iridix strength, because the gain applied by iridix is also proportional to the visible boost of noise in the image. The maximum gain applied by iridix should be determined by the dynamic range of the camera system. This is governed by the equation presented in this section.

With iridix strength is zero, all tone curves are linear for all images. As iridix strength is increased, the variation between curves in shadows, mid tones and highlights increases, resulting in increasing compression of global dynamic range.

Iridix strength is calculated as follows:

$$\text{iridix strength} = \text{Max} \left( 0, \text{Min} \left( \frac{\text{IR\_Gain\_Target} - 1}{\text{IR\_Gain\_Max} - 1}, f(\text{analog gain}) \right) \right) * 255$$

glbce-843

**Figure 7-52. GLBCE Iridix Strength Formula**

Where:

- IR\_Gain\_Target is the desired iridix gain to be applied to the image. This is calculated from the image's histogram on a per-frame basis by the auto exposure algorithm (in RAWFE H3A module). The histogram is analysed to compute an exposure ratio for the desired global histogram shift. This computed exposure ratio is then used to feed a look-up-table which in turn generates the IR\_Gain\_Target parameter.
- IR\_GainMax is the maximum iridix gain. If the fwd\_percep\_lut is disabled, then the IR\_GainMax should be set to 64, and if the fwd\_percep\_lut is enabled, then the IR\_Gainmax should be set to 16.
- f(analog gain) is a function that determines the maximum iridix strength in relation to noise. f(analog gain) is characterised as follows:

**Figure 7-53. GLBCE Iridix  $f(\text{Analog Gain})$  Function**

$f(\text{analog gain})$  should only be used when the RAWFE is in linear mode. Otherwise, it should be set to 1

#### **7.7.3.5.3.3 GLBCE Iridix Configuration Registers**

##### **7.7.3.5.3.3.1 GLBCE Iridix Frame Width**

Frame Width is the number of pixels in an active line and is controlled from GLBCE\_FRAME\_WIDTH[15:0] VAL. Recommended value 2560 (decimal)

##### **7.7.3.5.3.3.2 GLBCE Iridix Frame Height**

Frame Height is the number of active lines in a frame and is controlled from GLBCE\_FRAME\_HEIGHT[15:0] VAL. Recommended value 1920 (decimal)

##### **7.7.3.5.3.3.3 GLBCE Iridix Control 0**

This is the main control register for the iridix core is GLBCE\_CONTROL0 where GLBCE is enabled/disabled and the type of processing algorithm is selected.

##### **7.7.3.5.3.3.4 GLBCE Iridix Control 1**

This register is reserved for debugging purposes. Recommended value 6 (decimal)

##### **7.7.3.5.3.3.5 GLBCE Iridix Strength**

GLBCE\_STRENGTH\_IR[7:0] VAL register sets the processing strength of the iridix core. Recommended value 128 (decimal)

##### **7.7.3.5.3.3.6 GLBCE Iridix Variance**

The GLBCE\_VARIANCE parameter affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). GLBCE\_VARIANCE[7:4] VARIANCEINTENSITY recommended value 12 (decimal). GLBCE\_VARIANCE[3:0] VARIANCESPACE recommended value 7 (decimal).

##### **7.7.3.5.3.3.7 GLBCE Iridix Dither**

When the number of color gradations of a display device is small (for example 6 bits per color), pixel dithering can make gradients look smother. Dithering of the least significant bits is applied and then these bits can be later truncated. The three least significant bits (D2, D1, D0) of this GLBCE\_DITHER register are responsible for the strength of dithering. There are 4 possible levels of dithering. Recommended value 0 (decimal)

#### 7.7.3.5.3.3.8 GLBCE Iridix Amplification Limit

The parameters dark amplification limit and bright amplification limit are used to restrict the luminance space in which iridix can adaptively generate tone curves for each pixel. GLBCE\_LIMIT\_AMPL[7:4] BRIGHTAMPLIFICATIONLIMIT recommended value 0 (decimal). GLBCE\_LIMIT\_AMPL[3:0] DARKAMPLIFICATIONLIMIT recommended value 0 (decimal).

#### 7.7.3.5.3.3.9 GLBCE Iridix Slope Min and Max

GLBCE\_SLOPE\_MIN[7:0] SLOPEMINLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 64 (decimal).

GLBCE\_SLOPE\_MAX[7:0] SLOPEMAXLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 72 (decimal).

#### 7.7.3.5.3.3.10 GLBCE Iridix Black Level

The value stored in the Black Level register GLBCE\_BLACK\_LEVEL[15:0] VAL will be used as the zero level for iridix processing in all data channels. Data below the Black level will not be processed and remain unchanged. Recommended value 0 (decimal).

#### 7.7.3.5.3.3.11 GLBCE Iridix White Level

The value stored in White Level register GLBCE\_WHITE\_LEVEL[15:0] VAL will be used as white level for iridix processing in all data channels. Data above White level will not be processed and stay unchanged. Recommended value 65535 (decimal).

#### 7.7.3.5.3.3.12 GLBCE Iridix Asymmetry Function Look-up-table

The Asymmetry function is used to balance the iridix effect between the dark and bright regions of the image. The Asymmetry Function Lookup Table geometry is 33 words, each of which is 16-bits wide.

GLBCE\_LUT\_FI\_00

GLBCE\_LUT\_FI\_01

... repeat until...

GLBCE\_LUT\_FI\_32

Recommended values (decimal):

The C-code for generating the Asymmetry LUT is shown below:

```
#include <math.h>
int AsymmetryTable[33];
void GenerateAsymmetry(int Asymmetry, int SecondPole)
{
    double x = (double(Asymmetry)+1)/257 * 2 - 1;
    int ai = (int)floor(0.5 + 255 * (1- 1/(1000*x*x*x) + x - ((x >= 0)*2)));
    double as = fabs(double(ai) / 255);
    double dp = double(SecondPole) / 255;
    int ii;
    for (ii = 0 ; ii < 33 ; ++ii)
    {
        if(ai >= 0)
        {
            x = double(ii) / 32;
        }
        else
        {
            x = double(32 - ii) / 32;
        }
        int y = (int)floor((dp+(1-dp)*pow((fabs(1-dp-x)/dp), 3)) * (x*(as+1)/(as+x) ) *
            65535.0 + 0.5);
        y = y < 0 ? 0 : y > 65535 ? 65535 : y;

        if (ai < 0)
        {

```

```

        y = 65535 - y;
    }
    AsymmetryTable[ii] = y;
}

```

#### 7.7.3.5.3.3.13 GLBCE Iridix Forward and Reverse Perceptual Functions Look-up-tables

The iridix core works in a perceptually uniform space and thus when linear data is presented to the core it needs to be processed with special perceptual functions. These are implemented as two perceptual LUTs namely: Forward Perceptual LUT and Reverse Perceptual LUT. Each LUT is made up of sixty-five 32-bit words.

#### 7.7.3.5.4 GLBCE Embedded Memory

GLBCE needs 2 lines of line memories and 1 set of cache memories.

**Table 7-104. GLBCE Memories**

Memory Type	Qty	Size	Clock	ECC Supported	Description
DELAY LINE	1	2122 x 64 (GLBCE_LINE_SIZE /2+10)x64	FCLK	No	GLBCE line memory
STATMEM	8 banks	16 bit x 1024	FCLK	Yes	GLBCE Cache memory (computes and stores the statistics from the frame)

#### 7.7.3.5.5 GLBCE General Processing

GLBCE block needs appropriate statistics information to be stored to its cache memory in prior to processing incoming frame. Usually, this takes a two-pass process.

1. GLBCE is configured for input frame-A
2. Frame-A is given to GLBCE
3. GLBCE processes the input frame-A
4. GLBCE generates statistic (statistics-A) data based on frame-A in vertical blanking period
5. (Optional process) statistics-A is read from cache memory and moved to SDRAM
6. GLBCE is configured for input frame-B
7. Frame-B is given to GLBCE
8. GLBCE processes the input frame-B with the statistics-A generated from frame-A
9. GLBCE generates statistics-B based on frame-B in vertical blanking period
10. (Optional process) statistics-B is read from cache memory and moved to SDRAM

Alternatively, GLBCE can process in the following manner

1. Pre-calculated Statistics-C is copied to GLBCE cache memory from SDRAM
2. GLBCE is programmed for input frame-D
3. Frame-D is given to GLBCE
4. GLBCE processes frame-D based on statistics-C
5. GLBCE generates statistics-D based on frame-D in vertical blanking period
6. (Optional process) statistics-D is read from cache memory and moved to SDRAM

In [Section 7.7.3.5.6](#), some examples closer to real world use cases are explained based on the above two processes.

#### 7.7.3.5.6 GLBCE Continuous Frame Processing

This is a very basic case, which does not need transferring statistics between cache memory and SDRAM. The most common example is video capture. In this case, the most straight forward way to run GLBCE, is to generate statistics from N-th frame, and apply it to (N+1)-th frame. The effect from using statistics of different frame should be small if the difference between frames is small. For example, it is expected this does not generate artifact, if the video frame rate is 30fps or larger. Below this rate, the single frame processing programming model explained in [Section 7.7.3.5.7](#) should be considered.

In the case of continuous frame processing, GLBCE is operated in the following manner:

1. GLBCE is programmed for incoming frame

2. Input frame comes in
3. GLBCE processes Input frame based on the statistics from the previous frame
4. GLBCE generates statistics based on the current input frame in the vertical blanking period
5. Repeat Step 1 through 4 as required

For the first frame of a set of sequential frames, Strength parameter should be 0, so GLBCE does not affect the image based on wrong statistics. SW may need to increase the strength value gradually after the first frame.

#### **7.7.3.5.7 GLBCE Single Image Processing**

For a single image, GLBCE needs to process the image twice, once for statistics generation, and once for actual GLBCE process.

1. GLBCE is configured for the input image.
2. The image is given to GLBCE. (Output image from GLBCE should be suppressed, for example, by disabling the next module in the path)
3. Statistics is generated in vertical blanking period.
4. The input image is given to GLBCE again. Output image with right GLBCE is generated.

Also, GLBCE can take in small size image in the first pass to reduce processing time.

5. A small size version (IMG-S) of the input image (IMG-IN) is generated.
6. GLBCE is configured for the small size image (IMG-S).
7. The small size image (IMG-S) is given to GLBCE.
8. Statistics for the small size image is generated in vertical blanking period.
9. GLBCE is configured for the original input image (IMG-IN).
10. The original input image (IMG-IN) is given to GLBCE.

### 7.7.3.6 VISS Flexible Color Processing (FCP) Module

#### 7.7.3.6.1 FCP Overview

The Flexible Color Processing module is responsible for performing CFA Interpolation as well as performing a host of color processing functions for generating different color outputs.

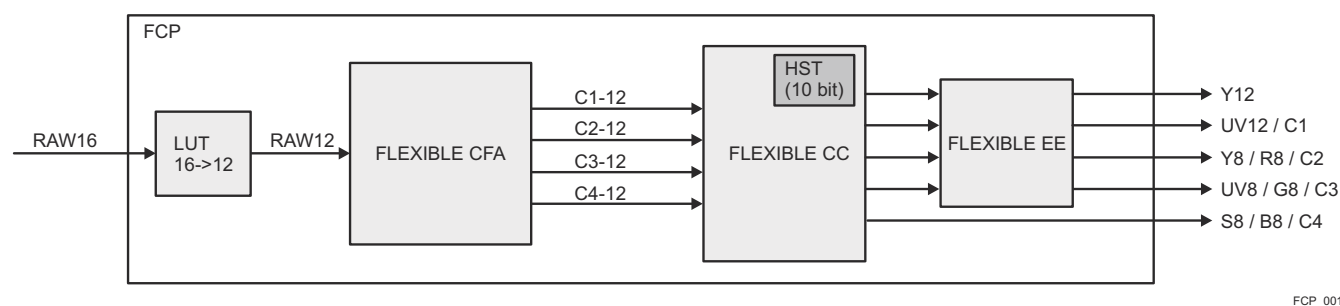

##### 7.7.3.6.1.1 FCP Features Supported

The FCP include the following main features:

- Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
  - Can generate up to 4 independent color planes
  - Support for up to 3 directions per color plane
  - Adaptive Threshold based on intensity measure
- Support for multiple color format output generation:
  - Support 12-bit YUV output
  - Supports RGB output
  - Supports Saturation outputs (8 bits only)
  - Supports Grayscale/Luma/IR/Clear output.
- Support for 16 to 12 compression (LUT based) at the entry of the block
- Support for flexible output format generation including YUV as well as RGB, SV, and so forth.
- Single cycle/pixel performance

##### 7.7.3.6.2 FCP Functional Description

The Flexible Color Processor (FCP) receives data from RAW-FE and does demosaicing and color conversion. The output of FCP is sent to external memory.

**Figure 7-54. FCP Block Diagram**

The FCP consists of the following major sub-blocks for supporting different sensor and output formats:

- LUT based compression: used to reduce the bit width from 16 bits to 12 bits while still preserving the dynamic range.
- Flexible CFA: this block takes in as input any 2x2 raw sensor pattern and is capable of generating up to 4 full resolution color planes.
- Flexible Color Conversion (Flexible CC): this block takes in the output of the Flexible CFA and generates multiple standard as well as custom data formats.
- Flexible Edge Enhancer (Flexible EE): this block can take the output of the Color Conversion and align the Y and UV channels as well as enhance the edges in the luma channel.

##### 7.7.3.6.3 FCP Submodule Details

###### 7.7.3.6.3.1 Flexible CFA / Demosaicing

###### 7.7.3.6.3.1.1 Feature-set

The Flexible CFA include the following main features:

- Support for Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats.

- Can generate up to 4 independent color planes.
- Supports Clear (C) pixel.
- Supports Infrared (IR) pixels.
- Edge aware CFA interpolation.
- Software programmable filter for interpolation up to 4 color channels.
- Support for up to 4 phases and 3 directions per color channel.
- Software controlled algorithm for direction selection.
- Adaptive threshold calculation for direction selection.
- Support of up to 2 sets of programmable mask based gradient selection

#### 7.7.3.6.3.1.2 Block Diagram of Flexible CFA

The Flexible CFA module follows the VPORT (internal) interface for both the input/output to the RAW-FE or Flexible CC module.

##### 7.7.3.6.3.1.2.1 Gradient/Threshold Calculation

The Flexible CFA incorporates 2 sets of gradient and direction selection logic. Typically for symmetric 2x2 patterns like Bayer, only a single set is sufficient; however in sensors wherein one of the channels is working on a different data type, the second set can be used for that channel. An example of such sensors is the RGB-IR sensor, wherein the 2x2 pattern consists of one pixel of each color channel and one pixel of the IR channel. In this case, mixing the gradients and intensity of the color channels with the IR channel could be meaningless.

The gradient selection uses bit masks to select the desired pixel position for calculating the horizontal and the vertical gradient.

Figure 7-55 shows the notation for the bit-mask values. The same notation is used for vertical masks as well and the notation implies that setting a '1' in any field of the bit Mask enables the absolute difference of those 2 pixels to be summed in the gradient calculation.

FCP\_007

**Figure 7-55. Gradient Bit Masks**

Similar masks are also used to calculate the intensity (see Figure 7-56), however instead of taking the absolute difference, the bit masks are used to sum up the pixels in those locations.

FCP\_008

**Figure 7-56. Intensity Bit Mask**

The 4 bit Intensity mask is used to choose which pixels in the 6 rows should be used for creating the intensity sum. The same masks are used for every 2x2 window within the 6x6 buffer. (Thus setting all 4 bits to '1' will be equivalent to summing up the entire 6x6 window.) A programmable shift is then used to bring the intensity down to the 0-16k range. The maximum value of intensity can be  $6 \times 6 \times 4k = 144k$ , so the maximum value of shift is 4 (divide by 16). The shift value can be programmed to any value between 0 and 4 and should be chosen based

on the mask. Note that dependent on the shift value, it's possible that the full range of 0-16k of the intensity may not be reached, hence the adaptive threshold should be programmed accordingly.

The adaptive threshold calculation uses the calculated intensity. For more information, see [Section 7.7.3.6.3.1.2.2, Software Controlled Direction Selection](#).

#### 7.7.3.6.3.1.2.2 Software Controlled Direction Selection

Software can control or guide direction selection at frame or sequence level as shown in [Figure 7-57](#).

FCP\_009

**Figure 7-57. Software Controlled Direction Selection**

[Table 7-105](#) summarizes number of option available to software.

**Table 7-105. Summary of HSX Spaces**

Mode	Name	Details
0	Horizontal	Dir = 0
1	Vertical	Dir = 1
2	HV	Dir = 2
3	HV_Threshold (Fixed threshold is MMR)	in Dir = 0: $\text{gradH} \geq \text{gradV} + \text{threshold}$ in Dir = 1: $\text{gradV} \geq \text{gradH} + \text{threshold}$ in Dir = 2: Otherwise
4	HV_AdaptiveThreshold	in Dir = 0: $\text{gradH} \geq \text{gradV} + \text{threshold}$ in Dir = 1: $\text{gradV} \geq \text{gradH} + \text{threshold}$ in Dir = 2: Otherwise

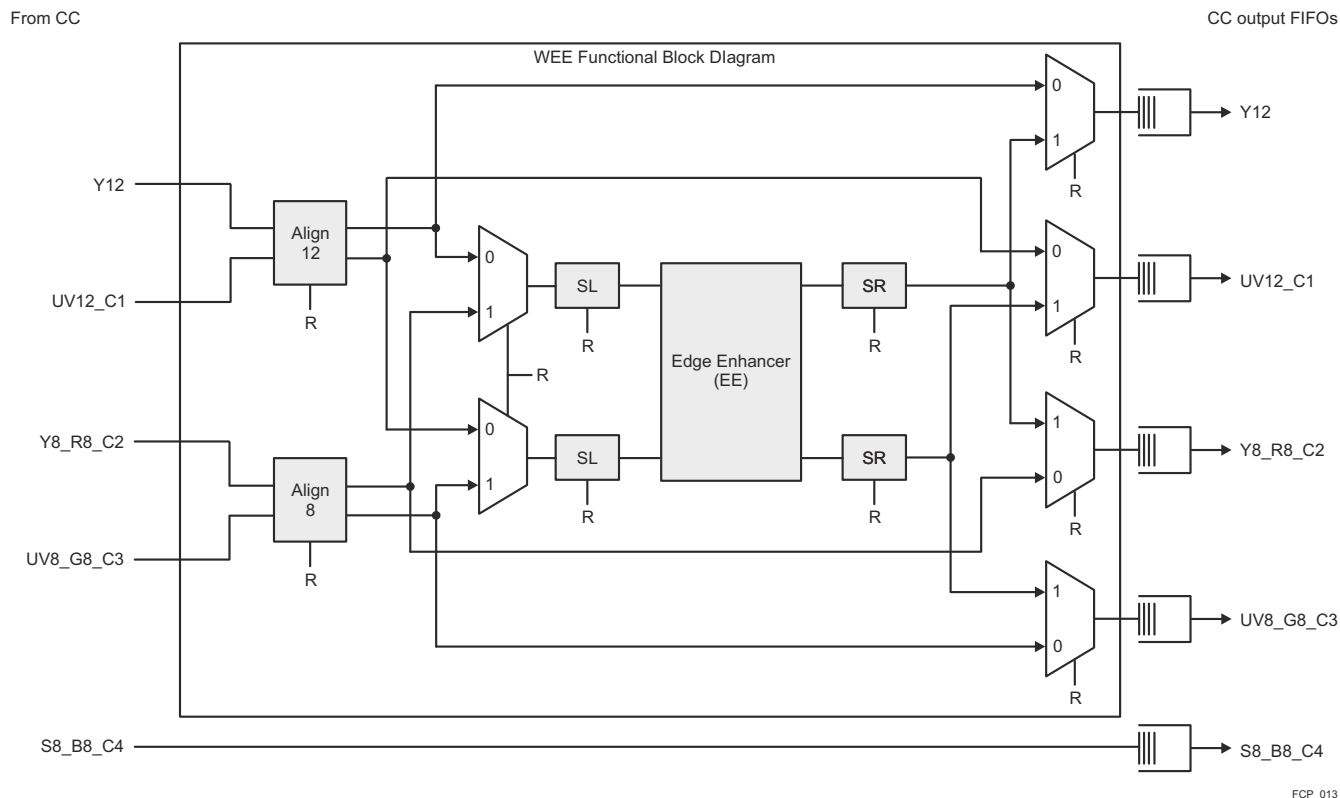

For calculation of adaptive threshold, 7 options are used. Each one defines a threshold to be used as a different intensity level as it follows:

- Entry-0 -> Intensity = 0
- Entry-1 -> Intensity = 512
- Entry-2 -> Intensity = 1024
- Entry-3 -> Intensity = 2048
- Entry 4 -> Intensity = 4096
- Entry 5 -> Intensity = 8192
- Entry 6 -> Intensity = 16384

The adaptive threshold can then be calculated as a linear interpolation between 2 successive entries based on the given intensity.

### 7.7.3.6.3.2 Edge Enhancer Module Wrapper (WEE)

Figure 7-58 shows a high level block diagram of the Edge Enhancer (EE) module wrapper. For more information about the Edge Enhancer algorithm, see *Edge Enhancer (EE)*. The wrapper places the Edge Enhancer within the FCP structure along with associated muxes.

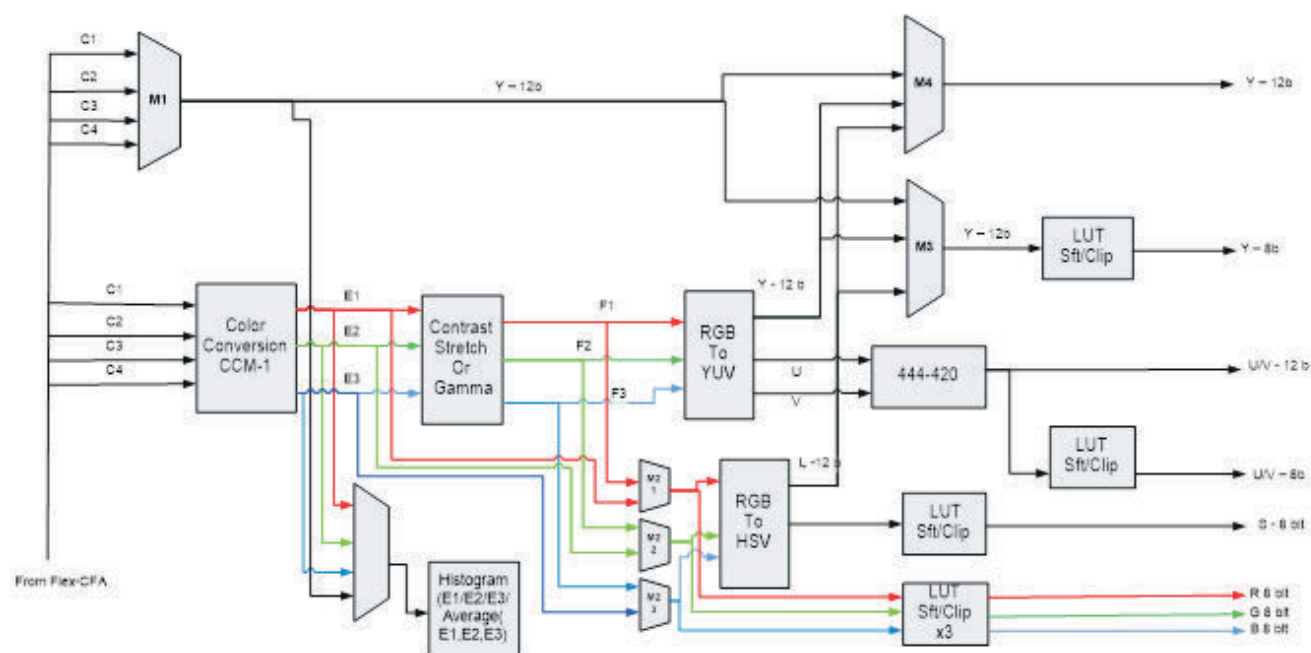

**Figure 7-58. Block Diagram of Edge Enhancer Module Wrapper**

#### 7.7.3.6.3.2.1 EE - Edge Enhancer Block

The Edge Enhancer module is used to enhance the visual quality of the image by increasing its sharpness. The module only works on Y (Luma) data and uses a combination of 2D High-Pass Filtering to detect edges and then apply them on the input image.

#### 7.7.3.6.3.3 Flexible Color Conversion (CC)

Figure 7-59 shows a high level block diagram of the Flexible Color Conversion (CC) module.

**Figure 7-59. Flexible CC Block Diagram (Logical View)**

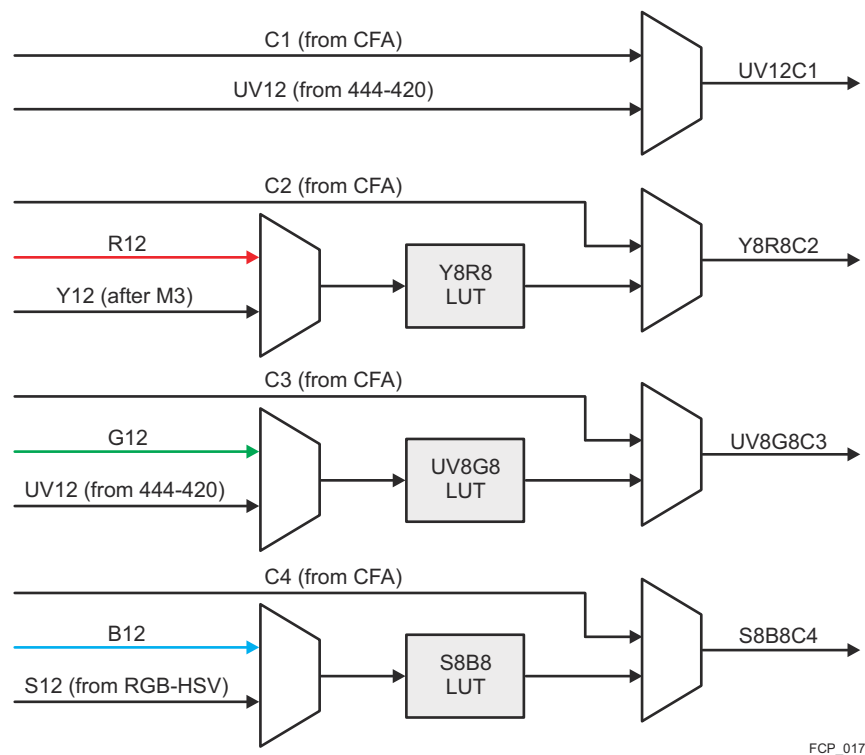

The Flexible CC enables multiple use cases and allows different color formats to be generated.

The Flexible CC module follows the VPORT (Internal) Interface for both the input to the Flexible CC module.

#### 7.7.3.6.3.3.1 Interface Mux

The Flexible CC logical block diagram has 5 primary outputs connecting to the LSE modules in the VISS. For more information about LSE modules, see *Load Store Engine (LSE)*. A multiplex scheme is used to connect multiple outputs on to 5 interfaces using the interface Mux. The Flexible CC output can optionally also allow data from Flexible CFA to be tapped out on to one of the primary interfaces. Note that 12-8 LUTs are shared between the RGB generation and the Y/UV 8-bit generation logic.

Figure 7-60 shows the details of the interface mux. There are only 3 LUTs shared in different mode and only 5 concurrent output streams can be activated at any point of time. For 8-bit outputs, the data is stored in the MSB 11-4 bits of the 12-bit bus. Further, the Y12 output is dedicated and not multiplexed with other interface signals.

**Figure 7-60. Flexible CC Interface Mux**

#### 7.7.3.6.3.3.2 Color Conversion (CCM-1)

The Color Conversion (CCM-1) is defined using the mathematical equations from [Figure 7-61](#).

$$\begin{aligned} E1(x, y) &= W11 \times C1(x, y) + W12 \times C2(x, y) + W13 \times C3(x, y) + W14 \times C4(x, y) + Offset\_1 \\ E2(x, y) &= W21 \times C1(x, y) + W22 \times C2(x, y) + W23 \times C3(x, y) + W24 \times C4(x, y) + Offset\_2 \\ E3(x, y) &= W31 \times C1(x, y) + W32 \times C2(x, y) + W33 \times C3(x, y) + W34 \times C4(x, y) + Offset\_3 \end{aligned}$$

**Figure 7-61. CCM-1**

The CCM matrices weights ( $W^{**}$ ) are 12 bit signed each (S12Q8) representing a range from -8 to +7.996 with 8 bits of fraction. The offsets are 13 bit signed notation (S13Q11) representing a range of -4096 to +4095. The offset is effectively shifted by one (left shifted/ multiplied by 2) before being applied. The effective range of offset is -2 to +1.995 with 11 bits of fraction.

The 4 component CCM allows for a power combination of color format generation to be addressed.

#### 7.7.3.6.3.3.3 RGB to HSX Conversion

The RGB-HSV module is used for converting color spaces and creating custom luminance data plane. This way the 8-bit Saturation and 12-bit Luminance (L or V) plane are generated.

[Figure 7-62](#) shows the block which generates the Luminance / Gray Scale Plane as well as the Saturation (8-bit) plane.

FCP\_019

Figure 7-62. S & V Generation

#### 7.7.3.6.3.3.3.1 Weighted Average Block

The Weighted Average block implements the equation shown on Figure 7-63.

$$GrayScale(x, y) = W1 \times H1(x, y) + W2 \times H2(x, y) + W3 \times H3(x, y) + Offset\_1$$

Figure 7-63. Gray Scale Computation

In the equation on Figure 7-63 the Weights (W1\*) are 12 bits signed with a range of -8 to +7.9996 in S12Q8 format. The offset is Signed 13 bits in S13Q11 format with a range of -2 to +1.995.

Figure 7-64 depicts the architecture of the Weighted Average block:

FCP\_020

Figure 7-64. Weighted Average Block

The mux before the matrix chooses whether the native R/B channels are transmitted or alternatively the Min/Max (RGB) from the Min-Max block are transmitted. Further, the calculation of V can work on either the non-WB corrected data or the WB corrected version. For more information about WB correction, see Section 7.7.3.6.3.3.3.2, Saturation Block.

The combination of the Min-Max block, the mux and the Weighted Matrix allows any of the Gray Scale calculation as shown in Table 7-106.

**Table 7-106. Summary of HSX Spaces**

No	Formula	Configuration
Grey scale (HSI)	$(R+G+B) / 3$	H1 = R, H2 = B; Offset_1 = 0; W1 = W2 = W3 = 1/3 = 85;
Gray Scale (HSV)	Max(RGB)	H1 = Max(RGB); H2 = NA Offset_1 = 0; W2/W3 = 0; W1 = 1 (256);
Gey Scale HSL	$(\text{Max}(\text{RGB}) + \text{Min}(\text{RGB})) / 2$	H1 = Max(RGB), H2 = Min(RGB); W1 = W2 = 0.5 (128) Offset_1 = 0; W3 = 0;
		H1 = R, H2 = G; W1 = W3 = 0.25 (64); W2 = 0.5 (128) Offset_1 = 0

**Table 7-107. Grey Scale and Saturation Calculation**

No	HSI Color Space	HSV Color Space	SHL Color Space	Customer Requirements
Grey Scale Computation	$(R+G+B) / 3$	Max(R,G,B)	$(\text{Max}(\text{R,G,B}) + \text{Min}(\text{R,G,B})) / 2$	$(R+2*G+B) / 3$
Saturation (S) Computation	$1 - (\text{Min}(\text{R,G,B}) / (R+G+B))$	$(\text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})) / \text{Max}(\text{R,G,B})$	$(\text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})) / 255 - \text{Gray value}$	S = Max(R,G,B) - Min(R,G,B)
Hue (H) Computation	Complex formula involving (R-G) (R-B) & (G-B)	Division formula livolving (R-G) (R-B) & (G-B)	Complex formula involving all component	Separate output for (R-G) and Yellowness

#### 7.7.3.6.3.3.2 Saturation Block

The Saturation block first applies a dynamic white balance offset to correct the saturation plane when the image is in log domain and is used for analytics data flow. Once the WB offset is applied, the saturation calculation proceeds as described below. Note that the White balance offset is only applied if the independent pixel values are below a threshold (VISS\_FCP\_FCC\_RGBHSV\_WB\_LINLOGTHR\_1/2). Further, even the minimum of RGB is compared against a threshold (VISS\_FCP\_FCC\_RGBHSV\_WB\_LINLOGTHR\_2[27-16] SATMINTHR bit field) and the higher of the two is used. The saturation calculation always uses the data with the WB correction applied, however the V calculation can choose between WB corrected or uncorrected data using VISS\_FCP\_FCC\_CFG\_1[26] MUXRGBHSV\_MUX\_V.

Table 7-107 shows the condensed form for the Grey Scale and Saturation calculation. In the Flexible CC the saturation calculation is supported using two modes based on the VISS\_FCP\_FCC\_CFG\_2[6] HSVSATMODE bit as follows.

- HSVSATMODE = 0: Max(RGB) - Min(RGB)
- HSVSATMODE = 1: SUM(RGB) - Min(RGB)

Similarly the denominator for the dvision is chosen using the following selection on the VISS\_FCP\_FCC\_CFG\_2[5-4] HSVSATDIVMODE bit field.

- HSVSATDIVMODE = 0: No division, denominator = 1
- HSVSATDIVMODE = 1: Max(RGB)
- HSVSATDIVMODE = 2: 4095 – Gray value (computed in [Figure 7-63](#))
- HSVSATDIVMODE = 3: Sum(RGB)

#### 7.7.3.6.3.3.3 Division Block

The division operation is implemented to calculate 1/x followed by a multiplication with the value. The input to the LUT is 12-bit unsigned value and the output is 8-bits fraction representing 1/x calculation. The divide LUT is implemented as a non-linear ROM with 1216 (1280 for aligning to 128 size boundary) entries and up to 2 segments to reduce error. Ideally to implement a full ROM for an input space of 12 bits would require 4k entires, however to save space and reduce error, the ROM is partitioned such that it is full resolution for the first 256 entries where the curve is highly non linear, whereas the next 4k - 256 entires have a step size of 4. Each ROM entry has a bit size of 20 bits in U20Q20.

FCP\_022

**Figure 7-65. Division LUT**

These are the parameters that need to be calculated based on the range of the input.

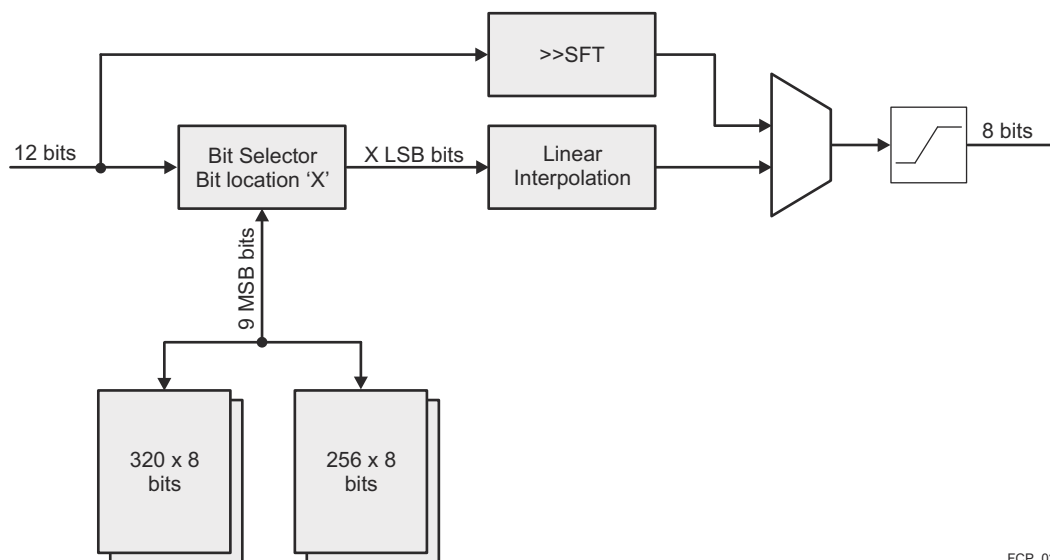

- SFT: '0' if input <256, 2 otherwise
- Mask: '0' if input <256, 4 otherwise
- Add\_off: '0' if input <256, 256 otherwise
- Sub\_off: '0' if input <256, 256 otherwise

The 'shift' parameter at the end is a configuration register which needs to be programmed. Typical programming value is 8 to generate a result in Q12 format (such that the range is 0 to1). This is usually the case when the denominator is greater than the numerator.

#### 7.7.3.6.3.3.4 LUT Based 12 to 8 Downsampling

In the final step the generated saturation value (12 bit) or the incoming RGB values (12 bit) needs to be scaled down to 8 bits using the linear LUT with 513 entries.

Figure 7-66 is a high level block diagram of the LUT block. It shows the weight calculation for the LUT assuming the incoming data can be of any bit depth between 8 and 12 bits.

FCP\_023

**Figure 7-66. LUT Based 12-8 Compression**

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only  $4095/512 = 8$ .

Figure 7-67 shows the high level block diagram of the interpolation process. The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different usecases. However, since the

step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that.

A shift operation can be performed instead of LUT to reduce bitwidth from 12 down to 8 bits.

FCP\_024

**Figure 7-67. Linear Interpolation on LUT**

The code below shows the addressing for the LUT as well as the weight calculation logic for supporting multiple bit widths at the input from 8 – 12 bits.

#### 12-8 Bit LUT Curve

```
CASE BIT_SEL
12 (12 bit data): Addr = Inp[3:11]; wt1 = Inp[2:0]
11 (11 bit data): Addr = Inp[2:10]; wt1 = Inp[1:0] & '0'
10 (10 bit data): Addr = Inp[1:9]; wt1 = Inp[0] & '00'
9 (9 bit data): Addr = Inp[0:8]; wt1 = '000'
8 (8 bit data): Addr = Inp[0:7]; wt1 = '000';
//wt0 is always calculated at 8 - wt1
wt0 = 8 - wt1
```

The input bit width (BIT\_SEL) is specified using a dedicated register for generating Y8 output. However for other paths (RGB/UV/Sat) the 8 bit conversion is done using either 12 bits (if data is tapped prior to contrast block) as the bitwidth or the clipping value after contrast block (VISS\_FCP\_FCC\_CFG\_2[12-9] CONTRASTBITCLIP, if data is tapped after contrast block).

#### 7.7.3.6.3.3.4 Histogram

The histogram can work on either one of the color components after the CCM-1 or the fourth color component routed directly from the Flexible CFA. The Histogram can also work on internally generated Luma value using simple averaging of RGB components. The Histogram module supports a local memory which can be read by the host processor. The Histogram provides data which can be used by the software to generate tone curves for the Contrast Stretch LUT.

The input to the Histogram module is calculated based on the control MMR as it follows:

- 0: R
- 1: G
- 2: B
- 3: MuxC1\_4
- 4:  $(R+2 \cdot G+B) / 4$

The histogram module downsamples the image in the horizontal direction by a factor of 2 using simple averaging filter. This ensures that the memory access requirements of the module are limited to 1 read + 1 write access every 2 cycles (1 access/cycle) and thus can be achieved using a simple memory architecture.

The histogram module requires a ping-pong memory which is mapped to the configuration bus. This allows for histogram operation to run in concurrent with the Read operation from the host. For ease of software complexity, both the Ping/Pong memories map to the same address and it is the responsibility of the design to ensure that the muxing logic always take care of the correct access from both the host and the module. To detect error conditions, if the host is not able to read fast enough from the memory, an error interrupt should be generated whenever the host has initiated a read transfer from the first location of the memory but has not initiated a read transfer from the last location of the memory.

The Histogram module has 2 banks of memories each of 256x20 bits which are used in ping pong fashion. The input pixel has to be downshifted to match the bin size. The Histogram module has separate registers for creating an ROI using horizontal/vertical start postions as well as horizontal/vertical size.

Typically the ROI registers (VISS\_FCP\_FCC\_CFG\_HIST\_1 and VISS\_FCP\_FCC\_CFG\_HIST\_2) have to be set that at least one line is skipped for histogram calculation. The one line of time can be used by the histogram module to set the value of each of the bins to zero. This also puts a constraint on the histogram ROI to have a minmum width of 256 pixels.

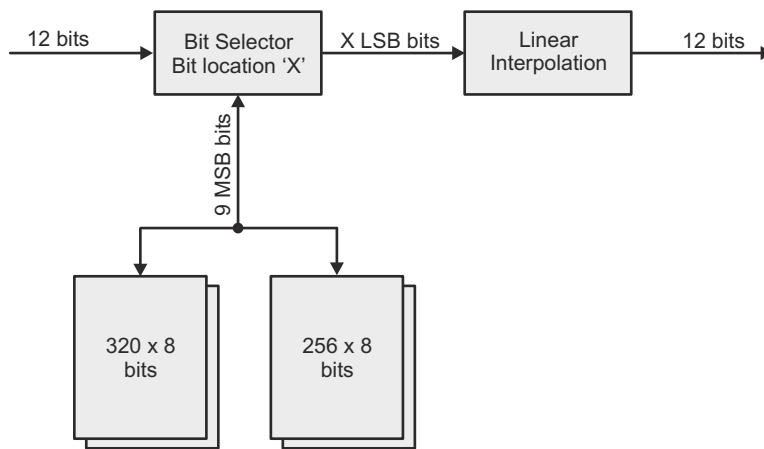

FCP\_026

**Figure 7-68. Histogram Module**

#### 7.7.3.6.3.3.5 Contrast Stretch / Gamma

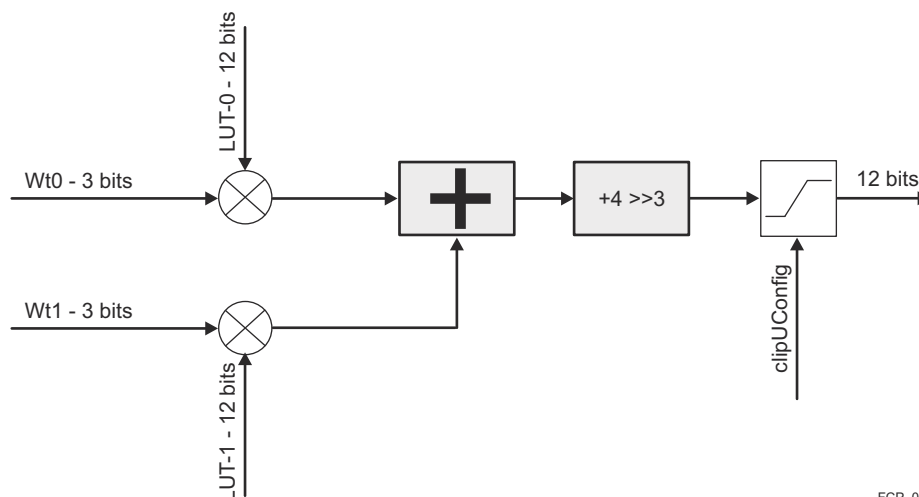

The logic of the Contrast/Gamma unit is based on the same as that of the 12-8 bit conversion LUTs. There are 3 copies of the logic, one for each color channel. The standard data flow allows for a 12 bit input and 12 bit unsigned output, however different bit width combinations are possible using the select bit of the LUT and the clip value. Each entry of the LUT table is 12 bits.

Figure 7-69 and Figure 7-70 show the block diagram and implementation of linear interpolation for the Contrast Stretch/Gamma module.

FCP\_027

**Figure 7-69. Contrast Enhancement Module**

FCP\_028

**Figure 7-70. Contrast Enhancement Linera Interpolation**

The code below shows the LUT addressing scheme which is similar to the 12-8 bit conversion module. The configurable clip at the end of processing allows for less than 12 bit output to be supported directly from the module.

### Contrast Enhancement, LUT Addressing

```
CASE BIT_SEL
0 (12 bit data): Addr = Inp[3:11]; wt1 = Inp[2:0]
1 (11 bit data): Addr = Inp[2:10]; wt1 = Inp[1:0] & '0'
2 (10 bit data): Addr = Inp[1:9]; wt1 = Inp[0] & '00'
3 (9 bit data): Addr = Inp[0:8]; wt1 = '000'
4 (8 bit data): Addr = Inp[0:7]; wt1 = '000';
//Wt0 is always calculated at 8 - wt1
Wt0 = 8 - wt1
```

#### 7.7.3.6.3.3.6 RGB-YUV Conversion

The RGB-YUV conversion is a matrix based conversion from 12-bit RGB to 12-bit YUV. The output after conversion is YUV444.

The conversion is carried out using the equation on [Figure 7-71](#).

$$Y(x,y) = WRY \times R(x,y) + WGY \times G(x,y) + WBY \times B(x,y) + Offset\_1$$

$$Cb(x,y) = WRCb \times R(x,y) + WGCb \times G(x,y) + WBCb \times B(x,y) + Offset\_2$$

$$Cr(x,y) = WRCr \times R(x,y) + WGCr \times G(x,y) + WBCr \times B(x,y) + Offset\_3$$

**Figure 7-71. RGB-to-YUV Conversion**

In this equation, the weights are signed 12 bits (S12Q8) with 8 bit of fraction precision, representing a range of -8 to +7.996. The offsets are signed 13 bits.

Figure 7-72 shows the implementation of the RGB to YUV module. The output after conversion is YUV444, as such it is followed by a chroma downsampling stage where in the Chroma resolution is reduced by half in both the horizontal and vertical direction.

FCP\_030

**Figure 7-72. RGB to YUV**

#### 7.7.3.6.3.4 444-422/420 Chroma Down-sampler

This module down-samples the chroma components from 444-420 format; effectively reducing the chroma resolution to 50% in both the horizontal and vertical direction.

The downsampling is performed using a 3 Tap filtering [1 2 1] followed by decimation. The conversion logic generates chroma in co-sited/co-located format in both the horizontal and vertical direction.

Figure 7-73 shows the block diagram of the format conversion module. The Chroma output can be optionally downshifted from 12 bits to 8 bits using the LUT/SFT module. Only one copy of the Horizontal averaging filter is required since there is a decimation step following the filtering. Only even locations of both Cb/Cr are retained while the odd locations are decimated, however from design perspective the Hz Averager module works on Cb on even cycles and Cr on odd cycles.

FCP\_031

**Figure 7-73. 444 to 420 Module**

Additionally another mode of operation is to support planar YUV422 mode. In this case the chroma is only downsampled in the horizontal direction and the vertical averaging/downsampling is disabled.

The mode is referred to pseudo 422 since actual 422 mode requires the data to be interleaved between the Y and the chroma channels. In this case the interleaving of Y & C is handled by LSE whereas the Flexible CC module will only generate Y & Cb/Cr (interleaved) planes separately.

#### 7.7.3.6.4 FCP Interrupts

The FCP module has three interrupts, as it follows:

- LUT\_CFG\_ERR - 16-12 LUT is written during active window
- CFA\_PIX\_ERR - Access to line memories by CFG during active window
- CFA\_MMR\_ERR - Non-Shadowed registers are written during active window

There are two additional events:

- SOL\_EVENT - Start of line processing for Flexible CFA, triggered when the line enters the Flexible CFA
- SOF\_EVENT - Start of frame processing for Flexible CFA, triggered when the frame enters the Flexible CFA

For information about the FCP interrupt events, see Section *VISS Top Level Functional Description*.

#### 7.7.3.6.5 FCP Programmer's Guide

##### 7.7.3.6.5.1 HWA Core Programming Details

The following fields should be programmed correctly for the FCP module to function.

- Input LUT
  - Use the LUT to reduce the bitwidth of the data to 12 bits so that it can pass through the Flexible CFA pipe.
  - If the GLBCE module is disabled, set the bit width and enable the LUT.
- Flexible CFA
  - Program the Flexible CFA kernels based on the input data pattern. Program only 3 channels for Bayer sensors and up to 4 for other non-standard formats like RGB-IR.
  - Set up the correct thresholds (use only one set for Bayer type sensors and two sets for non-standard formats like RGB-IR).
- Flexible CC
  - Set up the Flexible CC for either visual or analytics data flow.

- For visual, program the CCM-1 to be used as RGB2RGB and Contrast to be used as Gamma with clip at 10 bits. Only the 8-bit outputs are used and the Y8/C8 data is generated using shift down from 10 to 8 (instead of LUT).
- For analytics, CCM-1 is programmed depending on sensor input format and the histogram is used to populate the contrast table. 12-bit outputs are used however Y8/C8 can be generated using 12 to 8 LUT based downshifting. The correct Saturation generation parameters should also be set.

### 7.7.3.7 VISS Edge Enhancer (EE)

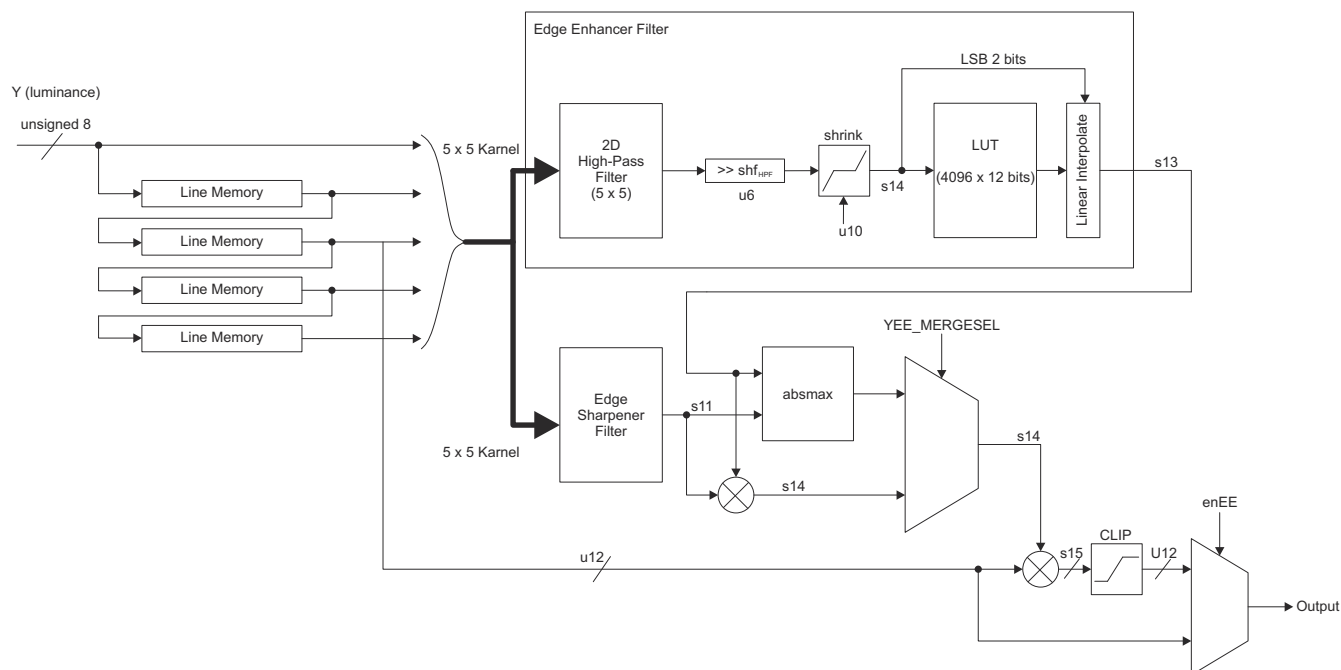

This section describes the Edge Enhancer module.

#### 7.7.3.7.1 Edge Enhancer Introduction

The Edge Enhancer module is used to enhance the visual quality of the image by increasing the sharpness of the image. The module only works on Y (Luma) data and uses a combination of 2D HPF (High-Pass Filter) filtering to detect edges and then apply them on the input image.

The Edge Enhancer consists of two separate blocks internally, the edge enhancer filter and the edge sharpener filter. The module can be programmed to either select the output of one of the filters or to use a blend of both.

Figure 7-74 below shows a conceptual block diagram of the edge enhancer filter. The input data is assumed to be a 12 bits/pixel. The EE module is tuned to process 8-bit images (MSB aligned) but has support to process 10-bit and 12-bit images as well.

**Figure 7-74. Edge Enhancer Block Diagram**

#### 7.7.3.7.1.1 Edge Enhancer Filter

The edge enhancer filter works on a  $5 \times 5$  HPF filter (M) with programmable coefficients. The filter is symmetric as such only  $3 \times 3$  coefficients are programmable.

Here, M is a  $5 \times 5$  matrix with programmable coefficients specified by VISS\_FCP\_EE\_YEE\_COEF\_Ri\_Cj (i and j are 0, 1, or 2). The shift value (shf<sub>HPF</sub>) is specified by VISS\_FCP\_EE\_YEE\_SHIFT[5-0] YEE\_SHIFT.

$$HPF(h, v) = \left( \sum_{j=-2}^2 \sum_{i=-2}^2 M_{i,j} Y(h+i, v+j) \right) \gg shf_{HPF}$$

$$M = \begin{pmatrix} M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,0} & M_{1,0} & M_{0,0} & M_{1,0} & M_{2,0} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \end{pmatrix}$$

**Figure 7-75. Edge Enhancer Linear Filter**

The HPF value is shrink by a threshold value,  $threshold_{HPF}$  ( $u6 = 10$ ), specified by VISS\_FCP\_EE\_YEE\_E\_THR register, and clipped to signed 14 bits to get the index for the LUT. The MSB 12 bits of the index are used for the LUT address (4k locations) whereas the LSB 2 bits acts as weight to the linear interpolation logic.

$$index = clip(shrink(HPF, threshold_{HPF}), -8k, 8k)$$

$$shrink(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \leq x \leq threshold \\ x - threshold & threshold < x \end{cases}$$

$$clip(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \leq x \leq limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

**Figure 7-76. Edge Enhancer Indexing**

The edge enhancement intensity is looked up from the LUT, where A is the MSB 12 bits of the index.

$$E_{int} = Interpolate(LUT[A], LUT[A+1])$$

**Figure 7-77. Edge Intensity LUT Formula**

The  $5 \times 5$  HPF filter is not fully programmable, rather only the top left quadrant is programmable coefficients. The rest of the kernel is symmetric along the y and the x axis.

**Figure 7-78** below depicts how the kernels are implemented, with the kernel locations marked inside the boxes. The green color shows the kernels that are programmable.

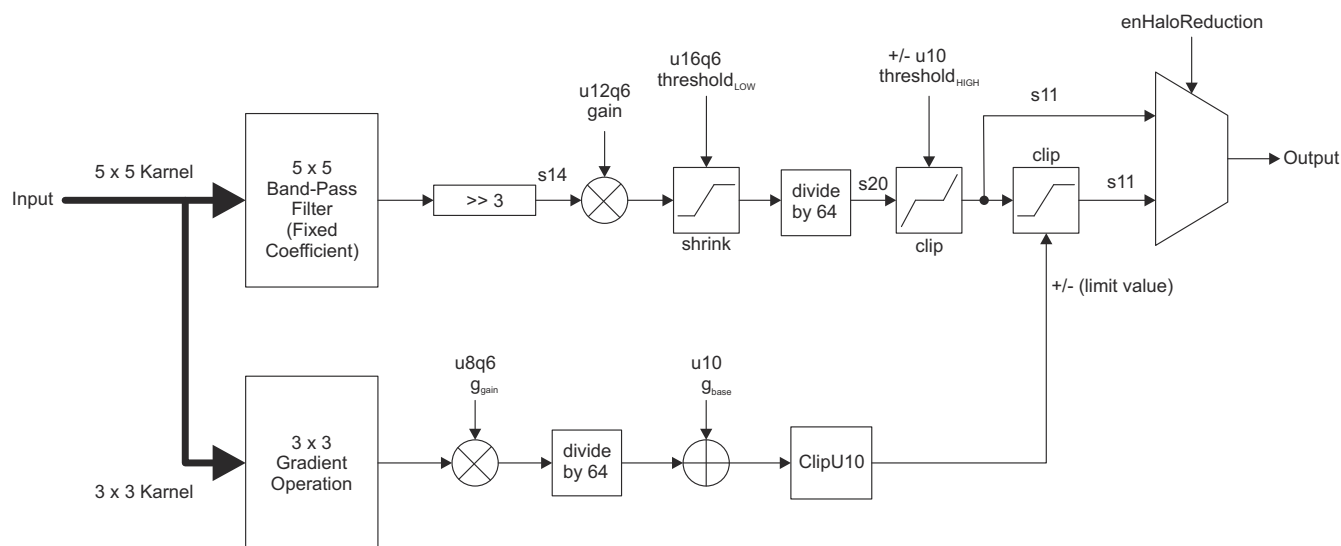

**Figure 7-78. 5 × 5 HPF Filter**

The border conditions are handled by data duplication on each of the borders when the desired pixel goes out of range.

The output of the LUT is the final output of the edge enhancer filter.

#### 7.7.3.7.1.2 Edge Sharpener Filter

Figure 7-79 below shows a high level block diagram of the edge sharpener function.

**Figure 7-79. Edge Sharpener Function**

In edge sharpener filter module, enabled when VISS\_FCP\_EE\_YEE\_MERGESEL[0] YEE\_MERGESEL = 1, edge clarity is enhanced without producing a halo artifact. In this module, edge intensity is derived by the following 2D linear filter with fixed coefficients shown in Figure 7-80.

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = \text{clip} \left( \text{shrink} \left( g \times \left( \sum_{j=-2}^2 \sum_{i=-2}^2 S_{i,j} Y(h+i, v+j) \right) \gg 3 \right), threshold_{LOW} \right) \gg 6, -threshold_{HIGH}, threshold_{HIGH}$$

**Figure 7-80. Edge Sharpener Details**

The gain ( $g$ ) and threshold values for shrink/clip function ( $threshold_{LOW}$ ,  $threshold_{HIGH}$ ) are determined by register values (VISS\_FCP\_EE\_YES\_E\_GAIN, VISS\_FCP\_EE\_YES\_E\_THR1, VISS\_FCP\_EE\_YES\_E\_THR2). The precision of  $g$  is in U12Q6,  $threshold_{LOW}$  is in U16Q6 and that of  $threshold_{HIGH}$  is in U10.

This edge intensity is then clipped by a threshold value in the formula shown in [Figure 7-81](#).

$$S_{int} = \begin{cases} \text{clip}(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

**Figure 7-81. Edge Intensity Clipping Formula**

The threshold value ( $grad$ ) is a function of the activity around the target pixel, which is derived from gradient values. Gain ( $g_{grad}$ ) and offset ( $g_{base}$ ) are specified by VISS\_FCP\_EE\_YES\_G\_GAIN and VISS\_FCP\_EE\_YES\_G\_OFT.

$$grad = g_{grad} (\min(gx_L, gx_R) + \min(gy_T, gy_B)) \gg 6 + g_{base}$$

$$gx_L = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{xL}(i,j) \cdot y(h+i, v+j) \right)$$

$$gx_R = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{xR}(i,j) \cdot y(h+i, v+j) \right)$$

$$gy_T = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{yT}(i,j) \cdot y(h+i, v+j) \right)$$

$$gy_B = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{yB}(i,j) \cdot y(h+i, v+j) \right)$$

$$G_{xL} = \frac{1}{4} \begin{pmatrix} 1 & -1 & 0 \\ 2 & -2 & 0 \\ 1 & -1 & 0 \end{pmatrix}$$

$$G_{xR} = \frac{1}{4} \begin{pmatrix} 0 & 1 & -1 \\ 0 & 2 & -2 \\ 0 & 1 & -1 \end{pmatrix}$$

$$G_{yT} = \frac{1}{4} \begin{pmatrix} 1 & 2 & 1 \\ -1 & -2 & -1 \\ 0 & 0 & 0 \end{pmatrix}$$

$$G_{yB} = \frac{1}{4} \begin{pmatrix} 0 & 0 & 0 \\ 1 & 2 & 1 \\ -1 & -2 & -1 \end{pmatrix}$$

**Figure 7-82. Edge Threshold Value Formula**

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

### 7.7.3.7.1.3 Merge Block

The output from edge enhancer filter and edge sharpener filter are merged with the following function.

$$E_{merge} = \begin{cases} E_{int} + S_{int} & VISS\_FCP\_EE\_YEE\_MERGESEL[0]YEE\_MERGESEL = 0 \\ \text{absmax}(E_{int}, S_{int}) & VISS\_FCP\_EE\_YEE\_MERGESEL[0]YEE\_MERGESEL = 1 \end{cases}$$

$$\text{absmax}(x, y) = \begin{cases} x & \text{abs}(y) \leq \text{abs}(x) \\ y & \text{otherwise} \end{cases}$$

**Figure 7-83. Edge Enhancer and Sharpener Merger Formula**

The  $E_{merge}$  value is added to the Y input value to make the final output.

The contribution of each of the filters can be modified. The edge sharpener filter block can be turned off or reduced in strength using the gain fields. The edge enhancer filter block can be disabled using the LUT.

### 7.7.3.7.2 Edge Enhancer Programming Model

Table 7-108 captures the programming parameters and the programming model of the Edge Enhancer module.

#### Note

UMQN implies M bits with N bits of fraction and M-N bits of Integer.

For more information, see *Edge Enhancer Registers*.

**Table 7-108. Edge Enhancer Programming Parameters**

Parameter Name	New Precision	Tuning Methodology
VISS_FCP_EE_EE_CFG_0[12-0] WIDTH	13 bits	Width of the image
VISS_FCP_EE_EE_CFG_0[28-16] HEIGHT	13 bits	Height of the image
VISS_FCP_EE_EE_ENABLE[0] YEE_ENABLE	1	Enable Module
VISS_FCP_EE_YEE_SHIFT[5-0] YEE_SHIFT	U6	-
VISS_FCP_EE_YEE_COEF_R0/1/2_C0/1/2[9-0] YEE_COEF_R0/1/2_C0/1/2	Signed 10	-
VISS_FCP_EE_YEE_E_THR[9-0] YEE_E_THR	U10	Shrink Threshold before LUT, scale by 16×
VISS_FCP_EE_YEE_MERGESEL[0] YEE_MERGESEL	1 bit	Mergesel: Off(0), On(1)
VISS_FCP_EE_YES_E_HAL[0] YES_E_HAL	1 bit	Halo Reduction; Off(0)/On(1)
VISS_FCP_EE_YES_G_GAIN[7-0] YES_G_GAIN	U8Q6	Usually 1.5 times YES_E_GAIN
VISS_FCP_EE_YES_G_OFT[9-0] YES_G_OFT	U10	Scale by 16
VISS_FCP_EE_YES_E_GAIN[11-0] YES_E_GAIN	U12Q6	Same as previous
VISS_FCP_EE_YES_E_THR1[15-0] YES_E_THR1	U16Q6	Scale by 16
VISS_FCP_EE_YES_E_THR2[9-0] YES_E_THR2	U10	Scale by 16

### 7.7.4 VPAC Lens Distortion Correction (LDC) Module

This section describes the Lens Distortion Correction (LDC) module.

#### 7.7.4.1 LDC Overview

The LDC module deals with lens geometric distortion issues in the camera system. The distortion can be common optical distortions, such as barrel, pin-cushion, or fisheye distortion. LDC is not limited to just these types of distortions. Affine transformation support is also added to support the image and video stabilization application, where multiple images of the same scene need to be aligned. Perspective warp is an extension to affine transform and offers additional capabilities. Perspective transformations can align two images that are captured from different camera viewpoints or locations. This can also be used to rectify the left and right images of a stereo camera to reduce the complexity of a disparity computation. Perspective transformations can also generate new viewpoints.

##### 7.7.4.1.1 LDC Features

- Autonomous memory-to-memory operation
  - Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Support multiple input and output YUV data formats:
  - Among the supported data formats are UYVY (YCbCr 422), NV12 (YCbCr 420) and NV21 (YCbCr 420)
- Support up to 8192 x 8192 image dimension
- Pixel Interpolation
  - Bi-cubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode to offer double throughput
- Performance
  - 1 cyc/pixel (bilinear)
  - 2 cyc/pixel (Bi-cubic)
- Support to process either Luma only or Chroma only modes in YUV420 input data format to save bandwidth
- Support for independent block size in multiple regions (up to 9 regions)
- Dual output channels for programmable output pixel size
- ECC support on Mesh Data internal storage memories and width conversion LUTs on dual output channel
- Interface to HTS module for block level synchronization with other IPs
- Circular addressing support for Output Write (for SL2 interface) and Input Read
- Event for Block/Frame completion and Error scenarios

#### 7.7.4.2 LDC Functional Description

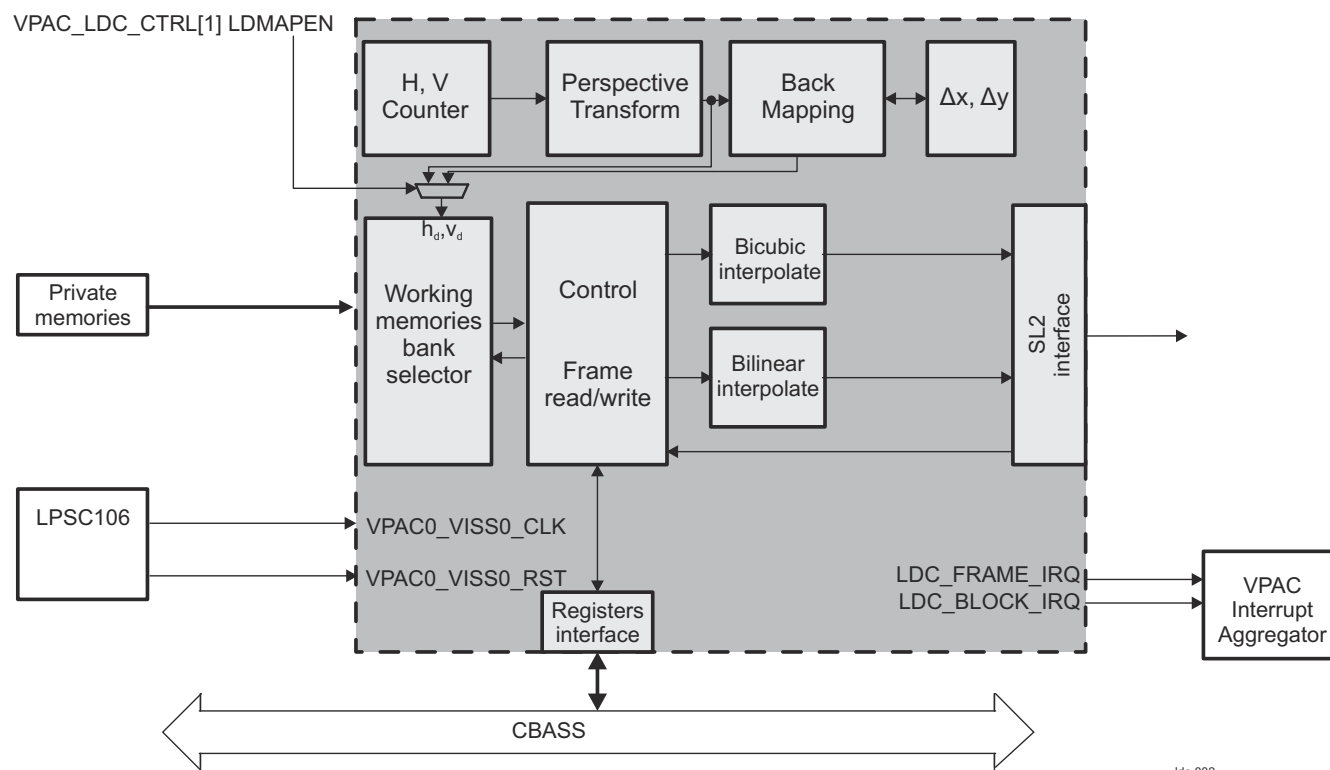

##### 7.7.4.2.1 LDC Block Diagram

Most digital cameras suffer from some degree of nonlinear geometric distortion. A spatial transformation is required to correct the distortion. In automotive applications, cameras use wide angle lenses, including fisheye lenses to provide 180+° field of view. To visually present the scene to the user in an easy-to-consume representation, these distortions need to be corrected

Back mapping gives coordinates of the distorted image as a function of coordinates of the undistorted output image. Correction involves back-mapping each output pixel to a location in the source distorted image, and thus the corrected image is fully populated. As the distorted pixel locations mostly fall onto fractional coordinates, correction involves interpolation.

As shown in [Figure 7-84](#), the LDC consists of a back mapping block, a x/y offset table, image buffer interface, buffer, an interpolation block, and SL2 interface.

[Figure 7-84](#) is a block diagram of the LDC.

**Figure 7-84. LDC Block Diagram**

Given the coordinates of the undistorted image, the corresponding coordinates of the distorted image are calculated by combining the output coordinates and the offsets from the offset table. Distorted pixels are read from the image buffer, and buffered for the bilinear interpolation. After the interpolation, corrected image is written back to the SL2 memory.

The LDC processes the image in small two-dimensional (2D) blocks. The software configures appropriate parameters, then initiates the LDC function by writing to an LDC register. The LDC controls the sequencing through 2D blocks, DMA transfers, and computation to process an entire image autonomously. Interrupt, if enabled, is asserted at the completion of the image.

The LDC write is controlled by HTS at block level.

To start the LDC, software must set the LDC\_CORE\_CTRL[0] LDC\_EN bit to 1. The LDC\_CORE\_CTRL[2] BUSY bit is a status that reflects LDC activity.

#### 7.7.4.2.2 LDC Clocks

Complete VPAC LDC operates on single clock (that is, VPAC0\_LDC0\_CLK). Except the signals that are coming from LPSC, all other LDC sub-block clock domains are synchronous to VPAC0\_LDC0\_CLK.

#### 7.7.4.2.3 LDC Interrupts

LDC generates interrupt events and these are made available to the VPAC. VPAC implements compatible interrupt function via the interrupt aggregator, see chapter [Section 7.7.2 VPAC Subsystem](#).

All the interrupts are active high and pulsed for one VPAC0\_VISS0\_CLK cycle. Following interrupts events are generated. Out of these only ECC interrupt should be treated as real interrupt and others are used as events for the interrupt aggregator at VPAC level.

**Table 7-109. LDC Interrupt Events**

Interrupt Event	Type	Category	Description
PIX_IBLK_OUTOFBOUND	pulse	func	PIX_IBLK_OUTOFBOUND pulse interrupt event

**Table 7-109. LDC Interrupt Events (continued)**

Interrupt Event	Type	Category	Description
MESH_IBLK_OUTOFBOUND	pulse	func	MESH_IBLK_OUTOFBOUND pulse interrupt event
IFR_OUTOFBOUND	pulse	func	IFR_OUTOFBOUND pulse interrupt event
INT_SZOVF	pulse	func	INT_SZOVF pulse interrupt event
VPAC_LDC_FR_DONE_EVT	pulse	func	LSE frame done event
VPAC_LDC_SL2_WR_ERR	pulse	func	LSE SL2 VBUSM Write Error interrupt event
PIX_IBLK_MEMOVF	pulse	func	Input pixel block internal memory overflow event
MESH_IBLK_MEMOVF	pulse	func	Input mesh block internal memory overflow event
VPAC_LDC_VBUSM_RD_ERR	pulse	func	Error event on VBUSM Read Interface
UNCORR_PULSE	pulse	error	ECC Aggregator uncorrectable error, pulse
UNCORR_LEVEL	level	error	ECC Aggregator uncorrectable error, level
CORR_PULSE	pulse	error	ECC Aggregator correctable error, pulse
CORR_LEVEL	level	error	ECC Aggregator correctable error, level

#### 7.7.4.2.3.1 LDC Interrupt Events Description

##### 7.7.4.2.3.1.1 PIX\_IBLK\_OUTOFBOUND

Generated when back mapping of block non-corner pixel co-ordinate goes out of the pre-computed input bounding box (i.e. data required for processing is not available in private pixel storage). This event is generated for the first occurrence of error in each frame. Upon this error, PIX\_PAD setting needs to be reviewed. Upon pixel out of bound, pixel co-ordinate will be clipped to the pre-fetched block boundary. Usually no special treatment is required on this error event. Only few pixels are expected to be have this condition..

##### 7.7.4.2.3.1.2 MESH\_IBLK\_OUTOFBOUND

Generated when mesh data required for non-corner mesh co-ordinate goes out of the pre-computed mesh bounding box (i.e. mesh data required for processing is not available in internal mesh storage). This event is generated for the first occurrence of error in each frame. This error condition is handled inside design by clipping the mesh data location to the pre-fetched block boundary. No special treatment is expected on this error event.

##### 7.7.4.2.3.1.3 IFR\_OUTOFBOUND

Generated when back mapped input pixel co-ordinate goes out of valid input frame boundary or co-ordinates post Perspective warping goes out of valid Mesh frame size (Frame size for which mesh data is available). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the co-ordinates to valid frame boundary. It is recommended to review the source of the error to make sure that it is expected.

##### 7.7.4.2.3.1.4 INT\_SZOVF

Generated when intermediate variables of affine or perspective transform operation goes above what hardware supports (U16Q3). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the variables the size to what HW supports. Upon this error, Affine and Perspective coefficients need to be reviewed.

##### 7.7.4.2.3.1.5 VPAC\_LDC\_FR\_DONE\_EVT

Generated on once complete output frame is written into SL2.

#### 7.7.4.2.3.1.6 VPAC\_LDC\_SL2\_WR\_ERR

This event is generated whenever the LDC SL2 Output VBUSM Interface write status is something other than 0 (success).

#### 7.7.4.2.3.1.7 PIX\_IBLK\_MEMOVF

Generated when input pixel block memory storage requirement is more than internal pixel memory or each side of input block size goes above 1023. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size setting needs to be reviewed.

#### 7.7.4.2.3.1.8 MESH\_IBLK\_MEMOVF

Generated when Mesh block internal storage requirement is more than internal Mesh memory or either side of input block size goes above 1010. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size or Affine/Pwarp parameters or mesh sub-sampling factor setting needs to be reviewed.

#### 7.7.4.2.3.1.9 VPAC\_LDC\_VBUSM\_RD\_ERR

This event is generated whenever the LDC Read VBUSM Interface status is something other than 0 (success).

#### 7.7.4.2.4 LDC Affine Transform

The LDC first performs an affine transform, which can be used for rotations and scaling, as shown in [Figure 7-85](#). The output of the pixel coordinate is used as the input address to the affine transform.

ldc-010

**Figure 7-85. LDC Affine Transformation**

The mapping from destination coordinate to the source coordinate is expressed as:

$$h_{aff} = a \times h_u + b \times v_u + c$$

$$v_{aff} = d \times h_u + e \times v_u + f$$

This transform allows full rotation, expansion, contraction, and translation. The parameters {a, b, d, e} are in S16Q12 (signed number on 14 bits with 2 bits for integer and 12 bits of fraction) format, and parameters {c, f}

are in S16Q3 format (signed number on 16 bits with 13 bits for integer and 3 bits of fraction). These parameters must be set in following bit fields:

- $a = \text{LDC\_CORE\_AFF\_AB}[15:0]$  A
- $b = \text{LDC\_CORE\_AFF\_AB}[31:16]$  B
- $c = \text{LDC\_CORE\_AFF\_CD}[15:0]$  C
- $d = \text{LDC\_CORE\_AFF\_CD}[31:16]$  D
- $e = \text{LDC\_CORE\_AFF\_EF}[15:0]$  E
- $f = \text{LDC\_CORE\_AFF\_EF}[31:16]$  F

#### 7.7.4.2.5 LDC Perspective Transformation

When a camera is viewing a scene from two different positions or when multiple cameras are viewing the scene from different positions, a transformation between the two viewing angles is needed to align the images. Under specific conditions, the class of geometric transformations known as homography, or planar-perspective transformation, will capture the geometric relationship between the images accurately. Common applications of homography transforms are to align (or stitch) multiple frames of the same scene to compute a panoramic output image. A second application is the alignment of planar surfaces in the world. Finally, perspective transforms are also useful in computing depth maps from a stereo image pair. By rectifying the two views, the search to compute disparity between the two views is simplified to a 1-D search problem. The homography is defined by a 3x3 transformation matrix, as in

$$h_{\text{aff}} = a * h_u + b * v_u + c \quad (3)$$

$$v_{\text{aff}} = d * h_u + e * v_u + f \quad (4)$$

$$z = \max(0, g * h_u + h * v_u + 1) \quad (5)$$

$$h_p = h_{\text{aff}} / z \quad (6)$$

$$v_p = v_{\text{aff}} / z. \quad (7)$$

The affine transform is a subset of the perspective transformation. By setting  $g = h = 0$ ,  $h_p = h_{\text{aff}}$  and  $v_p = v_{\text{aff}}$ .

In image alignment applications, the homography matrices are computed by locating corresponding points in the two frames and estimating the matrix parameters to transform the set of points in one frame onto the corresponding points in the second frame. In the stereo rectification application, the matrix is determined (pre-computed) at the calibration step and remains fixed.

When LDC is requested to provide a change in the frame size between the input and output, the affine/perspective parameters must be programmed to implement the coordinate scaling (see for programming details). In the following sections, the mesh table is used to program distortion correction. The table sizes are defined based on the total output frame size.

#### 7.7.4.2.6 LDC Lens Distortion Back Mapping

In YCbCr mode, the offset table defines a (x,y) vector for a regular grid of output points. The grid can be fully sampled or down sampled. A fully sampled grid will define an offset vector for every output pixel, defining exactly where to fetch the input data to compute the output pixel. This is the most precise definition and can capture rapidly changing offset tables. The drawback is that it will require a large amount of memory bandwidth as the LDC engine will be reading offset values for every output pixel. Since most offset tables are not expected to change rapidly in a small spatial region, LDC supports reading a subsampled offset table. Offset tables can be subsampled by powers of two in both horizontal and vertical directions and the subsampling factor is set in the register,  $\text{LDC\_CORE\_MESHTABLE\_CFG}[2:0]$  M. This mode conserves memory bandwidth by reducing the amount of data read to describe the offset vectors, but requires more hardware to interpolate the missing offset vectors. LDC supports bilinear interpolation to interpolate missing offset vectors.

The mapping procedure is described by the following series of equations. Given an output pixel at location, we compute the input pixel location.

$$x_c = \text{CLIP}(x_o, 0, 8 \times W - 1), \text{ W: Mesh Frame Width} \quad (8)$$

$$y_c = \text{CLIP}(y_o, 0, 8 \times H - 1), \text{ H: Mesh Frame Height} \quad (9)$$

$$\text{Mask} = (1 \ll (3 + M)) - 1 \quad (10)$$

$$i_{x0} = (x_c \gg (3 + M)), f_x = x_c \& \text{Mask} \quad (11)$$

$$i_{y0} = (y_c \gg (3 + M)), f_y = y_c \& \text{Mask} \quad (12)$$

Clip new locations to previously fetched mesh block boundaries.

$$i_x = \text{CLIP}(i_{x0}, \text{block\_startmx}, \text{block\_endmx} - 1) \quad (13)$$

$$i_y = \text{CLIP}(i_{y0}, \text{block\_startmy}, \text{block\_endmy} - 1) \quad (14)$$

$$\begin{aligned}
 \text{Ofst0} &= \text{READ32}(\text{OfstTable}[i_x, i_y]) \\

ldc-023

**Figure 7-86. LDC Lens Distortion Back Mapping Offset Calculation**

Graphically, this procedure is shown in [Figure 7-87](#).

ldc-024

**Figure 7-87. LDC Back Mapping Procedure Using Offset Table**

The input coordinate  $(x_i, y_i)$  refers to final input frame co-ordinates and is used to fetch the appropriate input pixels for interpolation. The interpolation procedure is described in . Before fetching data  $(x_i, y_i)$ , is clipped to the input frame boundary.

#### 7.7.4.2.6.1 LDC Mesh Table Storage Format

The size of the mesh table is dependent on the Total output frame size. The size must be:

$$\text{Table Width} = \text{CEIL}((\text{Mesh Frame Width})/2^M) + 1 \quad (15)$$

$$\text{Table Height} = \text{CEIL}((\text{Mesh Frame Height})/2^M) + 1. \quad (16)$$

Mesh frame width and height are specified by registers: LDC\_CORE\_MESH\_FRSZ[13-0] W and LDC\_CORE\_MESH\_FRSZ[29-16] H. The downsampling factor, M, is specified by register LDC\_CORE\_MESHTABLE\_CFG[2] M.

The mesh table should be stored with delta(x) and delta(y) offsets interleaved and stored in raster order. Each offset is S16Q3, so a table entry is 32-bits, including both delta(x) and delta(y). The location of the mesh table is configured by registers LDC\_CORE\_MESH\_BASE\_H and LDC\_CORE\_MESH\_BASE\_I. The buffer width ( $\geq$  Table Width), is provided by LDC\_CORE\_MESH\_OFST[15-0] OFST. The mesh table must be aligned on a 16-byte boundary.

#### 7.7.4.2.7 LDC Pixel Interpolation

In UYVY and NV12 mode, the pixel interpolation type can be set to bi-cubic interpolation for best quality or bilinear interpolation for faster performance.

As the coordinates ( $h_d, v_d$ ) calculated by the back-mapping function are not generally integer values, bi-cubic or bilinear interpolation is applied to the distorted pixels.

Depending on register configuration, bi-cubic or bilinear interpolation is used to interpolate the output Y pixels:

- LDC\_CORE\_CFG[6] YINT\_TYP = 0, bi-cubic interpolation for Y, bilinear for other components
- LDC\_CORE\_CFG[6] YINT\_TYP = 1, bi-linear interpolation for all components

In the case of bi-cubic interpolation, the distorted pixel is interpolated from the 16 Y pixels in the 4 x 4 grid around the distorted location, as shown in [Figure 7-88](#). Bi-cubic interpolation is used first along the horizontal direction, then the vertical direction.

**Figure 7-88. LDC Bi-cubic Interpolation for Y**

If bi-linear interpolation is selected, the distorted pixel is interpolated from the four Y pixels in the 2 x 2 grid around the distorted location, as shown in [Figure 7-89](#).

**Figure 7-89. LDC Bi-linear Interpolation for Y**

For Cb and Cr components, simple bilinear interpolation is used. Each distorted pixel is interpolated from the four same-color pixels on the 2 x 2 grid around the distorted location. For UYVY data, the Cb/Cr grid is not square, but is 2x wider compared to the height. This is shown in [Figure 7-90](#).

**Figure 7-90. LDC Bilinear Interpolation for CB/Cr in UYVY and NV12 Format**

#### 7.7.4.2.8 LDC Buffer Management

Nonlinear nature of the Back Mapping suggests 2-D processing to make more efficient use of external memory bandwidth. Since the mapping computation is non-trivial, the hardware requires the software to provide a number of data management parameters to assist hardware with data transfers.

##### 7.7.4.2.8.1 LDC Buffer Management

Once mesh block fetch is completed, final input co-ordinates are calculated by applying back mapping on previously calculated perspective warp corner pixel co-ordinates. Additional padding is applied on top of these back mapped corner co-ordinates based on the interpolation type.

The LDC processes a block of LDC\_CORE\_OUT\_BLKSZ[7:0] OBW x LDC\_CORE\_OUT\_BLKSZ[15:8] OBH (output block width by output block height) pixels at a time in a raster-scan order throughout the image. OBW is constrained to be a multiple of a base width, depending on the operating mode. This is described in [Table 7-110](#). OBH should be even. The LDC uses four corners of the output block plus some padding to fetch the input block. Due to extreme scenarios, there will be scenarios where above bounding box calculated by hardware doesn't cover all the input data required to generate particular output block. To cover those cases, software needs to supply additional PixelPad, the amount of padding in input block in all directions. Software must supply OBW, OBH, and LDC\_CORE\_OUT\_BLKSZ[19:16] PIXPAD, the amount of padding in input pixels. Software must guarantee that, for EVERY output pixel in the OBW x OBH output block, the input pixels required are bounded by back mapping of the four corners plus/minus the padding. More precisely, the input block is determined by:

- $IBX\_start = \min(\text{truncate}(\text{distortx}(\text{corner1})), \text{truncate}(\text{distortx}(\text{corner3}))) - \text{HwPad} - \text{PixelPad}$
- $IBX\_end = \max(\text{truncate}(\text{distortx}(\text{corner2})), \text{truncate}(\text{distortx}(\text{corner4}))) + \text{HwPad} + \text{PixelPad}$
- $IBY\_start = \min(\text{truncate}(\text{distorty}(\text{corner1})), \text{truncate}(\text{distorty}(\text{corner2}))) - \text{HwPad} - \text{PixelPad}$
- $IBY\_end = \max(\text{truncate}(\text{distorty}(\text{corner3})), \text{truncate}(\text{distorty}(\text{corner4}))) + \text{HwPad} + \text{PixelPad}$

where corner1, corner2, corner3, and corner4 are upper-left, upper-right, lower-left, and lower-right corners of the OBW x OBH output block, and distortx(.), distorty(.) are X and Y distorted coordinates of the corners. Distorted coordinates computed by the back-mapping process described in [Section 7.7.4.2.6, LDC Lens Distortion Back-Mapping](#). [Figure 7-91](#) shows the input block bound calculation. [Table 7-110](#) lists the OBW requirements.

Figure 7-91. LDC Input Block Bound

Table 7-110. LDC OBW Requirements

Data Format	OBW must be a multiple of
YUV422	8
YUV420	8

Typically for geometric distortion, the LDC\_BLOCK[19:16] PIXPAD bit field must be 4 to accommodate neighbor sets for all colors. Software must set the PIXPAD bit field correctly.

OBH and OBW must be large enough for efficient operation of the lens distortion operation. As shown in [Table 7-110](#), OBW is constrained to ensure efficient external memory write. Another constraint is that input block size,  $(IBX\_end - IBX\_start + 1) \times (IBY\_end - IBY\_start + 1)$ , for EVERY input block of the image, must fit the allocated input buffer. These parameters must not be specified pessimistically (OBH, OBW too small, or PixelPad too large). Pessimistic parameter setting degrades performance and incurs unnecessary external memory transfer.

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image (See Multi-pass Frame processing).

An intermediate event, *hts\_tdone*, is also provided on completion of each macro block output write. This allows the LDC operation to be pipelined with other tasks. The LDC output write stall after this event, waiting for a pulse on the *hts\_tstart* signal to begin writing the next macro block.

#### 7.7.4.2.9 LDC Multi Region with Variable Block size

Distortion in wide angle lenses causes output block size to be very small due to extreme scaling in particular regions of the Image. This could be caused by high field-of-view or viewing position. The range of “Ratio of Output block to input pixel block size” is very high across the frame.

In order to solve this, LDC supports dividing the frame into multiple regions and output block size can be programmed independently for each region. Frame can be divided up to 9 regions. Frame can be divided into maximum of three slices horizontally and maximum of three slices vertically as shown in [Figure 7-92](#). All the regions in a vertical slice share the common horizontal start location and all the regions in a horizontal slice share the common vertical start location. Width of vertical slices can be configured using LDC\_CORE\_REGN\_W12\_SZ[13-0] W1, LDC\_CORE\_REGN\_W12\_SZ[29-16] W2 and PAC\_LDC\_REGN\_W3\_SZ[13-0] W3 register fields. Height of horizontal slices can be configured using LDC\_CORE\_REGN\_H12\_SZ[13-0] H1, LDC\_CORE\_REGN\_H12\_SZ[29-16] H2 and LDC\_CORE\_REGN\_H3\_SZ[13-0] H3 register fields.

**Figure 7-92. LDC Variable Block Size with Multiple Regions**

Hardware will process the each region as independent frame, hence processing of the pixels will in 2D sequence with in the region. Up on completing processing of one region, it will process next region in raster direction.

#### 7.7.4.2.9.1 LDC Region Skip Feature

In surround view use case, some regions of the frame won't be used for stitching of final frame. By programming VPAC\_LDC\_REGION\_CTRL[j][0] ENABLE to low, hardware will skip the processing of particular region.

## Note

Hardware has to make sure that FRAME\_DONE information to LSE is generated on last pixel of last valid region.

As an example shown in [Figure 7-93](#), Region-5, 7 and 8 are skipped for processing. FRAME\_DONE is passed on last pixel of Region-6. Ordering and numbering of the regions will remain the same even in the case of skipping some regions.

Idc-027

**Figure 7-93. LDC Region Skipping Example**

#### 7.7.4.2.9.2 LDC Support for sub-set of 3x3 regions

HW supports dividing the frame into sub-set of 3x3 regions. Following combinations of regions are supported.

- 3 vertical slices
  - $RW1 = x$ ,  $RW2 = y$  and  $RW3 = z$
- 2 vertical slices
  - $RW1 = x$ ,  $RW2 = y$  and  $RW3 = 0$
  - Last region width has to be zero
- 1 vertical slice
  - $RW1 = x$ ,  $RW2 = 0$  and  $RW3 = 0$
  - Last two regions width has to be zero
- 3 horizontal slices
  - $RH1 = x$ ,  $RH2 = y$  and  $RH3 = z$
- 2 horizontal slices
  - $RH1 = x$ ,  $RH2 = y$  and  $RH3 = 0$
  - Last region height has to be zero
- 1 horizontal slice
  - $RH1 = x$ ,  $RH2 = 0$  and  $RH3 = 0$
  - Last two regions height has to be zero

As shown in [Figure 7-94](#), 2x2 region partitioning can be done by programming  $RW3=RH3=0$ .

#### Note

Region numbering remains as in 3x3 region partitioning with R3, R6-R8 being null regions.

Idc-028

**Figure 7-94. LDC 2x2 Region Partitioning Example**

#### 7.7.4.2.9.3 LDC Limitations of Multi Region Scheme

Following features can't be supported when multi region processing is enabled.

- Circular buffer support can't be enabled on Input data fetch
- HTS synchronization can't be enabled on Input data fetch
- LDC can't be joined with other HWAs in the VPAC. LDC output needs to be written to external memory.
- HTS can't make use of multiple BPR buffers available in SL2 circular buffer

#### 7.7.4.2.9.4 LDC Multi Region Block Constrains

- $RW1 + RW2 + RW3$  must be equal to OFW
- $RH1 + RH2 + RH3$  must be equal to OFH
- SW to program the LSE buffer Stride, at-least the size of largest output block width among all regions.
- SW to program buffer height at-least twice the maximum block height among all regions

#### 7.7.4.2.10 LDC Multi-pass Frame processing

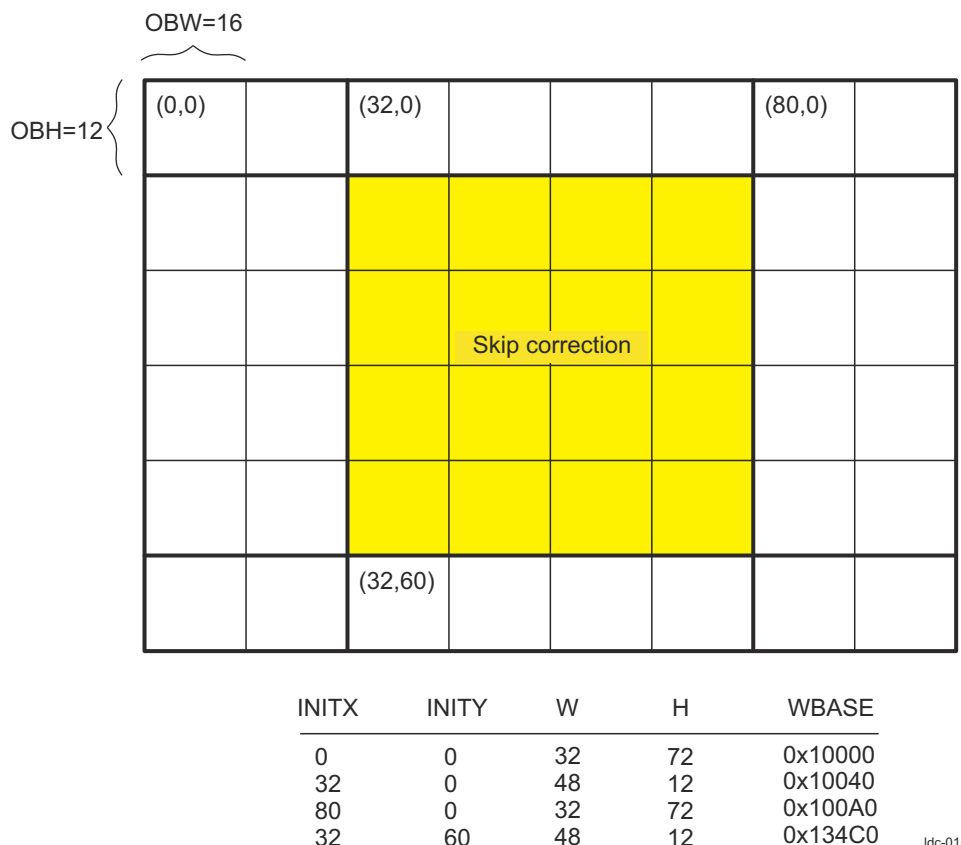

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image.

An intermediate interrupt can occur after processing each macro block. This lets the LDC operation be pipelined with other tasks.

To process only a portion of the image, the following parameters are required:

- LDC\_CORE\_INITXY[12:0] INITX: X coordinate of upper-left corner of output frame
- LDC\_CORE\_INITXY[28:16] INITY: Y coordinate of upper-left corner of output frame
- LDC\_CORE\_INPUT\_FRSZ[13:0] W: Width of output frame
- LDC\_CORE\_INPUT\_FRSZ[29:16] H: Height of output frame
- FrameBase SDRAM address of upper-left corner of output frame (Y and Cb/Cr base needed in case of YCbCr420)
- FrameOfst SDRAM frame width (in bytes)

Figure 7-95 is an example of multiple-pass processing with middle-of-the-image skipped.

ldc-015

**Figure 7-95. LDC Multiple-Pass Correction Example**

The LDC does not copy skipped blocks from the input frame to the output frame (necessary task unless output frame = input frame); software must set up and initiate this memory copy.

A note on in-place operation to conserve external memory: Depending on the offset table and configuration parameters, it may not be feasible to point the output image at the input image and have corrected pixels overwriting the source image. Software must determine whether it is feasible to overwrite, and allocate a separate frame buffer when it is not feasible. The LDC does not care if the input and output image pointers coincide, nor does it check any dependency violations.

The starting address of the input frame, corresponding to input coordinate (0, 0), is specified in the LDC\_RD\_BASE[31:0] RBASE bit field and offset in the LDC\_RD\_OFST[15:0] ROFST bit field ((Y and Cb/Cr base required for YCbCr4:2:0: LDC\_420C\_RD\_BASE[31:0] RBASE)). The LDC does not clips input block to input frame size if any of the input block falls outside the input frame.

#### Note

- Any number of input blocks CAN fall partially or totally outside the input frame by assuming coordinates that are outside valid range (negative or exceeding maximum image width defined by the line offset).
- If any output pixel refers to any input pixel outside the input frame, the computed value for that output pixel would be same as neighbor pixel which falls into valid input frame. The other output pixels can still have correct outcomes.

#### 7.7.4.2.11 LDC Input/Output Data Formats

Table 7-111 captures valid number of LDC input and output data mode/format combinations.

**Table 7-111. LDC Supported Data Format Combinations**

Input		Output	
Data Mode	Data format	Data Mode	Data format
420 420_Y 420_UV	8-bit	Same as input	8bit
	12-bit - packed		12-bit - packed
	12-bit - unpacked		12-bit - packed
	12-bit - packed		12-bit - unpacked
422	8-bit	420	8-bit (on channel[2/3] using LUT)
			8-bit (on channel[0/1] with shift)
			8-bit (on channel[2/3] using LUT)
			8-bit
422	8-bit	422	12-bit – packed
			8-bit

Output data mode will be same as input data mode except when input data is 422, output data can also be converted to 420. In the case of input data format is 8-bit and output data format is 12-bit packed, valid data range is only 8-bit. Output data formatted into 12-bit packed format with 4 MSB bits being all zeros.

The following list contains the register fields used to configure data modes and formats:

- Input data mode - LDC\_CORE\_CTRL[4-3] IP\_DATAMODE
- Input data format - LDC\_CORE\_CTRL[6-5] IP\_DFMT
- Output Luma data format – LDC\_CORE\_LSE\_BUF\_CFG\_j (j = 0, 2) PIX\_FMT\_PW
- Output Chroma data format – LDC\_CORE\_LSE\_BUF\_CFG\_j (j = 1, 3) PIX\_FMT\_PW

LDC supports YCbCr 422 in the UYVY input data format. The sample grid for YCbCr 422\_UYVY is shown in [Figure 7-96](#).

ldc-029

**Figure 7-96. LDC Sample Grids for UYVY**

UYVY data are stored in 8-bit per color components as shown in [Table 7-112](#).

**Table 7-112. LDC UYVY 8-bit Per Color Components**

31			0
Y(1)	Cr(0)	Y(0)	Cb(0)

The sample grid for YUV420 NV12 is shown in [Figure 7-97](#).

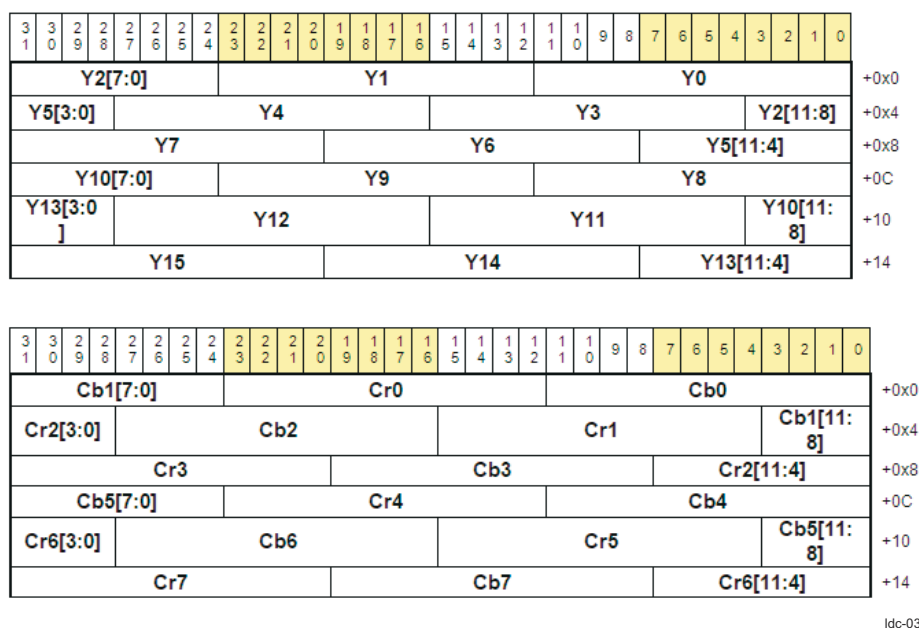

ldc-029

**Figure 7-97. LDC Sample Grids for NV12**

YCbCr 420 data are stored 8-bit per color components, and in two planes, Y by itself and Cb/Cr interleaved as shown in [Table 7-113](#)

**Table 7-113. LDC YCbCr 420 data stored 8-bit per color components**

31			0
(Y plane) Y(3)	Y(2)	Y(1)	Y(0)
(Cb/Cr plane) Cr(2)	Cb(2)	Cr(0)	Cb(0)

**Figure 7-98. LDC YUV420 (2-plane 12-bit Fully Packed Format)**

#### 7.7.4.2.12 LDC YUV422 to YUV420 Conversion

Supporting input YUV422 format enables external sensors providing the YUV data directly. YUV422 to YUV420 conversion is done after pixel interpolation and achieved by dropping odd Chroma lines in the block. This retains the Chroma co-sited relation with Luma as at LDC input.

Idc-032

**Figure 7-99. LDC YUV422 to YUV420 Conversion**

#### 7.7.4.2.13 LDC SL2 Interface (LSE)

LDC Output write interface is handled by LSE sub-module. LSE (Load Store Engine) module is a common component integrated in VPAC to perform data load and store tasks on the SL2 memory for the HWA algorithm core.

VBUSP interface is be used to transfer the data from LDC Core to LSE.

For more LSE details, see *Load Store Engine (LSE)*.

##### 7.7.4.2.13.1 LDC PSA (Parallel Signature Analysis)

LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA's internal paths. When enabled, every valid pixel data from the CORE is sampled by a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. Note that data used for PSA is raw data from the CORE rather than data written into SL2 with container alignment. For LDC, PSA signature is calculated in the same order as CORE data transfer to LSE which is 3D block order as against frame order. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC\_LDC\_LSE\_PSA\_SIGNATURE\_y y=0..#\_of\_Output Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature. The read-only register keeps the last saved value until a reset (set to 0) or is replaced by another frame data signature.

##### 7.7.4.2.14 LDC LUT Mapped Dual Output

LDC produces parallel 8-bit and 12-bit outputs to support surround view and ADAS applications concurrently. LDC produces parallel 8-bit output from 12-bit input using LUT based implementation. This 8-bit output is written into SL2 using LSE output channels (channel[2] for Luma and channel[3] for Chroma). Though use case requires 8-bit output, hardware is designed to be generic which supports any 8-12bit to 8-12bit conversion.

12 or 8 bit generated by data interpolation block is mapped to 8 to 12 bits using a LUT based mapping. The LUT is similar to the LUTs used in VISS and is a linear LUT with 513 entries.

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only  $4095/512 = 8$ . The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different use cases. However, since the step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that. LSE Shift operation can be instead of LUT to reduce bit width from 12 down to 8.

The input bit width (IN\_BITDEPTH explained above) is specified using a dedicated register. Output is clipped to programmable clip value ( $2^{\text{BitClip}-1}$ ). Combination of IN\_BITDEPTH, LUT values and Clip value programation allows any 8-12bit to 8-12bit conversion.

#### 7.7.4.2.15 LDC Band Width Controller

A Bandwidth Limiter is required to limit the mean BW that LDC can request over the VBUSM Read interface. The software sets the maximum allowed bytes per cycle in the register, LDC\_CORE\_VBUSMR\_CFG[27-16] BW\_CTRL.

To determine the maximum allowed bytes per cycle, the software needs to know the configuration of LDC, which determines the maximum input block size. Given a specific configuration, the `ldc_findMaxInputBuffer` utility provided with the functional C model, can be used to give the maximum input block size. The performance requirements determine the maximum number of cycles allowed per block.

#### 7.7.4.2.16 LDC Input Block Fetch Limit

In order to limit the band width hogging by LDC in case of wrong mesh table data, maximum amount of input block pixel data being fetched will be capped at maximum internal memory available for respective data (Note: Luma and Chroma has different size internal buffers).

In YUV420\* modes, limit is imposed by Luma data. Pixel data fetch is stopped on detecting the overflow condition and interrupt event is generated. Maximum of 2 requests can be issued upon overflow detection. In case of mesh data, only interrupt event is generated on detecting overflow condition and there is no stalling of fetch. These events are generated for the first overflow case per frame.

#### 7.7.4.2.17 LDC HTS Interface

The HTS interface is used to synchronize between blocks in VPAC Subsystem. In the case of LDC, it controls the start of LDC operation by issuing `hts_init`. LDC will be waiting for `hts_init` once it is enabled, so LDC is expected to be enabled before issuing `hts_init`.

HTS also controls the LDC output write which will indirectly control all LDC operations (that is, fetch and processing). LDC will start writing output pixel data when only it receives `hts_tstart` for that particular block. Once all output data is written, LDC will generate `hts_tdone` (also `hts_eop` if it is last block of the frame).

#### 7.7.4.2.18 LDC VBUSM Read Interface

VBUSM Read interface has following features

- Data Width – 128 Bit
- Address width – 48 Bit
- Maximum of number of Tags – 32
  - Design can be constrained to use lesser number of Tags
- Maximum Command Size: Programmable
  - 32/64/128/256 Bytes
  - Command will split at maximum command size address boundary
- Chanid Encode: `chanid[1:0]` identify the source/type of the data interface is requesting. `Chanid[11:2]` is tied low.
  - Chanid[1:0] decoding
    - 00 – Mesh Data.
    - 01 – Luma data in 420 mode/422 data.
    - 10 – Chroma data in 420 mode.

#### 7.7.4.3 LDC Programmers Guide

##### 7.7.4.3.1 LDC Programming Geometric Distortion Mode

Geometric distortions, barrel and pincushion distortion, can be corrected on UYVY and NV12 data formats. The Mesh based back mapping is used in this mode. An additional affine transform can be configured at the same time.

1. Check and wait for LDC\_CORE\_CTRL[2] BUSY to become IDLE (0).
2. Set LDC\_CORE\_CTRL[4-3] IP\_DATAMODE for UYVY (0) or NV12 data (2). Program LDC\_CORE\_CTRL[6-5] IP\_DFMT to required data storage format.
3. Set LDC\_CORE\_CTRL[1] LDMAPEN = 1 to enable lens distortion back mapping.

4. Set the input frame base address in LDC\_CORE\_RD\_BASE\_H / LDC\_CORE\_RD\_BASE\_L registers. Note that the frame base address must be aligned on a 16-byte boundary. In case of YUV420, YUV422SP, Y1\_Y2 and Y1\_Y2Y3 modes, configure LDC\_CORE\_RD\_420C\_BASE\_H / LDC\_CORE\_RD\_420C\_BASE\_L registers for Chroma Data.
5. Set the input frame line offset in LDC\_CORE\_RD\_OFST[15:0] OFST.
6. If reading the input image from a circular buffer:
  - a. Set LDC\_CORE\_CTRL[9] IP\_CIRCEN = 1.
  - b. LDC computes the row number and applies modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in LDC\_CORE\_RD\_OFST[29:16] MOD register field. In YUV420 modes, the number of rows in the buffer is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in VPAC\_LDC\_REGION\_OUT\_BLKSZ\_j[15:8] OBH and VPAC\_LDC\_REGION\_OUT\_BLKSZ\_j[7:0] OBW. Note the constraints on OBW in [Table 7-110](#).
8. Set the pixel pad in VPAC\_LDC\_REGION\_OUT\_BLKSZ\_j[19:16] PIXPAD.
9. Set the input frame size in LDC\_CORE\_INPUT\_FRSZ[29:16] H and LDC\_CORE\_INPUT\_FRSZ[13:0] W.
10. Set the output frame size in LDC\_CORE\_MESH\_FRSZ[29:16] H and LDC\_CORE\_MESH\_FRSZ[13:0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in LDC\_CORE\_COMPUTE\_FRSZ[29:16] H and LDC\_CORE\_COMPUTE\_FRSZ[13:0] W.
12. Set the starting output point in LDC\_CORE\_INITXY[12:0] INITX and LDC\_CORE\_INITXY[28:16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 7.7.4.3.4](#).
14. Set the mesh offset table pointer to the correct address (LDC\_CORE\_MESH\_BASE\_H / LDC\_CORE\_MESH\_BASE\_L[31:0] ADDR and LDC\_CORE\_MESH\_OFST[15:0] OFST). Set the table down sampling factor for MxM down sampling in LDC\_CORE\_MESHTABLE\_CFG[2:0] M.
15. Set the Y plane interpolation type to bilinear or bi-cubic in LDC\_CORE\_CFG[6] YINT\_TYP.
16. If also using affine transform, set the six affine transform parameters in LDC\_CORE\_AFF\_AB.A, LDC\_CORE\_AFF\_AB.B, LDC\_CORE\_AFF\_CD.C, LDC\_CORE\_AFF\_CD.D, LDC\_CORE\_AFF\_EF.E, and LDC\_CORE\_AFF\_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.
17. If also using perspective transform, enable LDC\_CORE\_CTRL[7] PWARPEN and set LDC\_CORE\_PWARP\_GH[15:0] G and LDC\_CORE\_PWARP\_GH[31:16] H. If perspective transform is not used, disable LDC\_CORE\_CTRL[7] PWARPEN and set LDC\_CORE\_PWARP\_GH[15:0] G = 0 and LDC\_CORE\_PWARP\_GH[31:16] H = 0.
18. Set LDC\_CORE\_CTRL[0] LDC\_EN = 1 to start the LDC operation.
19. Start the HTS init sequencing. LDC fetch/processing is gated with hts\_init.
20. Wait for LDC\_CORE\_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

#### 7.7.4.3.2 LDC Programming Rotational Video Stabilization (Affine Transformation)

In the rotational video stabilization use case, consecutive frames capturing the same scene are aligned to minimize camera shake. Camera motions cause the frames to have translation or rotation differences. Thus, the frames need to be aligned to maintain a stable output video. The affine transform offers control to account for scaling, rotation, and translation transforms. For example, the rotation use case can be parameterized with the following affine transform parameters:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o - h_o \cos(\theta) - v_o \sin(\theta) \\ v_o - v_o \cos(\theta) - h_o \sin(\theta) \end{bmatrix}$$

ldc-035

where theta is the angle of rotation. In the scaling case, the affine transform uses:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \alpha & 0 \\ 0 & \alpha \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o(1-\alpha) \\ v_o(1-\alpha) \end{bmatrix}$$

ldc-036

where alpha is the scale factor. Translation uses an identity matrix along with the translation vector as the affine transform parameters, as in:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} T_h \\ T_v \end{bmatrix}$$

ldc-037

where  $T_h$  and  $T_v$  are the translation parameters. More complex transforms can be derived and the affine transformation is general so that optimization routines may be used to provide the best parameters to align two frames. In all affine transforms, the perspective warp parameters,  $g$  and  $h$ , should be set to 0.

The following steps need to be performed by the application to initialize and run LDC to perform affine transform.

1. Check and wait for LDC\_CORE\_CTRL[2] BUSY to become IDLE (0).
2. Set LDC\_CORE\_CTRL[4-3] IP\_DATAMODE and LDC\_CORE\_CTRL[6-5] IP\_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the affine transform, set LDC\_CORE\_CTRL[1] LDMAPEN = 1. Otherwise, set LDC\_CORE\_CTRL[1] LDMAPEN = 0.
4. Set the input frame base address in LDC\_CORE\_RD\_BASE\_H / LDC\_CORE\_RD\_BASE\_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in LDC\_CORE\_RD\_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
  - a. Set LDC\_CORE\_CTRL[9] IP\_CIRCEN = 1.
  - b. If using row address, LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in LDC\_CORE\_RD\_OFST[29-16] MOD. In YUV420 modes, the number of rows in the Y buffer is MOD and the number of rows in the Cb/Cr buffers is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in LDC\_CORE\_OUT\_BLKSZ[15-8] OBH and LDC\_CORE\_OUT\_BLKSZ[7-0] OBW. Note the constraints on OBW in [Table 7-110](#).
8. Set the pixel pad in LDC\_CORE\_OUT\_BLKSZ[19-16] PIXPAD.
9. Set the input frame size in LDC\_CORE\_INPUT\_FRSZ[29-16] H and LDC\_CORE\_INPUT\_FRSZ[13-0] W.
10. Set the output frame size in LDC\_CORE\_MESH\_FRSZ[29-16] H and LDC\_CORE\_MESH\_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in LDC\_CORE\_COMPUTE\_FRSZ[29-16] H and LDC\_CORE\_COMPUTE\_FRSZ[13-0] W.
12. Set the starting output point in LDC\_CORE\_INITXY[12-0] INITX and LDC\_CORE\_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 7.7.4.3.4](#).
14. If the data format is NV12, set the 420 UV input plane base address in LDC\_CORE\_RD\_420C\_BASE\_H / LDC\_CORE\_RD\_420C\_BASE\_I. This address must be 16-byte aligned.
15. Set the mesh offset table pointer to the correct address (LDC\_CORE\_MESH\_BASE\_H / LDC\_CORE\_MESH\_BASE\_I and LDC\_CORE\_MESH\_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE\_CFG.M.
16. Set the Y plane interpolation type to bilinear or bicubic in LDC\_CORE\_CFG[6] YINT\_TYP.
17. Set the six affine transform parameters in LDC\_CORE\_AFF\_AB.A, LDC\_CORE\_AFF\_AB.B, LDC\_CORE\_AFF\_CD.C, LDC\_CORE\_AFF\_CD.D, LDC\_CORE\_AFF\_EF.E, and LDC\_CORE\_AFF\_EF.F. If

affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.

18. Disable perspective warp transform with LDC\_CORE\_CTRL[7] PWARPEN = 0. Set the two perspective transform parameters LDC\_CORE\_PWARP\_GH[15-0] G = 0 and LDC\_CORE\_PWARP\_GH[31-16] H = 0.
19. Set LDC\_CORE\_CTRL[0] LDC\_EN = 1 to start the LDC operation.
20. Start the HTS init sequencing. LDC fetch/processing is gated with hts\_init.
21. Wait for LDC\_CORE\_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

#### 7.7.4.3.3 LDC Programming Perspective Transformation

Perspective transforms are used to align the image data of two different cameras viewing the same scene from different positions. It can also be used in the case of stereo image rectification to align the epipolar lines of the left/right image pair with their scan lines.

The following steps need to be performed by the application to initialize and run LDC to perform perspective transform.

1. Check and wait for LDC\_CORE\_CTRL[2] BUSY to become IDLE (0).
2. Set LDC\_CORE\_CTRL[4-3] IP\_DATAMODE and LDC\_CORE\_CTRL[6-5] IP\_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the perspective transform, set LDC\_CORE\_CTRL[1] LDMAPEN = 1. Otherwise, set LDMAPEN = 0.
4. Set the input frame base address in LDC\_CORE\_RD\_BASE\_H / LDC\_CORE\_RD\_BASE\_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in LDC\_CORE\_RD\_OFST[15-0] OFST.
6. Set the tile size in LDC\_CORE\_OUT\_BLKSZ[15-8] OBH and LDC\_CORE\_OUT\_BLKSZ[7-0] OBW. Note the constraints on OBW in [Table 7-110](#).
7. Set the pixel pad in LDC\_CORE\_OUT\_BLKSZ[19-16] PIXPAD.
8. Set the input frame size in LDC\_CORE\_INPUT\_FRSZ[29-16] H and LDC\_CORE\_INPUT\_FRSZ[13-0] W.
9. Set the output frame size in LDC\_CORE\_MESH\_FRSZ[29-16] H and LDC\_CORE\_MESH\_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
10. Set the output compute frame size in LDC\_CORE\_COMPUTE\_FRSZ[29-16] H and LDC\_CORE\_COMPUTE\_FRSZ[13-0] W.
11. Set the starting output point in LDC\_CORE\_INITXY[12-0] INITX and LDC\_CORE\_INITXY[28-16] INITY.
12. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 7.7.4.3.4](#).
13. If the data format is NV12, set the 420 UV input plane base address in LDC\_CORE\_RD\_420C\_BASE\_H / LDC\_CORE\_RD\_420C\_BASE\_I. This address must be 16-byte aligned.
14. Set the mesh offset table pointer to the correct address (LDC\_CORE\_MESH\_BASE\_H / LDC\_CORE\_MESH\_BASE\_I and LDC\_CORE\_MESH\_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE\_CFG.M.
15. Set the Y plane interpolation type to bilinear or bicubic in LDC\_CORE\_CFG[6] YINT\_TYP.
16. Set the eight perspective transform parameters in LDC\_CORE\_AFF\_AB.A, LDC\_CORE\_AFF\_AB.B, LDC\_CORE\_AFF\_CD.C, LDC\_CORE\_AFF\_CD.D, LDC\_CORE\_AFF\_EF.E, and LDC\_CORE\_AFF\_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, F = 0, G = 0 and H = 0. Enable LDC\_CORE\_CTRL[7] PWARPEN = 1.
17. Set LDC\_CORE\_CTRL[0] LDC\_EN = 1 to start the LDC operation.
18. Start the HTS init sequencing. LDC fetch/processing is gated with hts\_init.
19. Wait for LDC\_CORE\_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

#### 7.7.4.3.4 LDC Programming LSE

Following provides the LSE general programming guideline.

It also captures an additional secondary specific use case configuration values for some registers.

- Frame Size = 1920x1080
- Output Block size = 64x32
- Luma data being consumed by MSC and Chroma is written out by UDMA
  - Block to line conversion done for Luma data via SL2.

- Chroma data is written out at block level.
  - Circular buffer size just to do ping-pong between LDC – MSC(Y) and LDC – UDMA(C)
  - 12-bit pixel data
1. Pixel Data Format
    - a. LDC\_CORE\_LSE\_BUF\_CFG\_j (PIX\_FMT\_PW, PIX\_FMT\_CNTRSZ, and PIX\_FMT\_ALIGN) parameters define the pixel output data format for this output channel.
    - b. Common data formats:
      - i. Fully packed 12-bit : PIX\_FMT\_PW=1, PIX\_FMT\_CNTRSZ=1, PIX\_FMT\_ALIGN=0
      - ii. 12-bit unpacked (MSB aligned) : PIX\_FMT\_PW = 1, PIX\_FMT\_CNTRSZ=2, PIX\_FMT\_ALIGN=1
  2. Output SL2 Circular Buffer Configuration
    - a. LDC\_CORE\_LSE\_BUF\_ATTR0\_j (buf\_stride) – define the line stride size (must be 64 byte multiple)
      - i. LDC\_CORE\_LSE\_BUF\_ATTR0\_j[15-6] BUF\_STRIDE = 2880 (1920 \* 1.5)
      - ii. LDC\_CORE\_LSE\_BUF\_ATTR0\_j[15-6] BUF\_STRIDE = 96 (64 \* 1.5)
    - b. LDC\_CORE\_LSE\_BUF\_ATTR0\_j (cbuf\_size) – define the size of the circular buffer in the SL2 (number of lines)
      - i. LDC\_CORE\_LSE\_BUF\_ATTR0\_j[24-16] CBUF\_SIZE = 68 (2\*OBH+4)
      - ii. LDC\_CORE\_LSE\_BUF\_ATTR0\_j[24-16] CBUF\_SIZE = 64 (2\*OBH)
  3. Output SL2 Circular Buffer 2D mode Configuration (applicable for LDC only - TBD)
    - a. LDC\_CORE\_LSE\_BUF\_ATTR1\_j (buf\_blk\_width) – defines the number of bytes equivalent to OBW (output block width) pixels.
      - i. LDC\_CORE\_LSE\_BUF\_ATTR1\_j.buf\_blk\_width = 96 (64\*1.5)
    - b. LDC\_CORE\_LSE\_BUF\_ATTR1\_j (cbuf\_bpr) – defines the number of 2D blocks per row in the SL2 circular buffer.
      - i. LDC\_CORE\_LSE\_BUF\_ATTR1\_j[25-16] CBUF\_BPR\_CHAN = 30
      - ii. LDC\_CORE\_LSE\_BUF\_ATTR1\_j[25-16] CBUF\_BPR\_CHAN = 1
  4. Base Address and Channel Enable:
    - a. LDC\_CORE\_LSE\_BUF\_BA\_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
    - b. LDC\_CORE\_LSE\_BUF\_BA\_j[31] ENABLE – enables this output channel.

#### 7.7.4.3.5 LDC Programming Restrictions and Special Cases

The following list of LDC programming restrictions should be considered:

1. LDC\_CORE\_LSE\_BUF\_ATTR1\_j[25-16] CBUF\_BPR\_CHAN supports 1023 number of block per row. Hence, with output block width of 8, maximum line size supported in SL2 memory is 8184 pixels.
2. In 422 mode, always program as data format as 8-bit (design does not select data format automatically based on mode)
3. Due to hardware limitations, make sure that input block size (height and width) does not cross 1023 (pixels/lines).
  - The hardware generates either PIX\_IBLK\_MEMOVF or MESH\_IBLK\_MEMOVF events in this case.
4. LDC\_CORE\_CTRL[0] LDC\_EN should be high before issuing hts\_init.

### 7.7.5 VPAC Multi-Scaler (MSC)

#### 7.7.5.1 MSC Overview

VPAC\_MSC (VPAC Multi-Scaler, hereinafter simply referred to also as MSC) is a Hardware Acceleration (HWA) module in Vision Pre-processing Accelerator (VPAC) . MSC supports two sets of multi-output scaling filters to accelerate generation of pyramid (Octave) and intra-octave scales required by Optical Flow processing and DSP vision algorithms.

##### 7.7.5.1.1 MSC Features

- 10 scaled outputs independently mapped to 1 or 2 processing threads (any number up to 10 scaler outputs can be mapped to one thread, while the remaining scaler outputs can be mapped to the other thread)
- Programmable scaling engine:
  - Pyramid or intra-octave scale generation
  - $1x \sim x/4$  image downscaling
  - $1x$  generic separable convolution filtering
  - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (thus, frame width not constrained by internal line buffer width).
- Polyphase filters:
  - 5-tap separable filter kernel structure
  - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
  - Polyphase implementation with support of 64 or 32 phases
  - Independent programming of vertical/horizontal filters with initial phase programming option
- Filter Coefficients (shared by all scalers):
  - Coefficients in signed 10-bit number (typically 1-bit integer with 8 fractional bits)
  - Programmable Coefficient shift size to set precision of coefficient number (shift size represents the fractional bit width)
  - 2 dedicated sets of 5-tap single phase filter coefficients (for example, Gaussian) for Pyramid (Octave) generation or custom convolution filtering.
  - 4 sets of 5-tap x 32 phase coefficients
    - Two can be combined to support 5-tap x 64-phase filters
    - First can be configured to hold additional 5-tap single-phase convolution filters for non-resizing application.
- Input/output format support:
  - Each thread can support the following input source formats:
    - One plane (uniform or interleaved format - Y, CbCr interleaved, R)
  - Each Input channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
  - Each Output channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
- Performance:
  - 1 cycle/pixel per plane
  - Input line skip for thread performing only pyramid-generation (50% less processing time)
- Other features:
  - Programmable Input and Output Region of Interest (ROI) (or clipping) for each scaler
  - Support for Vertical and Horizontal edge Padding (replication) for both luma/chroma data plane inputs
- Functional Safety Support: CRC frame data signature capture on all output channels for fault detection in the data path.

##### 7.7.5.1.2 MSC Not Supported Features

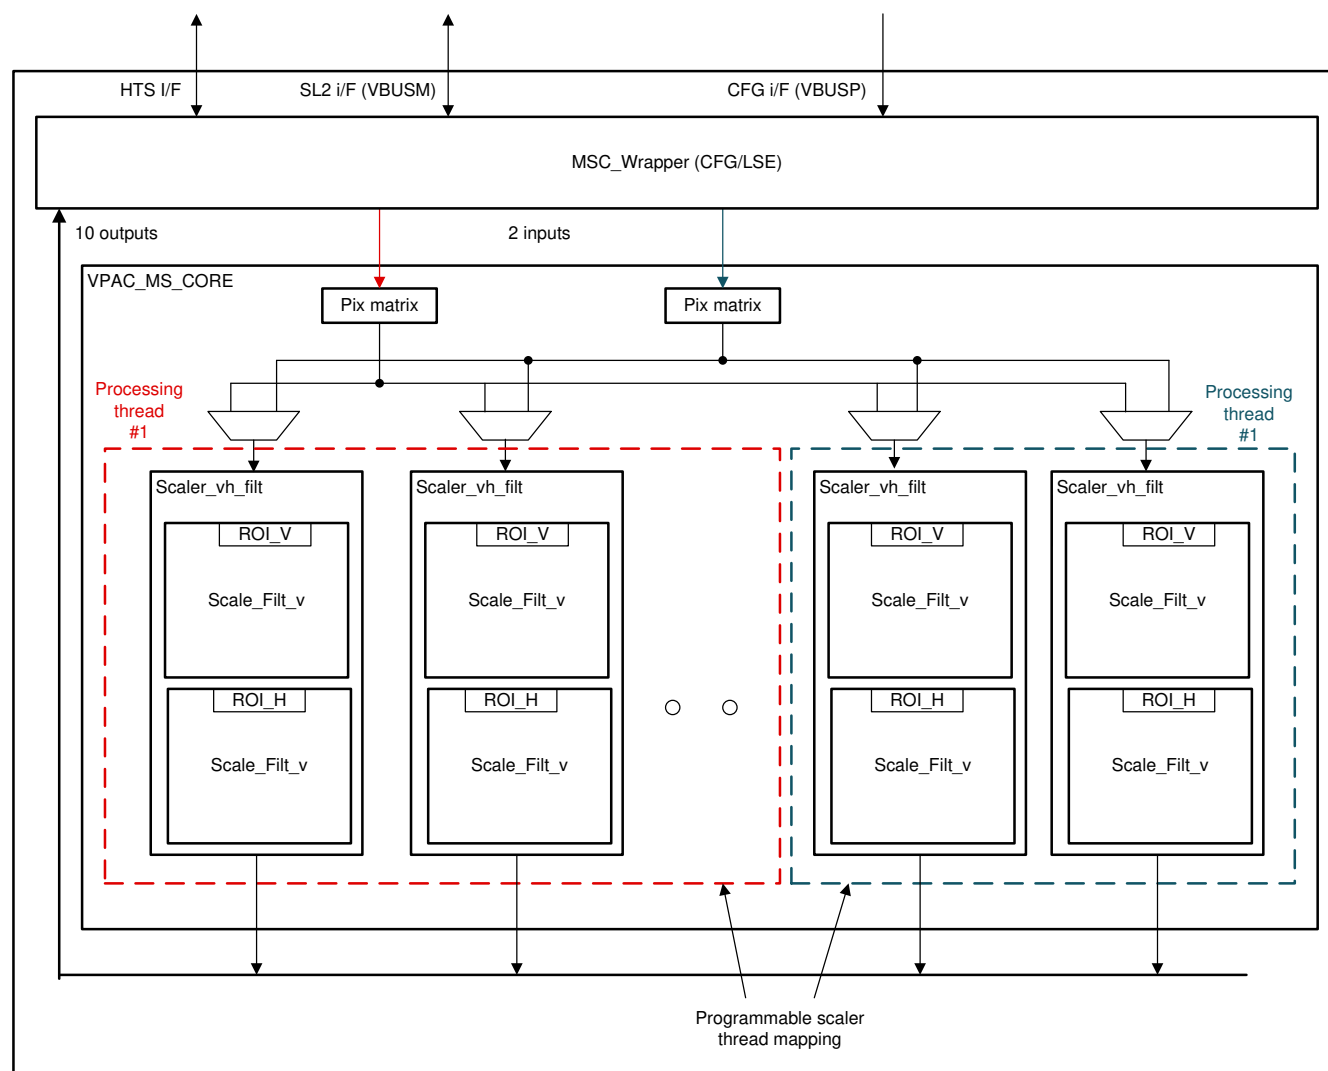

- More than 2 input threads or 10 outputs
- Block based operation for scalar
- Multi-component (RGB) Scaling
- Error checks for out of bound parameters

## 7.7.5.2 MSC Functional Description

### 7.7.5.2.1 MSC Functional Overview

VPAC\_MSC consists of 10 programmable resizers performing multi-thread/multi-scaling operations (1-input to N-outputs and 1-input to M-outputs where  $N+M$  is 10 or less). Each processing thread of MSC HWA reads its input plane data from a Shared Memory buffers (SL2) circular line buffers, performs multi-scaling operations (ratios between X and 0.25X) on the selected thread channel input, and writes out results to SL2 circular line buffers. In case of OTF operation, the source data is generated from another HWA. In case of M2M operation, the source data is read from the DDR memory. Data transfers from/to SL2 to/from external memory (or another HWA) are handled by VPAC level DMA controller with transfer request events coming from VPAC top level HWA Thread Scheduler (HTS), see *HWA Threads Scheduler (HTS)*.

A typical configuration of the MSC module uses one input plane data to generate 7 intra-octave scales and the next octave image. Multi-pass processing is then utilized to generate up to next 6 or 7 sets of scales/octaves. Since the resolution after each octave is essentially reduced by 4x, the performance requirement for generating an infinite number of scales is bounded by 1.33x of the base input image pixel rate. The second input can be used to enable a pyramid generation processing for another input data or a set of scales/pyramid generation for chroma data as long as the total number of scales needed by both threads is 10 or less. Each resizer in a processing thread can access any coefficient set.

**Figure 7-100. Block Diagram of Multi-Scaler Filter Core**

For details on MSC integration in VPAC, see [Section 7.7.2, VPAC Subsystem Level](#).

#### **7.7.5.2.1.1 MSC Submodule Details**

The MSC\_LSE (Load Store Engine) handles all interfacing to the SL2 memory space and performs following functions:

- Provides interface to SL2 circular buffers via a common VBUSM controller interface
- Manages input and output channel updates in sync with HTS
- Provides data unpacking for core and packing for SL2 interface
- Manages LSE specific configuration registers

The MSC\_CORE performs all filtering operations for various 2-in/10-out multi-scaling/multi-thread configurations. It has no direct connection to external interface and it works on a frame data coming in and out in raster scan order.

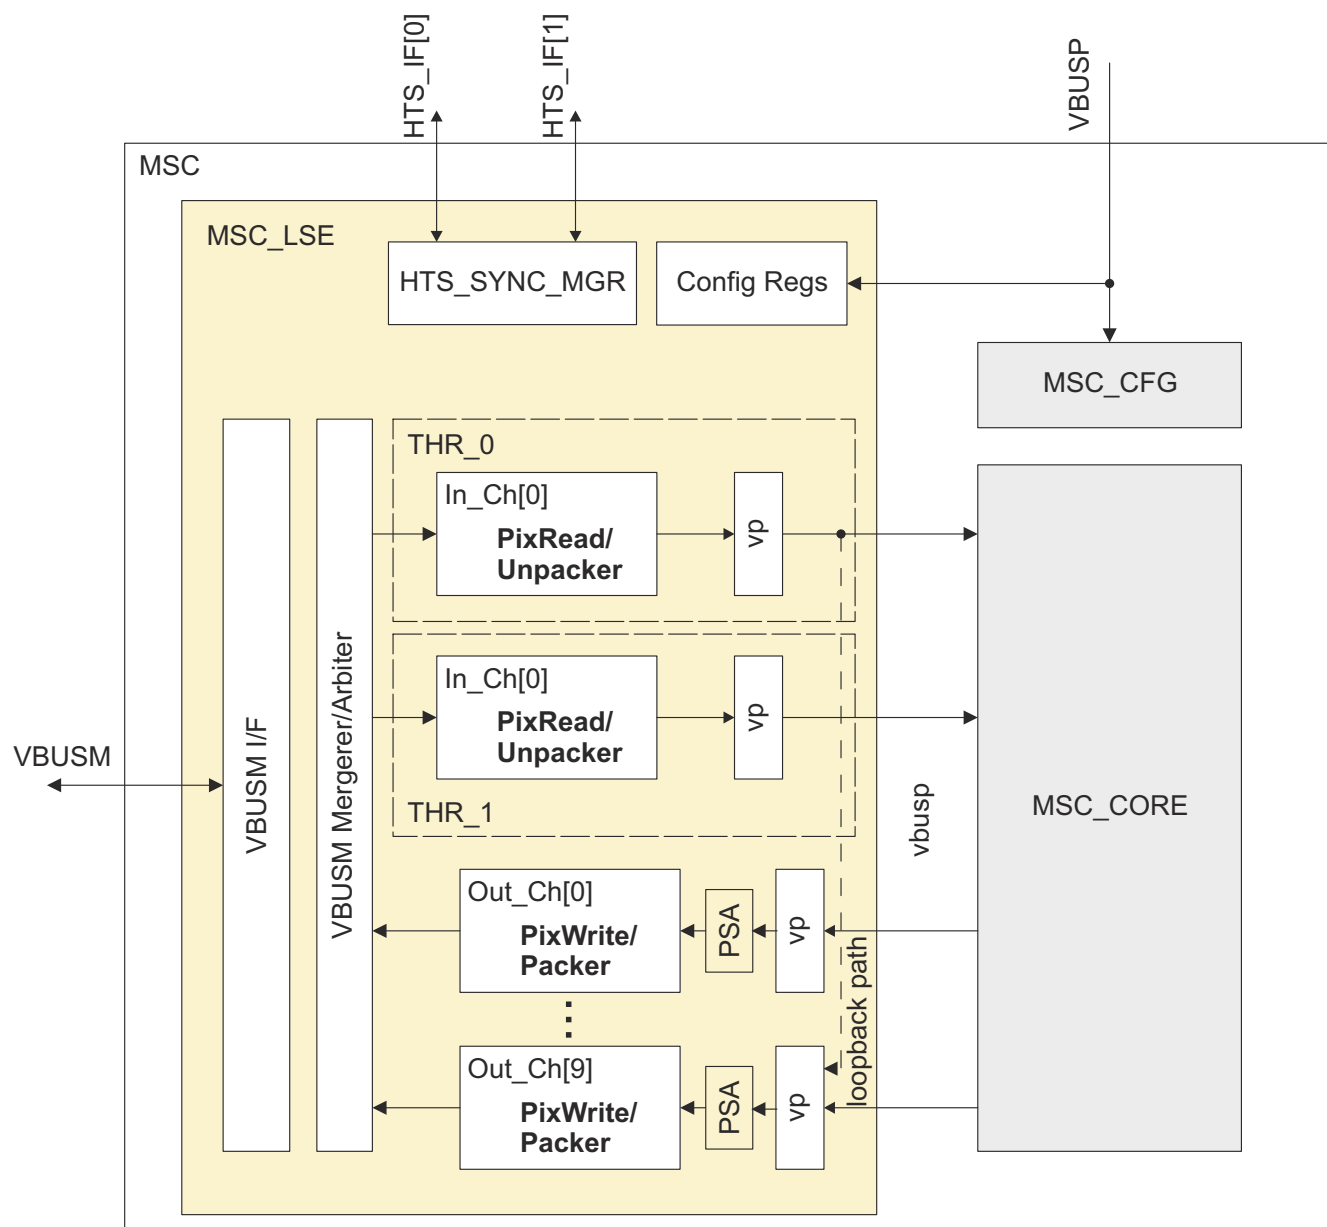

The internal data transfers between the MSC\_LSE and MSC\_CORE are done over VBUSP write-only streaming interfaces.

#### **7.7.5.2.1.1.1 MSC Load Store Engine (MSC\_LSE)**

##### **7.7.5.2.1.1.1.1 MSC\_LSE Overview**

[Figure 7-101](#) shows the MSC\_LSC block diagram.

**Figure 7-101. MSC\_LSC Block Diagram**

#### 7.7.5.2.1.1.1.1 MSC\_LSE Features

The MSC\_LSE supports following VPAC\_LSE features:

- Up to 2 processing threads supported (a thread is a processing chain with its own HTS start/done).
- Input channel features:
  - One SL2 input channel per thread with following features for the input channel:
    - Single data plane support
    - 8/12 packed and 12-bit unpacked source format support
    - Up to 5 lines - input kernel height support
    - 1D addressing mode only with CBUF address handling
    - Input Line Skip Support
    - Vertical boundary Edge Padding (Replication only) support
    - Channel enable
    - Video frame data with frame sync signals over a common vbusp streaming write-controller interface

- Output Channel Features:
  - Up to 10 SL2 output channels (pixel data output only)
  - Single data plane support for each output channel
  - Programmable thread mapping for each output channel
  - 8/12 packed and 12-bit unpacked output pixel data format support
  - 1D addressing mode support with CBUF address handling
  - Channel enable
  - Video frame data with frame sync signals (along with optional in-band control signals) over a separate vbusp streaming write-target interface
- HTS synchronization support
- LSE internal data bypass mode support
  - Input channel 0 can be configured to bypass/loopback mode the data to the core and/or directly to the output channel 9 (bypassing the core).

#### 7.7.5.2.1.1.2 MSC\_LSE Internal Data Loopback Channel

The MSC\_LSE provides a data loopback channel.

When enabled (VPAC\_MSC\_LSE\_CFG\_LSE[0] LOOPBACK\_EN), the LSE sends the “loopback-enabled” input channel unpacked data directly to the designated output channel packing logic without going through the HWA\_CORE. The looped back data can be packed in a different format in the output channel to perform a data format conversion or can be packed in the same format as the input.

When the loopback mode is enabled, the “loopback” designated output channel is no longer available for HWA\_CORE output data transfer. But, the input channel can still operate normally to read in the data for the HWA\_CORE (provided that the other output channel is used for transferring out the HWA\_CORE output data) by setting VPAC\_MSC\_LSE\_CFG\_LSE[1] LOOPBACK\_CORE\_EN. In this mode, the input channel flow is throttled by both the core and the loopback data path.

The data flow of the loopback mode is also controlled by the HTS synchronization signals.

#### 7.7.5.2.1.1.3 MSC\_LSE PSA Support

As a safety function, LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA internal paths. When enabled (VPAC\_MSC\_LSE\_CFG\_LSE[8] PSA\_EN), every valid transfer frame data from the MSC is passed through a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC\_MSC\_LSE\_PSA\_SIGNATURE\_y[31-0] VAUE = 0,...,Number\_of\_Output\_Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature.

The PSA signature register is based on the following IEEE 802.3 standard 32-bit CRC polynomial:

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The PSA module is inserted in the LSE data path as shown in [Figure 7-101](#).

#### 7.7.5.2.1.1.4 MSC\_LSE Feature Detailed Description

For detailed LSE feature description, see *Load Store Engine (LSE)*.

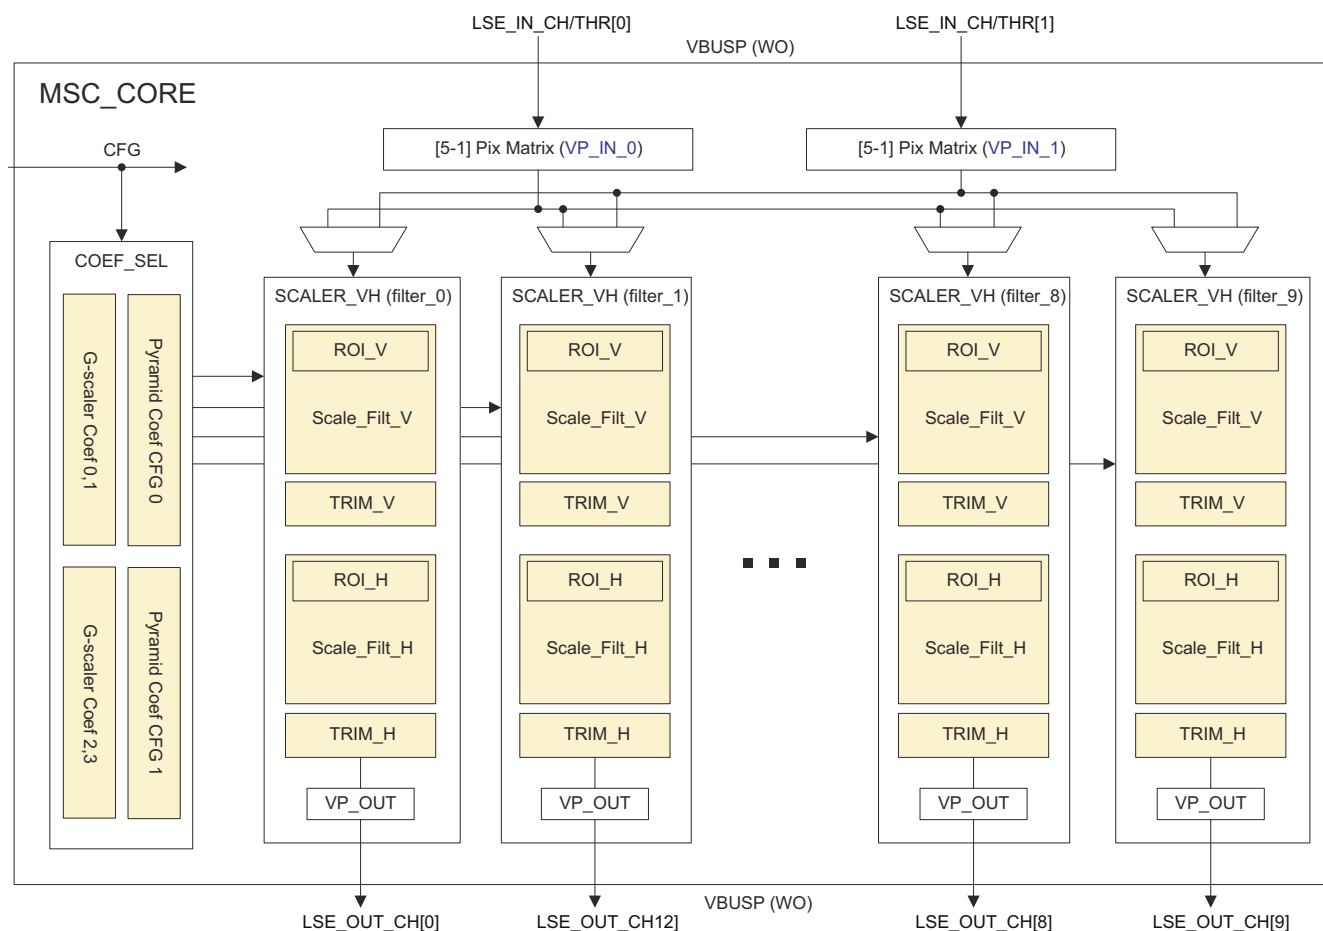

#### 7.7.5.2.1.1.2 MSC\_CORE (HWA Core)

The MSC\_CORE (HWA\_CORE) is configured as two multi-scaling engines each of which can perform 1-to many (multi) scaling operations on an independent input source. The number of outputs (scaler filters) assigned to each multi-scaling engine is user-configurable.

#### 7.7.5.2.1.1.2.1 MSC\_CORE Overview

[Figure 7-102](#) shows the architectural overview of the MSC\_CORE. Each reconfigurable multi-scaling engine in the MSC\_CORE receives its input frame data from its own dedicated VP (vbusp write only target) interface. VP\_IN\_0 port is used for the thread #0 (multi-scaling engine-0) and VP\_IN\_1 port is used for the thread

#1 (multi-scaling engine-1). The `THREAD_MAP` parameter of the `MSC_LSE` output channel configuration register (`VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP`) controls which input port is connected to which scaling filter (filter\_0 ~ filter\_9).

**Figure 7-102. MSC\_CORE Block Diagram**

The scaling filter implements the vertical-before-horizontal architecture in order to avoid intermediate result line buffers that would be needed in the horizontal-before-vertical configuration. This architecture also allows the source frame width to be not restricted by internal line buffer sizes.

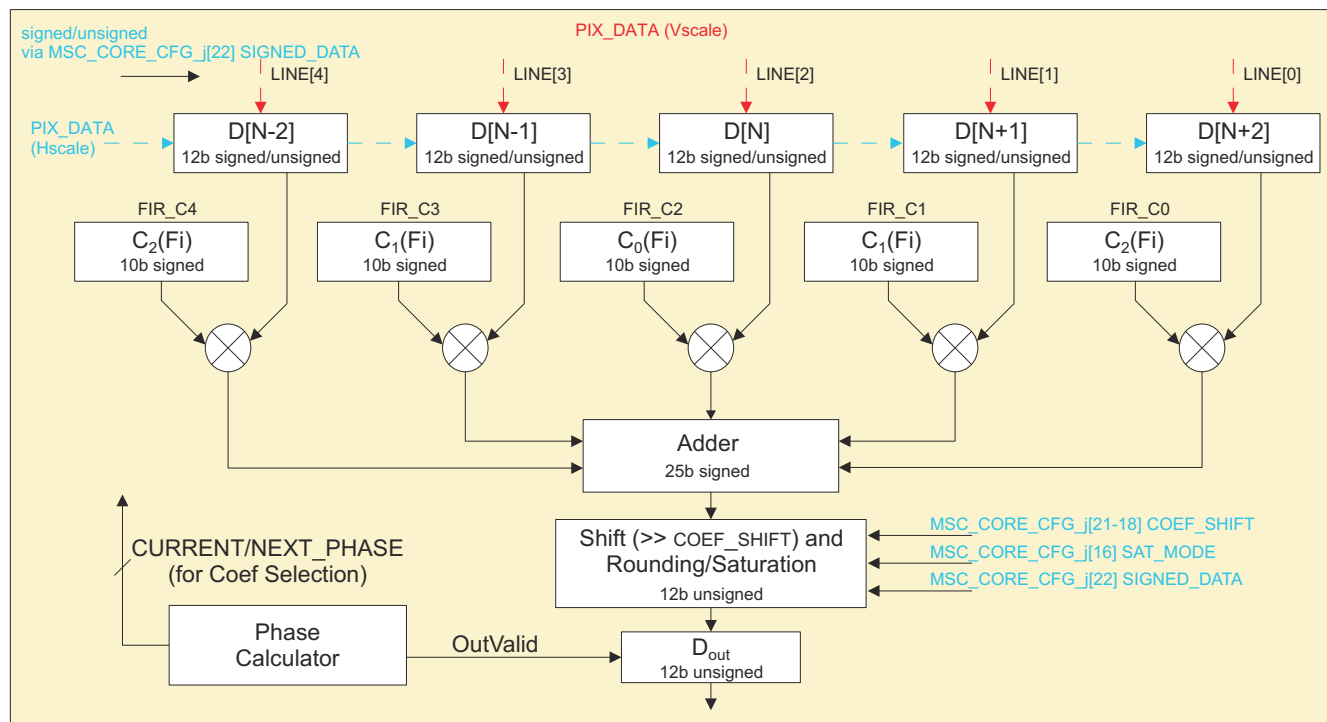

Each scaling filter in the `MSC_CORE` consists of 5-tap (32/64-phase) Polyphase filter based vertical and horizontal resizers. At the input of each resizer, a ROI checker determines the input start position (that is, marks the input data as valid). Output of each resizer is then trimmed to the configured output size of the scaling filter in each respective direction.

For `MSC`, the vertical input edge padding is performed in the `MSC_LSE` while the horizontal input boundary padding is done within the `MSC_CORE` before the horizontal resizer.

#### 7.7.5.2.1.1.2.2 Polyphase Filter of Vertical/Horizontal Resizers

##### 7.7.5.2.1.1.2.2.1 Filter Data Path Logic

Figure 7-103 shows the micro-architecture of the polyphase filter data path. The 5-tap filter structure can be programmed to perform a 5-tap Gaussian filter (for Octave generation) or a 4-tap bi-cubic downscaling filter (for scale generation). Or, it can be configured to perform a custom convolution filter without resizing. Filter coefficients for any unused taps should be set to 0. For example, in case of a 4-tap filtering, `C2(Fi)` filter coefficient should be set to 0. For 3-tap filtering, `C-2(Fi)` and `C2(Fi)` filter coefficients should be set to 0.

**Figure 7-103. Polyphase Filter Micro-Architecture**

### Kernel Size Configuration

There is no separate configuration required to set the filter kernel size (number of taps) within the polyphase filter. The filter always works as a 5-tap filter but requires unused taps to be masked using the zero coefficients.

### Coefficient Precision Selection

The precision of the coefficients is user-configurable using VPAC\_MSC\_CORE\_CFG\_j[21-18] COEF\_SHIFT which determines the number of fractional bits of the coefficient.

### Unsigned/Signed Data Type support

Typically for image resizing, the input and output data are in unsigned (positive) integer numbers in the range of [0..4095]. But, in some non-image convolution filtering (for example, Sobel filter), the input and output data may be in signed integer data format. The MSC supports a user-selectable data type mode bit (VPAC\_MSC\_CORE\_CFG\_j[22] SIGNED\_DATA) per resizer to specify whether the input/output data is in signed or unsigned data format. The selection determines the input range and output clipping limits as shown below:

VPAC\_MSC\_CORE\_CFG\_0[22] SIGNED\_DATA = 0 -> [0..4095]

VPAC\_MSC\_CORE\_CFG\_0[22] SIGNED\_DATA = 1 -> [-2048..2047]

Note that all filters in the same processing thread should have the SIGNED\_DATA bit set to a same value.

### Rounding Logic

The rounding is done by “adding 0.5 and dropping fractional bits”. This achieves the following:

For data  $\geq 0$ : “round to nearest, ties away from zero”

For data  $< 0$ : “round to nearest, ties toward zero”

### Output Saturation Logic

For some non-image unsigned data filtering, the result of the final adder could be negative numbers. To avoid clipping all negative numbers to 0, the MSC filter data processing supports a mode

(VPAC\_MSC\_CORE\_CFG\_j[22] SAT\_MODE = 1) to offset the result by 2048 and then clip the final result to [0..4095] in the output saturation logic to preserve the full data range.

### Edge Pixel Replication

Pixel replication in vertical direction (edge line replication) is done in the MSC\_LSE.

Pixel replication in horizontal direction (edge pixel replication) is performed in the horizontal filter. For chroma data plane, Cb/Cr pixel replication is done independently with edge Cb/Cr data respectively.

#### 7.7.5.2.1.2.2.2 Filter Parameters

[Table 7-114](#) lists the parameters used to define the configuration of the resizing (downsampling) vertical/horizontal filters.

**Table 7-114. Parameters of the Resizing (Downsampling) Vertical/Horizontal Filters**

Parameter	Bit Precision	Description
FIRINC_V VPAC_MSC_CORE_FIRINC_j[30-16] VS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Vertical Resizing Ratio value (vertical filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling) +1 in the above equation is optional. +1 forces non-repeating coefficients in integer ratio scaling cases.
FIRINC_H VPAC_MSC_CORE_FIRINC_j[14-0] HS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Horizontal Resizing Ratio value (Horizontal filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling)
ACC_INIT_V VPAC_MSC_CORE_ACC_INIT_j[27-16] VS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Vertical Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095
ACC_INIT_H VPAC_MSC_CORE_ACC_INIT_j[11-0] HS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Horizontal Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095

Additionally, [Table 7-115](#) lists the mode parameters defined the filter operation and coefficient selection.

**Table 7-115. Filter Mode and Coefficient Selection via VPAC\_MSC\_CORE\_CFG\_j Registers**

Parameter	Bit Width	Description
SIGNED_DATA VPAC_MSC_CORE_CFG_j[22] SIGNED_DATA	1-bit	Integer type of input and output frame data: 0 : Unsigned 12-bit (default) 1 : Signed 12-bit
UV_MODE VPAC_MSC_CORE_CFG_j[17] UV_MODE	1-bit	Source data interleave format: 0 - non-interleaved (Y data) 1 - interleaved (UV data)
SP_VS_COEF_SEL VPAC_MSC_CORE_CFG_j[15-12] SP_VS_COEF_SEL	4-bits	Single Phase – Vertical Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N < 10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.

**Table 7-115. Filter Mode and Coefficient Selection via VPAC\_MSC\_CORE\_CFG\_j Registers (continued)**

Parameter	Bit Width	Description
SP_HS_COEF_SEL VPAC_MSC_CORE_CFG_j[10-7] SP_HS_COEF_SEL	4-bits	Single Phase – Horizontal Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N+10) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N < 10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.
VS_COEF_SEL VPAC_MSC_CORE_CFG_j[5-4] VS_COEF_SEL	2-bits	Multi-phase Vertical Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
HS_COEF_SEL VPAC_MSC_CORE_CFG_j[3-2] HS_COEF_SEL	2-bits	Multi-phase Horizontal Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
PHASE_MODE VPAC_MSC_CORE_CFG_j[1] PHASE_MODE	1-bit	Filter Phase mode selection 0 - 64 phases 1 - 32 phases
FILTER_MODE VPAC_MSC_CORE_CFG_j[0] FILTER_MODE	1-bit	Filter Mode 0 – Single Phase Filter (for example, Gaussian Filter for Pyramid) 1 – Multi-phase Scaling Filter
FILT_SAT_MODE VPAC_MSC_CORE_CFG_j[16] SAT_MODE	1-bit	Filter Output Saturation Mode 0 - [0..4095] clipping 1 - [-2048.. 2047] clip followed by +2048 This parameter is used only when signed_data = 0 (unsigned data type).
COEF_SHIFT VPAC_MSC_CORE_CFG_j[21-18] COEF_SHIFT	4-bits	Coef Shift Size: configures the precision of the 10-bit signed filter coefficients (valid Shift range: 5~9) : 5: Shift by 5 (5-bit fraction) 6: Shift by 6 (6-bit fraction) 7: Shift by 7 (7-bit fraction) 8: Shift by 8 (8-bit fraction) 9: Shift by 9 (9-bit fraction) Integer size = 9 - #_of_fraction_bits

#### 7.7.5.2.1.1.2.2.3 Single-Phase Filter Parameters

For a single-phase filter configuration (VPAC\_MSC\_CORE\_CFG\_j[0] FILTER\_MODE = 0), software must ensure that FIRINC parameters (VPAC\_MSC\_CORE\_FIRINC\_j[30-16] VS and VPAC\_MSC\_CORE\_FIRINC\_j[14-0] HS) are programmed with one of the following values only:

- 0x4000 (1/4 X resizing)
- 0x2000 (1/2 X resizing)
- 0x1000 (1X – no scaling)

VPAC\_MSC\_CORE\_ACC\_INIT\_j[27-16] VS and VPAC\_MSC\_CORE\_ACC\_INIT\_j[11-0] HS configuration values are ignored by the MSC hardware (internally set to 0x0) when VPAC\_MSC\_CORE\_CFG\_j[0] FILTER\_MODE = 0. If any phase offsets are needed, the starting pixel/line locations of the frame and the filter coefficient values should be adjusted to implement the desired phase shift.

#### **7.7.5.2.1.1.2.2.4 Interleaved Mode Handling**

When the input is in the interleaved data format (for example, YUV420 Chroma data), the horizontal filter supports two sets of 5-input buffers (Cb and Cr buffers) and alternates filtering operation between two. Phase calculation and coefficient updates are done every other sample. Edge replications at the start of the line and at the end of the line are handled separately for Cb and Cr data.

There is no change in how the vertical filter handles an interleaved data format source.

#### **7.7.5.2.1.1.2.2.5 Input Skip Line Support**

When a processing thread is only performing an octave generation (1/2x single phase resizing), the next input lines can be offset by 2 lines since the output is only generated every other input line times. By skipping lines (VPAC\_MSC\_LSE\_SRC\_CFG\_j[7] SRC\_LN\_INC\_2), the SL2 access is reduced in half for this mode and the cycle time to complete an Octave generation is equal to 1/2 of the input frame size.

Line N: Read Line N-2, N-1, N, N+1, N+2

Line N+1: Skip

Line N+2: Read Line N, N+1, N+2, N+3, N+4

Line N+3: Skip

Even though “N+1” line processing is skipped, all source lines are still required for proper filtering. Therefore, the DMA transfer from DDR to SL2 should include all lines. VPAC\_MSC\_CORE\_FIRINC\_j[30-16] VS should be set to 4096 (1x resizing) to compensate for source line skip (if it is doing a 1/2 resizing).

Horizontal Skip is done normally as 1/2 x resizing by the core HScale Filter.

#### **7.7.5.2.1.1.2.3 Scaler Filter Thread Mapping**

The scaling filter\_# (# = 0..9) is enabled and its input is connected to one of the processing thread source VP ports (VP\_IN\_0 or VP\_IN\_1) by configuring the output channel #n buffer configuration:

VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[7] THREAD\_MAP: 0 maps the filter to VP\_IN\_0, 1 maps to the VP\_IN\_1.

VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[TBD] ENABLE: enables both filter and output channel

By mapping each output to a thread explicitly in the output channel configuration register, MSC guarantees that a filter can only be connected to one processing thread.

#### **7.7.5.2.1.1.2.4 Filter Coefficients**

Since each resizer needs to access the common coefficients independently, the coefficients are stored in registers (instead of memory). Each resizer selects directly from these register using the coefficient selection scheme as shown in [Figure 7-104](#). The same mux is used to select either vertical or horizontal coefficients.

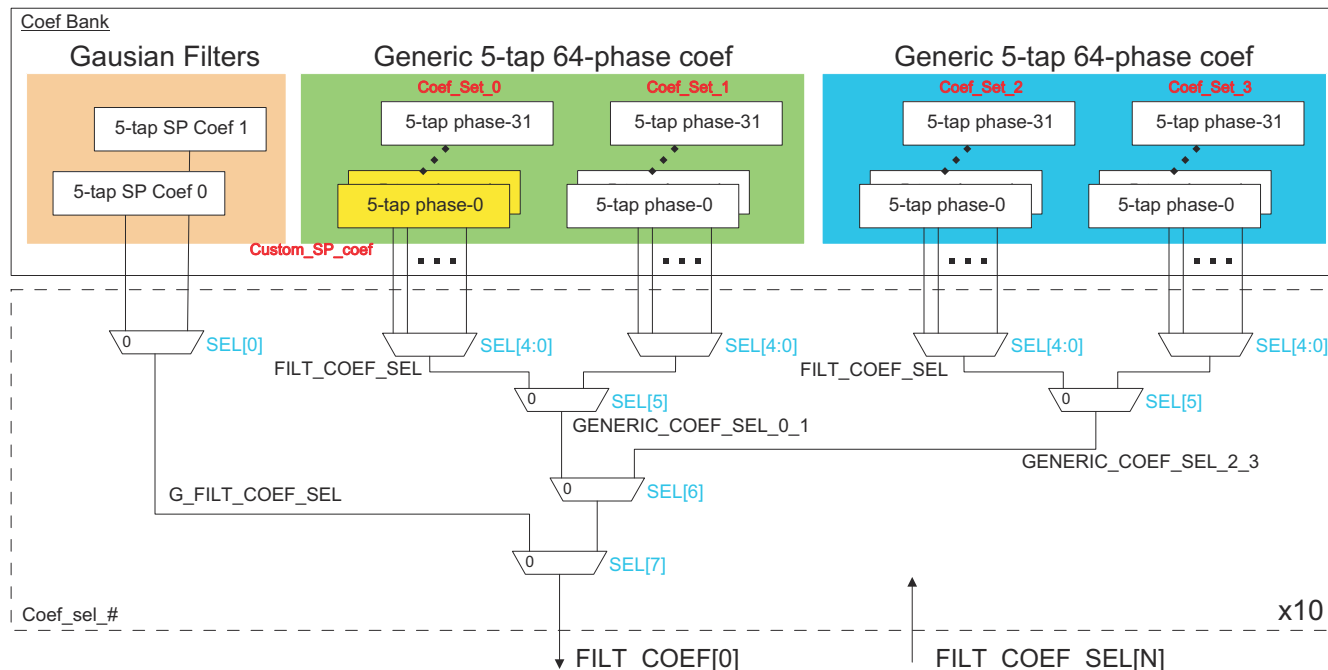

Figure 7-104. Coefficient Selection

#### 7.7.5.2.1.2.4.1 Filter Coefficient Parameter Configuration

Each coefficient table entry consists of 5 coefficients stored in two memory mapped configuration registers - VPAC\_MSC\_CORE\_C210\_j and VPAC\_MSC\_CORE\_C43\_j. FIR\_C4-0 parameters map to C-2, C-1, C0, C1, and C2 coefficients (see Figure 7-102).

#### 7.7.5.2.1.2.4.2 3/4/5-Tap Filter Configuration

All filters operate in 5-tap filter mode – requiring 5-tap coefficients regardless of the filter usage. For less-than-5 tap filter configurations, coefficients corresponding to the unused taps should be set to 0.

For example, FIR\_C0 and FIR\_C4 will need to be set to 0x0 for a 3-tap configuration.

For 4-tap configuration, FIR\_C0 will need to be set to 0x0.

#### 7.7.5.2.1.2.5 Input/Output ROI Trimmers

Each scaler filter implements the ROI scaling as shown below with input and output trimmers. The input trimmer simply marks the beginning of the ROI to indicate where the valid source pixels and lines start in the source image. Doing the source ROI marker allows the exact specification of a sub-image in a common source image (no position or size restriction) while keeping the original boundary pixels (that is, not use the replicated pixels/lines).

The output trimmers then uses destination size parameters (VPAC\_MSC\_CORE\_OUT\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_CORE\_OUT\_SIZE\_j[12-0] WIDTH) to trim out the exact final output image sizes.

VPAC\_MSC does not perform output size correction by stuffing extra pixels in the case the programmed VPAC\_MSC\_CORE\_OUT\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_CORE\_OUT\_SIZE\_j[12-0] WIDTH exceeds the actual output size of the scaler. In this case, VPAC\_MSC simply outputs the actual size.

#### 7.7.5.2.2 Resizer Algorithm Details

This section describes the algorithm details of the Horizontal and Vertical Down-Scaling engines.

##### 7.7.5.2.2.1 Multiple Scales Generations

For a high number of scales needed by vision image processing algorithm (for example, 32 or more), there are many options in generating the multiple scales as shown in Figure 7-105. Among the options, the “linear rescale

from octave resolution” gives the best tradeoff in video quality and design simplicity. The MSC implements 1-to-N multi-rescaling (that is, from one base image to multi-intra-scales and the next octave image generation) as shown as option B in [Figure 7-105](#).

**Figure 7-105. Multiple Scale Generation**

#### 7.7.5.2.2.2 Polyphase Filter

Both vertical and horizontal resizers in MSC hardware are implemented using a programmable Polyphase filter structure supporting 5-tap kernel with either 64 or 32 phases.

##### 7.7.5.2.2.2.1 Interpolation/Resampling

[Figure 7-106](#) illustrates the interpolation principle. The assumptions are that the input pixels are evenly spaced. The distance between each input pixel is assumed to be 1. The magnification ratio is given by  $64/N$  and  $p/64$  is the initial phase of the output data. The output pixels are evenly spaced as well. The distance between each output pixel is given by  $N/64$  (in the example below,  $N > 64$ ). The position of the  $n$ -th output pixel is given by  $(n \times N + p) / 64$ .

**Figure 7-106. Interpolation Principle**

Figure 7-107 illustrates the interpolation principle at the  $n$ -th output pixel ( $o_n$ ) at position  $x_n$ . Interpolation method with  $m$  and  $d$  parameters, are described as:

$$m = \text{floor}((n \times N + p) / 64)$$

$$d = ((n \times N + p) / 64) - m$$

Figure 7-107 illustrates the concept when the filters are configured in 4-tap mode for non-integer rescaling (the first coefficient corresponding to  $O_{m-2}$  is set to zero).

**Figure 7-107. Interpolation Process**

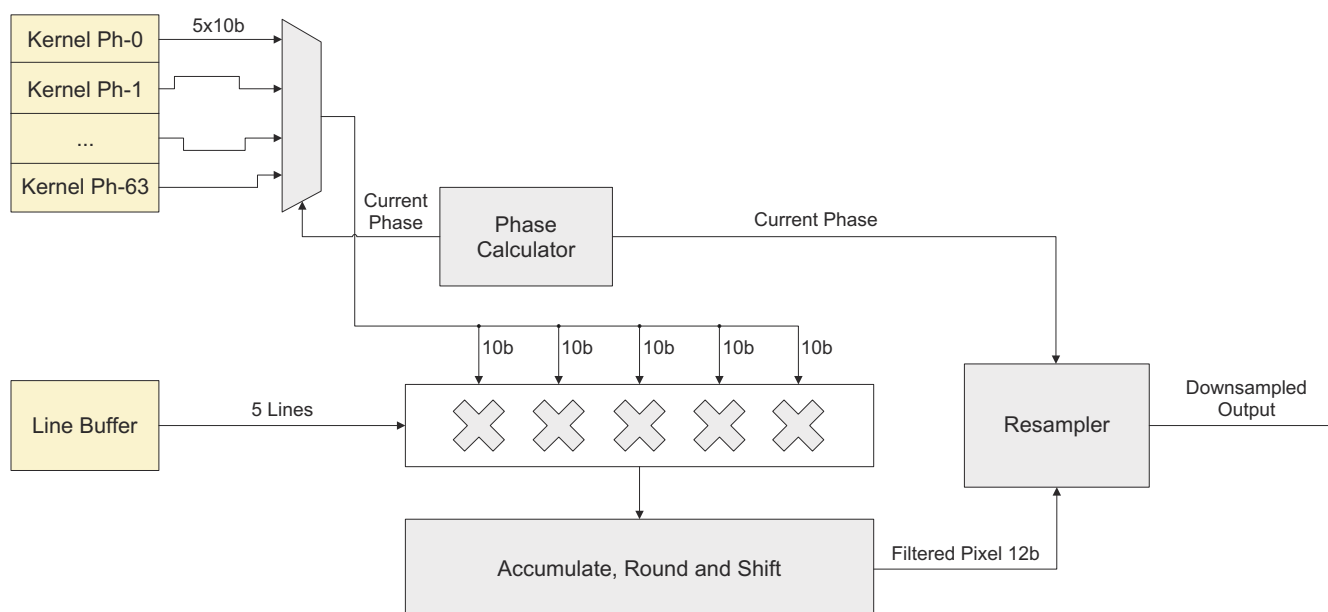

Figure 7-108 illustrates another explanation of the concept of a Polyphase filter using a simple 2-tap linear filter in a design which supports 5 phases.

**Figure 7-108. Polyphase Filtering**

For each one of the 5 phases, the weights (or filter coefficients) are different and after the 5 phases the weights start repeating, see [Figure 7-108](#).

[Figure 7-109](#) depicts the architecture for the independent polyphase filter unit.

**Figure 7-109. Polyphase Filter Unit**

Both the horizontal and vertical filter described earlier are an instance of the Polyphase filter unit, though only the vertical filter requires line memories (implemented in SL2 memory space). In all, there will be 20 instances of the Polyphase filter unit, 2 filters per channel and 10 total channels in the VPAC\_MSC module.

#### 7.7.5.2.2.2 Phase Calculation and Re-sampler

The phase calculation block calculates the current phase which in turn is used for selecting the right coefficient set and for the output qualifier in the Re-sampler block. The Re-sampler engine then decides whether or not the output created by the interpolation unit is a valid output or not.

#### 7.7.5.2.2.3 Shared Coefficient Buffers

The MSC module supports up to 4 sets of multi-phase coefficients for generic non-integer resizing and up to 10 sets of single-phase coefficients (5x1 entries) for Octave generation and integer resizing applications. The multi-phase coefficients can also be configured in one of two following options:

- 4 sets of 5-tap x 32 phase coefficients
- 1 set of 5-tap x 64 phase coefficients and 2 sets of 5-tap x 32 phase coefficients
- 2 sets of 5-tap x 64 phase coefficients

The 32 phase configuration option allows using independent coefficients for vertical and horizontal resizer to achieve aspect ratio change during the scaling.

#### 7.7.5.2.2.4 Border Pixel Padding

The MSC module replicates missing lines and pixels at top/bottom and left/right sides of the input frame for non-interleaved (luma) and interleaved (chroma) data.

The missing lines at the top/bottom are replicated in the LSE sub-module prior to the vertical scaler and the missing pixels at the left/right sides of each line are replicated in the core prior to the horizontal scaler. For more information about LSE module, see *Load Store Engine (LSE)*.

Replication scheme simply repeats the edge line or pixel to create missing lines/pixels. [Figure 7-110](#) shows horizontal pixel replication.

**Figure 7-110. Horizontal Pixel Replication**

If a scaling is performed on a sub-frame (ROI) within the input frame, no replicated lines/pixels will be used since the lines/pixels outside the sub-frame are already present in the input frame.

For interleaved data format, the horizontal replication is done separately for U and V data. For U-data, edge U-pixel will be replicated. For V-data, edge V-pixel will be replicated. There is no distinction in the vertical edge padding.

#### 7.7.5.2.2.3 ROI Handling

- ROI supported during scaling generation
  - Only one ROI at Input Frame and one ROI at Output frame per scale
  - ROI definitions (for input as well as all output scales) can be changed at every input frame under software control.
  - ROI for each scale (for output) can be different among scales (as well as with respect to the input). It is set under software Control.
  - The key purpose of ROI is DDR bandwidth reduction. There is additional help by reduction on processing power on DSP and hardware.
- The input ROI is a superset area considering following two scenarios.
  - Multiple ROIs in given Input Frame, if there are multiple ROI for input frame
  - Input Frame area from Overlapped ROI across scales

[Figure 7-111](#) shows an example of multiple ROIs in the source superset ROI area.

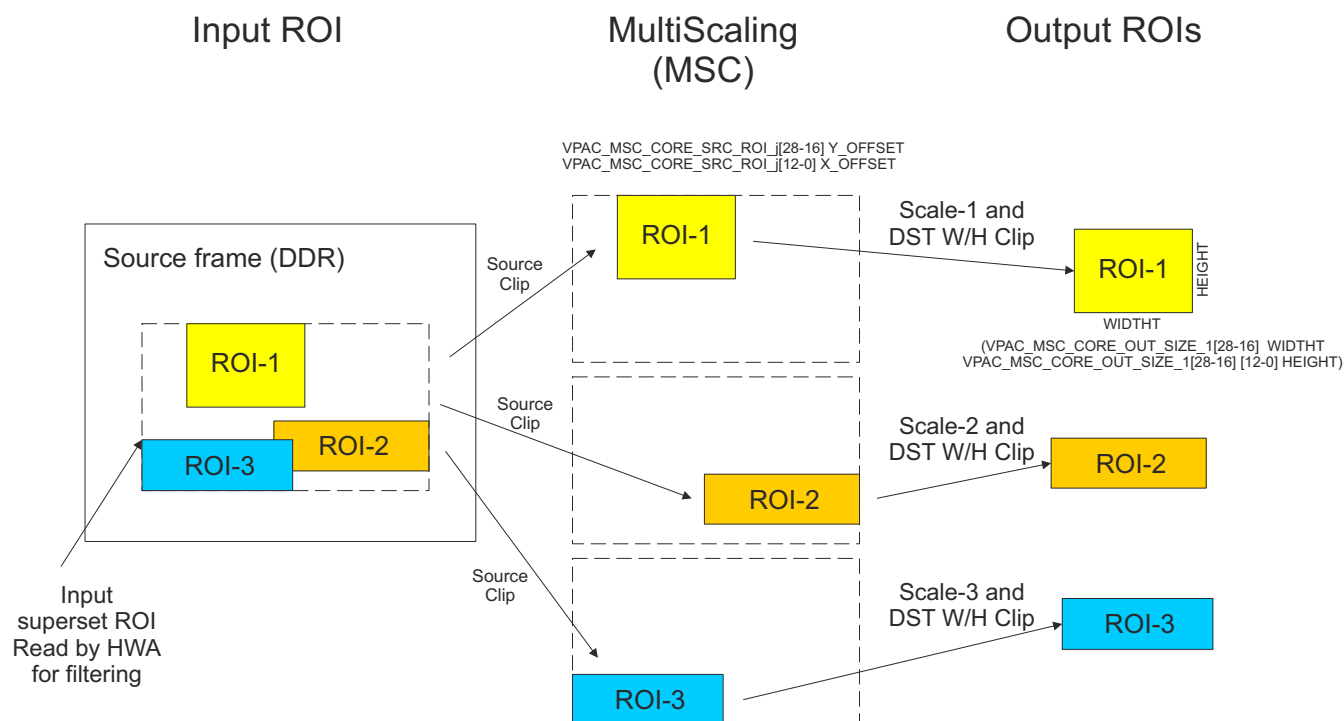

Figure 7-111. Multiple-ROI Support Illustration

Figure 7-112 illustrates another application of generating output ROIs with different scales from a common source region.

Figure 7-112. Multiple-ROI From a Common Source ROI

By defining output ROIs, only the data within ROI in the “superset ROI” scaled output image is saved thus reducing the DDR traffic significantly.

### 7.7.5.2.3 MSC Data Formats Supported

Table 7-116 summarizes data format supported by MSC.

**Table 7-116. MSC Input/Output Data Formats**

Module (IO)	Bit-Depth	Chroma Format	Packing
MSC Input	8-bit	YUV420	Fully Packed
	12-bit	YUV420	Fully Packed
	12-bit	YUV420	Unpacked in 16-bit
MSC Output	8-bit	YUV420	Fully Packed
	12-bit	YUV420	Fully Packed
	12-bit	YUV420	Unpacked in 16-bit

Table 7-117 and Table 7-118 show the pixel data memory organization for YUV420 (2-plane 12-bit fully packed format).

**Table 7-117. YUV420 (2-plane 12-bit Fully Packed Format), First Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Y2[7:0]								Y1								Y0																+0x0
Y5[3:0]								Y4								Y3								Y2[11:8]								+0x4
Y7								Y6								Y5[11:4]																+0x8
Y10[7:0]								Y9								Y8																+0C
Y13[3:0]								Y12								Y11								Y10[11:8]								+10
Y15								Y14								Y13[11:4]																+14

**Table 7-118. YUV420 (2-plane 12-bit Fully Packed Format), Second Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Cb1[7:0]								Cr0								Cb0															+0x0	
Cr2[3:0]								Cb2								Cr1								Cb1[11:8]								+0x4
Cr3								Cb3								Cr2[11:4]															+0x8	
Cb5[7:0]								Cr4								Cb4															+0C	
Cr6[3:0]								Cb6								Cr5								Cb5[11:8]								+10
Cr7								Cb7								Cr6[11:4]															+14	

Table 7-119 and Table 7-120 show the pixel data memory organization for YUV420 (2-plane 8-bit fully packed format)

**Table 7-119. YUV420 (2-plane 8-bit Fully Packed Format), YUV 4:2:0 – NV12, First Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Y3								Y2								Y1								Y0				+0x0			
Y7								Y6								Y5								Y4				+0x4			
Y11								Y10								Y9								Y8				+0x8			
Y15								Y14								Y13								Y12				+0xC			

**Table 7-120. YUV420 (2-plane 8-bit Fully Packed format), YUV 4:2:0 – NV12, Second Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Cr1								Cb1								Cr0								Cb0				+0x0			
Cr3								Cb3								Cb2								Cb2				+0x4			
Cr5								Cb5								Cr4								Cb4				+0x8			
Cr7								Cb7								Cb6								Cb6				+0xC			

### Note

MSC supports both NV12 and NV21 chroma component ordering. Since there is no color processing, the ordering of Cb and Cr is irrelevant. Simply, if a NV12 chroma plane is the input, the output will be a NV12 chroma plane.

### 12-bit unpacked format (16-bit container) with LSB/MSB alignments is shown below

Table 7-121 and Table 7-122 show the pixel data memory organization for YUV420 (2-plane 12-bit unpacked format – LSB aligned)

**Table 7-121. YUV420 (2-plane 12-bit Unpacked Format – LSB aligned), YUV 4:2:0 – NV12 (12-bit) (0x3D), First Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 7.7.5.3 MSC Interrupt Conditions

### 7.7.5.3.1 CPU Interrupts

Table 7-125 lists the interrupts generated by the MSC module.

**Table 7-125. Interrupts**

Interrupt	Type	Description
VPAC_MSC_LSE_FR_DON E_EVT_0	Pulse	Frame Processing complete for all filters in the processing thread 0.
VPAC_MSC_LSE_FR_DON E_EVT_1	Pulse	Frame Processing complete for all filters in the processing thread 1.
VPAC_MSC_LSE_SL2_RD _ERR	Pulse	Set whenever there is an error response on VBUSM read command request for any input channel
VPAC_MSC_LSE_SL2_WR _ERR	Pulse	Set whenever there is an error response on VBUSM write command request for any output channel

All interrupts are single pulse event signals that are mapped to the VPAC level interrupt aggregation logic. The MSC has no mask/set/clear registers for these events. For more information see [Section 7.7.2, VPAC Subsystem](#).

#### 7.7.5.3.2 Interrupt Event Description

##### 7.7.5.3.2.1 VPAC\_MSC\_LSE\_FR\_DONE\_EVT\_0/1 Events

These events are generated when all filters associated with the thread 0 or 1 complete the frame processing. This is set when input EOF (end of frame) event and output EOF (end of frame) events are detected.

##### 7.7.5.3.2.2 VPAC\_MSC\_LSE\_SL2\_RD\_ERR Interrupt Event

This event is generated whenever the VBUSM read status is something other than 0 (success).

The VPAC status register VPAC\_MSC\_STATUS\_ERROR[4-0] VM\_RD\_ERR stores the last non-zero RSTATUS value and the input channel number for user to see what type of error has occurred on which channel.

**Table 7-126. Encoding for RSTATUS**

RSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive read fail

##### 7.7.5.3.2.3 VPAC\_MSC\_LSE\_SL2\_WR\_ERR Interrupt Event

This event is generated whenever the VBUSM write status is something other than 0 (success).

The VPAC status register VPAC\_MSC\_STATUS\_ERROR[14-8] VM\_WR\_ERR stores the last non-zero WSTATUS value and the output channel number for user to see what type of error has occurred on which channel.

**Table 7-127. Encoding for WSTATUS**

WSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive write fail

#### 7.7.5.4 MSC Performance

Since the resizer performs only downscaling operations, the throughput of scaler is mostly dictated by the input processing rate – 1 input pixel per 1 clock cycle. Once the data is made available to the scaler filter after the initial set up and data fetching, the scaler should be fully active except for few cycles at the end of each line to flush the line.

If a processing thread is performing a pyramid generation only, the vertical line skip feature can be enabled to reduce the frame processing time approximately by ½.

### 7.7.5.5 MSC Clocking

Complete VPAC\_MSC module operates on single clock - VPAC0\_MSC\_CLK.

### 7.7.5.6 MSC Reset

VPAC\_MSC has one synchronous active low reset input. The entire module is reset by this reset.

### 7.7.5.7 MSC Programmer's Guide

#### 7.7.5.7.1 Programming Model

##### 7.7.5.7.1.1 MSC Programming Guidelines

MSC does not support shadow registers for its configuration registers. All changes must be done prior to the HTS.INIT request for a frame processing.

Input and output channels are individually enabled. It is expected that at least one input and output channels are enabled for each HTS thread enabled.

The MSC does not check for proper programming of all configuration parameters. It is strictly software responsibility to ensure programming of MSC (Core and LSE) registers do not cause conflict with each other.

##### 7.7.5.7.1.2 MSC\_Core Programming Details

All filters enabled for a multi-scaling thread are programmed via:

- VPAC\_MSC\_CORE\_CFG\_j[0] FILTER\_MODE; Coefficient Set Selection - VPAC\_MSC\_CORE\_CFG\_j[3-2] HS\_COEF\_SEL, VPAC\_MSC\_CORE\_CFG\_j[5-4] VS\_COEF\_SEL, VPAC\_MSC\_CORE\_CFG\_j[10-7] SP\_HS\_COEF\_SEL, VPAC\_MSC\_CORE\_CFG\_j[15-12] SP\_VS\_COEF\_SEL; and filter tap size parameters VPAC\_MSC\_CORE\_CFG\_j[11] SP\_VS\_COEF\_SRC and VPAC\_MSC\_CORE\_CFG\_j[6] SP\_HS\_COEF\_SRC.
- Coefficients set in VPAC\_MSC\_CORE\_C210\_j, VPAC\_MSC\_CORE\_C43\_j, VPAC\_MSC\_CORE\_C210\_j\_k, VPAC\_MSC\_CORE\_C43\_j\_k registers.
- ROI source offset - VPAC\_MSC\_CORE\_SRC\_ROI\_j[28-16] Y\_OFFSET and VPAC\_MSC\_CORE\_SRC\_ROI\_j[12-0] X\_OFFSET, and size. The size of ROI depends on the X and Y offsets. For full-size set the offsets to 0. Note that the ROI\_SIZE may or may not be same as the MSC frame size (set in MSC\_FRAME\_SIZE\_j[28-16] HEIGHT and MSC\_FRAME\_SIZE\_j[12-0] WIDTH) - depending on whether ROI is full or sub-frame sized.
- Output size - VPAC\_MSC\_CORE\_OUT\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_CORE\_OUT\_SIZE\_j[12-0] WIDTH.
- Filter parameters - VPAC\_MSC\_CORE\_FIRINC\_j[14-0] HS, VPAC\_MSC\_CORE\_FIRINC\_j[30-16] VS, VPAC\_MSC\_CORE\_ACC\_INIT\_j[27-16] VS, and VPAC\_MSC\_CORE\_ACC\_INIT\_j[11-0] HS.

Filter thread mapping is done with output channel configuration parameters (MSC\_BUF\_CFG\_j[7] THREAD\_MAP). Specifying the mapping in one register for each channel prevents any resource conflict.

##### 7.7.5.7.1.3 MSC\_LSE Programming Details

Two processing threads can be activated independently.

##### 7.7.5.7.1.3.1 Input Thread Configuration:

1. Pixel Data Format
  - a. VPAC\_MSC\_LSE\_SRC\_CFG\_j[1-0] PIX\_FMT\_PW, VPAC\_MSC\_LSE\_SRC\_CFG\_j[3-2] PIX\_FMT\_CNTRSZ, and VPAC\_MSC\_LSE\_SRC\_CFG\_j[4] PIX\_FMT\_ALIGN parameters define the pixel input data format for all input channels of the thread.
  - b. Common data formats:
    - i. Fully packed 12-bit: PIX\_FMT\_PW = 1, PIX\_FMT\_CNTRSZ = 1, PIX\_FMT\_ALIGN = 0
    - ii. Fully packed 8-bit: PIX\_FMT\_PW = 0, PIX\_FMT\_CNTRSZ = 0, PIX\_FMT\_ALIGN = 0
2. Pixel Input Matrix Configuration
  - a. VPAC\_MSC\_LSE\_SRC\_CFG\_j[15-12] KERN\_LN\_OFFSET defines the starting line offset number of the input pixel matrix (for 5-tap filter configuration, offset = 0, for 4-tap configuration, offset = 1)

- b. VPAC\_MSC\_LSE\_SRC\_CFG\_j[11-8] KERN\_SZ\_HEIGHT defines the height of the input pixel matrix (for example, MSC = 5, VISS = 1, NF = 5)
- c. VPAC\_MSC\_LSE\_SRC\_CFG\_j[21-19] KERN\_TPAD\_SZ, and VPAC\_MSC\_LSE\_SRC\_CFG\_j[18-16] KERN\_BPAD\_SZ defines the number of padding lines required at top and bottom of the frame (for example, for 5-tap filter configuration for MSC, both of these parameters are set to 2. For 4-tap filter configuration for MSC, TPAD\_SZ = 1 while BPAD\_SZ = 2).
3. Source Frame Size
  - a. VPAC\_MSC\_LSE\_SRC\_FRAME\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_LSE\_SRC\_FRAME\_SIZE\_j[12-0] WIDTH – define the width and height (pixels/lines) of the source video frame.
4. Source SL2 Circular Buffer Configuration
  - a. VPAC\_MSC\_LSE\_SRC\_BUF\_ATTR\_j[15-6] BUF\_STRIDE – defines the line stride size (must be 64 byte multiple)
  - b. VPAC\_MSC\_LSE\_SRC\_BUF\_ATTR\_j[24-16] CBUF\_SIZE – define the size of the circular buffer in the SL2 (number of lines)
  - c. VPAC\_MSC\_LSE\_SRC\_BUF\_ATTR\_j[31-25] START\_NIB\_OFFSET – defines the line start offset in smaller resolution (start address within the first SL2 512-bit word in 4-bit resolution).
5. Source BA and Enable Configuration
  - a. VPAC\_MSC\_LSE\_SRC\_i\_BUF\_BA\_y[23-6] ADDR – defines the SL2 base address of the Circular buffer for the input channel. VPAC\_MSC\_LSE\_SRC\_i\_BUF\_BA\_y[31] ENABLE – enables the input channel.

#### 7.7.5.7.1.3.2 Output Channel Configuration

1. Pixel Data Format
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[1-0] PIX\_FMT\_PW, VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[3-2] PIX\_FMT\_CNTRSZ, and VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[4] PIX\_FMT\_ALIGN parameters define the pixel output data format for this output channel.
  - b. Common data formats:
    - i. Fully packed 12-bit: PIX\_FMT\_PW = 1, PIX\_FMT\_CNTRSZ = 1, PIX\_FMT\_ALIGN = 0
    - ii. Fully packed 8-bit: PIX\_FMT\_PW = 0, PIX\_FMT\_CNTRSZ = 0, PIX\_FMT\_ALIGN = 0
2. Output Thread Map
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[7] THREAD\_MAP defines the output channel thread mapping.
3. Output SL2 Circular Buffer Configuration
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_ATTR0\_j[15-6] BUF\_STRIDE – define the line stride size (must be 64 byte multiple)
  - b. VPAC\_MSC\_LSE\_DST\_BUF\_ATTR0\_j[24-16] CBUF\_SIZE – define the size of the circular buffer in the SL2 (number of lines)
4. Base Address and Channel Enable:
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_BA\_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
  - b. VPAC\_MSC\_LSE\_DST\_BUF\_BA\_j[31] ENABLE – enables this output channel.

#### 7.7.5.7.1.4 MSC HTS Programming Details

There is no configuration required for HTS interface in the MSC\_HWA. All programming is done in the separate HTS module. It is expected that at least one input and output channel is enabled for each HTS thread. For more details on programming HTS, see *Hardware Accelerator (HWA) Thread Scheduler (HTS)*.

#### 7.7.5.7.1.5 MSC Data Transfer Programming Details

Refer to *VPAC Subsystem Programmer's Guide*.

#### 7.7.5.7.1.6 LSE Interrupt Programming

MSC does not have any interrupt MASK/SET/CLEAR registers. Interrupts are pulse output events that go to the VPAC top level interrupt aggregation logic. For more information about the aggregation logic, see [Section 7.7.2, VPAC Subsystem](#).

MSC does, however, provide a set of statuses for VBUSM interface errors. These status are mapped to VPAC\_MSC\_STATUS\_ERROR and they are cleared by writing all 1's to the status bit field.

#### **7.7.5.7.2 Initialization Sequence**

For details, see [Section 7.7.2, VPAC Subsystem Level](#).

#### **7.7.5.7.3 Real-Time Operating Requirements**

For details, see [Section 7.7.2, VPAC Subsystem Level](#).

#### **7.7.5.7.4 Power Up/Down Sequence**

For details, see [Section 7.7.2, VPAC Subsystem Level](#).

## 7.8 Depth and Motion Perception Accelerator (DMPAC)

This chapter describes the Depth and Motion Perception Accelerator (DMPAC) in the device.

### 7.8.1 DMPAC Overview

The Depth and Motion Perception Accelerator (DMPAC) is a power efficient hardware accelerator that computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs.

The image/video sensor-based environmental perception (also known as scene understanding) is at the core of many emerging applications in automotive, industrial and consumer electronics. Typically, this involves detection of all objects in the scene along with their 3D position and motion with regards to the observer or the car by analyzing one or many related input video streams. Various computer vision algorithms are used to achieve these tasks.

A very robust method of obtaining the 3D depth from images is to use two cameras in a stereo setup - two cameras with known relative positions and camera parameters. The two images of the same scene, captured from two different camera poses/perspectives, are analyzed to find disparities among every pixel positions in the images. This is known as the Stereo Disparity map. The disparity values of every pixel can be used to obtain the 3D positions of the object/space they belong to via triangulation.

On the other hand, by analyzing two images from a single camera, captured at two different time instances (that is, two temporal frames in a video), one can determine where each pixel in a past frame moved to in the future frame. This is known as the Optical Flow vector. The flow vectors for each pixel position can be used to obtain 3D structure of the scene, identify moving objects and determine their relative speed and direction of motion.

The DMPAC is dedicated to the aforesaid image processing tasks. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common shared local memory, DMA, external messaging and control infrastructure.

#### 7.8.1.1 DMPAC Features

The DMPAC supports the following main features:

- Input image resolution up to 2 MPix with maximum horizontal resolution of up to 2048 pixels and maximum vertical resolution of up to 1024 pixels
- Input pixel format of 12-bit fully packed luminance data, and other formats using the integrated Format Conversion (FOCO) module
- Pixel level output packed in 16bpp and 32bpp formats for stereo disparity estimates and optical flow estimates, respectively
- Simultaneous operation of SDE and DOF, each processing inputs of up to 1 MPix image resolution (1 MPix = 1280 × 720 pixels)
- Resolution vs. frame rate scalability (higher frame rate at lower resolution)
- A Dense Optical Flow (DOF) engine: The DOF engine implements Texas Instruments' proprietary algorithm for estimation/calculation of the optical flow between the input image pair. The algorithm uses hierarchical coarse-to-fine block search strategy leveraging image pyramids in which proprietary binary pixel descriptors are used for pixel correspondence determination. In the scheme accuracy and smoothness of the flow map is enforced using optical flow estimates of the causal neighbors of a pixel in the given and higher (lower resolution) pyramid level (pixels are processed in raster scan order in a pyramid level to refine existing optical flow estimates). The DOF engine supports:
  - Optical flow vector lengths up to +/- 191 pixels in horizontal direction and +/- 62 pixels in vertical direction for each input pixel
  - Dense flow vector map for each input pixel
  - Optical flow vector precision of 1/16<sup>th</sup> of inter pixel distance
  - Post filtering of the optical flow estimates using 2D median filtering
  - 16 level confidence score for every output flow vector
- A Stereo Disparity Engine (SDE): The SDE implements Texas Instruments' proprietary algorithm in order to find the disparity map between the input image pair. The SDE supports:

- Disparity search range (SR) of 64/128/192. It can support either "0 to SR-1" or "-3 to SR-4"
- 1/16<sup>th</sup> pixel accurate sub-pixel level disparity estimate
- Disparity estimate post processing using 2D median filtering
- 8 level confidence score for each disparity output
- Common top level infrastructure:
  - Shared Level 2 (SL2) memory sub-system, which serves both DOF and SDE blocks, along with the FOCO modules when required as an intermediate storage exchange data across sub-modules (FOCO to DOF/SDE) and from DDR/System Memory
  - A Unified Transfer Controller (UTC), which serves as a DMA engine
  - Messaging and control mechanism via a Hardware Thread Scheduler (HTS) block
  - A Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the SDE and DOF hardware threads

The DMPAC does not support (but relies on other HWAs/processors on the SoC to perform these tasks):

- Epipolar rectification of the stereo input images
- Image pyramid generation for the optical flow input images

#### 7.8.1.2 DMPAC Not Supported Features

The DMPAC does not support the following features:

- Arbitrary binary feature descriptor as input
- Flexible block matching on any image/feature vector plane
- Standalone use of any of the DMPAC internal modules by any SoC level resources, even when the DMPAC is not in use

The following processing steps, although essential parts of the stereo and optical flow algorithms supported inside DMPAC, are expected to be handled outside the DMPAC module:

- Epipolar Rectification on both the stereo input image streams
- 6 levels (including base) of Image Pyramid generation on the optical flow input image stream

## 7.9 Graphics Accelerator (GPU)

This chapter describes the integration of the Graphics Processing Unit (GPU) subsystem in the device.

### 7.9.1 GPU Overview

The Graphics Processing Unit (GPU) accelerates 3-dimensional (3D), 2-dimensional (2D) graphics, and compute applications.

The GPU is based on the PowerVR® BXS 4-64 MC1 core from Imagination Technologies.

#### 7.9.1.1 Features Supported

- Base architecture, fully compliant with the following APIs:
  - OpenGL ES 3.2
  - OpenCL 1.2 EP
  - Vulkan 1.2
- Tile-based deferred rendering architecture for 3D graphics workloads, with concurrent processing of multiple tiles
- Support for DRM security
- Support for GPU virtualization
  - Up to 8 virtual GPUs
  - Separate IRQ for each OSID
- Multi-threaded Unified Shading Cluster (USC) engine incorporating pixel shader, vertex shader and GP-GPU (compute shader) functionality
- USC incorporates an ALU architecture with high SIMD efficiency
- Fully virtualized memory addressing (up to 64 GB address space), supporting unified memory architecture
- Fine-grained task switching, workload balancing and power management

- Advanced DMA driven operation for minimum host CPU interaction
- 256KB System Level Cache (SLC)
- Specialized Texture Cache Unit (TCU)
- Compressed Texture Decoding
- Lossless data compression (PVRGC) - The PowerVR's geometry compression, which is performed in the Geometry Processing phase of the 3D graphics workload.
- Dedicated RISC-V processor for firmware execution
- Separate power island for the firmware processor for low latency power domain transitions
- On-Chip Performance, Power and Statistics Registers.
- Resolution Support
  - Frame buffer max size = 8K × 8K
  - Texture max size = 8K × 8K
- Anti-aliasing
  - Maximum 4× multisampling
- Performance
  - Floating Point Operations (F32) - 64 operations per clock
  - Floating Point Operations (F16) - 128 operations per clock
  - Texture performance - 4 texels per clock (@32 BPP)
  - Pixel performance - 4 pixel(s) per clock (@32 BPP)
  - Geometry Performance - 0.25 triangles per clock
  - Max performance
    - ~50 GFLOPS, 4 GTex/s or 4 GPix/s @ 800MHz

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

**7.9.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

Chapter 8

Inter-processor Communication Scheme (IPC)

---

Device has multiple hardware mechanisms to provide inter-processor level communication.

8.1 Mailbox.....	1081
8.2 Spinlock.....	1088
8.3 Secure Proxy (SEC_PROXY).....	1092

## 8.1 Mailbox

This chapter describes the Mailbox module of the device.

### 8.1.1 Mailbox Overview

Mailbox module serves to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors (users) through a set of registers and associated interrupt signals.

#### 8.1.1.1 Mailbox Features

Each mailbox module supports the following features:

- Parameters configured at design time:
  - Number of mailbox clusters
    - Each mailbox cluster has the same configuration
    - Clusters are accessed via separate VBUS regions. Clusters can be treated as mailbox module instances.
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Partial writes do not advance the FIFO pointers
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 8.1.2 Mailbox Functional Description

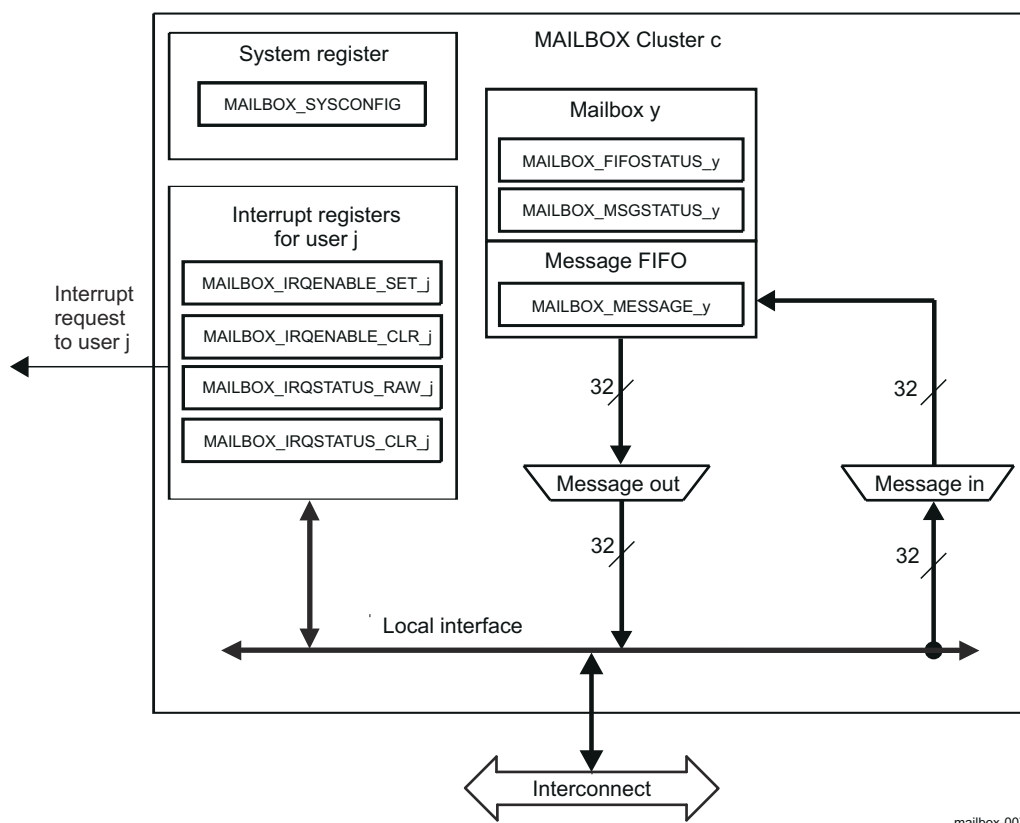

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX\_IRQ\_ENABLE\_SET\_j (or MAILBOX\_IRQ\_ENABLE\_CLR\_j) register.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each MAILBOX\_IRQ\_STATUS\_RAW\_j/MAILBOX\_IRQ\_STATUS\_CLR\_j interrupt status register corresponds to a particular user.

#### 8.1.2.1 Mailbox Block Diagram

Figure 8-1 shows the mailbox internal block diagram.

mailbox-007

**Figure 8-1. Mailbox Block Diagram**

c = 0 to 11

j = 0 to 3

y = 0 to 15

#### 8.1.2.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX\_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX\_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

### 8.1.2.3 Mailbox Power Management

The clkstop\_idle will be asserted if all of the following are true:

- The VBUSP interface is inactive
- All mailboxes are empty
- There are no enabled events or outstanding interrupts

An enabled event means there is pending action required from one of the users, and it means one or more mailboxes still expect data.

### 8.1.2.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 8-1 lists the event flags, and their mask, that can cause module interrupts.

**Table 8-1. Interrupt Events**

Non-Maskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQ_STATUS_RAW_j[0+y*2]	MAILBOX_IRQ_STATUS_CLR_j[0+y*2]	MAILBOX_IRQ_ENABLE_CLR_j[0+y*2]	MAILBOX_IRQ_ENABLE_SET_j[0+y*2]	Mailbox y receives a new message.
NEWMSGSTATUSMBY	NEWMSG_STATUSMBY	NEWMSG_STATUSMBY	NEWMSG_STATUSMBY	
MAILBOX_IRQ_STATUS_RAW_j[1+y*2]	MAILBOX_IRQ_STATUS_CLR_j[1+y*2]	MAILBOX_IRQ_ENABLE_CLR_j[1+y*2]	MAILBOX_IRQ_ENABLE_SET_j[1+y*2]	Mailbox y message queue is not full.
NOTFULLSTATUSMBY	NOTFULLSTATUSMBY	NOTFULLSTATUSMBY	NOTFULLSTATUSMBY	

(1) MAILBOX\_IRQ\_STATUS\_RAW\_j register is mostly used for debug purposes.

#### CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX\_IRQ\_STATUS\_CLR\_j register.

Writing a logical 1 in a bit of the MAILBOX\_IRQ\_STATUS\_CLR\_j register will also clear to 0 the corresponding bit in the appropriate MAILBOX\_IRQ\_STATUS\_RAW\_j register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX\_IRQ\_ENABLE\_SET\_j register. Events are reported in the appropriate MAILBOX\_IRQ\_ENABLE\_CLR\_j and MAILBOX\_IRQ\_STATUS\_RAW\_j registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX\_IRQ\_ENABLE\_CLR\_j register. Events are only reported in the appropriate MAILBOX\_IRQ\_STATUS\_RAW\_j register.

In case of the MAILBOX\_IRQ\_STATUS\_RAW\_j register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

### 8.1.2.5 Mailbox Assignment

#### 8.1.2.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX\_IRQ\_ENABLE\_SET\_j register. The receiver reads the MAILBOX\_MESSAGE\_y register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX\_FIFO\_STATUS\_y and/or MAILBOX\_MSG\_STATUS\_y registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX\_IRQ\_ENABLE\_SET\_j register, where  $u$  is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX\_FIFO\_STATUS\_y or MAILBOX\_MSG\_STATUS\_y registers
- Write the message to the corresponding MAILBOX\_MESSAGE\_y register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX\_IRQ\_ENABLE\_SET\_j register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX\_IRQ\_STATUS\_CLR\_j register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX\_IRQ\_STATUS\_CLR\_j register acknowledges, and subsequently clears, an interrupt.

#### CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

### 8.1.2.6 Sending and Receiving Messages

#### 8.1.2.6.1 Description

When a 32-bit message is written to the MAILBOX\_MESSAGE\_y register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

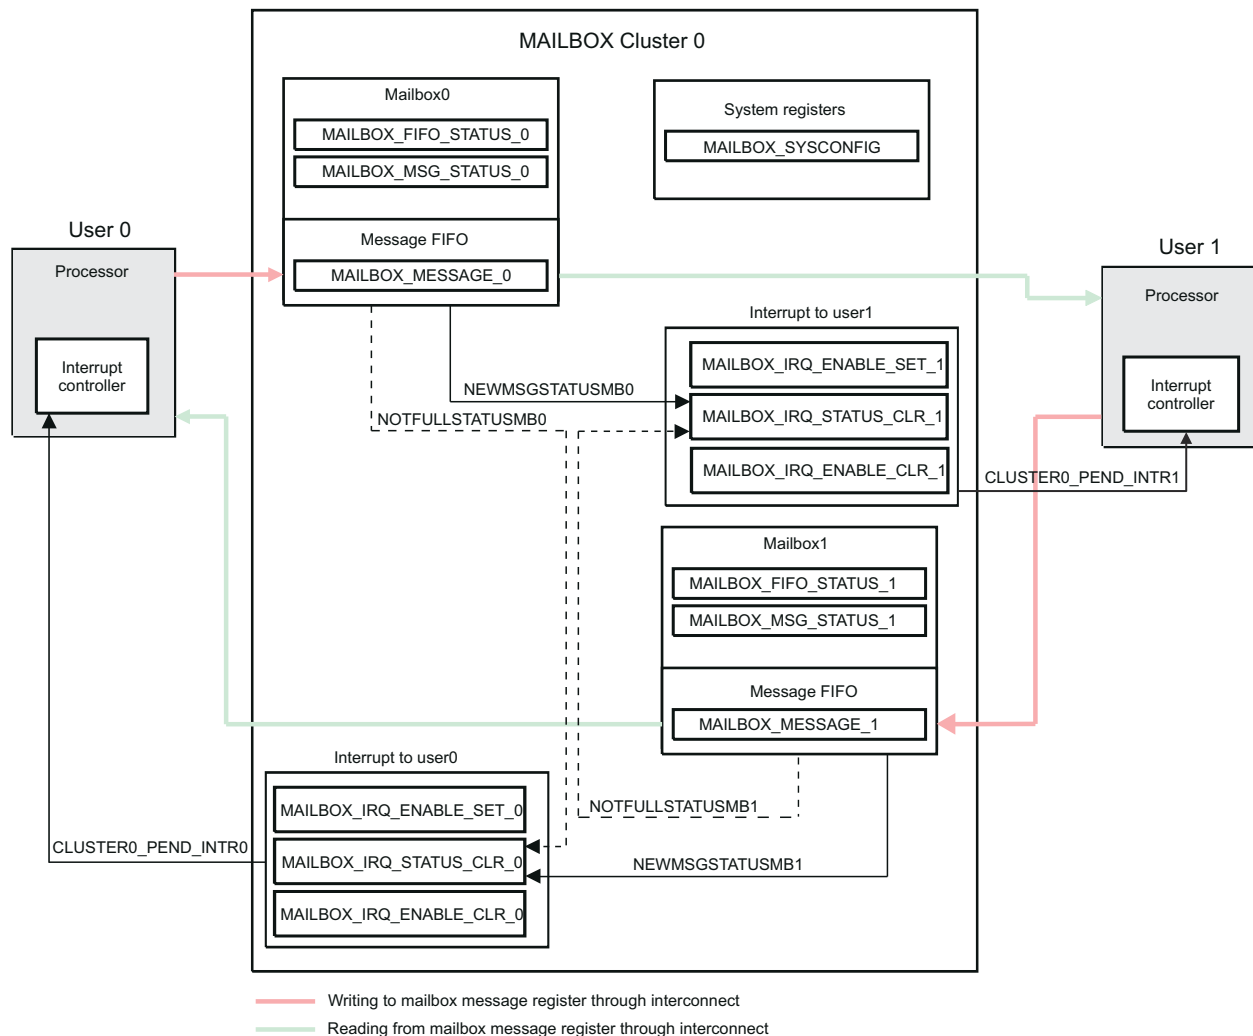

Queue overflow can be avoided by first reading the MAILBOX\_FIFO\_STATUS\_y register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX\_MESSAGE\_y register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX\_MESSAGE\_y register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX\_MSG\_STATUS\_y register.

### 8.1.2.7 Example of Communication

Figure 8-2 shows an example of communication between two processors.

**Figure 8-2. Example of Communication**

### 8.1.3 Mailbox Programming Guide

#### 8.1.3.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

##### 8.1.3.1.1 Global Initialization

##### 8.1.3.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See *Mailbox Integration*, for further information.

**Table 8-2. Global Initialization of Surrounding Modules for MAILBOX**

Surrounding Modules	Comments
LPSC	The MAILBOX functional and interface clock must be enabled.
Interrupt Controllers	Processor's (user's) interrupt controller must be configured to enable the interrupt request generation.

##### 8.1.3.1.1.2 Mailbox Global Initialization

##### 8.1.3.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

**Table 8-3. Mailbox Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFT_RESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFT_RESET	=0x0

##### 8.1.3.1.2 Mailbox Operational Modes Configuration

##### 8.1.3.1.2.1 Mailbox Processing modes

##### 8.1.3.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

**Table 8-4. Sending a Message (Polling Method)**

Step	Register/Bit Field/Programming Model	Value
IF: Is FIFO full?	MAILBOX_FIFO_STATUS_y[0] FULL	=0x1
Wait until at least one message slot is available	MAILBOX_FIFO_STATUS_y[0] FULL	=0x0
<b>ELSE</b>		
Write message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-
<b>ENDIF</b>		

##### 8.1.3.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

**Table 8-5. Sending a Message (Interrupt Method)**

Step	Register/Bit Field/Programming Model	Value
IF: Is FIFO full?	MAILBOX_FIFO_STATUS_yMAILBOX_FIFO_STATUS_y[0] FULL	=0x1
Enable interrupt event	MAILBOX_IRQ_ENABLE_SET_jMAILBOX_IRQ_ENABLE_ SET_j[1+ y*2]	0x1
User (processor) can perform another task until interrupt occurs See <a href="#">Section 8.1.3.1.3.1</a> for interrupt handling in sending mode		
<b>ELSE</b>		

**Table 8-5. Sending a Message (Interrupt Method) (continued)**

Step	Register/Bit Field/Programming Model	Value
Write message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-
<b>ENDIF</b>		

#### 8.1.3.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

**Table 8-6. Receiving a Message (Polling Method)**

Step	Register/Bit Field/Programming Model	Value
IF: Number of messages is not equal to 0	MAILBOX_MSG_STATUS_y[2:0] NUM_MESSAGES	≠0x0
Read message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-
<b>ENDIF</b>		

#### 8.1.3.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

**Table 8-7. Receiving a Message (Interrupt Method)**

Step	Register/Bit Field/Programming Model	Value
Enable interrupt event	MAILBOX_IRQ_ENABLE_SET_j[0 + y*2]	0x1

## 8.2 Spinlock

This chapter describes the Spinlock module of the device.

### 8.2.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device.

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 8-3 shows an overview of the Spinlock module.

**Figure 8-3. Spinlock Overview**

#### Note

Some features may not be available. See *Module Integration* for more information.

### 8.2.2 Spinlock Functional Description

#### 8.2.2.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK\_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK\_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

#### 8.2.2.2 Spinlock Power Management

The Spinlock module supports the Power Idle interface. Software must arrange to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

1. Software must check that all controllers that may be using the Spinlock module are either:
  - a. Already powered off (all in-use flags are 0)
  - b. Notified that Spinlock is not available and the notification is acknowledged
2. If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK\_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any controller that is still active. Alternatively, you may decide to wait a timeout period to allow any active controller to clean up its locks before powering down.

The Spinlock module may now be powered off.

#### 8.2.2.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).

2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

#### 8.2.2.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK\_LOCK\_REG\_i[0] TAKEN bit. There are two states: Taken (SPINLOCK\_LOCK\_REG\_y[0] TAKEN = 1) or Not Taken (SPINLOCK\_LOCK\_REG\_y[0] TAKEN = 0), where y = 0h to FFh.

When the status of lock y (where y = 0 to 255) is Not Taken (free), a read from the SPINLOCK\_LOCK\_REG\_y register returns 0 and sets the lock to Taken (locked). When the status of lock y is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK\_LOCK\_REG\_y register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

Figure 8-4 shows the SPINLOCK\_LOCK\_REG\_y register state diagram.

spinlock-003

**Figure 8-4. Lock Register State Diagram**

#### Note

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

## 8.2.3 Spinlock Programming Guide

### 8.2.3.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

#### 8.2.3.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

**Table 8-10. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC	Spinlock functional and interface clock must be enabled. For more information, see <i>Clocking</i>

#### 8.2.3.1.2 Basic Spinlock Operations

The main Spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

##### 8.2.3.1.2.1 Spinlocks Clearing After a System Bug Recovery

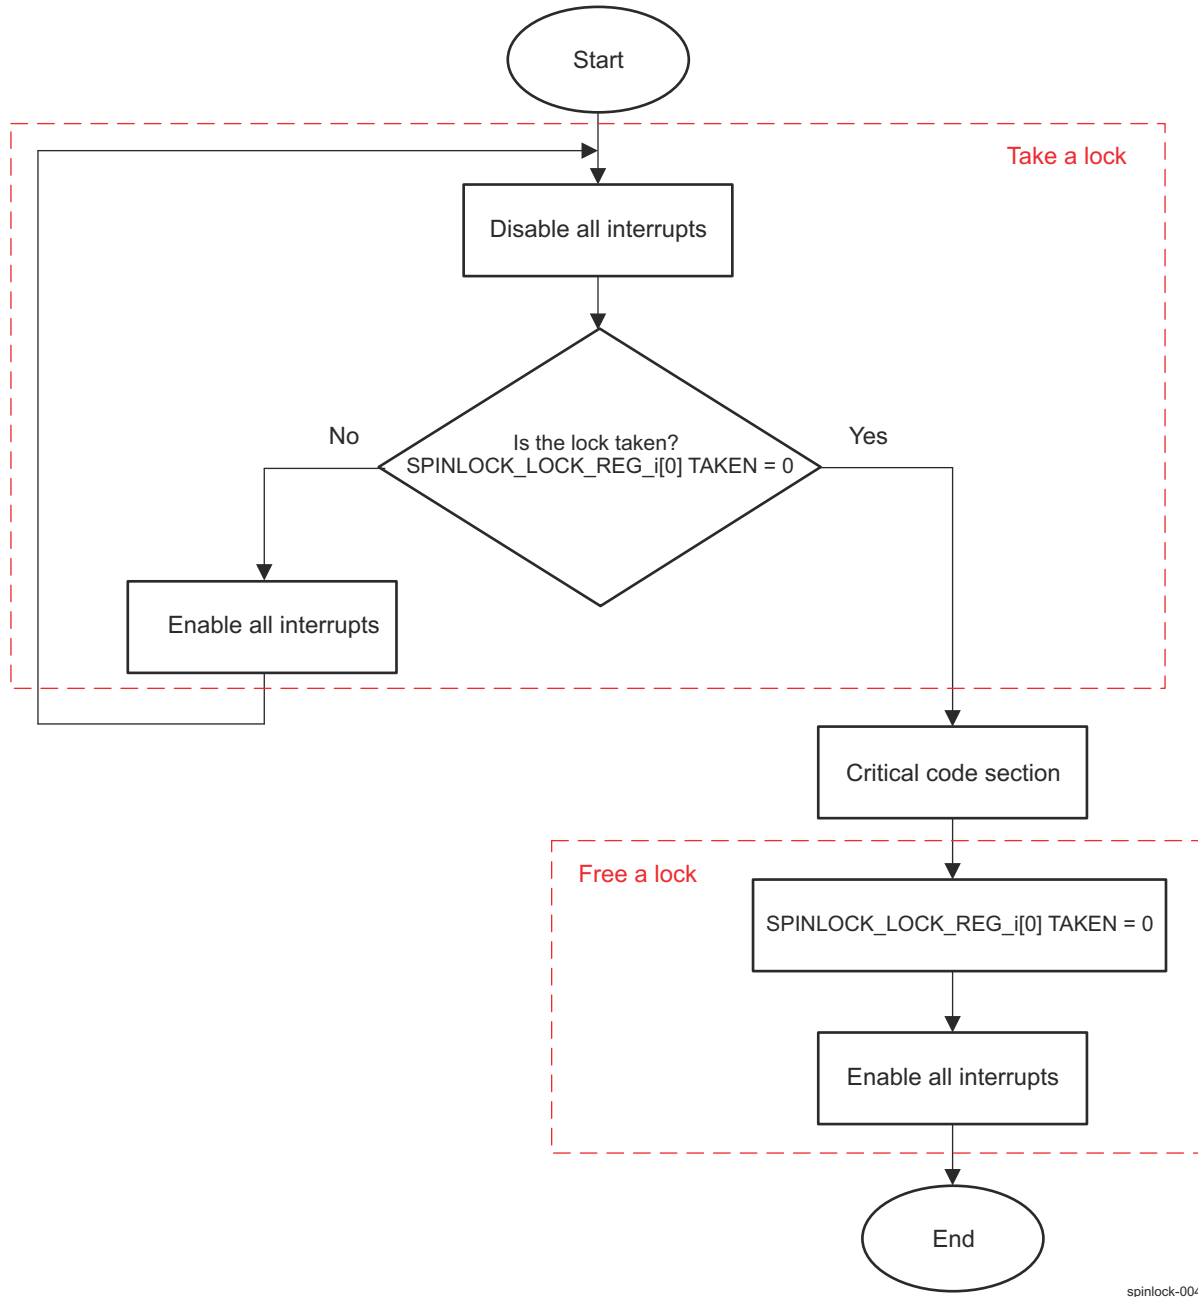

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK\_LOCK\_REG\_y registers at system startup to insure that all locks are initialized to Not Taken.

**Table 8-11. Spinlock System Bug Recovery**

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = 1?	SPINLOCK_SYSTATUS[0] IU0	=1
Free the 256 locks	SPINLOCK_LOCK_REG_y[0] TAKEN (y = 0 to 255)	0x0
END		

##### 8.2.3.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software must disable interrupts. Then it must read the SPINLOCK\_LOCK\_REG\_y[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it must proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition must be reattempted. To prevent unknown interrupt disabled time, interrupts must be re-enabled and then disabled before reattempting to acquire the lock. [Figure 8-5](#) shows the described above procedure.

**Figure 8-5. Take and Release Spinlock**

**Table 8-12. Register Call Summary**

Register Name
SPINLOCK_LOCK_REG_y[0] TAKEN

**Table 8-13. Subprocess Call Summary**

Subprocess Name	Description
Disable (Mask) All Interrupts	For information about disabling/enabling all interrupts in an Arm® processor, refer to Arm <i>Technical Reference Manual</i> , available at <a href="http://infocenter.arm.com/help/index.jsp">infocenter.arm.com/help/index.jsp</a> .
Enable (Unmask) All Interrupts	For information about disabling/enabling all interrupts in other processors, refer to the corresponding processor chapter.

### 8.3 Secure Proxy (SEC\_PROXY)

The third IPC hardware mechanism is to use SEC\_PROXY, which provides an IPC mechanism which carries a large message for complex communications among processors. It allows processors to read and write a message in small chunks.

There are two sets of SEC\_PROXY in the device, one SEC\_PROXY is dedicated for IPC for HSM M4F, and the second SEC\_PROXY is for the rest. When the SEC\_PROXY generates events, an IPC message is received or sent, and events are sent to interrupt aggregators before those events are converted into interrupts to the processors. The utilization of SEC\_PROXY is user defined through memory map allocation. Each processor can be allocated with its own SEC\_PROXY region to receive and send IPC messages.

<b>9.1 DDR Subsystem (DDRSS).....</b>	<b>1094</b>
---------------------------------------	-------------

## 9.1 DDR Subsystem (DDRSS)

This section describes the DDR Subsystem (DDRSS) for the device.

### 9.1.1 DDRSS Overview

The DDR subsystem in this device comprises DDR controller, DDR PHY and wrapper logic to integrate these blocks in the device. The DDR subsystem is referred to as DDRSS0 and is used to provide an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS0 is accessed via CBASS0 interconnect.

The DDRSS0 supports:

- Memory Types:
  - LPDDR4 up to @ 0.75V or 0.85V VDD\_CORE
- Memory Bus Features:
  - Up to 32-bit width with in-line ECC
  - Up to 2 ranks
  - LPDDR4 densities up to 8GBytes (4GBytes each rank)
- Two System Bus Interfaces - one for real time and another for non-real time traffic:
  - 256-bit data width
  - Little endian only
  - Address aliasing prevention to block accesses to unpopulated SDRAM region
  - Clock asynchronous to DDR clock
- Configuration Bus Interface:
  - 32-bit data width
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
  - Clock asynchronous to DDR clock
- Key Features:
  - Full coherency across all commands
  - Bank interleaving
  - Priority based scheduling
  - Scheduling based on bank openness
  - Class of Service (CoS) - Three latency classes supported
  - Leaky bucket function to avoid blocking of Low Priority Thread
  - Drain function to expedite execution of reads in the controller
  - Read/write scheduling to avoid turn-around time
  - Prioritized refresh scheduling
  - Dynamic change of refresh rate via software for extended temperatures
  - Statistical counters for performance management
- SDRAM ECC Features:
  - In-line ECC
  - 64-byte ECC calculated over 512-byte data
  - Read-modify-write ECC for sub-word writes
  - Support ECC cache to improve in-line ECC performance
  - Support 64 cache-lines each 512-byte wide
  - In-line ECC performance impact shall be minimum of 12.5% for linear cached traffic
  - ECC address error logging
  - Statistical counters for counting ECC errors
- Low Power Features:
  - All power modes defined by JEDEC (clock stop for LPDDR4, self-refresh, power-down, etc.)
  - Self-refresh entry and exit via software or hardware clock stop request/acknowledge
  - System bus clock stop via hardware clock stop request/acknowledge when controller is idle

- Automatic idle power saving mode when no or low activity is detected
- DDR and system bus clock frequency change using self-refresh via software or hardware clock stop request/acknowledge
- Turning off SoC power after DDR is put into self-refresh (DDR reset and CKE I/O retention)
- Tri-stating of all DDR I/O cells via software while driving CKE and RESETn pins during self-refresh
- LPDDR4 Frequency Set Point (FSP)
- Support power switches on DDR subchip for low leakage power in low-power modes
- Functional Safety Features:
  - VBUSM2AXI bridge AXI bus timeout
  - DDR4 command bus parity
- DDR PHY Features:
  - Automatic and software controllable initialization and calibration (ZQ) for the DDR PHY and I/O cells
  - Automatic and software controllable delay line calibrations with Voltage and Temperature (VT) compensation
  - Automatic and software controllable write levelling with VT compensation
  - Automatic read DQS gate training per rank with VT compensation
  - Automatic and software controllable DQ/DQS eye training per rank
  - Automatic and software controllable read and write data bit deskew
  - Automatic and software controllable Command/Address (CA) levelling with VT compensation for LPDDR4
  - Automatic and software controllable CA bit deskew for LPDDR4
  - Refreshes to SDRAM during leveling and training
  - No seeding requirement based on board topology for any of the leveling and training algorithms
  - Dynamic/automatic I/O Receiver disable when read transfer is not on going
  - Capability of disabling data macros and I/O cells when not in use

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 9.1.2 DDRSS Environment

Please refer to the [AM62Ax DDR Board Design and Layout Guidelines](#) application note for detailed information on DDR interface connections to LPDDR4 and DDR4 memory devices

Table 9-1 describes the DDRSS0 I/O signals used for connection to SDRAM devices.

**Table 9-1. DDRSS0 I/O signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description
RESETN	DDR0_RESET0_n	O	SDRAM reset
CK	DDR0_CK0	O	SDRAM differential clock pair
CKN	DDR0_CK0_n	O	
ALERTN	DDR0_ALERT_n	IO	SDRAM parity error output
A[13-0]	DDR0_A[13-0]	O	SDRAM address and command bus
WEN	DDR0_WE_n	O	SDRAM write enable
CASN/CSN[3]	DDR0_CAS_n/DDR0_CS3_n	O	SDRAM column address strobe (DDR4). SDRAM chip select (LPDDR4)
RASN/CSN[2]	DDR0_RAS_n/DDR0_CS2_n	O	SDRAM row address strobe(DDR4). SDRAM chip select(LPDDR4)
ACTN	DDR0_ACT_n	O	SDRAM activate
BA[1-0]	DDR0_BA[1-0]	O	SDRAM bank address
BG[1-0]	DDR0_BG[1-0]	O	SDRAM bank group
PAR	DDR0_PAR	O	SDRAM command parity
CSN[1-0]	DDR0_CS[1-0]_n	O	SDRAM chip select
ODT[1-0]	DDR0_ODT[1-0]	O	SDRAM on-die termination
CKE[1-0]	DDR0_CKE[1-0]	O	SDRAM CKE
DQ[31-0]	DDR0_DQ[31-0]	IO	SDRAM data bus
DM[3-0]	DDR0_DM[3-0]	IO	SDRAM data and mask/DBI
DQS[3-0]	DDR0_DQS[3-0]	IO	SDRAM data strobe
DQSN[3-0]	DDR0_DQS[3-0]_n	IO	SDRAM data strobe invert

(1) I = Input; O = Output

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 9.1.3 DDRSS Functional Description

#### 9.1.3.1 Real Time and Non-Real Time Threads

The VBUSM2AXI supports two VBUSM interfaces:

- Real Time High Priority Thread (HPT)
- Non-Real Time Low Priority Thread (LPT)

HPT will have priority over LPT. In addition to the thread priority, the bridge will also reorder commands within a particular thread based on VBUSM priority. Therefore, the execution of commands from the command FIFO can be out-of-order. As a result, the read data can also be returned out-of-order.

The bridge will NOT maintain data coherency across threads. However, coherency within a particular thread will be maintained.

For low area implementation, the same FIFO resources are shared between HPT and LPT for write status and read data return interfaces. Therefore, system must ensure that there is no pushback on the write status and read data return interfaces by LPT to guarantee execution of HPT is not blocked.

#### 9.1.3.2 Class of Service (CoS)

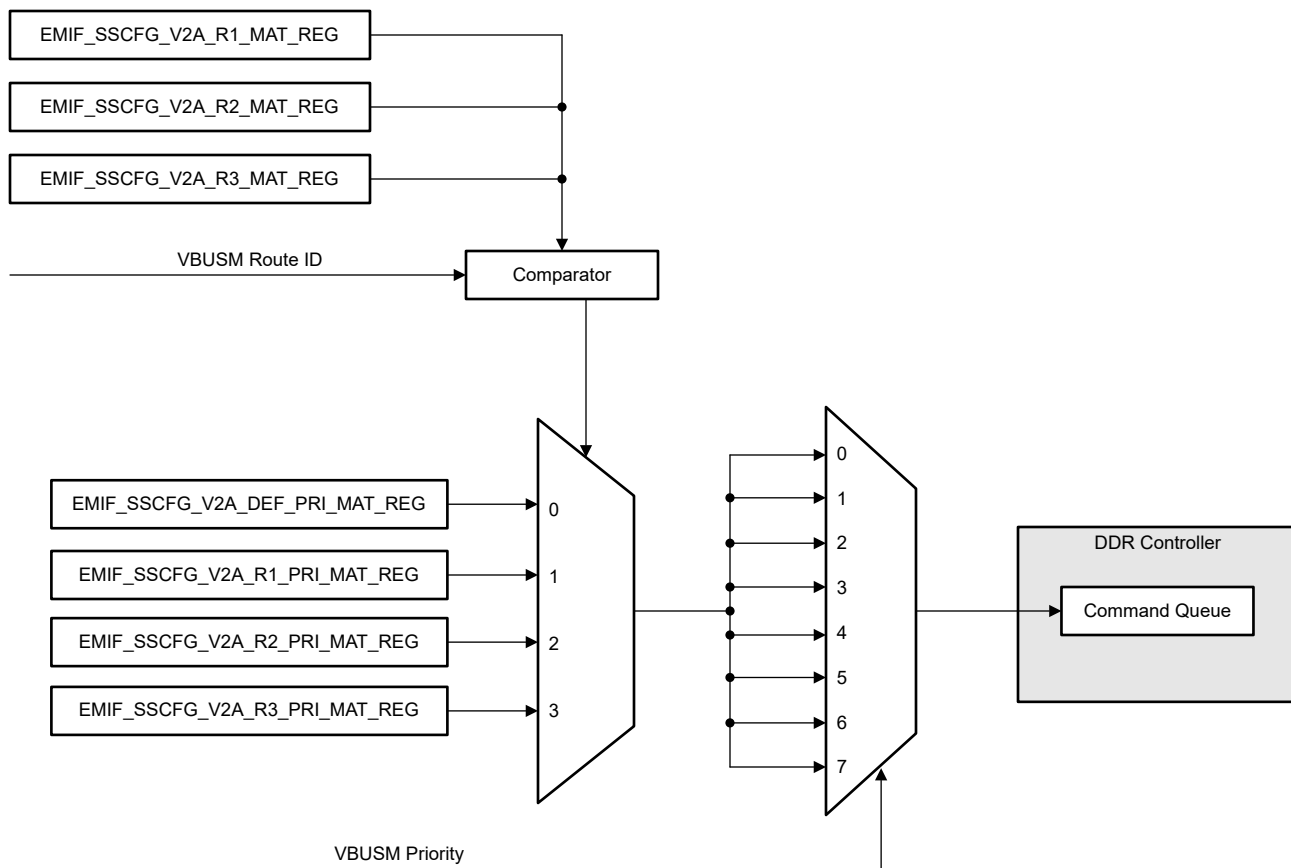

Commands arriving on LPT and HPT to the DDRSS0 carry the VBUSM priority whereas the DDR controller uses AXI priority. The VBUSM2AXI bridge has the following registers for flexible mapping of the VBUSM priority to DDR controllers's priority:

- Range match registers:
  - EMIF\_SSCFG\_V2A\_R1\_MAT\_REG
  - EMIF\_SSCFG\_V2A\_R2\_MAT\_REG
  - EMIF\_SSCFG\_V2A\_R3\_MAT\_REG
- Priority map registers:
  - EMIF\_SSCFG\_V2A\_LPT\_DEF\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_LPT\_R1\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_LPT\_R2\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_LPT\_R3\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_HPT\_DEF\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_HPT\_R1\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_HPT\_R2\_PRI\_MAP\_REG
  - EMIF\_SSCFG\_V2A\_HPT\_R3\_PRI\_MAP\_REG

This allows the system to essentially create different classes of service based on the initiator (Route ID) and the priority of the commands.

Each thread has a set of corresponding Priority Map Registers to map the incoming priority on that thread to appropriate AXI priority. The default values of these registers are such that inherently the HPT traffic will have higher priority than the LPT traffic inside the controller. However, these settings can be changed via software per system needs.

The controller performs command arbitration based on AXI priority and the state of the DDR device (openness of banks, etc.). Commands with higher priority will be given execution preference over commands with lower priority. However, due to the state of the DDR device (openness of banks, etc.), a command with higher priority may not be executed before a lower priority command. Therefore, transactions within a thread can be reordered. In addition, the controller does not have any information on the thread type of the transactions. Therefore, commands can also be reordered between thread types. However, at all times the controller maintains coherency across all commands within a given thread.

**Figure 9-1. DDRSS CoS Mapping Diagram**

### 9.1.3.3 AXI Write Data All-Strobes

The DDR controller data path is connected to the VBUSM2AXI bridge through AXI interface. To enable higher performance and lower latency, the bridge drives the AXI AWALLSTRB signal to a "1" when the AXI write data does not have any byte enable holes. This allows the DDR controller to accept and start processing the write command as soon as possible without waiting for all data. The AXI0\_ALL\_STROBES\_USED\_ENABLE bit in the DDR Controller must be set to a 0x1 to utilize this feature. The controller ignores the AWALLSTRB signal if AXI0\_ALL\_STROBES\_USED\_ENABLE is set to 0x0.

### 9.1.3.4 Inline ECC for SDRAM Data

For SDRAM data integrity, the VBUSM2AXI bridge supports inline ECC on the data written to or read from the SDRAM. ECC is enabled by programming the bits in the EMIF\_SSCFG\_ECC\_CTRL\_REG register. ECC is stored together with the data so that a dedicated SDRAM device for ECC is not required.

8-bit single error correction double error detection (SECCDED) ECC is calculated over 64-bit data quanta. For every 512-byte data block 64 bytes of ECC is stored inline. Thus 1/9th of the total SDRAM space is used for ECC storage and the rest 8/9th is available for system use. From system point of view that 8/9th of the SDRAM data space are seen as consecutive byte addresses. Even if there are non-ECC protected regions the previously described 1/9th-8/9th rule still applies and consecutive byte addresses are seen from system point of view. Note that 8/9 of the total SDRAM space is available for system use regardless of the size of the ECC region(s). In other words, only 8/9 of the memory is available even in non-ECC regions when ECC is enabled.

The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified through the following registers:

- EMIF\_SSCFG\_ECC\_R0\_STR\_ADDR\_REG
- EMIF\_SSCFG\_ECC\_R0\_END\_ADDR\_REG

- EMIF\_SSCFG\_ECC\_R1\_STR\_ADDR\_REG
- EMIF\_SSCFG\_ECC\_R1\_END\_ADDR\_REG
- EMIF\_SSCFG\_ECC\_R2\_STR\_ADDR\_REG
- EMIF\_SSCFG\_ECC\_R2\_END\_ADDR\_REG

Note that the addresses in these address range registers should be in terms of the DDRSS address space, not the SoC memory space. Even though the SoC memory space for DDR may be split into multiple regions, the DDRSS address space is continuous.

For example, if the beginning of DDR is in SoC memory space 0x8000\_0000 to 0xFFFF\_FFFF, this corresponds to DDRSS address space 0x00000000 to 0x7FFFFFFF. If the SoC has greater DDR address reach, even at a discontinuous address, the address range for these registers would be continuous (eg, if the next DDR address at the SoC level is 0x880000000, the corresponding address would be continuous at 0x80000000).

Note that the value programmed in the ECC range start/end registers does not include the lower 16 bits of the address. For example, to represent an address of 0x40000000, the register contents would be 0x4000.

The ECC is read and verified during reads if both the EMIF\_SSCFG\_ECC\_CTRL\_REG[0] ECC\_EN and EMIF\_SSCFG\_ECC\_CTRL\_REG[2] ECC\_CHK bits are set to 0x1. For 1-bit ECC error, the bridge corrects the data and returns it to the requestor. Although the error is corrected on the returned data, the SDRAM is not corrected. It is responsibility of the system software to correct the ECC error at that location.

It is also responsibility of the system software to pre-load the ECC protected region with known data before functional reads and writes are performed. This can be done by writing to the SDRAM with ECC enabled (EMIF\_SSCFG\_ECC\_CTRL\_REG[0] ECC\_EN = 0x1 and EMIF\_SSCFG\_ECC\_CTRL\_REG[1] RMW\_EN = 0x1) and ECC check disabled (EMIF\_SSCFG\_ECC\_CTRL\_REG[2] ECC\_CHK = 0x0). Once the data is loaded in the SDRAM, ECC check must be enabled (EMIF\_SSCFG\_ECC\_CTRL\_REG[2] ECC\_CHK = 0x1) before using the DDR interface.

#### 9.1.3.4.1 ECC Cache

The VBUSM2AXI bridge implements a 64-line deep ECC cache for improving inline ECC performance. Each cache line can be allocated to an initiator in the system based on its Route ID. The Route ID allocation to cache line can be done by writing to the EMIF\_SSCFG\_ECC\_RID\_INDX\_REG and EMIF\_SSCFG\_ECC\_RID\_VAL\_REG registers. Since the bridge uses unallocated cache lines for all read accesses without Route ID allocation, one or more locations in the cache should be kept unallocated for better performance. To ensure that at least one cache line remains unallocated, in the case all cache lines are allocated by software, the bridge automatically unallocates the 63rd cache line. Write accesses without Route ID allocation result in ECC and data writes to the SDRAM, when the EMIF\_SSCFG\_ECC\_CTRL\_REG[4] WR\_ALLOC bit is set to 0x0. When EMIF\_SSCFG\_ECC\_CTRL\_REG[4] WR\_ALLOC is set to 0x1, an unassigned cache-line is allocated to write accesses without Route ID allocation.

#### 9.1.3.4.2 ECC Cache Flush

For low power modes, the bridge supports flushing the cache when DDRSS stop clock request is asserted. When a clock stop is requested, the bridge will start issuing writes to the DRAM until all dirty cache locations are written to the DRAM. Once the writes are complete, the bridge asserts an acknowledge signal to let the subsystem know that the operation is complete. The subsystem uses this acknowledge signal along with acknowledgments from other submodules to generate the final DDRSS stop clock acknowledge to the system.

#### 9.1.3.4.3 ECC Statistics

For 1-bit ECC error, the bridge logs the address location for the error in an internal 2-level deep FIFO. It stores the first two 1-bit ECC errors. The EMIF\_SSCFG\_ECC\_1B\_ERR\_ADR\_LOG\_REG register shows the address on top of the internal FIFO. Software should write 0x1 to the EMIF\_SSCFG\_ECC\_1B\_ERR\_ADR\_LOG\_REG[29:0] ECC\_1B\_ERR\_ADR field to pop the FIFO and display the next address stored. The FIFO is loaded with the address for the next 1-bit ECC error if it is not full. No address comparison will be performed, that is, if a single address is associated with more than one ECC error, that address is logged twice.

The number of 1-bit ECC errors can be counted using the EMIF\_SSCFG\_ECC\_1B\_ERR\_CNT\_REG register. The bridge also supports programming a threshold in the EMIF\_SSCFG\_ECC\_1B\_ERR\_THRSH\_REG register. When the 1-bit error count is equal to or greater than the programmed threshold, the bridge sets the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[3] ECC1BERR bit and also triggers the DDR0\_DDRSS\_DRAM\_ECC\_CORR\_ERR\_LVL\_0 interrupt. When servicing the interrupt, software needs to clear the error count otherwise further interrupts will not be triggered. For 2-bit ECC errors, the bridge sets the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[4] ECC2BERR bit and also triggers the DDR0\_DDRSS\_DRAM\_ECC\_UNCORR\_ERR\_LVL\_0 interrupt. The bridge does not correct the data for these uncorrectable errors. Along with generating the interrupt, the bridge also reports an error to the requesting initiator and sends all zeros for the data. The bridge also logs the address location for the error in the EMIF\_SSCFG\_ECC\_2B\_ERR\_ADR\_LOG\_REG register.

The bridge sets the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[5] ECCM1BERR bit and triggers the DDR0\_DDRSS\_DRAM\_ECC\_UNCORR\_ERR\_LVL\_0 interrupt whenever it receives multiple 1-bit errors in different data words of the same SDRAM burst. This is done because the probability of receiving multiple 1-bit errors in different data words of the same SDRAM burst is very low. If this occurs, the chances are that there were multi-bit errors in each data word. Therefore, for reliability, pessimistic approach is taken to report these as a fatal error. The threshold for the number of 1-bit errors that result in an uncorrected error, reporting can be set by writing to the EMIF\_SSCFG\_ECC\_CTRL\_REG[11-8] COR\_ECC\_THRESH field. For reliability, the threshold is always kept at 0/1 meaning 1-bit error in 2 or more data words is reported as a 2-bit error. For debug, the threshold can be changed to a higher value. Note that since these are multiple 1-bit errors, the statistic logging is done in the EMIF\_SSCFG\_ECC\_1B\_ERR\_CNT\_REG and EMIF\_SSCFG\_ECC\_1B\_ERR\_ADR\_LOG\_REG registers.

#### 9.1.3.5 Address Alias Prevention

The VBUSM2ZXI bridge checks the VBUSM address received against the valid SDRAM address space programmed in the EMIF\_SSCFG\_V2A\_CTL\_REG register. If the VBUSM address for an access falls outside the programmed range the bridge sets to 0x1 the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[1] AERR bit and also triggers the DDR0\_DDRSS\_V2A\_OTHER\_ERR\_LVL\_0 interrupt. The address and the Route ID for the command that caused error are logged in the EMIF\_SSCFG\_V2A\_AERR\_LOG1\_REG and EMIF\_SSCFG\_V2A\_AERR\_LOG2\_REG registers.

The bridge fragments all incoming transactions into 64-byte accesses aligned at a 64-byte boundary. Therefore, for commands greater than 64 bytes with an address error, each fragment will report an error. This can cause multiple interrupts to be reported if software clears the error interrupt for the first fragment while other fragments are being executed. The address log register will always log the address for the fragment which caused the last interrupt. The valid address range can be programmed using the EMIF\_SSCFG\_V2A\_CTL\_REG[9-5] SDRAM\_IDX and EMIF\_SSCFG\_V2A\_CTL\_REG[4-0] REGION\_IDX fields.

[Table 9-2](#) summarizes the scenarios for determining valid address range and interrupt generation.

**Table 9-2. REGION\_IDX and SDRAM\_IDX Scenarios**

Condition	Description
REGION_IDX = SDRAM_IDX	DDR region size is equal to the connected SDRAM size. It is the SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX < SDRAM_IDX	DDR region size is less than the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX > SDRAM_IDX	DDR region size is greater than the connected SDRAM size. Address error is generated if the address received falls outside the connected SDRAM size.

A write access outside the programmed range is discarded. A write error associated status is sent back to the VBUSM interface.

A read access outside the programmed range is executed on the SDRAM interface as a normal read, but data will contain all zeroes before forwarding it to the VBUSM interface. A read error associated status is sent back to the VBUSM interface along with the read data containing all zeroes.

When inline ECC is enabled, the available SDRAM size is reduced by 1/9th of the size programmed in the SDRAM\_IDX field. Therefore, the bridge reports an error if an access falls outside the reduced SDRAM size when inline ECC is enabled. The reduced SDRAM size limit applies to all accesses, both to the protected and non-protected ECC regions.

#### 9.1.3.6 AXI Bus Timeout

The VBUSM2AXI bridge has a timeout counter that expires when no AXI transaction can be sent to the DDR controller or no AXI response is received from the controller for a programmed time interval. The counter only counts when there are pending commands in the bridge and the AXI bus is idle. Therefore, the bridge will not time out during low-power modes. The time interval can be programmed by writing to the EMIF\_SSCFG\_V2A\_BUS\_TO[23-0] BUS\_TIMER field.

Upon the expiry of the counter, the bridge terminates all pending commands in its internal FIFOs, returns error responses, sets the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[2] TOERR bit and triggers the DDR0\_DDRSS\_V2A\_OTHER\_ERR\_LVL\_0 interrupt.

After a timeout occurs, the bridge terminates any new commands received and returns error response. Writing a value of 0x0 to the EMIF\_SSCFG\_V2A\_BUS\_TO[23-0] BUS\_TIMER field exits the timeout mode. The other method to exit the timeout mode is to reset the DDRSS0, thus resetting the VBUSM2AXI bridge, the DDR controller, and the DDR PHY.

#### 9.1.3.7 Leaky Bucket Function

The VBUSM2AXI bridge implements a leaky bucket mechanism at each LPT-HPT arbitration point. This will prevent LPT commands from getting stuck in the pipe forever due to overload of HPT commands.

A programmable system threshold will be used to trigger leaky bucket. This can be programmed in the EMIF\_SSCFG\_V2A\_LEAKY\_THRESH\_REG. The threshold determines how many HPT commands can be sent in a row before a single LPT command is forwarded.

#### 9.1.3.8 Drain Function

The VBUSM2AXI bridge implements a mechanism to drain the DDR controller. The drain action will temporarily pause the submission of commands to the controller until the read command(s) that triggered the drain operation have been resolved.

Each read going to the DDR controller will have an associated internal counter that starts at zero. This counter will increment for each write or read command given to the controller after that particular read is sent. If any read command counter exceeds the programmed threshold the bridge will start a drain action. The threshold can be programmed in EMIF\_SSCFG\_V2A\_DRAIN\_THRESH\_REG.

#### 9.1.3.9 DDRSS Interrupts

The VBUSM2AXI bridge sets to 0x1 the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[1] AERR bit, if the VBUSM address for an access that falls outside the DDR space programmed in the EMIF\_SSCFG\_V2A\_CTL\_REG register.

The VBUSM2AXI bridge sets to 0x1 the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[2] TOERR bit, if it detects a hang on its interface to the DDR controller.

The VBUSM2AXI bridge sets to 0x1 the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[3] ECC1BERR bit, if the threshold for 1-bit ECC errors is met.

The VBUSM2AXI bridge sets to 0x1 the EMIF\_SSCFG\_V2A\_INT\_RAW\_REG[4] ECC2BERR bit, in case of 2-bit errors for a read access performed within the SDRAM address range protected by ECC.

The DDRSS0 asserts particular interrupt line only if the interrupts are enabled by writing 0x1 to the corresponding bit in the EMIF\_SSCFG\_V2A\_INT\_SET\_REG register. The interrupts can be disabled by writing 0x1 to the corresponding bit in the EMIF\_SSCFG\_V2A\_INT\_CLR\_REG register.

When interrupts are enabled, the corresponding bits in the EMIF\_SSCFG\_V2A\_INT\_STAT\_REG register are also set if an interrupt condition occurs. The interrupts can be cleared once serviced by writing 0x1 to the corresponding bit in the EMIF\_SSCFG\_V2A\_INT\_STAT\_REG register as well as writing to the EMIF\_SSCFG\_V2A\_EOI\_REG register. The subsystem will send an interrupt pulse, if there are any bits set in the Interrupt Status register (EMIF\_SSCFG\_V2A\_INT\_STAT\_REG) when the End of Interrupt register (EMIF\_SSCFG\_V2A\_EOI\_REG) is written.

[VBUSM2AXI Bridge Events](#) shows the events that are generated by the VBUSM2AXI bridge.

**Table 9-3. VBUSM2AXI Bridge Events**

Event Flag	Event Mask	Description
EMIF_SSCFG_V2A_INT_RAW_REG[4] ECC2BERR EMIF_SSCFG_V2A_INT_STAT_REG[4] ECC2BERR	EMIF_SSCFG_V2A_INT_SET_REG[4] ECC2BERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[4] ECC2BERR_EN	Generated in case of 2-bit errors for a read access within the ECC protected SDRAM address range. For more information, see <a href="#">Section 9.1.3.4.3</a> .
EMIF_SSCFG_V2A_INT_RAW_REG[3] ECC1BERR EMIF_SSCFG_V2A_INT_STAT_REG[3] ECC1BERR	EMIF_SSCFG_V2A_INT_SET_REG[3] ECC1BERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[3] ECC1BERR_EN	Generated in case of meeting the threshold for 1-bit ECC errors. For more information, see <a href="#">Section 9.1.3.4.3</a> .
EMIF_SSCFG_V2A_INT_RAW_REG[2] TOERR EMIF_SSCFG_V2A_INT_STAT_REG[2] TOERR	EMIF_SSCFG_V2A_INT_SET_REG[2] TOERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[2] TOERR_EN	Generated in case of a hang of the interface between the bridge and the DDR controller. For more information, see <a href="#">Section 9.1.3.6</a> .
EMIF_SSCFG_V2A_INT_RAW_REG[1] AERR EMIF_SSCFG_V2A_INT_STAT_REG[1] AERR	EMIF_SSCFG_V2A_INT_SET_REG[1] AERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[1] AERR_EN	Generated if the VBUSM address for an access falls outside the programmed range. For more information, see <a href="#">Section 9.1.3.5</a> .

### 9.1.3.10 DDRSS Memory Regions

[Table 9-4](#) shows all memory regions associated with the DDRSS0.

**Table 9-4. DDRSS0 Memory Regions**

Region	Start Address	End Address	Region Size
DDRSS0 wrapper logic registers	0x00F300000	0x00F3001FF	512 B
DDR controller registers	0x00F308000	0x00F309FFF	8 KB
DDR PHY independent module registers	0x00F30A000	0x00F30BFFF	8 KB
DDR PHY registers	0x00F30C000	0x00F30FFFF	16 KB
External SDRAM data space	0x080000000	0xFFFFFFFF	2 GB
	0x880000000	0xFFFFFFFF	30 GB

### 9.1.3.11 DDRSS Dynamic Frequency Change Interface

This interface is used for handshaking between DDRSS0 and CTRL\_MMR0 to dynamically change DDR clock frequency to support LPDDR4 Frequency Set Point (FSP). The frequency change can be initiated either by a SoC processor or by the DDRSS0.

The associated CTRL\_MMR0 registers for processor initiated frequency change are:

- CTRLMMR\_CHNG\_DDR4\_FSP\_REQ

- CTRLMMR\_CHNG\_DDR4\_FSP\_ACK

The associated CTRL\_MMR0 registers for DDRSS0 initiated frequency change are:

- CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ
- CTRLMMR\_DDR4\_FSP\_CLKCHNG\_ACK

The sequence for an SoC processor initiated frequency change is as follows:

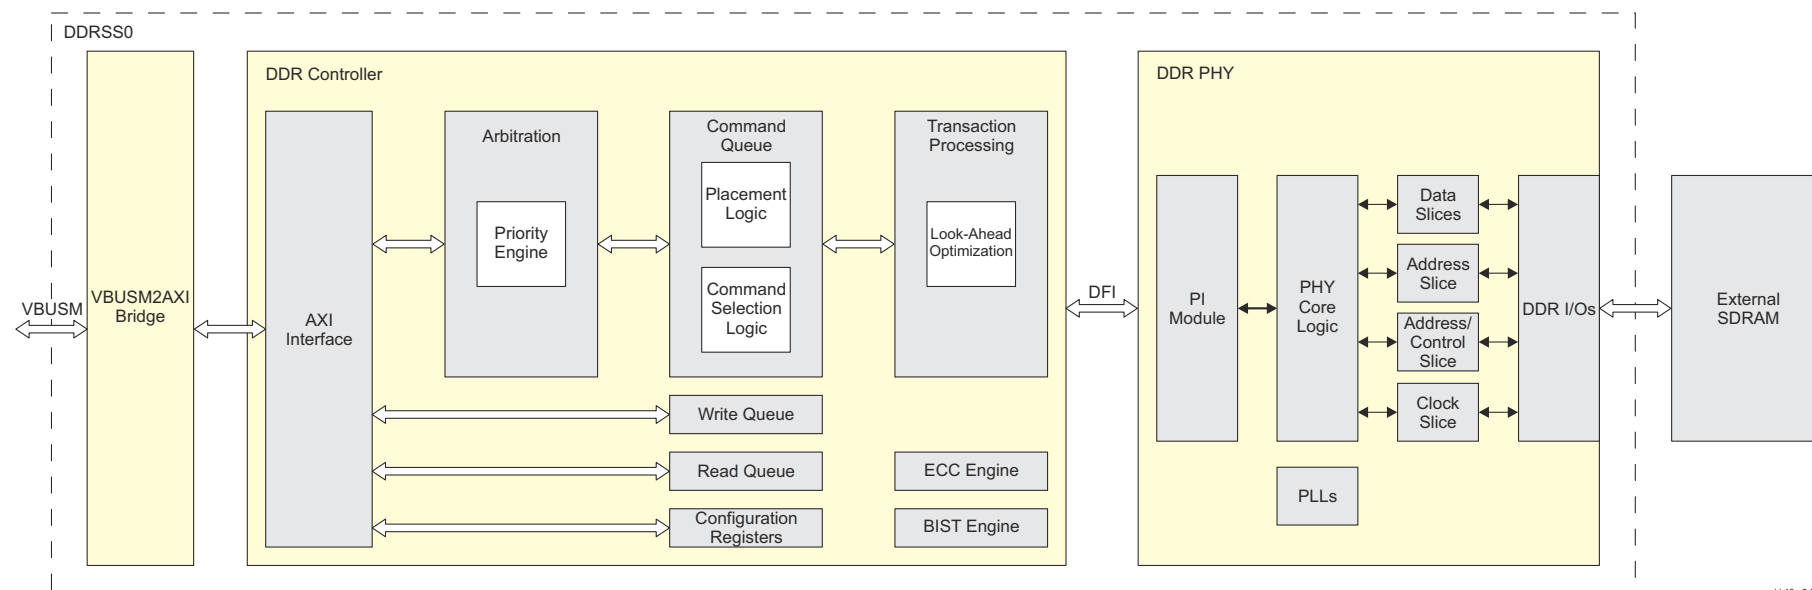

1. The processor writes the desired frequency to the CTRLMMR\_CHNG\_DDR4\_FSP\_REQ[1-0] REQ\_TYPE field.
2. The processor sets to 0x1 the CTRLMMR\_CHNG\_DDR4\_FSP\_REQ[8] REQ bit to initiate frequency change.
3. The processor programs PLL12 according to the CTRLMMR\_CHNG\_DDR4\_FSP\_REQ[1-0] REQ\_TYPE value.
4. The processor polls the CTRLMMR\_CHNG\_DDR4\_FSP\_ACK[7] ACK and CTRLMMR\_CHNG\_DDR4\_FSP\_ACK[0] ERROR bits to check if the frequency change has been completed successfully.

The sequence for DDRSS0 initiated frequency change is as follows:

1. DDRSS0 requests frequency change by asserting the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ[7] REQ bit and the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ[1-0] REQ\_TYPE field. The REQ bit is also connected to the DDR0\_DDRSS\_PLL\_FREQ\_CHANGE\_REQ\_0 interrupt.
2. Software reads the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ[1-0] REQ\_TYPE value and programs PLL12 accordingly.
3. After the DDRSS0\_FCLK has been changed software should set to 0x1 the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_ACK[0] ACK bit.

### 9.1.3.12 DDR Controller Functional Description

Figure 9-2 shows the DDR controller blocks along with the DDR PHY and VBUSM2AXI bridge.

ddr16sa0-005

The ECC Engine block of the DDR controller is not supported.

**Figure 9-2. DDR Controller Functional Blocks**

#### 9.1.3.12.1 DDR PHY Interface (DFI)

The DDR controller and DDR PHY are connected via DDR PHY Interface (DFI) which is used for transferring control information and data between the PHY and the controller. For more information about DFI, see <http://www.ddr-phy.org/>.

#### **9.1.3.12.2 Command Queue**

The DDR controller contains a command queue which uses a placement algorithm to determine the order of commands to be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at a time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. The placement logic also attempts to maximize efficiency of the DDR controller through command grouping and bank splitting.

##### **9.1.3.12.2.1 Placement Logic**

The placement logic is a 2-stage queue which determines the order of commands that run in the DDR controller. The placement logic follows rules for determining placement of new commands into the queue, relative to the contents of the command queue at that time. Placement is determined by considering coherency, address collisions, source collisions, data collisions, user assigned priority, latency, age, and command type to offer low latency for critical controllers while optimizing bandwidth for all controllers. A second reordering stage allows ready-to-run commands to start even if the head-of-queue command is not yet ready to run. In addition, the queue can be disabled completely, resulting in an in-line queue that services requests in the order that they arrive.

The DDR controller also has a full look-ahead facility that reduces the effect of page misses by pre-conditioning rows for upcoming requests by using “spare” cycles in preceding transactions.

##### **9.1.3.12.2.2 Command Selection Logic**

After a command is in the command queue, command selection logic determines the method of pulling commands from the queue for running. On each clock cycle, the selection logic scans the entries of the command queue for determining the command to run. Commands for running are based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing, and conflicts. Similar to the placement rules, a command does not run before a command that was placed ahead of it in the command queue if it conflicts with address, source ID, or bank commands. Lower priority commands can run ahead of higher priority commands if the higher priority commands are not ready to run, as long as they do not conflict with commands that are ahead in the command queue.

##### **9.1.3.12.3 Transaction Processing**

The transaction command processing logic is used to process the commands in the command queue. The logic organizes the commands to the memories in such a way that data throughput is maximized. Bank opening and closing cycles are used for data transfers. The logic reviews the entire command queue for look-ahead of which banks have to be accessed in the future and ensures that the programmed memory timing conditions are met. This flexibility allows the controller to be tuned to extract the maximum performance out of memories. During processing, the controller examines the commands and issues the appropriate set of signals to the memory.

##### **9.1.3.12.4 Paging Policy**

The DDR controller offers a flexible paging policy that allows open page operation, closed page operation, or an auto-precharge-per-command option that allows both modes simultaneously. Auto-precharge-per-command allows marking a particular controller or transaction (for example, a CPU cache) as a closed-page transaction. This type of transaction reduces power and improves latency for the next transaction to a different row in the same SDRAM bank. Other transactions can be marked as open page transactions. This type of transaction reduces power and improves latency and bandwidth to the next transaction to the same row in the same SDRAM bank.

##### **9.1.3.12.5 DDR Controller Initialization**

Once the power to the SDRAM and SoC is stable, the DDR controller must be initialized. It then automatically initializes the external memory. Please refer to the Processor SDK for the software drivers to initialize the DDR registers and memory

---

**Note**

To facilitate the programming of these registers, refer to the device-specific DDR Subsystem Register Configuration Tool available at <http://dev.ti.com/sysconfig>.

10.1 Interrupt Architecture.....	1110
10.2 Interrupt Controllers.....	1117
10.3 Interrupt Router (INTROUTER).....	1122
10.4 Interrupt Sources.....	1122

## 10.1 Interrupt Architecture

J722S Interrupt Architecture includes information on how to utilize various interrupts and events in the system and relationships between interrupts and events.

An interrupt is defined as a physical signal which can be routed to the interrupt controller of various processors, which can cause the Interrupt Service Routine (ISR). This physical signal can be either a pulse or level and the polarity can be either negative or positive. And an interrupt is correspondent to an individual wire.

An event is defined as information transported by the event bus or PSI\_L bus. Events are coded using an event index. The same event bus or PSI\_L bus is used to transport multiple events. An event can also be routed and multiplexed to different locations. Events can't trigger a processor's ISR directly. They must go through the Interrupt Aggregator (IA) to convert the event into an interrupt line. For more information, see *Interrupt Aggregator (INTAGGR)*

The DMA transfer using BCDMA and PktDMA in J722S can only be triggered using an event. The SoC level interrupt could be used as a BCDMA trigger using L2G logic. Interrupts in the SoC level can't be used to trigger a pktDMA transfer.

Each type of processor has its unique interrupt controller. All A53 cores share a single Generic Interrupt Controller (GIC). Each R5 micro controller has its own dedicated interrupt controller, called Vectored Interrupt Manager (VIM). Please refer to [Section 10.2](#) for the detailed usage.

J722S also contains multiple SoC level interrupt routers. The main function of those SoC level interrupt routers is to provide flexibility to select interrupt sources from a large group of interrupt sources. Many places use this feature, such as GPIO interrupts and some time synchronization related interrupts.

J722S contains two ESM modules. ESM is used to consolidate/monitor the error events in the device. In this document, ESM may also be referred to as ESM0.

J722S also has some chip level glue logic to convert some miscellaneous signals used as interrupt sources. Those miscellaneous signals are normally self-clear signals and do not need to clear after the Interrupt Service Routine (ISR) like the normal interrupts generated by the peripherals.

[Figure 10-1](#) shows the high level interrupt architecture in J722S.

**Figure 10-1. J722S Interrupt Architecture**

### 10.1.1 ESM Connectivity

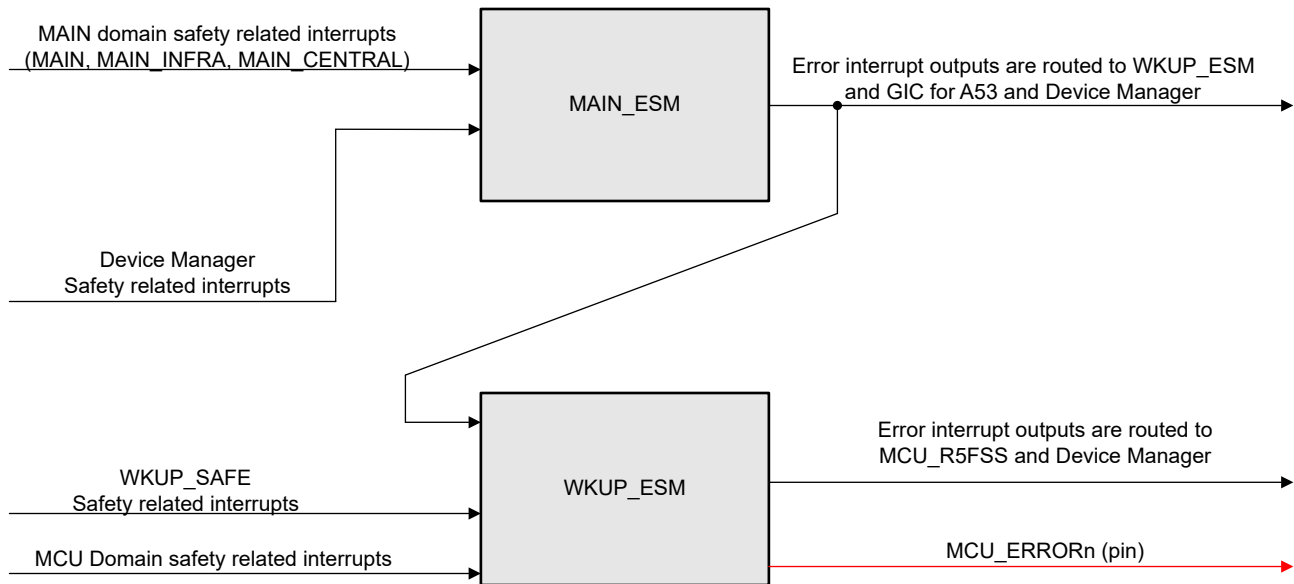

J722S contains two ESM modules to consolidate the error interrupts in SoC. One is in the MAIN domain and one is in the WKUP domain. [Figure 10-2](#) shows how error interrupts are connected to these two ESM. See also *ESM0 INTERRUPT MAP* and *WKUP\_ESM0 INTERRUPT MAP*.

**Figure 10-2. ESM Connections**

The error interrupts from the WKUP\_R5FSS domain are routed to both MAIN\_ESM and WKUP\_ESM. Users can configure ESM to cause ESM generating interrupt output from the interrupt inputs. The interrupt outputs of the MAIN\_ESM are routed as interrupt inputs to the WKUP\_ESM. The interrupt outputs of the WKUP\_ESM are routed as the interrupt inputs to the MAIN\_ESM. This means that user can configure the device to use one ESM to monitor the error interrupts for the whole device. J722S supports the following three use cases.

#### 10.1.1.1 Using WKUP\_ESM to Monitor All Error Events in SoC

In this use case, the MAIN\_ESM is used to consolidate all the error interrupts in the MAIN domain and the WKUP\_R5FSS domain as MAIN\_ESM's interrupt outputs, which are routed as interrupt inputs to the WKUP\_ESM.

**Figure 10-3. Using WKUP\_ESM for All Error Interrupts in SoC**

In this use case, the MAIN\_ESM should be configured to disable the interrupt inputs coming from the WKUP\_ESM interrupts. If those interrupt inputs are not disabled by the MAIN\_ESM, the dependence loop will be formed as following:

1. Error interrupts in the MAIN domain are routed to MAIN\_ESM trigger interrupt outputs generated by the MAIN\_ESM
2. The error interrupt outputs from the MAIN\_ESM are routed to the WKUP\_ESM as interrupt inputs
3. Those error interrupt inputs trigger the WKUP\_ESM generating its error interrupts outputs
4. Those interrupt outputs from the WKUP\_ESM are routed back to the MAIN\_ESM as interrupt inputs. If those interrupts are not disabled at the MAIN\_ESM, they trigger MAIN\_ESM generating interrupt outputs in the MAIN\_ESM again. Going back to step 1 again.

In addition, since WKUP\_R5FSS error events are already routed to the MAIN\_ESM, so the input events in the WKUP\_ESM connecting to those error events from the WKUP\_R5FSS domain shall be disabled, otherwise those events can trigger the interrupt in both the MAIN\_ESM as well as the WKUP\_ESM

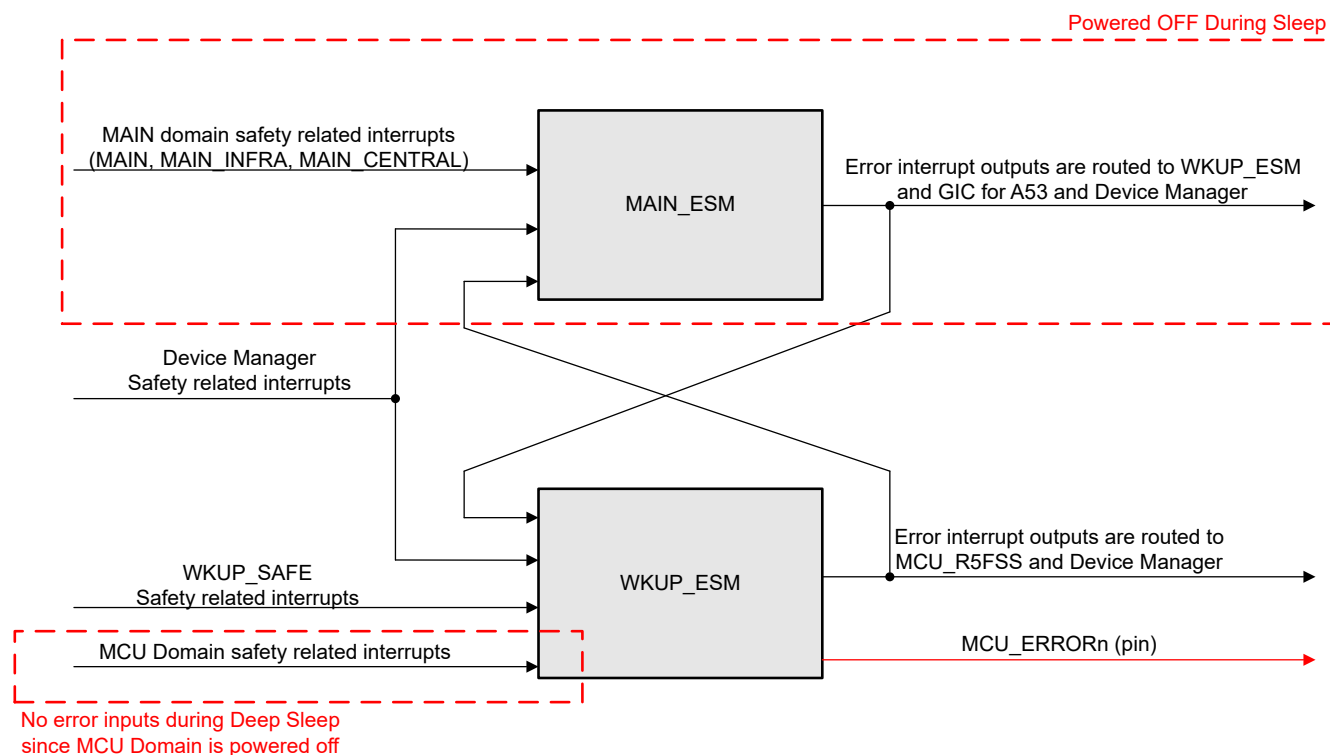

#### 10.1.1.2 Using MAIN\_ESM to Monitor All Error Interrupts in SoC

In this configuration, the WKUP\_ESM is used to consolidate all the error interrupts from the WKUP domain and the WKUP\_safe domain as interrupt outputs, and those interrupt outputs from the WKUP\_ESM are routed as interrupt inputs to the MAIN\_ESM. In order to avoid the interrupt dependence loop, the WKUP\_ESM shall disable the interrupt inputs from ESM0.

**Figure 10-4. Using MAIN\_ESM to Monitor All Error Interrupts in SoC**

#### 10.1.1.3 ESM Configuration During Deep Sleep Mode

When device is in deep sleep mode, only the components in the WKUP\_R5FSS domain and the WKUP\_SAFE are available. The MAIN domain is powered off, so the MAIN\_ESM is no longer available. Since WKUP\_ESM is located in the WKUP\_SAFE domain, the WKUP\_ESM is monitoring all of the error events during the deep sleep mode and informs the device manager.

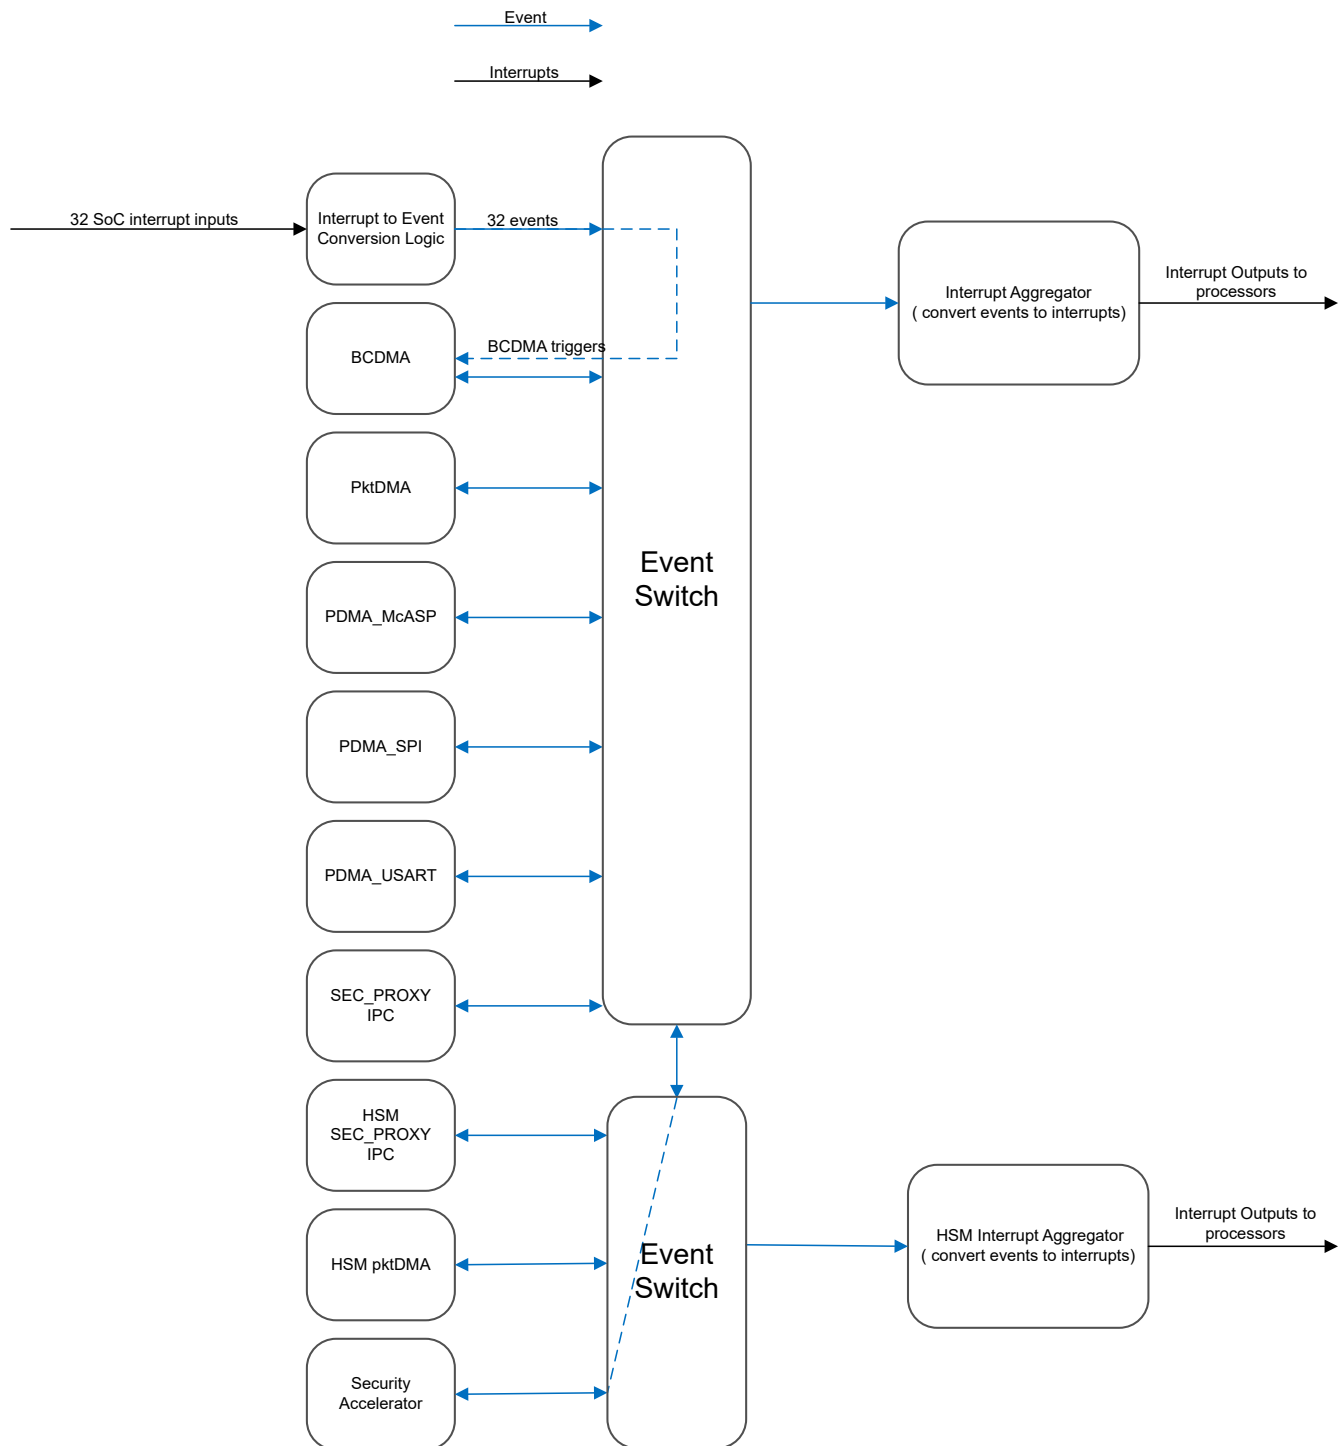

**Figure 10-5. Deep Sleep Use Case**

### 10.1.2 PSIL Events

PSIL Events are mainly generated by the BCDMA and the pktDMA. In addition, the SEC\_PROXY IPC module also generates event outputs. PSIL Events can be directly utilized by the BCDMA and the pktDMA. If those events need to be processed by processor, the events need to be converted to interrupts through the Interrupt Aggregator (IA) Module. Refer to *Interrupt Aggregator (INTAGGR)* for information on how IA is used. [Figure 10-6](#) shows which modules generate events and how the events are converted to the interrupt.

BCDMA transfer can only be triggered through an event or by software. There are 32 SoC level interrupt signals that can be used to trigger a BCDMA transfer.

**Figure 10-6. Event Handling**

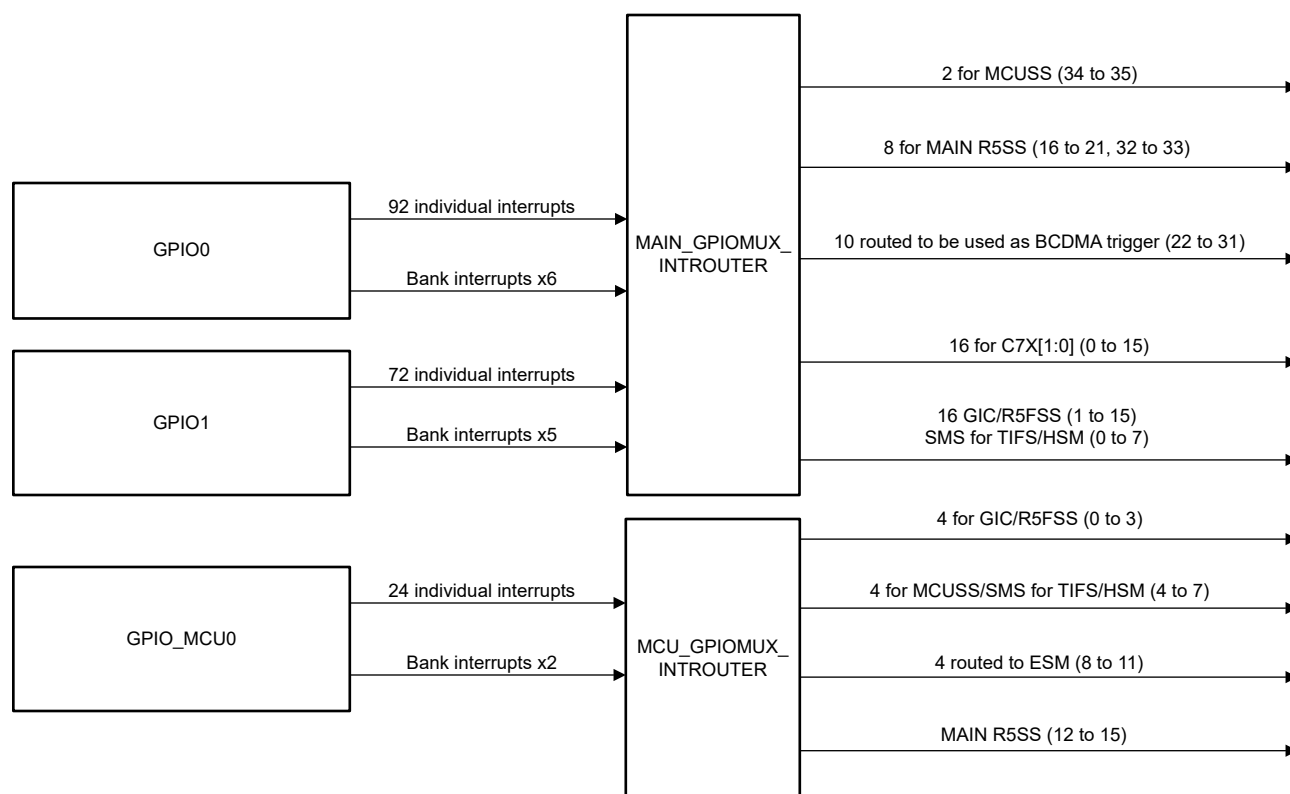

shows all the possible interrupt sources which can be used as BCDMA triggers.

### 10.1.3 GPIO Interrupt Handling

There are three GPIO modules in the device, which could generate almost 200 interrupts. Those GPIO interrupt outputs are routed to the GPIO interrupt router first before they are routed to the final interrupt destination. The GPIO interrupt router allows each output to select each GPIO interrupt independently.

The two GPIO modules in the Main domain use one GPIO interrupt router while the GPIO module in MCU domain has its own dedicated GPIO router. See [Figure 10-7](#). See also [MAIN\\_GPIOMUX\\_INTROUTER0\\_INTERRUPT\\_MAP](#) and [MCU\\_GPIOMUX\\_INTROUTER0\\_INTERRUPT\\_MAP](#)

**Figure 10-7. GPIO Interrupt Routing**

### 10.1.4 Utilizing Miscellaneous Signals as Interrupt

Some of the signals are aggregated through glue logic and need to be handled separately.

#### 10.1.4.1 Aggregated Interrupt from Timeout Gasket

There are multiple timeout gaskets in SoC, some of them are inserted at the initiator side and the others are inserted at the target interface side. Each timeout gasket module generates its own interrupt. Instead of routing the interrupt from each timeout gasket individually to the processor, the interrupts from all the timeout gasket inserted at the target sides are aggregated together (ORed), and all the interrupts from all the timeout gasket inserted at the initiator sides are aggregated together (ORed). The status of each interrupt status is captured by the TOG\_STAT registers in both WKUP\_CTRL\_MMR and MCU\_CTRL\_MMR. Refer to [Figure 10-8](#).

**Figure 10-8. Interrupt from Timeout Gaskets**

#### 10.1.4.2 Aggregated DCC Interrupt

There are multiple DCC modules in the main domain and each DCC module generates its own DCC\_done interrupt. The DCC\_done interrupt from all the DCC modules in the main domain are aggregated (ORed) together before it is routed to all the processors, refer to [Figure 10-9](#).

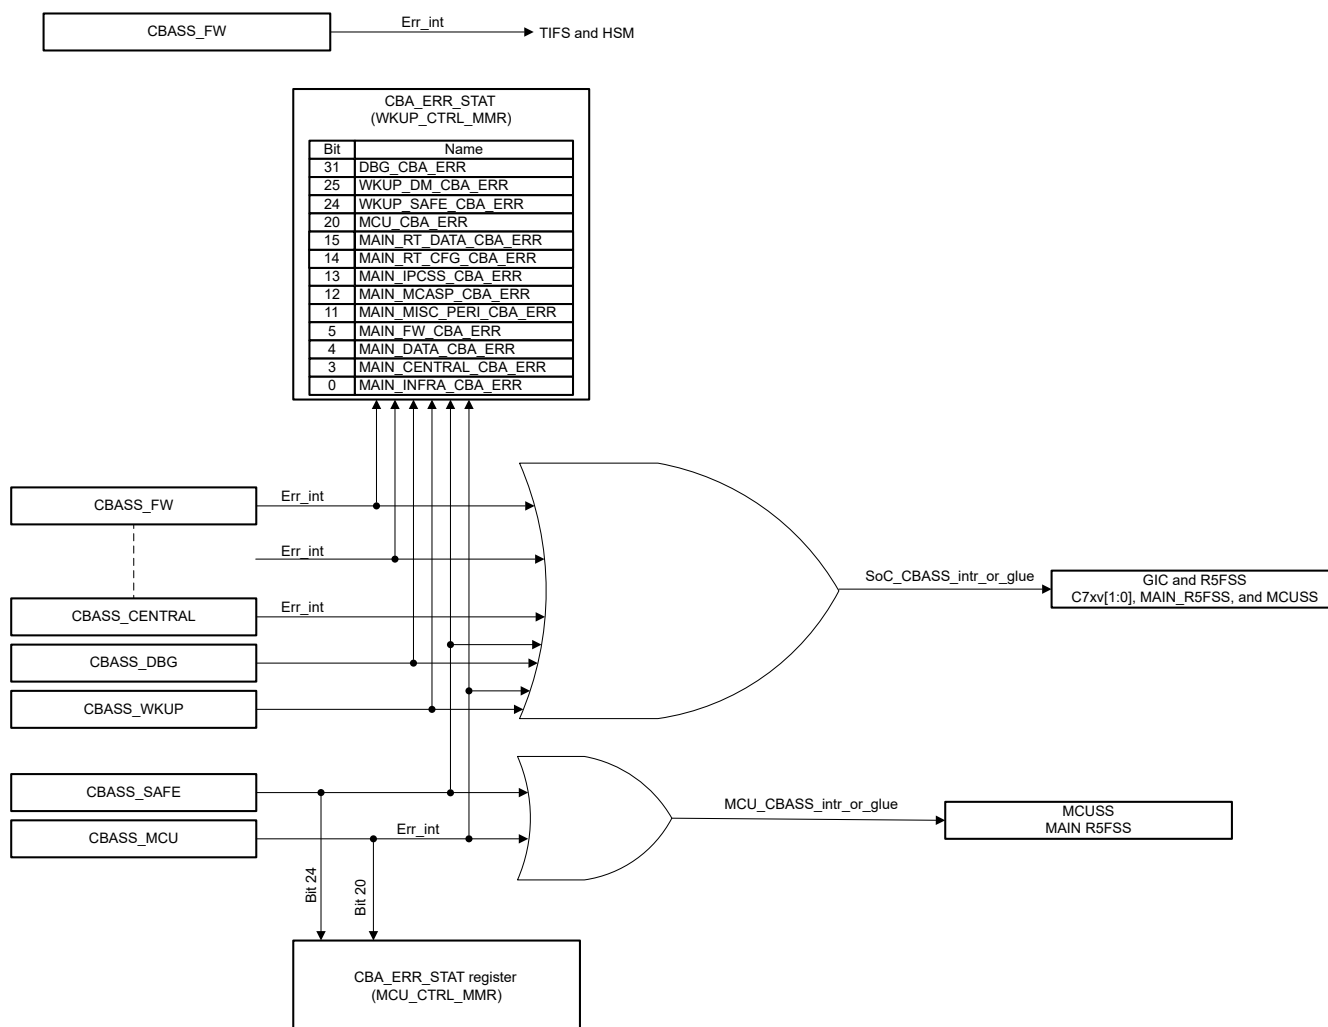

**Figure 10-9. DCC Intr\_done Interrupt Aggregation**

### 10.1.4.3 Aggregated Access Error Interrupt from CBASS

CBASS modules are the interconnection blocks on the SoC level to provide access path between initiators and targets. When the transaction is not completed successfully, an interrupt is generated by the CBASS and the error transaction is logged by the CBASS module.

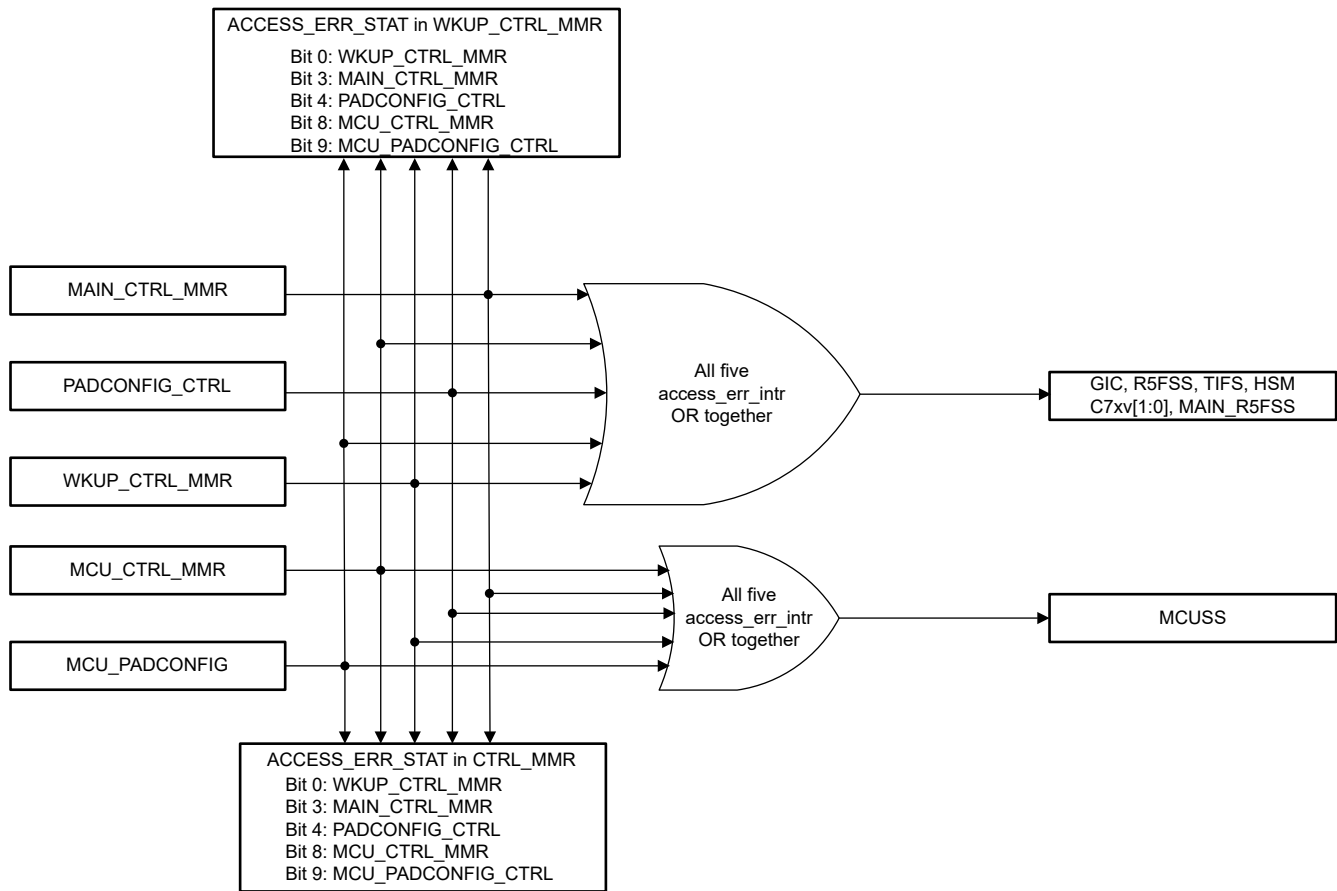

There are multiple CBASS modules on the SoC level to provide three layers of interconnect: the data plane, security configuration plane and debug configuration plane. The CBASS access error from the security configuration plane is only routed to TIFS and HSM, and the other CBASS access errors are aggregated before routing it to the processors, refer to [Figure 10-10](#).

**Figure 10-10. Aggregated CBASS Access Error**

### 10.1.4.4 Access Error to Control Register Block Interrupt Aggregation

There are multiple register blocks on the SoC level, and each register block generates an error interrupt when there is an access error. Those access error interrupts are aggregated together before they are routed to processor, refer to [Figure 10-11](#).

**Figure 10-11. Access Error Aggregation**

## 10.2 Interrupt Controllers

### 10.2.1 Generic Interrupt Controller (GICSS)

This section describes the Generic Interrupt Controller (GICSS) module in the device.

#### 10.2.1.1 GICSS Overview

The device GICSS is a TI module that is based on the Arm GIC-500 interrupt controller. The Arm GIC-500 is a high-performance, area-optimized, built-time configurable interrupt controller which detects, manages, and distributes system interrupts to the Arm Cortex-A53 processors in the Compute Cluster.

The Arm GIC-500 is compliant to the Arm GICv3 standard. It only supports cores (such as A53) that implement the Armv8 architecture and the GIC CPU interface with the standard GIC Stream Protocol Interface. The GICSS includes additional logic (TI wrapper) to fully integrate the Arm GIC-500 into the SoC.

##### 10.2.1.1.1 GICSS Features

#### Note

This chapter provides only a brief description of the GICSS functionality and features. For more details on this module, refer to the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

The Arm GIC-500 supports the following features in the device:

- Module revision: r1p1
- Supports both cores in the dual-A53 MPU cluster

- 16 software generated interrupts (SGIs) per core
- 16 private peripheral interrupts (PPIs) per core
- 256 shared peripheral interrupts (SPIs)
- Locality-specific peripheral interrupts (LPIs), used for message-based interrupts
- Interrupt translation service (ITS)
  - Device isolation
  - ID translation for message-based interrupts
  - This allows virtual machines to program devices directly
- Interrupt masking and prioritization
- Programmable, affinity-based interrupt routing
- 32 priorities for each interrupt
- Three different interrupt groups
  - Group 0
  - Non-secure group 1
  - Secure group 1

Additionally, the GICSS wrapper logic provides the following features:

- Synchronizes interrupt inputs to GICSS clock
- Implements AXI2VBUSM and VBUSM2AXI bridges
  - Used for bus protocol conversion (AXI-to-VBUSM and VBUSM-to-AXI, respectively)
- Implements an integrated ECC aggregator
  - Only used to inject errors (for testing purposes)

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

#### 10.2.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### **10.2.1.2 GICSS Integration**

See GICSS in the Module Integration section for information about clocks, resets, and hardware requests.

### 10.2.1.3 GICSS Functional Description

#### Note

This chapter provides only a brief description of the GICSS functionality and features. For more details on this module, refer to the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

#### 10.2.1.3.1 GICSS Block Diagram

Figure 10-12 shows the GICSS block diagram.

**Figure 10-12. GICSS Block Diagram**

#### 10.2.1.3.2 Arm GIC-500

The Arm GIC-500 is responsible for detecting, managing and communicating system interrupts to the dual-core A53 cluster. The main difference between the Arm GIC-500 and previous Arm GIC versions is the direct communication with the CPU(s). Previously, an interrupt controller would set a pending bit to a CPU and that CPU would then have to query an interrupt controller MMR to find out what to do. Now, the Arm GIC-500 sends interrupts to a CPU via a dedicated message interface and the CPU communicates back about interrupts through the same interface. The CPU now uses writes and reads to system registers instead of over the memory interface. This leads to reduced latency and the ability to route interrupts to different CPUs based on a set of rules.

The Arm GIC-500 is divided into three main sections:

- **Distributor:** The Distributor receives interrupts from the wire interrupts and the programming interface. It is responsible for prioritizing these interrupts and sending them to the CPU interface via the GIC Stream Protocol Interface.
- **Redistributor:** There is one Redistributor per core. Each Redistributor holds the state that is individual to a particular core (such as the settings for PPIs and SGIs). It also stores the LPIs for that core after they have been generated using the ITS.
- **ITS:** The ITS is responsible for translating message-based interrupts from device peripherals into LPIs. The user can also use the ITS to manage existing LPIs. Note that the ITS is not used for other types of interrupt

#### 10.2.1.3.3 GICSS Interrupt Types

The GICSS supports four types of interrupts:

- **Software Generated Interrupts (SGIs):** There are 16 SGIs (ID0-ID15). These are inter-processor interrupts. SGIs can be sent using either Arm system registers or by writing to the Software Generated Interrupt Register (GICD\_SGIR).

- **Private Peripheral Interrupts (PPIs):** There are 16 PPIs (ID16-ID31). These are wired interrupts dedicated to a specific CPU. Many are reserved to specific functions via convention. These can be either active-low levels (by default), or rising edge triggered (software programmable).
- **Shared Peripheral Interrupts (SPIs):** There are 256 SPIs (ID32-ID288). These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GICSS. These are active-high levels (by default), or rising edge triggered (software programmable).
- **Locality-Specific Peripheral Interrupts (LPIs):** There are 57,344 of these. These interrupts are used for message-based interrupts from a peripheral. They are generated through writes to the GICSS peripheral interface. The information associated with these is located in memory. The GICSS keeps a small 64-entries cache on-board in order to reduce latency either for specific interrupts or for most-recently-used. LPIs can be routed to different CPUs based on programmed rules.

#### 10.2.1.3.4 GICSS Interfaces

The GICSS has the following main interfaces:

- A pair of 64-bit VBUSM write-only and read-only controller interfaces
  - AXI2VBUSM bridge converts the standard 64-bit AXI4 controller interface into this pair of interfaces
  - The AXI4 controller interface allows the GICSS ITS and redistributors to access main memory
- 32-bit VBUSM peripheral interface
  - Provides access to Arm GIC-500 internal resources
  - Handles all message-based interrupts. Message-based interrupts can generate SPIs or LPIs, depending on the register that is written
  - VBUSM2AXI bridge converts this interface into an 32-bit AXI4 peripheral interface
- 32-bit VBUSP peripheral interface
  - Provides access to internal ECC aggregator
- Physical interrupt and power signals
  - Inputs: CPU active signals, SPIs and PPIs (can be programmed as either level-sensitive, or edge-triggered)
  - Outputs: Error signals and wake-up requests
- GIC Stream Protocol Interface
  - Consists of a pair of AXI4-Stream interfaces (one upstream and one downstream 16-bit AXI4-Stream interface) that the GICSS uses to send interrupts to the core and receive notifications when the core activates interrupts
  - There is a pair of physical interfaces, one in each direction, for each cluster

#### 10.2.1.3.5 GICSS Interrupt Outputs

Table 10-1 lists the interrupts that are generated by the GICSS.

**Table 10-1. GICSS Interrupt Outputs**

Interrupt Name	Description
GICSS0_AXIM_ERR_0	GICSS bus error interrupt. This interrupt is triggered if the GICSS receives an error on a bus transaction, such as a decode or protection error. This is a pulse-high interrupt. If this interrupt occurs, the GICSS might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GICSS0_ECC_FATAL_0	GICSS uncorrectable ECC error interrupt. Indicates an uncorrectable 2-bit error detected in one of the ITS cache memories. This is a pulse-high interrupt. If this interrupt occurs, the GICSS might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GICSS0_ECC_AGGR_CORR_LEVEL_0	GICSS ECC aggregator correctable (SEC) error interrupt
GICSS0_ECC_AGGR_UNCORR_LEVEL_0	GICSS ECC aggregator uncorrectable (DED) error interrupt
GICSS0_GIC_PWR0_WAKE_REQUEST_0	GICSS wake requests for A53 cores. Asserted state indicates that an interrupt is pending for a processor that has set the PROCESSORSLEEP bit in the GICR_WAKER register. This bit indicates that the SoC should wake up the indicated CPU so that it can process the interrupt.
GICSS0_GIC_PWR0_WAKE_REQUEST_1	

### 10.2.1.3.6 GICSS ECC Support

The Arm GIC-500 has built-in SECDED ECC on its memories to protect against errors. The syndrome generation and checking is done internally.

Additionally, the GICSS wrapper integrates an ECC aggregator (GICSS0\_ECC\_AGGR) in order to allow errors to be injected for testing purposes. The generic ECC aggregator functionality is described in *ECC Aggregator*. Note that the GICSS0\_ECC\_AGGR supports only a subset of this functionality.

Table 10-2 shows the memory ID for each ECC endpoint. The corresponding memory ID needs to be written in the GICSS0\_ECC\_AGGR\_VECTOR[10-0] ECC\_VECTOR bit field for proper operation.

**Table 10-2. GICSS0\_ECC\_AGGR Memory ID Mapping**

ECC Aggregator	Memory ID	ECC Endpoint
GICSS0_ECC_AGG R	0	ICB RAM
	1	ITE RAM
	2	LPI RAM
	3	VBUSM2AXI bridge
	4	AXI2VBUSM read bridge
	5	AXI2VBUSM write bridge

### 10.2.1.3.7 GICSS AXI2VBUSM and VBUSM2AXI Bridges

The GICSS uses the AXI4 controller interface to allow the ITS and redistributors to access main memory. It is expected that the main memory (attached to a CBASS VBUSM port) holds the following:

- ITS translation tables
- ITS command queue, which is written by software in order to program the ITS
- LPI configuration table, which holds the priorities and enable bits for LPIs
- LPI pending tables, which can hold information on whether each LPI is pending on each core

The AXI2VBUSM bridge converts the standard 64-bit AXI4 controller interface into a pair of 64-bit VBUSM write-only and read-only controller interfaces. AXI4 has a separate command channel for read and write, and the AXI2VBUSM bridge keeps them separate, so that the system may prioritize or arbitrate the traffic between them as appropriate.

The GICSS uses the AXI4 peripheral interface to provide access to the programming interfaces of all its parts (distributor, redistributors, ITS). The VBUSM2AXI bridge converts the standard 32-bit VBUSM controller interface into an 32-bit AXI4 peripheral interface.

#### Note

The AXI2VBUSM and VBUSM2AXI bridges do not implement any MMRs.

## 10.3 Interrupt Router (INTROUTER)

### 10.3.1 INTROUTER Integration

See the Interrupts section of the Module Integration Chapter for details on clocks, resets and hardware requests.

## 10.4 Interrupt Sources

### 10.4.1 C7X256V0\_CLEC\_INTERRUPT\_MAP

Chapter 11

# Data Movement Architecture

---

This chapter describes the data movement architecture of the device.

11.1 Data Movement Architecture Overview.....	1200
11.2 Data Movement Subsystem (DMSS).....	1261
11.3 Peripheral DMA (PDMA).....	1292

## 11.1 Data Movement Architecture Overview

This chapter is a high-level summary of the data movement architecture implemented in the device.

### 11.1.1 Overview

The primary goal of the device Data Movement Architecture and related Subsystems is to ensure that data can be efficiently transferred from a producer to a consumer while meeting the real time requirements of the system can be met.

The Data Movement Subsystem (DMSS) aims to facilitate direct memory access (DMA) and provides a consistent Application Programming Interface (API) to the host software.

Data movement tasks are commonly offloaded from the host processor to peripheral hardware to increase system performance. Significant performance gains may result from careful design of the interface between the host software and the underlying acceleration hardware. In networking applications, packet transmission and reception are critical tasks. In general purpose compute, ping pong buffer prefetch and store are critical tasks as well as general mis-aligned block copy operations.

The design goals for the device Data Movement Architecture and are as follows:

- Minimize cost
- Minimize host overhead
- Maximize memory use efficiency
- Maximize bus burst efficiency
- Maximize symmetry between transmit/receive operations
- Maximize scalability for number of connections / buffer sizes / queue sizes / protocols supported
- Minimize protocol specific features
- Minimize complexity

#### 11.1.1.1 Ring Accelerator (RINGACC)

The ring accelerator (RINGACC or RA) is a hardware module that is responsible for accelerating management of various types of queues in the system. The RINGACC accelerates passing of packets between a producer and consumer in normal system memory (including cached memory). The RINGACC is capable of accelerating the read/write pointer maintenance and occupancy tracking operations.

The ring accelerator operates like a bus infrastructure bridge in that it passes transactions through it between a source and destination interface. As transactions are passed, the RINGACC modifies the address, byte count, and transaction identifiers and internally updates the occupancies/pointers.

Each queue that the RINGACC provides can operate in either exposed-ring-mode or private-queue-mode.

- The exposed ring mode allows software to directly access the underlying ring structure to add or remove items from the tail or head of the ring respectively. Whenever items are added or removed from a ring, the host software is required to write to a corresponding doorbell register (RINGRT[a]\_RT\_DB) to increment or decrement the ring occupancy. When using the exposed ring mode, no proxy is required between the software and the RINGACC but all queue add operations require a memory fence to be performed to ensure that the data has landed in a snoopable cache before the doorbell register is written.
- The private queue mode provides an abstract view of the ring so that the host software does not need to know the actual physical address location or current read or write indexes of the ring. The private queue mode provides a memory window for each ring which when written redirects the write to the address pointed to by the write pointer and when read redirects the read to the address pointed to by the read pointer. The same address range is always used to push or pop elements from a given queue.

Rings are an implementation of a logical queue with the following limitations:

- Each ring has a finite size. When rings are used in exposed ring mode the following conditions apply:
  - A separate operation is required to write/read the contents of a ring and to update the occupancy of the ring

- It is not straightforward to allow multiple producers to write to a ring or multiple consumers to read from a ring. Additional synchronization and pointer passing is required since rings require software to manage one of the pointers for the queue.
- An exposed ring cannot be used when software or hardware needs to both read and write the same queue (such as for a DMA RX free queue where errors can have the DMA write the element back onto the same RX free queue). Since software owns one side of the pointers and hardware owns the other, they cannot be kept coherent if either side needs to update either at any time.

The RINGACC allows each ring to be configured to a different primary element size. Element sized chunks of data are placed onto and retrieved from rings when queuing or de-queuing occurs. Element sizes can be as small as 4 bytes or as large as 256 bytes.

#### 11.1.1.2 Secure Proxy (SEC\_PROXY)

A proxy provides a mechanism for software to access the RINGACC coherently when the processor does not support large bursts. The RINGACC requires a single burst for each operation so that it maintains atomicity and coherence by relying on the atomicity of the bursts on the bus interconnect fabric, since it only delivers a single burst to the RINGACC before the next. Since processors are usually limited in the size of a burst they can deliver natively, such as 32 to 128 bits, they cannot be used directly with the data access region of the RINGACC for larger element sizes. The proxy solves this gap by providing a temporary space for the software to form a larger burst of data before it is sent to the RINGACC. The proxy allows smaller processor accesses to the data and only forwards to the RINGACC when the entire data burst is complete, as directed by the software.

Each proxy hardware can support multiple threads of software (whether on the same or different processors) operating on bursts at the same time, and they do not interfere with each other, as long as each thread of software only operates on its thread in the proxy. Each proxy thread also supports access to any RINGACC queue via different offsets similar to how the RINGACC provides access to the queues via different offsets.

A special version of a proxy is the Secure Proxy that provides secured access to RINGACC queues for communication to the security initiator of the system. It provides basically the same function as a normal proxy. The data burst size is fixed for message sizes to the security initiator, so there is no support for all the element sizes of the RINGACC. The security initiator locks down the RINGACC queue to access and direction for each proxy thread so that the software cannot access anything they shouldn't, so the software only sees a single queue (unlike the normal proxy), and any attempts to access another queue or access it in violation of how the security initiator defined and an error will be flagged. This allows for a much more controlled setup for passing messages to the security initiator.

#### 11.1.1.3 Interrupt Aggregator (INTAGGR)

The interrupt aggregator (INTAGGR or INTA) is a hardware module which provides a persistent view of the real time status of various DMA components within the overall SoC DMA system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

The INTA block provides the following functions:

- Conversion of local event signal lines into global events
- Performing an 'Y-split' operation of global events
- Counting global events
- Steering and aggregation of global events into specified bit positions in one of N interrupt cause registers
- SoC interrupt-architecture-compliant set/clear and mask set/clear functionality to cover interrupt cause registers

#### 11.1.1.4 Packet DMA (PKTDMA)

The PKTDMA module supports the transmission and reception of various packet types. The PKTDMA is architected to facilitate the segmentation and reassembly of DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows

packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

A block diagram of the PKTDMA Controller is shown below:

**Figure 11-1. PKTDMA Block Diagram**

#### 11.1.1.4.1 PKTDMA Submodule Descriptions

##### 11.1.1.4.1.1 Bus Interface Unit

The Bus Interface Unit is responsible for merging and buffering all of the transactions that originate from the various initiator blocks inside the DMA controller into the 4 separate VBUSM initiator interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A 2 word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

##### 11.1.1.4.1.2 Config CR

The function of the Config CR is to switch transactions which arrive on the configuration interface to the various configuration targets within the DMA. The Config CR also provides a retiming buffer on the configuration bus primary interface ports.

##### 11.1.1.4.1.3 Configuration Registers

The Configuration Registers block is responsible for monitoring the fullness level of the Tx Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Tx PKTDMA core blocks, and writing back the updated state returned from those same DMA core blocks.

The Configuration Registers block is also responsible for providing memory mapped registers for configuration of the Rx DMA functions including the default settings for the free descriptor and destination queues. For modularity and high speed pipelining reasons, the Rx traffic is looped through the Configuration Registers block where the original stream information is merged with information from the configuration registers on its way to the Rx DMA unit module. This prevents the Rx DMA Core from having to spend cycles accessing the channel configuration information for the channel.

**Table 11-1. RX State Mapping Table**

Total Bits	Bits	Register Offset	Field	Description
31 - 0	31 - 0	0x80	sop_descriptor_ptr[35:4]	The descriptor pointer at start of packet
43 - 32	11 - 0	0x84	sop_descriptor_ptr[35:4]	The descriptor pointer at start of packet
47 - 44	15 - 12	0x84	sop_descriptor_asel	The asel for descriptor pointer at start of packet
63 - 48	31 - 16	0x84	curr_descriptor_ptr	The pointer for the current descriptor aligned on 16 byte boundary
91 - 64	27 - 0	0x88	curr_descriptor_ptr	The pointer for the current descriptor aligned on 16 byte boundary
95 - 92	31 - 28	0x88	curr_descriptor_asel	The asel of the current descriptor
127 - 96	31 - 0	0x8C	curr_buffer_ptr	The pointer for the current buffer
143 - 128	15 - 0	0x90	curr_buffer_ptr	The pointer for the current buffer
147 - 144	19 - 16	0x90	curr_buffer_asel	The asel for the current buffer
159 - 148	9 - 0	0x90	curr_buffer_length	The length of the current buffer
169 - 160	31 - 20	0x90	curr_buffer_length	The length of the current buffer
191 - 170	31 - 10	0x94	curr_buffer_offset	The offset inside the current buffer
192	0	0x98	curr_buffer_eop	The end of packet flag for the current buffer
213 - 193	21 - 1	0x98	pkt_length	The size of the packet length
214	22	0x98	flush	The packet is being flushed
220 - 215	28 - 23	0x98	ps_wordcnt	protocol specific word count
221	29	0x98	flowid_is_default	Use default flow id
223 - 222	31 - 30	0x98	drop_flush	The flush is a drop condition
230 - 224	6 - 0	0x9C	ps_offset	protocol specific offset
234 - 231	10 - 7	0x9C	ps_flags	protocol specific flags
247 - 235	23 - 11	0x9C	pktid_data	The pktid number for scoreboard
251 - 248	27 - 24	0x9C	orderid	The orderid of the packet
254 - 252	30 - 28	0x9C	priority	The priority of the packet

**Table 11-2. TX State Mapping Table**

Total Bits	Bits	Register Offset	Field	Description
31 - 0	31 - 0	0x80	sop_descriptor_ptr[35:4]	The descriptor pointer at start of packet
43 - 32	11 - 0	0x84	sop_descriptor_ptr[35:4]	The descriptor pointer at start of packet
47 - 44	15 - 12	0x84	sop_descriptor_asel	The asel for descriptor pointer at start of packet
63 - 48	31 - 16	0x84	curr_descriptor_ptr	The pointer for the current descriptor aligned on 16 byte boundary
91 - 64	27 - 0	0x88	curr_descriptor_ptr	The pointer for the current descriptor aligned on 16 byte boundary
95 - 92	31 - 28	0x88	curr_descriptor_asel	The asel of the current descriptor
127 - 96	31 - 0	0x8C	curr_buffer_ptr	The pointer for the current buffer
143 - 128	15 - 0	0x90	curr_buffer_ptr	The pointer for the current buffer
147 - 144	19 - 16	0x90	curr_buffer_asel	The asel for the current buffer
159 - 148	9 - 0	0x90	curr_buffer_length	The length of the current buffer
169 - 160	31 - 20	0x90	curr_buffer_length	The length of the current buffer
191 - 170	31 - 10	0x94	curr_buffer_offset	The offset inside the current buffer
192	0	0x98	curr_buffer_eop	The end of packet flag for the current buffer
214 - 193	22 - 1	0x98	rem_length	The remaining length in the buffer
215	23	0x98	info_present	The packet has info present
216	24	0x98	truncated_non_eop	Eop if packet length is greater than the total buffer length
223 - 217	31 - 25	0x98	psbytes_rem	Number of protocol specific bytes remaining
224	0	0x9C	psbytes_rem	Number of protocol specific bytes remaining
232 - 225	8 - 1	0x9C	psbytes_off	The offset of the protocol specific bytes
245 - 233	21 - 9	0x9C	wptr_data	The current write pointer in the data fifo
247 - 246	23 - 22	0x9C	pktid_data	The pktid number for scoreboard
251 - 248	27 - 24	0x9C	orderid	The orderid of the packet
254 - 252	30 - 28	0x9C	priority	The priority of the packet

#### 11.1.1.4.1.4 Tx Packet DMA Unit

The Tx Packet DMA Unit block implements all of the state machine functionality necessary to implement the KS3 DMA Host Tx protocol. The Tx Packet DMA unit initiates VBUSM transactions in order to read descriptor pointers from the memory mapped Tx ring, read descriptors from memory, and read data from buffers in memory.

#### 11.1.1.4.1.5 Tx Packet Coherency Unit

The Tx Packet Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the Tx DMA unit(s) and that all previous packets on that channel/flow have also completed prior to incrementing the reverse ring occupancy for the channel/flow.

#### 11.1.1.4.1.6 Tx Per Channel Buffers

The Tx Per Channel Buffers implement a FIFO for each Tx DMA channel that is used for buffering packet control and payload data that has been fetched by the Tx Packet DMA units. The buffers are byte oriented on write so that the data from the DMA units which may not be full words can be packed properly. The buffers are block

oriented on read and each Tx (source) channel in the PKTDMA controller maps directly onto a thread in the Tx PSI interface. The Tx Per Channel Buffer block outputs queue fullness information to the Tx Scheduler block which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Tx Per Channel Buffer will initiate transfers to the target whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round robin arbitration between the different threads for the use of the Transmit PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

#### 11.1.1.4.1.7 Rx Per Channel Buffers

The Rx Per Channel Buffers implement a FIFO for each Rx DMA channel that is used for buffering packet control and payload data that has been pushed into the DMA from the Rx PSI-L interface. The Rx Per Channel Buffers also includes an arbitration unit which determines which Rx DMA channel should be serviced next.

#### 11.1.1.4.1.8 Rx Packet DMA Unit

The Rx Packet DMA Unit block implements all of the state machine functionality necessary to implement the KS3 DMA Rx protocol for Host descriptor types. The Rx Packet DMA Unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read buffer descriptor information, write descriptors to memory, and write data to buffers in memory.

#### 11.1.1.4.1.9 Rx Packet Coherency Unit

The Rx Packet Coherency Unit is responsible for ensuring that all control structures and data have been written by the Rx DMA unit(s) and that all previous packets on that channel/flow have completed prior to incrementing the reverse ring occupancy for the channel/flow. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Rx free queues. Writes are not considered complete by this unit until the entire write status has been returned for all outstanding transactions for a given packet ID.

#### 11.1.1.4.1.10 Event Handler

The Event Handler block is responsible for generating channel completion and error events.

#### 11.1.1.4.2 Channel Classes

Not all channels within the PKTDMA require the same performance capabilities. Raw bandwidth and latency tolerance requirements will vary greatly between data transfers at various points in the system. Due to area concerns, several different classes of DMA channels are provided in the PKTDMA and are described as follows:

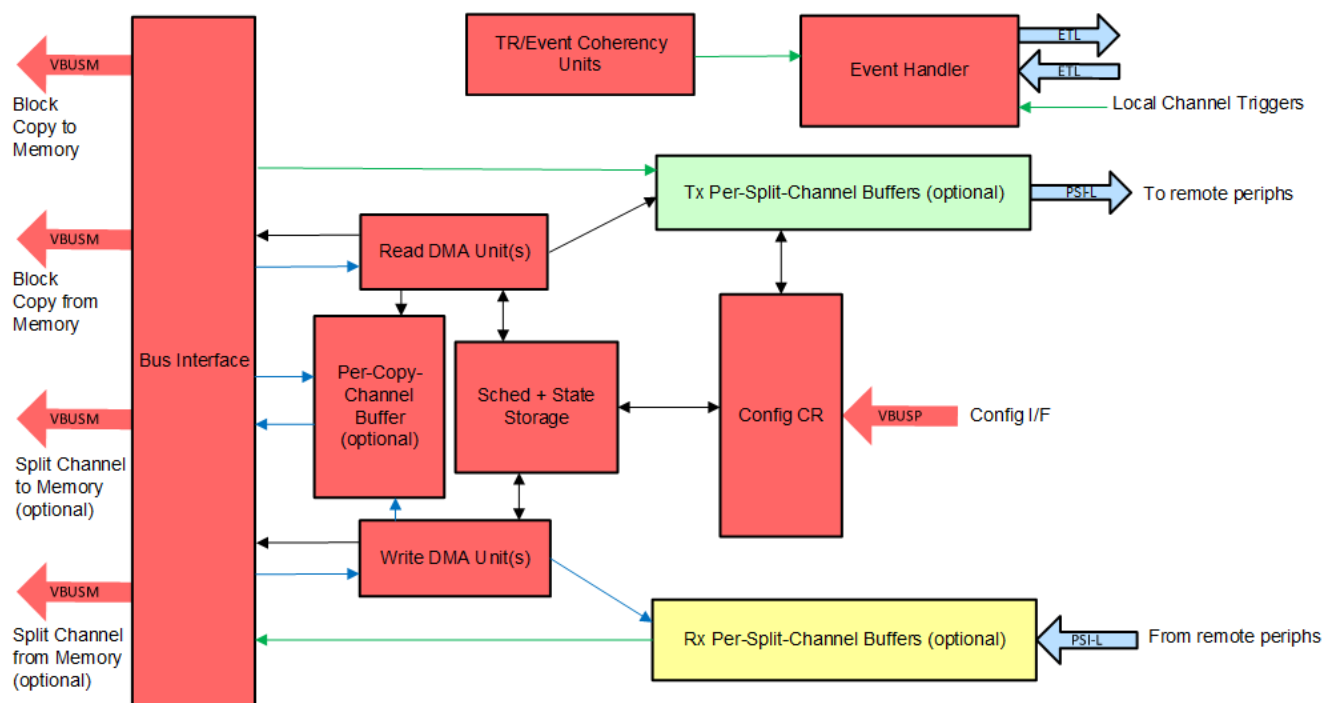

Class Name	Description
Normal Capacity	Provides baseline amount of descriptor prefetch and Tx/Rx control and data buffering. Suitable for most peripheral transfers which are communicating with on-chip memories and DDR
High Capacity	Provides an elevated amount of descriptor prefetch and custom Tx/Rx control and data buffering. Suitable for applications which require moderate per-channel bandwidth with significantly increased latency (ex. Transferring data to/from PCIe)
Ultra-High Capacity	Provides identical descriptor and TR prefetch as High Capacity but with increased Tx data buffering to allow for more read data in flight. Suitable for applications requiring high per-channel bandwidth with significantly increased latency (ex. 16+Gbps transfers to/from PCIe).

PKTDMA instances may provide support for any or all of the above channel classes through design time configuration parameters.

### 11.1.1.5 Block Copy DMA (BCDMA)

The Block Copy DMA is intended to perform similar functions as an Embedded DMA (EDMA) and the UDMA-P. The BCDMA module moves data from a memory mapped source address set to a corresponding memory mapped address. The BCDMA maintains state information for each of the channels which allows data copy operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

A block diagram of the Block Copy DMA Controller is shown below:

**Figure 11-2. Block Copy DMA Block Diagram**

#### 11.1.1.5.1 BCDMA Submodule Descriptions

##### 11.1.1.5.1.1 Bus Interface Unit

The Bus Interface Unit is responsible for merging and buffering all of the transactions that originate from the various controller blocks inside the DMA controller into the 4 separate VBUSM controller interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A 2 word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

##### 11.1.1.5.1.2 Config CR

The function of the Config CR is to switch transactions which arrive on the configuration interface to the various configuration targets within the DMA. The Config CR also provides a retiming buffer on the configuration bus primary interface ports.

##### 11.1.1.5.1.3 Configuration Registers

The Configuration Registers block is responsible for monitoring the fullness level of the Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Read and Write DMA units, and writing back the updated state returned from those same DMA units.

The Configuration Registers block is also responsible for providing memory mapped registers for configuration of the DMA channels.

**11.1.1.5.1.3.1 BCDMA Mapping Table**

**Table 11-3. BCDMA Mapping Table (continued)**

Total Bits	Bits	Register Offset	Field	Description
399	15	0xB0	sot	

#### 11.1.1.5.1.4 Read Unit(s)

The Read Units implement all of the state machine functionality necessary to perform the read transfers defined in the SW supplied Transfer Request records. The read DMA unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read descriptors, Transfer Request records, and payload data from memory.

#### 11.1.1.5.1.5 TR Coherency Unit

The TR Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the BCDMA unit(s) and all prior TRs have completed prior to incrementing the reverse ring occupancy for the flow/channel.

#### 11.1.1.5.1.6 Per-Copy-Channel Buffers

The Per-Copy-Channel Buffers implement a FIFO for each BCDMA generic block copy channel and is used for buffering payload data that has been fetched by read DMA unit modules. The write DMA units issue write transfers from the Per Channel Buffers to specified addresses in memory. The buffers are byte oriented on both write and read so that the data from the DMA units which may not be full words can be packed and unpacked properly. This unit is optional and is only present if one or more generic block copy channels are configured in the BCDMA instance.

#### 11.1.1.5.1.7 Tx Per-Split-Channel Buffers

The Tx Per-Split-Channel Buffers implement a FIFO for each BCDMA Tx split mode channel and is used for buffering payload data that has been fetched by read DMA unit modules. Data is transferred from the buffer to the remote peripheral via a PSI-L interface. This unit is optional and is only present if one or more Tx split mode channels are configured in the BCDMA instance.

#### 11.1.1.5.1.8 Rx Per-Split-Channel Buffers

The Rx Per-Split-Channel Buffers implement a FIFO for each BCDMA Rx split mode channel and is used for buffering payload data that has been received from remote peripherals via a PSI-L interface. Data is read from these FIFOs and written out to memory as directed by the write DMA unit modules. This unit is optional and is only present if one or more Rx split mode channels are configured in the BCDMA instance.

#### 11.1.1.5.1.9 Write Unit(s)

The Write Units implement all of the state machine functionality necessary to perform the write transfers defined in the SW supplied Transfer Request records. The write DMA unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read descriptors and/or Transfer Request records from memory mapped rings, read descriptor and Transfer Request records, and write payload data to memory.

#### 11.1.1.5.1.10 Event Coherency Unit

The Event Coherency Unit is responsible for ensuring that all writes have completed prior to signaling an output event for a channel/flow.

#### 11.1.1.5.1.11 Event Handler

The Event Handler block is responsible for generating channel completion and error events and for accepting and tracking channel triggering.

#### 11.1.1.5.2 Channel Classes

Not all channels within a DMA controller require the same performance capabilities. Raw bandwidth and latency tolerance requirements will vary greatly between data transfers at various points in the system. Due to area concerns, several different classes of DMA channels are provided in the BCDMA and are described as follows:

Class Name	Description
Normal Capacity	Provides baseline amount of descriptor and TR prefetch and Tx/Rx control and data buffering. Suitable for most peripheral transfers which are communicating with on-chip memories and DDR
High Capacity	Provides an elevated amount of descriptor and TR prefetch and custom Tx/Rx control and data buffering. Suitable for applications which require moderate per-channel bandwidth with significantly increased latency (ex. Transferring data to/from PCIe)
Ultra-High Capacity	Provides identical descriptor and TR prefetch as High Capacity but with increased Tx data buffering to allow for more read data in flight. Suitable for applications requiring high per-channel bandwidth with significantly increased latency (ex. 16+Gbps transfers to/from PCIe).

BCDMA instances may provide support for any or all of the above channel classes through design time configuration parameters.

### 11.1.2 Definition of Terms

**Host**— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.

**Channel**— A channel refers to the sub-division of information (flows) that is transported across a DMA engine. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (for example, CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). Information flow within a channel is a stream of strongly ordered information.

**Data Buffer**— A data buffer is a single data structure that contains payload information for transmission to or reception from a channel.

**Buffer Descriptor**— A buffer descriptor is a single data structure that contains information about one or more data buffers.

**Packet Descriptor**— A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. All Monolithic type descriptors are packet descriptors (and are also a Data Buffer).

**Queue**— A queue is a list of strongly ordered entries which is typically used to pass work between a producer and a consumer. Queue entries in most cases are references to a work payload which is being passed, but in some cases, (Transfer Request Packets for example) queue entries may actually contain data which is being transferred. Queues are used throughout DMA whenever communication is required between entities. Queues can have multiple different implementations and DMA uses two of the most common: linked lists and rings.

**Linked list**— A linked list is a data structure in which each entry stores not only the entry data but also a chaining pointer to the next entry in the list. The last entry in each list has its chaining pointer set to NULL (typically encoded as 0x0). The list manager maintains a pointer to the head element on the list and to the tail element on the list. Since the chaining pointer is stored with the entry data, linked lists have a length which is dynamically changeable and limited only by the ability to allocate additional entries which are to be queued/de-queued. Linked lists are present in Host Descriptors to chain multiple descriptors to form a packet.

**Ring**— A ring is a data structure in which a contiguous memory block defined by M N-byte entries (total size is M × N bytes) is statically allocated and sequentially written/read in order to pass data or data references. Rings are also referred to as circular buffers because when the last element in the contiguous memory array is written, the pointers wrap back to the beginning address for the ring and start the process all over again. The Ring Accelerator component uses rings in order to implement logical queues.

**Free Descriptor/Buffer Queue**— A free descriptor/buffer queue is a list of available descriptors with prelinked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Ring Accelerator.

**Free Descriptor Queue**— A free descriptor queue is a list of available descriptors that are not yet linked with buffers that are to be used by the receive ports for monolithic type descriptors. Free Descriptor Queues are implemented by the Ring Accelerator.

**Packet Queue**— A packet queue is a list of valid (that is, populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes. Packet Queues are implemented by the Ring Accelerator.

**Memory**— Memory is an area of data storage managed by the host. This area is visible to the port as a 64-bit addressable area.

**Device Driver**— A device driver is application independent software that runs on the host for purposes abstracting the low level hardware so that upper level software can use the hardware without knowing every bit field location or initialization sequence. General device driver functions include port initialization, transmit packet queuing, and receive packet processing.

**SOP**— Start of Packet. This refers to the descriptor/buffer that is the first buffer in a packet.

**MOP**— Middle of Packet. This refers to the descriptors/buffers that are neither the first or last buffers in a packet.

**EOP**— End of Packet. This refers to the descriptor/buffer that is the last buffer in a packet.

### 11.1.3 DMSS Hardware/Software Interface

The intent of the Data Movement architecture is to provide a uniform HW/SW interface which includes a rich set of mechanisms that SW can make use of to transfer data with low overhead and reasonable complexity. To this goal, the number of components which SW is required to interact with on an ongoing real time basis has been kept to a minimum and is as follows (in order of anticipated frequency of access):

- Interrupt Aggregator
- Packet DMA
- Block Copy DMA

When interrupts are used, the interrupt aggregator will provide the vast majority of interrupt sources from all DMA components in the system. Each non-exception/non-debug packet and TR completion signaling originates from the Interrupt Aggregator and the IA provides a uniform set of MMRs that can be queried to quickly determine the cause of a specific interrupt. Events from PSI-L/ETL components are all routed to the host via the Interrupt Aggregator.

Each PKTDMA and BCDMA instance includes an inbuilt ring control mechanism which is the primary means by which work is sent to or received from these DMAs. Each DMA instance also includes both static configuration type memory mapped registers and some real-time accessible memory mapped registers for monitoring and control of each individual channel.

Memory mapped data structures are used anytime information needs to be passed between components in the system. These components may be hardware or software. The following sections describe the data structures which are used within the DMSS for passing information. These data structures include data buffers, packet descriptors, buffer descriptors, queues (including transmit queues, transmit completion queues, and receive queues) and the configuration MMRs that are provided in the various components. The following sections provide a detailed description of these data structures.

#### 11.1.3.1 Data Buffers

A data buffer is a byte aligned contiguous block of memory used to store payload data. Each buffer is described in an entry in either a packet descriptor or in a buffer descriptor. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 64-bit memory space.

The Buffer Length field of the packet/buffer descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

#### 11.1.3.2 Descriptors

Descriptors are so named because their primary function is to describe other data structures.

The PKTDMA architecture provides for 2 basic types of descriptors whose characteristics are shown in [PKTDMA Descriptor Types and Attributes](#).

**Table 11-4. PKTDMA Descriptor Types and Attributes**

Descriptor Type	Includes Valid Packet Info	Provided # of Slots to Link In External Data	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Packet Descriptor	✓	1	✓	✓	Used to describe packet and SOP buffer in applications that require Host OS compatible data structures (i.e. applications where the descriptors and buffers cannot be managed independently but must instead be pre-linked by the Host software). These applications inherently require a separate descriptor for each buffer.
Host Buffer Descriptor		1		✓	Used to describe non-SOP buffers in applications that require Host OS compatible data structures

As the above table shows, the Host Packet Descriptor provides packet level information that is useful to both the ports and the Host in order to properly process the packet. These descriptors are referred to as Packet Descriptors and will always appear as the first descriptor within a packet.

The PKTDMA allows descriptors to be allocated on 16-byte address boundaries. This is intended to allow for better memory utilization by allowing on-chip descriptors which are not a power of 2 in length to be packed into arrays with little wasted memory space.

Even though descriptors and buffers may be allocated on any 16-byte alignment, careful consideration of the alignment effects should be made based on the storage location and any cache related affects that may exist. If data structures are placed in off-chip SDRAM the burst size and alignment restrictions of the memory devices must be considered in order to avoid performance issues related to continually fetching mis-aligned blocks. In this case, the memory efficiency can be reduced to 50% because 2 memory bank lines are read for every line sized data fetch. Similarly, placing more than one descriptor or buffer object within a single cache line can cause the adjacent object to become corrupted during cache line writeback operations.

Software/application specific control information may be added to the end of any of the packet descriptor types using as many extra words as necessary but the above alignment rules still apply.

The Block Copy DMA architecture provides a single descriptor type whose characteristics are shown in [Block Copy DMA Descriptor Types and Attributes](#).

**Table 11-5. Block Copy DMA Descriptor Types and Attributes**

Descriptor Type	Includes Valid Packet Info	Provided # of Slots to Link In External Data	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Transfer Request Packet Descriptor		0			Used to feed transfer request sequences to the BCDMA

**11.1.3.2.1 Host Packet Descriptor**

Host Packet Descriptors are designed to be used when the application requires support for true, unlimited fragment count scatter/gather type operations. The Host Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Host Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Protocol Specific Region Size
- Protocol Specific Control / Status Bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet
- Software specific information

Host Packet Descriptors always contain 48 bytes of required information and may also contain optional software specific information and protocol specific information. How much optional information (and therefore the allocated size of the descriptors) is required is application dependent.

The Host Packet descriptor layout is shown below.

**Table 11-6. Host Packet Descriptor Layout**

Packet Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)
Extended Packet Info Block (Optional) Includes Timestamp and Software Data (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Other SW Data (Optional and User Defined)

Host Packet Descriptors may be linked with zero or more additional Host Buffer Descriptors in a singly linked list fashion to form packets. Each Host Packet consists of a single Host Packet Descriptor followed by a chain of zero or more Host Buffer Descriptors linked together using the Next Descriptor Pointer fields in the descriptors. The last descriptor in a Host packet has a zero Next Descriptor Pointer.

The 'Other SW Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store completely private data. This region is not used in any way by HW components in a PKTDMA system and these modules will not modify any bytes within this region.

The contents of the Host Packet Descriptor words are detailed in [Table 11-7](#) through [Table 11-23](#)

**Table 11-7. Host Packet Descriptor Packet Information Word 0 (PD Word 0)**

Bits	Name	Description	Rx Overwrite
31:30	2'd1	64-bit Host Packet Descriptor Type Identifier	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	RESERVED	-	Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid # of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes ... 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is an error. The valid range for an exact packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information.	Yes

**Table 11-8. Host Packet Descriptor Packet Information Word 1 (PD Word 1)**

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags / information that can be assigned based on the packet type.	Yes
23:14	RESERVED	-	Yes

**Table 11-8. Host Packet Descriptor Packet Information Word 1 (PD Word 1) (continued)**

Bits	Name	Description	Rx Overwrite
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

**Table 11-9. Host Packet Descriptor Packet Information Word 2 (PD Word 2)**

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = Application specific	Yes
26:16	RESERVED	-	Yes
15:0	RESERVED	-	Yes

**Table 11-10. Host Packet Descriptor Packet Information Word 3 (PD Word 3)**

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L src_tag field bits 15:8.	Yes
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L src_tag field bits 7:0.	Yes
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L dst_tag field bits 15:8.	Yes
7:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L dst_tag field bits 7:0	Yes

**Table 11-11. Host Packet Descriptor Linking Word 0 (PD Word 4)**

Bits	Name	Description	Rx Overwrite
31:0	Next Descriptor Pointer LSB	The 32 LSBs of the 48-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero then the current buffer is the last buffer in the packet. The host sets the Next Descriptor Pointer.	No

**Table 11-12. Host Packet Descriptor Linking Word 1 (PD Word 5)**

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		No
19:16	Next Descriptor Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA initiators on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	No
15:0	Next Descriptor Pointer MSB	The 16 MSBs of the 48-bit next descriptor pointer. If a specific SoC uses less than 48 bits of address reach the width of this field may be reduced.	No

**Table 11-13. Host Packet Descriptor Buffer 0 Info Word 0 (PD Word 6)**

Bits	Name	Description	Rx Overwrite
31:0	Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. These are the 32 LSBs of the 48-bit buffer pointer. <b>THIS Value along with the MSB bits cannot be 0 or the buffer will be seen as a NULL PTR</b>	Yes

Bits	Name	Description	Rx Overwrite
31:0	Protocol Specific Data N	This field stores information which varies depending on the block and packet type.	Configurable

**11.1.3.2.2 Host Buffer Descriptor**

The Host Buffer Descriptor is identical in size and organization to a Host Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. Host Buffer Descriptors are designed to be linked onto a Host Packet Descriptor or another Host Buffer Descriptor to provide support for unlimited scatter / gather type operations. Host Buffer Descriptors provide information about a single corresponding data buffer. Every Host buffer descriptor stores the following information:

- Pointer to the first valid byte in the data buffer
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Host Buffer Descriptors always contain 48 bytes of required information. Since it is a requirement that it is possible to convert a Host descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Host Buffer Descriptors will be allocated using the same sizes as Host Packet Descriptors. The Host Buffer Descriptor layout is shown below.

**Table 11-24. Host Buffer Descriptor Layout**

Buffer Reclamation Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)

A Host Packet Descriptor and zero or more Host Buffer Descriptors may be linked together using the Next Descriptor Pointer fields to form packets. The last descriptor in a packet has a zero Next Descriptor Pointer. Each Host Buffer descriptor also points to a single data buffer.

The contents of the Host Buffer Descriptor words are detailed in : [Table 11-25](#) through [Table 11-33](#)

**Table 11-33. Host Buffer Descriptor Buffer N Info Word 2 (BD Word 8)**

Bits	Name	Description	Rx Overwrite
31:22	RESERVED		No
21:0	Buffer N Length	The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. This value will be overwritten during reception.	No

### 11.1.3.2.3 Transfer Request Descriptor

The Transfer Request Descriptor contains the following information:

- Indicator which identifies the descriptor as a TR Descriptor
- Set of one or more Transfer Request Records
- Set of one or more Transfer Response Records

Transfer Request Packet Descriptors always contain 16 bytes of required information and a variable number of Transfer Request / Transfer Response Records (request and response counts match).

The Transfer Request descriptor layout is shown below.

**Table 11-34. Transfer Request Packet Descriptor Layout**

Packet Info Given via Transfer Request Packet Descriptor Word 0-3 (16 bytes)
Null (0-102 bytes to bring start of TR request array into natural alignment for memory fetch efficiency)

**Table 11-34. Transfer Request Packet Descriptor Layout (continued)**

Array of Transfer Request Records
Array of Transfer Response Records

**Table 11-35. Transfer Request Packet Descriptor Word 0**

Bits	Name	Description	Rx Overwrite
31:30	2'd3	TR Packet Descriptor type.	No
29	RESERVED		No
28:20	Reload Count	Specifies what to do when the last entry is processed in this packet. This field specifies how many times to return to the Reload Index upon reaching the Last Entry. When an internal count is incremented to this value and the TR indicated by the Last Entry has been processed, this packet will be considered complete and the descriptor will be placed back on the return queue specified in Word 2. A value of 0x1FF indicates that a perpetual loop is desired. In this case, the loop count is considered infinite and the internal count will not be incremented. A teardown operation on the channel will cause the loop to be broken at the nearest iteration boundary.	No
19:14	Reload Index	Specifies the value to set the current processing index to when the last entry is processed and the Reload Enable is set to 1. This is basically an absolute index to jump to on the 2 <sup>nd</sup> and following passes through the TR packet.	No
13:0	Last Entry	Specifies the index of the last valid entry in this packet	No

**Table 11-36. Transfer Request Packet Descriptor Word 1**

Bits	Name	Description	Rx Overwrite
31:28	RESERVED	-	No
27	RESERVED		No

**Table 11-36. Transfer Request Packet Descriptor Word 1 (continued)**

Bits	Name	Description	Rx Overwrite
26:24	Transfer Request Nominal Element Size	Specifies the stride between TR entries. The value in this field must be set large enough that any TR in the buffer will fit within the given dimension. TRs are expected to be placed on boundaries as given in this dimension. This field is also used to calculate the location where the Transfer Responses will be written back. This field is encoded as follows: 0 = 16-byte Transfer Request record size 1 = 32-byte Transfer Request record size 2 = 64-byte Transfer Request record size 3 = 128-byte Transfer Request record size 4-7 = RESERVED	No
23:14	RESERVED	-	No
13:0	RESERVED	-	No

**Table 11-37. Transfer Request Packet Descriptor Word 2**

Bits	Name	Description	Rx Overwrite
31:17	RESERVED		Yes
16	RESERVED	-	Yes
15:0	RESERVED	-	Yes

**Table 11-38. Transfer Request Packet Descriptor Word 3**

Bits	Name	Description	Rx Overwrite

15:0	RESERVED	-	No

**Table 11-39. Transfer Request Packet Descriptor Payload Words 0-N**

Bits	Name	Description	Rx Overwrite
31:0	Transfer Control Record Array	Transfer Control Records. This is an array of records which encapsulate the Transfer Request and Transfer Response messages which are used by the BCDMA	Yes (partial)

### 11.1.3.3 Transfer Request Record

#### 11.1.3.3.1 Overview

This section describes the standard transfer request (TR) format to initiate a DMA transfer. The TRs can support both half and full duplex with multiple dimensions. Each TR will also generate a TR response. A TR can be sent to the BCDMA either through a TR descriptor using a pass-by-reference ring or as a Direct TR submission using a pass-by-value ring.

**Table 11-40. Terms and Definitions**

Term	Definition
TR	A transfer request to move data.
CR	A cache operation request. A request to send messages to a specified cache controller to prepare the cache for a future operation.

#### 11.1.3.3.2 Addressing Algorithm

For a basic TR request the same algorithm is used. The innermost loop always consumes physically contiguous elements from memory. Its implicit dimension is 1 byte. The pointer itself moves from fetch to fetch on the maximum byte alignments specified for the BCDMA, in increasing order. In each level outside the inner loop, the loop moves the pointer to a new location based on the size of that loop level's dimension.

##### 11.1.3.3.2.1 Linear Addressing (Forward)

The following code illustrates the basic algorithm for a 4-level loop nest block move. This model assumes that it transfers data 1 byte at a time and the input and output block are the same size in all dimensions.

```
// sptr is a byte pointer.
// dptr is a byte pointer.
// Source address is indirect
if (TR_ISA) {
    sptr = *sptr;
}
// Destination address is indirect
if (TR_IDA) {
    dptr = *dptr;
}
// TR_TRIGX can be selected to come from Global events, Local event, or none.
// Check for trigger of TYPE0
if (TR_TRIG0_TYPE == TYPE0) while(!TR_TRIG0);
if (TR_TRIG1_TYPE == TYPE0) while(!TR_TRIG1);
for (i3 = 0; i3 < ICNT3; i3++)
{
    sptr3 = sptr; // save current position before entering next level
    dptr3 = dptr; // save current position before entering next level
    // Check for trigger of TYPE1
    if (TR_TRIG0_TYPE == TYPE1) while(!TR_TRIG0);
    if (TR_TRIG1_TYPE == TYPE1) while(!TR_TRIG1);
    for (i2 = 0; i2 < ICNT2; i2++) {
        sptr2 = sptr; // save current position before entering next level
        dptr2 = dptr; // save current position before entering next level
        // Check for trigger of TYPE2
        if (TR_TRIG0_TYPE == TYPE2) while(!TR_TRIG0);
        if (TR_TRIG1_TYPE == TYPE2) while(!TR_TRIG1);
        for (i1 = 0; i1 < ICNT1; i1++) {
            sptr1 = sptr; // save current position before entering next level
            dptr1 = dptr; // save current position before entering next level
            // Check for trigger of TYPE3
            if (TR_TRIG0_TYPE == TYPE3) while(!TR_TRIG0);
            if (TR_TRIG1_TYPE == TYPE3) while(!TR_TRIG1);
            for (i0 = 0; i0 < ICNT0; i0++) {
                // BCDMA can combine these in optimized burst aligned accesses.
                *dptr = *sptr;
                sptr = sptr++;
                dptr = dptr++;
            }
            // Update based on saved pointer for this level
            sptr = sptr1 + SDIM1;
        }
    }
}
```

```

        dptr = dptr1 + DDIM1;
    }
    // Update based on saved pointer for this level
    sptr = sptr2 + SDIM2;
    dptr = dptr1 + DDIM2;
}

```

This form of addressing allows programs to specify regular paths through memory in a small number of parameters. Additionally, it allows for various stall points through the loop to allow for hardware or software induced pausing of the transfer. The following section defines these parameters in detail.

### 11.1.3.3.3 Transfer Request Formats

The BCDMA defines a four-level loop nest for addressing elements within the TR, using the algorithms described in the Addressing algorithm. Most of the fields in the TR template map directly to the parameters in those algorithms.

**Table 11-41. Transfer Request Fields**

Field Name	Description	Size
<b>FLAGS</b>	TR flags that specify type of TR and how the TR should be handled. It also supports the TR triggering and output events.	32 bits
<b>ICNT0</b>	Total loop iteration count for level 0 (innermost)	16 bits
<b>ICNT1</b>	Total loop iteration count for level 1	16 bits
<b>ADDR</b>	Starting address for the source data or destination data if it is a half-duplex write.	64 bits
<b>DIM1</b>	Signed dimension for loop level 1 for the source data	32 bits
<b>ICNT2</b>	Total loop iteration count for level 2	16 bits
<b>ICNT3</b>	Total loop iteration count for level 3 (outermost)	16 bits
<b>DIM2</b>	Signed dimension for loop level 2	32 bits
<b>DIM3</b>	Signed dimension for loop level 3	32 bits
<b>DDIM1</b>	Signed dimension for loop level 1 for the destination data	32 bits
<b>DADDR</b>	Starting address for the destination of the data	64 bits
<b>DDIM2</b>	Signed dimension for loop level 2 for the destination data	32 bits
<b>DDIM3</b>	Signed dimension for loop level 3 for the destination data	32 bits
<b>DICNT0</b>	Total loop iteration count for level 0 (innermost) used for destination	16 bits
<b>DICNT1</b>	Total loop iteration count for level 1 used for destination	16 bits
<b>DICNT2</b>	Total loop iteration count for level 2 used for destination	16 bits

**Table 11-41. Transfer Request Fields (continued)**

Field Name	Description	Size
<b>DICNT3</b>	Total loop iteration count for level 3 used for destination	16 bits

The TR assumes all iteration counts as unsigned integers, and all dimensions as signed integers representing byte offsets.

The template above fully specifies the type of elements, length, and dimensions of the transfer.

Since all transfers will not require all the fields the TRs have the type field which allow the number of words required to be sent for the TR to be reduced.

#### 11.1.3.3.4 Flags Field Definition

The next diagram expands the 32-bit FLAGS field. The numbers above each field here indicate bit numbers within the field.

**Table 11-42. Transfer Request Template FLAGS Field**

31	24	23	16
CONFIGURATION SPECIFIC FLAGS			
Reserved			
15	8	7	5 4 3 0
TRIGGER_SIZE1	TRIGGER1	TRIGGER_SIZE0	TRIGGER0
EVENT_SIZE	WAIT	STATUS	TYPE

The flags field fills in the remaining details about the stream, as follows:

**Table 11-43. FLAGS Field Descriptions**

Bit	Field	Description
<b>0-3</b>	<b>TYPE</b>	The TYPE of TR that is being sent 0: One dimensional data move 1: Two dimensional data move 2: Three dimensional data move 3: Four dimensional data move 4: Four dimensional data move with data formatting 5: Four dimensional Cache Warm 6-7: Reserved 8: Four Dimensional Block Move 9: Four Dimensional Block Move with Repacking 10: Two Dimensional Block Move 11: Two Dimensional Block Move with Repacking 12-14: Reserved 15 Four Dimensional Block Move with Repacking and Indirection
<b>4</b>	Reserved	Reserved for Future use.

**Table 11-43. FLAGS Field Descriptions (continued)**

Bit	Field	Description
5	WAIT	<p>This field is only valid on Type 15 TRs.</p> <p>This field indicates whether or not this TR should ensure it completes before allowing the next TR to start on this channel. The encoding is as follows:</p> <p>0 = Allow next TR to start immediately</p> <p>1 = Wait for this TR to complete before allowing next TR to start</p> <p>When set, the next TR will not be considered triggered (regardless of any other trigger conditions) until all write status responses for the current TR have landed.</p>
6-7	EVENT_SIZE	<p>This is how often the TR will generate an output event.</p> <p>0: Event is only generated with the TR is complete</p> <p>1: Event is generated when the second inner most loop (ICNT1) is decremented by 1.</p> <p>2: Event is generated when the third inner most loop (ICNT2) is decremented by 1.</p> <p>3: Event is generated when the outer most loop (ICNT3) is decremented by 1.</p>
8-9	TRIGGER0	<p>This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER0_TYPE Field.</p> <p>0: No Trigger</p> <p>1: Global Trigger 0 for the channel</p> <p>2: Global Trigger 1 for the channel</p> <p>3: Local Event for the channel</p>
10-11	TRIGGER0_TYPE	<p>This is the type of data transfer that will be enabled by receiving a trigger.</p> <p>0: The second inner most loop (ICNT1) will be decremented by 1.</p> <p>1: The third inner most loop (ICNT2) will be decremented by 1.</p> <p>2: The outer most loop (ICNT3) will be decremented by 1.</p> <p>3: The entire TR will be allowed to complete.</p>
12-13	TRIGGER1	<p>This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER1_TYPE Field.</p> <p>0: No Trigger</p> <p>1: Global Trigger 0 for the channel</p> <p>2: Global Trigger 1 for the channel</p> <p>3: Local Event for the channel</p> <p>This field is reserved for a Direct TR.</p>

**Table 11-43. FLAGS Field Descriptions (continued)**

Bit	Field	Description
14-15	TRIGGER1_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
16-23	Reserved	Reserved for Future use.
24-31	Configuration Specific Flags	These are flag bits that can be specified by the specific BCDMA configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific BCDMA implementation.

The following sections expand on each of these fields.

#### 11.1.3.3.4.1 Type: TR Type Field

The TR Type field gives the size of the TR and which fields are expected in the TR. Based on the type the number of words required to be sent to complete the TR can be decreased. The tables below show the minimum size for each TR as well if any fields will be treated as reserved.

**Table 11-44. Transfer Request Minimum Size Type 0 One Dimensional Transfer**

word 0	word 1	word 2	word 3	word 4	word 5	word 6	word 7	word 8	word 9	word 10	word 11	word 12	word 13	word 14	word 15
FLAGS	ICNT0	ADDR	RESERVED/NOT REQUIRED

#### 11.1.3.3.4.2 EVENT\_SIZE: Event Generation Definition

The BCDMA allows for an event to be generated at specified intervals for each TR. As the TR passes through the various loops in the addressing algorithm it will generate an event that then can be routed to other event receivers, such as other channels or interrupts to processors.

**Table 11-49. Event Size Encoding**

Value	Event Type	When it Fires
0	Completion Event	When the TR is complete and all status for the TR has been received.
1	ICNT1 Decrement	Type 0: When the last data transaction is sent for the TR. Type 1-11: When ICNT1 is decremented
2	ICNT2 Decrement	Type 0 – 1,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT2 is decremented
3	ICNT3 Decrement	Type 0 – 2,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT3 is decremented

#### 11.1.3.3.4.3 TRIGGER\_INFO: TR Triggers

The TR allows for two different triggers to be set to allow for the data transfer to be prevented or halted through the process of transferring the data. The triggers are specified by selecting a type of trigger and the size of the transfer that can be allowed for the receipt of a given trigger. The triggers themselves in the BCDMA are collected on a per channel basis and for each of three sources. Anytime the trigger event is received the internal counter is incremented. The trigger event will not be cleared until the specified block has started its transfer and it will **only** clear the triggers that are active.

#### CAUTION

This does allow for one TR in the channel to use global event 0 and the next TR to use global event 1. If while the first TR is running global event 0 can increment and will decrement each time the TR reaches the specified level. At the same time global event 1 will be incremented whenever it is received but it will not decrement until the next TR runs. If the global event 1 counter reaches overflows then an error event will NOT be generated but the event will be lost.

#### 11.1.3.3.4.4 TRIGGERX\_TYPE: Trigger Type

The trigger type sets the value of TR\_TRIGX as shown in the addressing algorithm description. The TR\_TRIGX value allows for the temporary halting of the TR until the expected event has been received. After the given loop has been entered the selected trigger will be decremented.

#### 11.1.3.3.4.5 TRIGGERX: Trigger Selection

The TR is able to select up to 2 of 3 trigger sources for a given TR. The events can come from the dedicated local event on the BCDMA itself or from two assigned global events that come from the PSI-L interface on the BCDMA. The trigger counters are always enabled so that events can be received prior to the TR getting loaded. The trigger counters are only decremented when the trigger is active and the TR has scheduled the first transfer of the transaction.

#### 11.1.3.3.4.6 Configuration Specific Flags Definition

The configuration specific flags are specific to a given TR type. If a TR type does not require additional flags the field should be filled with 0's. Currently only Types 0-4 and Type 15 support the following configuration specific flags:

Bit	Field	Description
0	ISA	Indirect Source Address 0: Source address in TR is a directly usable pointer to the data 1: Source address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
1	IDA	Indirect Destination Address 0: Destination address in TR is a directly usable pointer to the data 1: Destination address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
2	SUPR_EVT	Suppress Event Output: 0 = Output events will be generated according to FLAGS.EVENT_SIZE field 1 = No output events will be generated for the duration of this TR execution This field is only valid on split and type 15 TRs (Type 0-3, 15)
3	Reserved	Reserved for Future use.

Bit	Field	Description
6:4	EOL	<p>This field is only valid on split TRs (Type 0-3). On source (Read) split TRs, this field specifies whether or not the EOL delimiters should be produced on the Tx PSI-L bus. The encodings of this field for source split TRs is as follows:</p> <ul style="list-style-type: none"> <li>0 = SOL/EOL match SOP/EOP</li> <li>1 = SOL/EOL boundaries are each ICNT0 bytes</li> <li>2 = SOL/EOL boundaries are each ICNT0*ICNT1 bytes</li> <li>3 = SOL/EOL boundaries are each ICNT0*ICNT1*ICNT2 bytes</li> <li>4 = SOL/EOL boundaries are each ICNT0*ICNT1*ICNT2*ICNT3 bytes</li> </ul> <p>On destination (Write) split TRs, this field specifies how to handle EOL delimiters when they are encountered on the Rx (write) side of a TR. EOL delimiters can be produced from the Tx (read) side of a block copy operation or from a remotely paired peripheral when operating in split TR mode. The encodings of this field are as follows:</p> <ul style="list-style-type: none"> <li>0: Ignore EOL</li> <li>1: Line length is icnt0 bytes. Clear any remaining ICNT0 bytes and increment ICNT1 by 1</li> <li>2: Line length is icnt0*icnt1 bytes. Clear any remaining ICNT0/1 bytes and increment ICNT2 by 1</li> <li>3: Line length is icnt0*icnt1*icnt2 bytes. Clear any remaining ICNT0/1/2 bytes and increment ICNT3 by 1</li> <li>4: Line length is icnt0*icnt1*icnt2*icnt3 bytes. Move on to next TR</li> <li>5-7: RESERVED</li> </ul>
7	EOP	<p>This TR should generate an EOP on the streaming interface for any downstream packet oriented consumers to denote that a 'packet' of data is complete</p> <ul style="list-style-type: none"> <li>0: No EOP flag will accompany the last PSI-L data phase associated with transfers from this TR</li> <li>1: On egress the DMA will set the EOP flag coincident with transferring the last of the data for this TR. If the TR data does not complete an entire PSI-L data phase then the remaining bytes in the data phase will be skipped and the internal FIFO pointer will be updated to begin packing new data on a new data phase boundary.</li> </ul>

#### 11.1.3.3.5 TR Address and Size Attributes

The fields described below all describe the data transfer that needs to be made as described in the Linear Memory Addressing Block Move Algorithm.

##### 11.1.3.3.5.1 ICNT0

The ICNT0 is the number of elements to transfer in the inner loop of the TR. If the TR type does not contain a FMTFLAGS field then this count is assumed to be the number of bytes to transfer. If the FMTFLAGS field is included in the types then the number of bytes to be transferred will be ICNT0 times the Element size rounded up to the nearest byte.

##### 11.1.3.3.5.2 ICNT1

The ICNT1 field is the loop count for the second innermost loop count as defined in the Addressing algorithm.

##### 11.1.3.3.5.3 ADDR

The address location is the initial address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register.

While the ADDR field is 64 bits wide, the usable extent of the address is up to 48 bits of absolute offset plus a 4-bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the ADDR field is given as follows:

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA initiators on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit source or source starting address for the transfer. This address is assumed to be a physical address.  The actual width implemented for the address field on any given DMA instance may be adjusted to the needs of each specific KSLC SoC. 48 bits is just the maximum size which is envisioned to be supported. Some systems may have address widths as low as 32 or 36 bits. The HW implementation may choose to provide address width configurability in order to reduce costs.

##### 11.1.3.3.5.4 DIM1

This is the offset of the address from the initial address for the first access of the second loop. This will be added to the address from the loop before. This is a signed value so that the address can be both above and below the initial address.

#### 11.1.3.3.5.5 ICNT2

This is the count for the third innermost loop in the addressing algorithm.

#### 11.1.3.3.5.6 ICNT3

This is the count for the outermost loop in the addressing.

#### 11.1.3.3.5.7 DIM2

This is the offset of the address from the initial address to the next address in the third innermost loop. This is a signed value so that the address can be both above and below the previous address.

#### 11.1.3.3.5.8 DIM3

This is the offset of the address from the initial address to the next address in the outermost loop. This is a signed value so that the address can be both above and below the previous address.

#### 11.1.3.3.5.9 DDIM1

This is the offset of the destination address from the initial destination address for the first access of the second loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

#### 11.1.3.3.5.10 DADDR

The destination address location is the initial destination address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register

While the DADDR field is 64 bits wide, the usable extent of the address on a KSLC system is up to 48 bits of absolute offset plus a 4 bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the DADDR field is given as follows:

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA initiators on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit starting destination address for the transfer. This address is assumed to be a physical address. The actual width implemented for the address field on any given DMA instance may be adjusted to the needs of each specific KSLC SoC. 48 bits is just the maximum size which is envisioned to be supported. Some systems may have address widths as low as 32 or 36 bits. The HW implementation may choose to provide address width configurability in order to reduce costs.

#### 11.1.3.3.5.11 DDIM2

This is the offset of the destination address from the initial destination address for the first access of the third loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

#### 11.1.3.3.5.12 DDIM3

This is the offset of the destination address from the initial destination address for the first access of the outer loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

#### 11.1.3.3.5.13 DICNT0

This is the number of elements to use in the destination if the TR is repacking the data. This number reflects the number of elements to be transferred.

#### 11.1.3.3.5.14 DICNT1

This is the number of times to execute the second loop to use in the destination transfer.

#### 11.1.3.3.5.15 DICNT2

This is the number of times to execute the third loop to use in the destination transfer.

#### 11.1.3.3.5.16 DICNT3

This is the number of times to execute the fourth loop to use in the destination transfer. The value of DICNT0 x DICNT1 x DICNT2 x DICNT3 must equal ICNT0 x ICNT1 x ICNT2 x ICNT3. If any of the values are zero they are NOT included in the multiplication.

### 11.1.3.4 Transfer Response Record

Upon completing a TR, the BCDMA will send back a TR Response. The BCDMA TR response format is a single 32 bit word as shown in the [Table 11-51](#) below.

**Table 11-50. Transfer Request Response Template STATUS FLAGS Field**

31	24	23	16
CONFIGURATION SPECIFIC STATUS		RESERVED	
15	8	7	0
RESERVED		STATUS_INFO	STATUS_TYPE

**Table 11-51. STATUS FLAGS Field Descriptions**

Bit	Field	Description
3:0	STATUS_TYPE	The completion status of the TR.
7:4	STATUS_INFO	Information that is unique based on the STATUS_TYPE returned
15:8	Reserved	Reserved for Future use
23:16	Reserved	Reserved for Future use

**Table 11-51. STATUS FLAGS Field Descriptions (continued)**

Bit	Field	Description
31:24	Configuration Specific Flags	<p>These are flag bits that can be specified by the specific BCDMA configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific BCDMA implementation.</p> <p>For BCDMA channels which are capable of interfacing to endpoint peripherals (or via a PDMA) the format of these flags are as follows:</p> <p>31:28 error_flags – the error_flags field as is provided across PSI-L</p> <p>27:24 ps_flags – the ps_flags field as is provided across PSI-L</p>

**11.1.3.4.1 STATUS Field Definition**

The Status field is made up of two sub-fields STATUS\_TYPE and STATUS\_INFO. A value of 0 means it completed as requested any other value means an error has occurred. The Table below states the legal STATUS\_TYPES and the use of the STATUS\_INFO in each case.

**11.1.3.4.1.1 STATUS\_TYPE Definitions**

The STATUS\_TYPE field is used to determine what type of status is being returned. Depending on the type of Status it might additionally have information in the STATUS\_INFO to give more details about the specific reason why the status was returned.

**Table 11-52. STATUS\_TYPE Encoded Values**

Value	Error Type	Completion	STATUS INFO Definition
0	None	Complete	None
1	Transfer Error	None to Partial	CBA Non-Complete Status Received
2	Aborted Error	None to Partial	None
3	Submission Error	None	Submission Error Type
4	Unsupported Feature	None	Feature Type
5	Transfer Exception	Partial	Exception Type
6	Teardown Flush	None	None
7-15	Reserved	Unknown	Reserved

**11.1.3.4.1.1.1 Transfer Error**

A transfer error occurs anytime that one of the CBA transactions performed by the BCDMA returns a status other than complete. The BCDMA may continue the transfer or may abort the transfer and return back to an IDLE state. Once the transfer is finished (aborted or complete) the BCDMA will send back the TR Response with the STATUS TYPE of Transfer Error. The STATUS INFO will contain the 3 bit CBA Status field the upper bit specifies if it was a read status (1) or a write status (0).

**11.1.3.4.1.1.2 Aborted Error**

An aborted error occurs if the PSI-L interface asserts the drop signal prior to the completion of the TR. The BCDMA will return back to an IDLE state and send back the TR Response with the STATUS TYPE. If the

BCDMA receives a transfer error after receiving the abort the transfer error should be reported instead of the abort error.

#### 11.1.3.4.1.1.3 Submission Error

A submission error is returned for a TR that is received that cannot be run. The STATUS\_INFO field specifies the type of submission errors.

**Table 11-53. Submission Error STATUS\_INFO Encodings**

Value	Submission Error Type
0	ICNT0 was 0
1	Channel FIFO was full when TR received
2	Channel is not owned by the submitter. Either CC submitting to Direct or Direct submitting to a CC channel
3	Reserved
4	Reserved
5	Bad descriptor type
6-15	Reserved

#### 11.1.3.4.1.1.4 Unsupported Feature

An unsupported feature error is returned for a TR that is received that cannot be run because it specifies a feature that is optional and not supported by the BCDMA that received the TR. The STATUS\_INFO specifies the feature that was not supported. If it specifies multiple features that were not supported the BCDMA implementation can determine which type it wants to return.

**Table 11-54. Unsupported Feature STATUS\_INFO Encodings**

Value	Submission Error Type
0	TR Type not supported
1	STATIC not supported
2	EOL not supported
3	CONFIGURATION SPECIFIC not supported
4	AMODE not supported
5	ELTYPE not supported
6	DFMT not supported
7	SECTR not supported
8	AMODE SPECIFIC Field not supported
9-15	Reserved

#### 11.1.3.4.1.1.5 Transfer Exception

A transfer exception is returned for a TR that completed but experienced a known exception during reception. The STATUS\_INFO field specifies the type of transfer exception that was encountered.

**Table 11-55. Transfer Exception STATUS\_INFO Encodings**

Value	Transfer Exception Type
0	EOP on incoming data stream was encountered prematurely (short packet)
1	EOP on incoming data stream was encountered late (long packet)

**Table 11-55. Transfer Exception STATUS\_INFO Encodings (continued)**

Value	Transfer Exception Type
2-15	Reserved

#### 11.1.3.4.1.1.6 Teardown Flush

Split mode BCDMA Rx channels (write channels) can respond with a teardown flush in the case that they have received a teardown message, all data has been transferred, and TRs have been prefetched (in anticipation of more data being received). In this case, the BCDMA will simply return the prefetched TR to the completion queue with the status type set to teardown flush.

#### 11.1.3.5 Channels

Each DMA controller instance contains one or more channels. A channel represents a single thread of strongly ordered operations whose purpose is to move data from one interface to another. Operations between channels are orthogonal and have no assumption of ordering but operations within a channel must be completed in order. The DMA controller uses time division multiplexing to allow work from channels to momentarily use shared data transfer units and data paths.

#### 11.1.3.6 Flows

Each DMA channel will provide one or more flows which allow communication with one or more SW hosts. Each flow contains a single queue pair implemented within a shared circular buffer (ring) in memory. One queue provides uni-directional communication from SW to the DMA while the other queue provides uni-directional communication from the DMA back to SW. Flows are intended to allow traffic which is produced or consumed by a different Host SW process or traffic which is on different priorities to share a single physical DMA channel. A DMA channel will perform time division multiplexing between flows on specific work boundaries. Once a channel is in work on a specific flow, that entire unit of work will be completed before allowing work from a different flow to begin.

#### 11.1.3.7 Queues

Queues are used to hold either values or references that need to be passed between SW and HW components in the system. Queues are implemented in the PKTDMA and BCDMA modules using memory mapped rings. Each ring is comprised of a single contiguous memory block which contains an array of elements. Each element is 8 bytes. The size of the ring is selectable from 1 entry up to 64K entries with single entry granularity. Each ring is used to implement a forward and a reverse queue which share the same data elements but which have independent pointers and occupancies. The forward queue is used to pass work from SW to HW and the reverse queue is used to pass completed work back from HW to SW. A doorbell MMR is provided per ring to allow SW to add elements to the forward queue. A separate doorbell MMR is provided per ring to allow SW to acknowledge the popping of elements from the reverse queue. An occupancy MMR is provided for the reverse queue so that SW can know how many entries are currently completed. Entries are returned on the reverse queue in the exact same order and in the exact same index as the work was provided on the forward queue and because of this, the DMA controllers do not actually modify the ring entry for completion operations (the only exception being for acknowledgement of a teardown operation). Completion is indicated by incrementing of the reverse occupancy only.

#### 11.1.3.7.1 Queue Types

##### 11.1.3.7.1.1 Transmit Queues

Tx channels use packet queues referred to as “transmit queues” to store the packets that are waiting to be transmitted. Tx Queues only pass a pointer to a descriptor. For the PKTDMA, Tx Queues contain pointers to Host descriptors. For the BCDMA, Tx Queues contain a pointer to a TR packet descriptor. Transmit Queues are implemented as the forward queue on the shared ring structure for a Tx flow.

#### 11.1.3.7.1.2 Transmit Completion Queues

Tx channels also use packet queues referred to as “transmit completion queues” to return packets to the host after they are transmitted. A Tx Completion Queue is provided for each Tx Queue. The DMA controllers do not actually write anything back to completion queues (except for a teardown acknowledgement) but instead just increment the reverse occupancy. Transmit completion queues are implemented as the reverse queue on the shared ring structure for a Tx flow.

#### 11.1.3.7.1.3 Free Descriptor / Buffer Queues

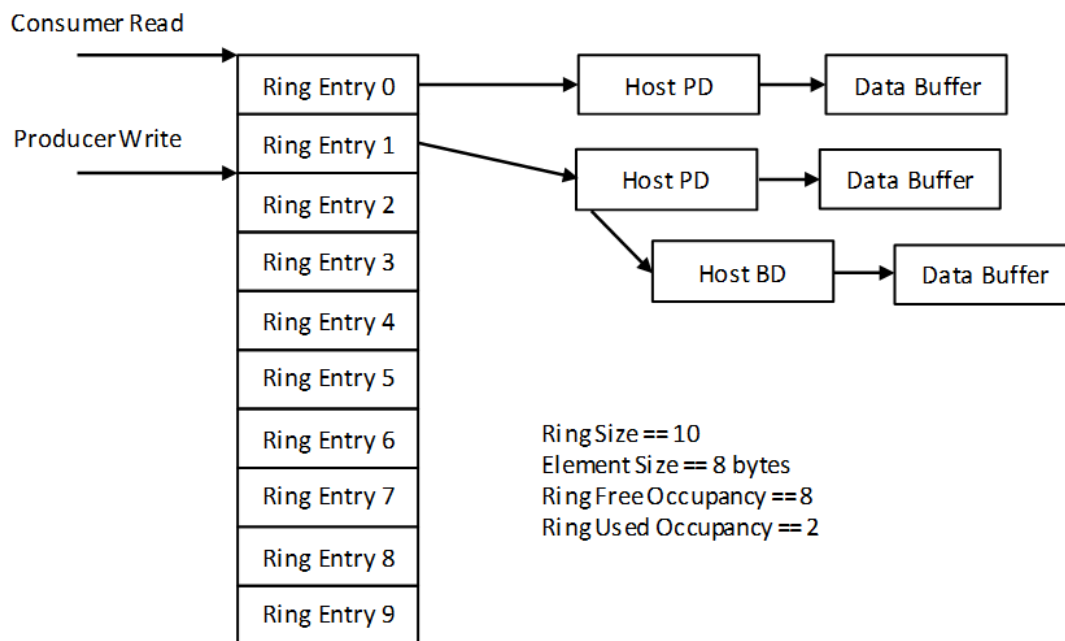

Free descriptor/buffer queues pass an empty list of pre-chained descriptors, each pointing to a single buffer, from SW to the DMA to use for receiving incoming packets. Free Descriptor/Buffer Queues are implemented as the forward queue on the shared ring structure for an Rx flow.

#### 11.1.3.7.1.4 Receive Queues

Rx queues pass a packet which has been received from the DMA back to the SW. Receive queues are implemented as the reverse queue on the shared ring structure for an Rx flow.

#### 11.1.3.7.1.5 Ring Based Queues Implementation

Work packets which are stored in a queue are shown in the following diagram:

**Figure 11-3. Ring Based Queue Structure**

### 11.1.4 Operational Description

#### 11.1.4.1 Resource Allocation

Rings, memory, interrupts, DMA channels, and flow table entries are shared resources within the data movement architecture and their ownership and use must be managed in order to provide stable, safe, and secure operation. The DMSS provides channelized firewalls which can be used to protect arrayed resources (like rings, channel control MMRs, etc.) from unwanted/unauthorized use as well as restricted access to the firewall configurations themselves. It is outside the scope of this document to define how the resource management system functions but it is assumed that all of these resources are isolate-able and secure-able.

### 11.1.4.2 PKTDMA/BCDMA - Ring Operation

#### 11.1.4.2.1 Queue Initialization

The base address and size for each ring must be initialized via the provided MMRs prior to using the ring. Ring initialization is typically done only on channel / flow setup as once initialized the rings can be used indefinitely.

#### 11.1.4.2.2 Queueing Entries

Entries can only be queued by SW onto the forward queue of a ring. To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor or a TR) to the memory location pointed to by the current write pointer and will decrement its internally maintained free entry occupancy. After the producer has confirmed that the data has actually landed in memory, it will then write to the forward doorbell register (RINGRT[a]\_RT\_FDB) for the ring to increment the pending forward occupancy count for the ring.

More than one entry can be queued with a single doorbell write as the entry count in the doorbell write indicates how many entries have been queued.

#### 11.1.4.2.3 De-queueing Entries

Entries can only be de-queued by SW from the reverse queue of a ring. The consumer (entity which is going to de-queue an entry from the ring) maintains a current read pointer for each ring it controls. To de-queue an entry the consumer will read the occupancy from the reverse occupancy register (RINGRT[a]\_RT\_ROCC) and will then read the entry contents from the memory location pointed to by the current read pointer. The consumer will then write a decrement value to the reverse doorbell register (RINGRT[a]\_RT\_ROCC) for the ring to decrement the waiting occupancy count for the reverse queue within the ring and will increment its internally maintained free entry occupancy for the ring.

### 11.1.4.3 PKTDMA/BCDMA - Output Event Generation

Each channel and flow within a DMA has the ability to generate specific types of events which can be routed to the IA in the system and from there re-routed to any event consumer. Events are output from the DMA controllers using a simple integer encoding. Up to 4 events can be generated from any given channel but only event types which have functional value are supported on each specific type of channel. The DMA channel event types are listed as follows:

**Table 11-56. Per-Channel/Flow Event Support and Encoding**

Name	Description	Per	BCDMA BC	BCDMA Tx	BCDMA Rx	PKTDMA Tx	PKTDMA Rx
Ring Entry Zero/Non-zero	Asserts an up event anytime the ring transitions to a non-zero occupancy / teardown state. Asserts a down event anytime the ring transitions to a zero occupancy / teardown state.	Flow	X	X	X	X	X

**Table 11-56. Per-Channel/Flow Event Support and Encoding (continued)**

Name	Description	Per	BCDMA BC	BCDMA Tx	BCDMA Rx	PKTDMA Tx	PKTDMA Rx
Channel Error	Asserts an up event anytime an error occurs on the channel. Asserts a down event when the channel error bit is cleared.	Channel	First flow in channel only	First flow in channel only	First flow in channel only	First flow in channel only	First flow in channel only
Rx Starvation	Asserts an up event when starvation occurs on a flow. Asserts a down event when entries are added to the ring for that flow.	Flow					First flow in channel only
RX Flow FW Error	Asserts an up event when a flow id arrives on the RX interface that is not between the flowid_start and flowid_end values for the channel. Asserts a down event when the RX Flow ID Firewall Status Register pend bit is cleared	Pktdma					X
Data Events	Asserts an up event when the selected loop counter has decremented. If the suppress event bit is not set in the TR	Channel	X	X	X		

Each BCDMA/PKTDMA instance will provide an event transport-lane (ETL) interface to pass outgoing events. The index field on this ETL will be calculated based on the event type and channel or flow offset. Each PKTDMA or BCDMA instance is configured with base values to which a channel or flow index is added for each type of event which can be generated. These base index values are listed in the specification for that specific instantiation of each DMA and are named as follows:

**Table 11-57. BCDMA/PKTDMA Event Base Index Parameters**

DMA	Event Base Parameter Name	Function	Offset
PKTDMA	tcomp_evtbase	Base index for Tx flow reverse ring completion events	Tx flow number
	rcomp_evtbase	Base index for Rx flow reverse ring completion events	Rx flow number
	terr_evtbase	Base index for Tx channel error events	Tx channel number
	rerr_evtbase	Base index for Rx channel error events	Rx channel number
	rstarve_evtbase	Base index for Rx flow starvation events	Rx flow number
	rflowfw_evtbase	Base index for Rx Flow Firewall event	None
BCDMA	tcomp_evtbase	Base index for split Tx flow reverse ring completion events	Tx flow number
	rcomp_evtbase	Base index for split Rx flow reverse ring completion events	Rx flow number
	bcomp_evtbase	Base index for normal Block Copy flow reverse ring completion events	BC flow number
	terr_evtbase	Base index for split Tx channel error events	Tx channel number
	rerr_evtbase	Base index for split Rx channel error events	Rx channel number
	berr_evtbase	Base index for normal Block Copy channel error events	BC channel number
	tdcomp_evtbase	Base index for Tx channel TR data completion events	Tx channel number
	rdcomp_evtbase	Base index for Rx channel TR data completion events	Tx channel number
	bdcomp_evtbase	Base index for Block Copy channel TR data completion events	BC channel number

**Example:**

The producer event map is set up so that the Tx flows from a PKTDMA instance are to start at 64 and proceed upward from there. The tcomp\_evtbase for that PKTDMA instance is set to 64. In this configuration, the reverse ring entry completion event for flow 0 will produce an event on index 64, flow 1 will produce an event on index 65, etc. The terr\_evtbase for the same PKTDMA instance is set to 128. In this configuration, error events for channel 2 would produce events with an index of 130.

**11.1.4.4 PKTDMA - Transmit Channel Setup**

This section describes the setup procedure for Tx channels within the PKTDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by configuring all of the Tx flow entries for the channel and then writing to the Tx Channel Configuration Register A (TCHAN[a]\_TCFG). The Host may choose to write

the enable bit in the Tx Channel Configuration Register A (TCHAN[a]\_TCFG) at the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

#### 11.1.4.5 PKTDMA - Transmit Channel Pause

Setting the tx\_pause bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]\_TRT\_CTL > [29] TX\_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source).

#### 11.1.4.6 PKTDMA - Transmit Channel Teardown

This section describes the teardown procedure for internal Tx channels within the PKTDMA. A Tx channel teardown is initiated by the host by writing the tx\_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]\_TRT\_CTL > [30] TX\_TEARDOWN).

Once the host has written the tx\_teardown bit, the PKTDMA will do the following:

1. Stops performing any additional descriptor fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR fetch has already been performed.
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Global Configuration Register (<TCHANRT[a]\_TRT\_CTL> [31] TX\_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) to indicate that a teardown has completed.
7. If the current Tx reverse ring occupancy is 0, issues an Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current TX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The Host can determine that a teardown is complete by using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) for the channel.

#### 11.1.4.7 PKTDMA - Transmit Operation

After a channel has been set up it can begin to be used to transmit packets. Packet transmission involves the following steps:

1. The Host is made aware of one or more chunks of data in memory that need to be transmitted as a packet. This may involve directly sourcing data from the Host or it may involve data which has been forwarded from another data source in the system.
2. The Host allocates and populates a host packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to Host).

- b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
  - c. Source Tag.
  - d. Destination Tag.
  - e. Packet Type.
  - f. Any protocol specific flags for the given packet type.
  - g. Buffer Pointer with the byte aligned address of the first chunk of buffer data.
  - h. Buffer Length with the number of bytes in the first chunk of buffer data.
  - i. The Next Descriptor Pointer with the 16-byte aligned address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero.
  - j. Any protocol specific descriptor sections that are required for the given packet type or system configuration.
3. The Host allocates and populates host buffer descriptors as necessary to point to any remaining chunks of data that belong to this packet. The host will initialize the following fields within the host buffer descriptor:
  - a. Buffer Pointer with the byte aligned address of the given chunk of buffer data.
  - b. Buffer Length with the number of bytes in the given chunk of buffer data.
  - c. The Next Descriptor Pointer with the 16-byte aligned address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero.
4. The Host writes queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue (if more than 1 flow is provided) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller / scheduler implementation.
5. The PKTDMA internally generates a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
6. The PKTDMA Tx engine is eventually brought into context for the corresponding channel and begins to process the packet.
7. The PKTDMA reads the packet descriptor pointer from the memory mapped ring for that channel/flow.
8. The PKTDMA reads the packet descriptor from memory.
9. The PKTDMA empties each buffer in sequence by transmitting the contents in one or more block data moves. The size of these blocks is application specific. The PKTDMA module specification is intended to document the block size used by a given implementation. As each buffer is emptied, the PKTDMA will read the next buffer descriptor to obtain the pointer and size of the data buffer as well as the pointer to the next descriptor in the chain.
10. When all data for the packet has been transmitted as specified in the packet size field, the DMA will increment the occupancy of the reverse queue (Tx Completion Queue).
11. After the occupancy is incremented, the PKTDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]\_STATUS\_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the PKTDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]\_RT\_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The PKTDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]\_STATUS) and potentially de-assert the interrupt line.

#### 11.1.4.8 PKTDMA - Receive Free Descriptor / Buffer Queue Setup

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. Each entry on the Rx Free Descriptor/Buffer Queue consists of one or more descriptors chained together with each descriptor also pointing to a single contiguous buffer. Each entry on the Rx Free

Descriptor/Buffer queue is intended to receive one packet of data. All chaining of descriptors within a packet is performed prior to placing the Rx resources onto the free queues.

Before the Host adds each Rx buffer descriptor chain to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Buffer Pointer with the byte aligned address of the buffer data
- Write the Buffer Size
- Write the next descriptor pointer to the next descriptor in the chain (non-eop) or to 0x0 (eop)

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

#### 11.1.4.9 PKTDMA - Receive Channel Setup

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register (<RCHANRT[a]\_RRT\_CTL> [31] RX\_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

#### 11.1.4.10 PKTDMA - Receive Channel Teardown

An Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408. This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the PKTDMA receives a data phase with the tdown attribute asserted it will immediately set the internal rx\_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]\_RRT\_CTL> [30] RX\_TEARDOWN).

Once a teardown has been initiated, the PKTDMA will do the following:

1. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
2. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]\_RRT\_CTL> [31] RX\_ENABLE).
3. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
4. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register to indicate that a teardown has completed (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE).
5. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
6. If the current RX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the PKTDMA. If that is not possible, the host may write the rx\_teardown bit directly to a 1.

The Host determines that a teardown is complete by using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) for the channel.

#### 11.1.4.11 PKTDMA - Receive Channel Pause

Setting the rx\_pause bit in the Rx Channel N Control Register (<RCHANRT[a]\_TRT\_CTL> [29] RX\_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overflow conditions from a downstream data sink or upstream data source).

#### 11.1.4.12 PKTDMA - Receive Operation

When packet reception begins on a given channel, the port will begin by fetching the descriptor and buffer from the ring for the channel / flow. If the SOP Buffer Offset in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fill additional descriptors + buffers as needed using the pre-linked buffers in the packet.

A detailed summary is as follows:

1. Host allocates, populates, and places pointers to free descriptor/buffer structures onto Rx Free Descriptor/Buffer Queues
2. PKTDMA fetches packet descriptor pointer from forward queue of ring for specified channel.
3. PKTDMA reads the packet descriptor to obtain the packet info, buffer pointer, buffer size, and next descriptor pointer.
4. PKTDMA fills the buffer with received data

If packet is not complete and the rx\_chan\_type field in the Rx Channel Configuration Register (<RCHAN[a]\_RCFG> [19:16] RX\_CHAN\_TYPE) is set to 2 (Normal Rx Host Mode). The machine will proceed to step 5 and will repeat steps 5-6 until all packet data is received at which point the Rx engine proceeds to step 8. If the rx\_desc\_type is set to 3 (Single Buffer Packet Host Mode) the Rx engine will proceed directly to step 7 regardless of whether or not an end of packet terminator has been reached on the incoming data stream. The current packet will be completed following the sequence through step 12 and a new packet will be started back at step 1.

5. PKTDMA fetches next buffer descriptor using next descriptor pointer obtained from previous descriptor.
6. PKTDMA fills the buffer with received data.

The PKTDMA performs the following operations when the entire packet has been received:

7. PKTDMA writes the packet descriptor to memory. This includes the following fields:
  - a. Descriptor Type (set to Host)
  - b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
  - c. Source Tag
  - d. Destination Tag
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. Any protocol specific words that are required for the given packet type
  - h. Extended Packet Information (optional)
8. PKTDMA increments the occupancy of the reverse queue for the channel / flow.
9. Once the occupancy is incremented it will send an up event to the Interrupt Aggregator
10. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register (VINT[a]\_STATUS\_SET) indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
11. The Host will pop the packet pointer from the Rx Queue by reading the ring contents and then pushing a decrement to the reverse occupancy for the ring.

12. If the pop causes the queue to become empty, the PKTDMA will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

#### 11.1.4.13 BCDMA - Block Copy Channel Setup

This section describes the setup procedure for channels within the BCDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Port DMA State. The host initializes the channel Port DMA State by initializing all of the channel flow entries and then writing to the Block Copy Channel Configuration Register A (BCHANRT[a]\_TRT\_CTL). The Host may choose to write the enable bit in the Block Copy Channel Configuration Register A (<BCHANRT[a]\_TRT\_CTL> [31] TX\_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a channel has been set up, packets can be added to the Queues for the channel to begin the copy operation.

For general purpose block copy channels, only the Block Copy DMA configuration, flow, and real-time registers will be present. For split mode channels, separate Tx and Rx configuration, flow, and real-time registers are provided. In all cases, configuration of all fields must be completed before a channel is enabled.

#### 11.1.4.14 BCDMA - Block Copy Channel Pause

Setting the pause bit in the Channel N Control Register (<BCHANRT[a]\_TRT\_CTL> [29] TX\_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events).

#### 11.1.4.15 BCDMA - Block Copy Channel Teardown

This section describes the teardown procedure for generic block copy channels within the BCDMA. A channel teardown is initiated by the host by writing the teardown bit in the Channel N Real-time Control Register (<BCHANRT[a]\_TRT\_CTL> [30] TX\_TEARDOWN). When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the forced\_teardown bit in the Channel N Real-time Control Register (<BCHANRT[a]\_TRT\_CTL> [28] TX\_FORCED\_TEARDOWN).

If the forced\_teardown bit is clear, a normal teardown has been initiated. In this case, the BCDMA will do the following:

1. Stops performing any additional fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/data fetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Channel N Global Configuration Register (<BCHANRT[a]\_TRT\_CTL> [31] TX\_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the BC Flow Reverse Ring Occupancy register to indicate that a teardown has completed.
7. If the current BC reverse ring occupancy is 0, issues an BC reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current BC Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. If the forced\_teardown bit is set, a destructive teardown has been initiated. In this case, the BCDMA will do the following:
  - a. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
  - b. Completes any packets which have been fetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).

- c. Clears the channel enable in the Channel Global Configuration Register.
- d. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
- e. Sets bit 31 of the BC Flow Reverse Ring Occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) to indicate that a teardown has completed.
- f. If the current BC reverse ring occupancy is 0, issues an BC reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively transferring data or not.

The Host determines that a teardown using either of the following methods:

- a. Periodically polling the teardown and enable bits for the channel
- b. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) for the channel.

Note that the teardown message will actually be written to the next available location in the ring following the last completed packet.

#### 11.1.4.16 BCDMA - Block Copy Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a type 15 TR packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to TR)
  - b. Reload Enable to 1 if looping is required, otherwise 0
  - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
  - d. Last Entry to TR count minus 1
  - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
  - f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Block Copy Queues for the desired BCDMA channel. Channels may provide more than one Queue (1 queue per provided flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The BCDMA internally provides a level sensitive status signal for the queue which indicates if any work is currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding read channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller sequentially empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. As a TR is read from the descriptor, it is stored in the internal state of the DMA channel until it is completed.
8. All of the data transfers specified in a TR will be completed as a series of reads followed later on by a set of corresponding writes (which may or may not be the same size based on the parameters in the block copy TR).
9. The BCDMA will wait until write status returns for the final write operation that was initiated for each TR. When the final write status is returned within each TR, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.

10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the BCDMA will increment the reverse occupancy for the channel/flow.
11. After the occupancy is incremented, the BCDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]\_STATUS\_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the BCDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]\_RT\_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The BCDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]\_STATUS) and potentially de-assert the interrupt line

#### 11.1.4.17 BCDMA - Block Copy Error/Exception Handling

There are 3 specific errors which may be encountered during generic block copy operation and which are trapped by the BCDMA. The following table lists the errors and how the BCDMA will process them:

**Table 11-58. BCDMA Generic Block Copy Mode Error / Exception Handling**

Condition	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	Selectable <sup>(1)</sup>	Yes	No	Just that TR	No
Unsupported TR Type	Selectable <sup>(1)</sup>	Yes	No	Just that TR	No
Bus Errors	Selectable <sup>(1)</sup>	Yes	Yes	No	Yes

(1) If pause\_on\_error bit is set in channel configuration

##### 11.1.4.17.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Block Copy engine in the BCDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

##### 11.1.4.17.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Block Copy engine in the BCDMA will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

##### 11.1.4.17.3 Bus Errors

If a bus error is encountered during transmit the BCDMA will log the error by asserting the tx\_error bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

#### 11.1.4.18 BCDMA - Split Transmit Channel Setup

This section describes the setup procedure for split Tx channels within the BCDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by configuring all of the Tx flow entries for the channel and then writing to the Tx Channel Configuration Register A (TCHANRT[a]\_TRT\_CTL). The Host may choose to write the enable bit in the Tx Channel Configuration Register A (<TCHANRT[a]\_TRT\_CTL> [31] TX\_ENABLE) at

the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

#### 11.1.4.19 BCDMA - Split Transmit Operation Pause

Setting the pause bit in the Channel N Control Register (<TCHANRT[a]\_TRT\_CTL> [29] TX\_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events).

#### 11.1.4.20 BCDMA - Split Transmit Channel Teardown

This section describes the teardown procedure for split mode Tx channels within the BCDMA. A Tx channel teardown is initiated by the host by writing the tx\_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]\_TRT\_CTL> [30] TX\_TEARDOWN). When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the tx\_forced\_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]\_TRT\_CTL> [28] TX\_FORCED\_TEARDOWN).

If the tx\_forced\_teardown bit is clear, a normal teardown has been initiated. In this case, the DMA will do the following:

1. Stops performing any additional descriptor fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR fetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Global Configuration Register (<TCHANRT[a]\_TRT\_CTL> [31] TX\_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) to indicate that a teardown has completed.
7. If the current Tx reverse ring occupancy is 0, issues a Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current TX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. If the tx\_forced\_teardown bit is set (only valid on BCDMA), a destructive teardown has been initiated. In this case, the BCDMA will do the following:
  1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
  2. Completes any packets which have been prefetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).
  3. Clears the channel enable in the Tx Channel Global Configuration Register (<TCHANRT[a]\_TRT\_CTL> [31] TX\_ENABLE).
  4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
  5. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) to indicate that a teardown has completed.
  6. If the current Tx reverse ring occupancy is 0, issues a Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The Host determines that a teardown using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (RINGRT[a]\_RT\_ROCC) for the channel.

#### 11.1.4.21 BCDMA - Split Transmit Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to TR)
  - b. Reload Enable to 1 if looping is required, otherwise 0
  - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
  - d. Last Entry to TR count minus 1
  - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
  - f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Transmit Queues for the desired BCDMA channel. Channels may provide more than one Queue (1 queue per provided flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The BCDMA internally provides a level sensitive status signal for the queue which indicates if any work is currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding read channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller sequentially empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. As a TR is read from the descriptor, it is stored in the internal state of the DMA channel until it is completed.
8. All of the data transfers specified in a TR will be completed as a series of reads.
9. The BCDMA will wait until data returns for each read operation that has been initiated. When the final read operation is returned within each TR, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the BCDMA will increment the reverse occupancy for the channel / flow.
11. After the occupancy is incremented, the BCDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]\_ENABLE\_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the BCDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]\_RT\_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The BCDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]\_STATUS) and potentially de-assert the interrupt line.

#### 11.1.4.22 BCDMA - Split Transmit Error / Exception Handling

There are 3 specific errors which may be encountered during Tx split operation and which are trapped by the BCDMA. The following table lists the errors and how the BCDMA will process them:

**Table 11-59. BCDMA Tx Error / Exception Handling**

Condition	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	Selectable <sup>(1)</sup>	Yes	No	Just that TR	No
Unsupported TR Type	Selectable <sup>(1)</sup>	Yes	No	Just that TR	No
Bus Errors	Selectable <sup>(1)</sup>	Yes	Yes	No	Yes

(1) If pause\_on\_error bit is set in channel configuration

#### 11.1.4.22.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Block Copy engine in the BCDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### 11.1.4.22.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Block Copy engine in the BCDMA will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### 11.1.4.22.3 Bus Errors

If a bus error is encountered during transmit the BCDMA will log the error by asserting the tx\_error bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

#### 11.1.4.23 BCDMA - Split Receive Channel Setup

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register (<RCHANRT[a]\_RRT\_CTL > [31] RX\_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

#### 11.1.4.24 BCDMA - Split Receive Channel Pause

Setting the pause bit in the Channel N Control Register (<RCHANRT[a]\_RRT\_CTL > [29] RX\_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events).

#### 11.1.4.25 BCDMA - Split Receive Channel Teardown

An Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408 . This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the BCDMA receives a data phase with the tdown attribute asserted it will immediately set the internal rx\_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]\_RRT\_CTL > [30] RX\_TEARDOWN).

Upon seeing the rx\_teardown bit asserted the port can perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the rx\_forced\_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]\_RRT\_CTL > [28] RX\_FORCED\_TEARDOWN).

If the rx\_forced\_tearardown bit is clear, a normal teardown has been initiated. In this case, the BCDMA will do the following:

1. Stops performing any additional prefetches for the channel (TR mode channels)
2. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
3. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]\_RRT\_CTL > [31] RX\_ENABLE).
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) to indicate that a teardown has completed.
6. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
7. If the current RX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
8. If the rx\_forced\_tearardown bit is set, a destructive teardown has been initiated. In this case, the BCDMA will do the following:
  - a. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
  - b. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using 'null' write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
  - c. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]\_RRT\_CTL > [31] RX\_ENABLE).
  - d. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
  - e. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) to indicate that a teardown has completed.
  - f. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the BCDMA. If that is not possible, the host may write the rx\_tearardown bit directly to a 1.

The Host determines that a teardown using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]\_RT\_ROCC> [31] TDOWN\_COMPLETE) for the channel.

#### 11.1.4.26 BCDMA - Split Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to TR)
  - b. Reload Enable to 1 if looping is required, otherwise 0
  - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
  - d. Last Entry to TR count minus 1
  - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer

- f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Rx TR Queues for the desired BCDMA channel. Channels may provide more than one Rx TR Queue (one per flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller / scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves.
8. All of the data transfers specified in a TR will be completed as a series of writes and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The BCDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the DMSS will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports / processors / prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard interrupts.

#### 11.1.4.27 BCDMA - Split Receive Error / Exception Handling

Several types of errors/exceptions may be encountered during reception of split Rx data. The following table outlines the various errors and exceptions that can occur:

**Table 11-60. Rx Error / Exception Handling**

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial <sup>(1)</sup>	Until EOP	-	No
EOP Asserted Late (Long Packet)	BCDMA – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All BCDMA	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No
Unsupported TR Type	All BCDMA	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No

- (1) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

#### **11.1.4.27.1 PKTDMA Exception Conditions**

There are a few cases which can occur when processing incoming packets which are not considered errors but which will require handling in order to avoid locking up the PKTDMA engines.

Packet mode channel exceptions include:

- Descriptor Starvation
- Protocol Errors
- Dropped Packets
- Long Packets

##### **11.1.4.27.1.1 Descriptor Starvation**

Descriptor starvation occurs when the Port needs to fetch a free descriptor from the RX ring and none are available. When the port detects that descriptor starvation has occurred it will react based on the value of the rx\_error\_handling bit which was programmed into the Rx Flow N Configuration Register A (<RFLOW[a]\_RFA> [28] RX\_ERROR\_HANDLING).

If the rx\_error\_handling bit is cleared:

- The Port will increment an internal per-channel starvation counter and will then flush the packet.

If the rx\_error\_handling bit is set:

- The Port will assert a RX descriptor starvation event (which may cause an interrupt to the Host) and will then wait for the doorbell for the selected flow to be written with a positive value. Note that the intention is that the port will wait for an entry to be added to the ring. It is assumed that when in this mode, if data loss is not desired that the host will guarantee that a chain of buffers will be provided that can receive the entire packet.

##### **11.1.4.27.1.2 Protocol Errors**

Protocol errors occur when the port logic detects that the received packet did not pass protocol specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors.

When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the Host descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

##### **11.1.4.27.1.3 Dropped Packets**

Packets can be dropped within an Rx Port for any number of reasons which with the exception of the starvation case which was covered above are application specific.

When a Port determines that it needs to drop a packet after reception of the packet has begun, it must flush the remainder of the packet, increment the dropped packets statistic, and rewind any fetched descriptor/buffer chain so that it can be used for the next packet.

##### **11.1.4.27.1.4 Long Packet**

For Rx channels which are not configured in single buffer mode, if the host provides a buffer chain whose total length is insufficient to receive the entire packet, whatever portion of the packet which has not been received will be flushed until an end of packet indicator is received on the PSI-L interface. This behavior will occur regardless of which error handling mode has been selected for the channel.

#### **11.1.4.27.2 BCDMA Exception Conditions**

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets
- Descriptor Starvation

##### **11.1.4.27.2.1 Reception of EOL Delimiter**

If an end of line delimiter is received by the Rx (write) side of the BCDMA the EOL\_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

##### **11.1.4.27.2.2 EOP Asserted Prematurely (Short Packet)**

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

##### **11.1.4.27.2.3 EOP Asserted Late (Long Packets)**

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

##### **11.1.4.27.2.4 Descriptor Starvation**

Descriptor starvation occurs when the Port receives enough data for a burst but the ring for the channel is currently empty. This causes push back on the receive port and can cause lost data.

The Port will assert a starvation bit in the RX Receive Channel Status register (RCHANRT[a]\_RRT\_STATUS[1-0]). When the doorbell register (RINGRT[a]\_RT\_DB) is written to populate the ring the starvation bit will clear. Note that the intention is that the port will wait for an entry to be added to the ring. It is assumed that if data loss is not desired that the host will guarantee that a descriptor is present.

## 11.2 Data Movement Subsystem (DMSS)

This chapter describes the Data Movement Subsystem (DMSS) module in the device.

## 11.2.1 Data Movement Subsystem (DMSS)

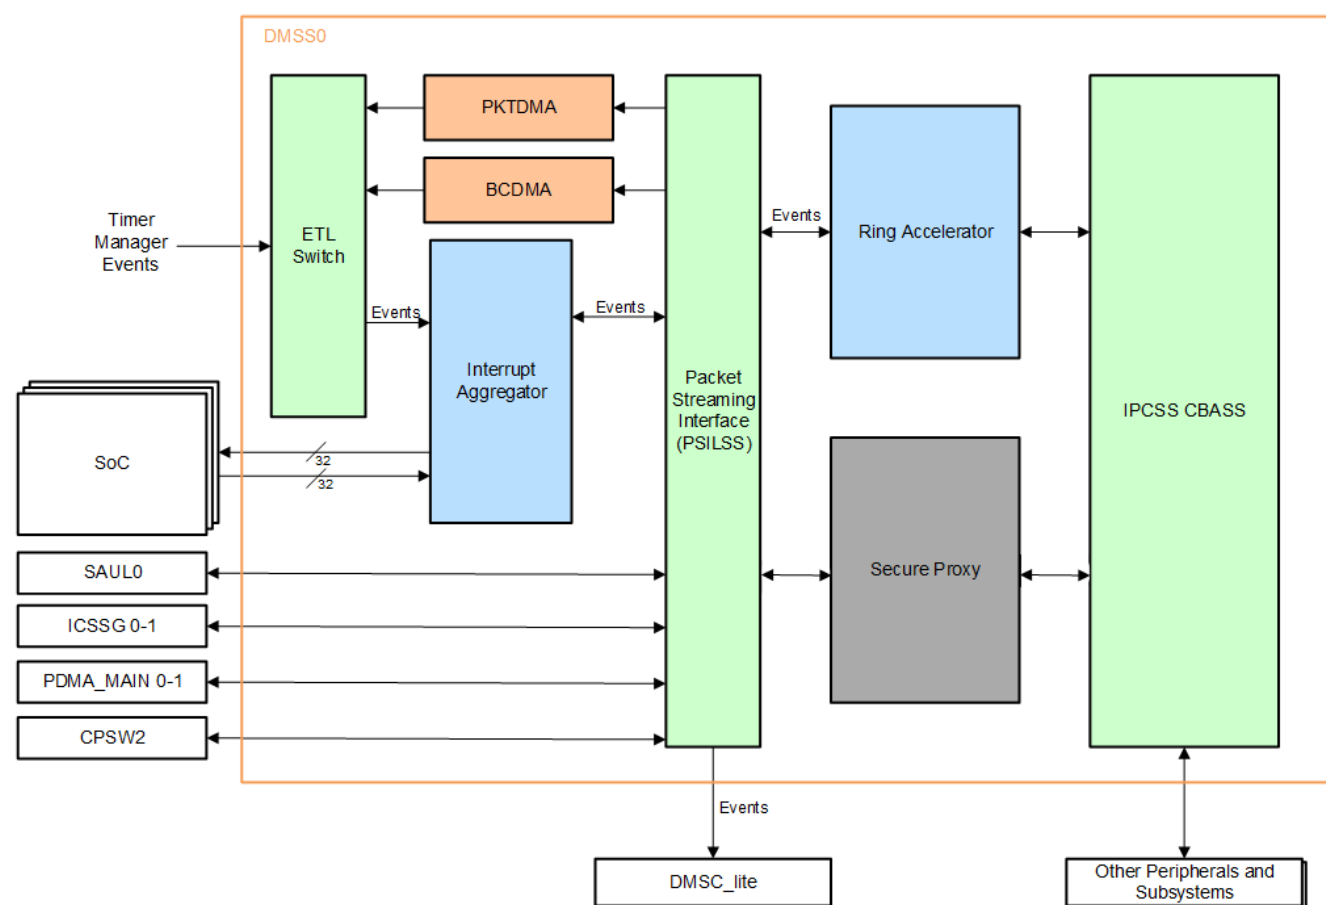

This chapter describes the features and functions of the Data Movement Subsystem (DMSS) hardware modules in the device.

### 11.2.1.1 DMSS Overview

The DMSS module on provides data movement (DMA) and bridges between the CBA switched interconnect and the packet streaming fabric (network on chip) on the device.

The Data Movement Subsystem (DMSS) consists of DMA/Queue Management components and Peripherals:

- Packet DMA
- Block Copy DMA
- Ring Accelerator
- Packet Streaming Interface (PSILSS)
- Infrastructure components such as CBASS, secure proxy, and an interrupt aggregator

dmss\_spruiem\_001

**Figure 11-4. DMSS Top-Level Block Diagram**

**Table 11-61. DMSS Allocation Within Device Domains**

Module Instance	Domain	
	MCU	MAIN
DMSS0	-	✓(DMSS)

**Note**

Some features may not be available. See *Module Integration* for more information.

**11.2.1.2 DMSS Functional Description**

See Section [Chapter 11](#), DMSS Architecture, for the TI Data Movement Architecture (DMA) specification.

See the following sections for the respective module description:

- PKTDMA - [Section 11.1.1.4](#)
- BCDMA - [Section 11.1.1.5](#)
- Ring Accelerator - [Section 11.1.1.1](#)
- Infrastructure Components:
  - CBASS - Chapter 3
  - Secure Proxy - [Section 11.1.1.2](#)
  - Interrupt Aggregator - [Section 11.1.1.3](#)

**11.2.1.3 DMSS Interrupt Configuration**

This section describes the actions needed to configure interrupts within the DMSS.

**Table 11-62. DMSS Parameters**

Parameter	Value DMSS	Description
RA_RING_CNT	20	Number of total rings supported (specific to each ring accelerator)
IA_SEVI	1536	Interrupt Aggregator Source Event Input (SEVI) count (specific to each interrupt aggregator)
IS_VINTR	184	Interrupt Aggregator Virtual Interrupt (VINTR) count (specific to each interrupt aggregator)
EO	See <i>Global Event Map</i> in Module Integration	
		Event offset

[DMSS Software Variables](#) lists software-configurable variables used in the examples and descriptions.

**Table 11-63. DMSS Software Variables**

Variable	Valid Range	Description
R#	0 – RA_RING_CNT-1	Ring number
E#	0 – (destination module specific)	Event number
GE#	= EO + E#	Global event number
SB#	0 – IA_SEVI-1	Interrupt aggregator status bit number
VI#	0 – IA_VINTR-1	Virtual interrupt number

**11.2.1.3.1 DMSS Event and Interrupt Flow**

[DMSS Interrupt Flow](#) illustrates the event and interrupt flow within the DMSS and output interrupts to a CPU.

**Figure 11-5. DMSS Interrupt Flow**

#### 11.2.1.3.1.1 DMSS Interrupt Description

This section describes the interrupt-related information that flows within DMSS and how this information is configured or generated.

1. Ring Number (R#)
  - Data is read from and written to a specific Ring Accelerator ring using direct ring-mode, or secure proxy access
  - The Ring Accelerator has specific ring number ranges for specific purposes. The R# must match the intended purpose of the ring (see Table 10-578, RINGACC Ring Mapping)
2. Global Event and Event Numbers (GE# and E#)
  - $GE\# = EO + E\#$
  - EO determines the destination module for the event. The PSILSS will route the GE# to the destination module per the DMSS event mapping, removing EO in the process. The destination module sees only E#. See *Global Event Map* in *Module Integration* for details.
  - For the INTAGGR module, E# ranges from 0 to (IA\_SEVI - 1)
3. Virtual Interrupt (VI#)
  - The INTAGGR maps E# (via software configuration) to any SB#
  - ranges from 0 to (IA\_SEVI - 1)
  - Each VI# (0 – (IA\_VINTR-1)) is driven by a group of 64 contiguous SB# numbers (VI# driven by SB#'s  $VI\# \times 64 - (VI\# \times 64) + 63$ )

#### 11.2.1.3.1.2 DMSS Event Description

1. Interrupt aggregator includes three orthogonal functions:
  - a. First is event mapping block which converts local/unmapped event to global event and send those events out.
  - b. Second is aggregating global events and convert them into interrupt outputs
  - c. Third is the L2G block: this is a block to convert the event/interrupt from SoC level into global events. L2G block takes wired signal from SoC (interrupt signal or DMA signal) converted into local events.
2. L2G: this is a block to convert the event/interrupt from SoC level into global events. L2G block takes wired signal from SoC (interrupt signal or DMA signal) converted into local events. Those local events are sent to ETL and sent to event mapping logic inside interrupt aggregator to convert them into global event. And then those global events are sent out again.
3. PSIL and ETL: PSIL is a streaming protocol which carries both data information and event information. ETL is the PSIL portion which only carries event. PSIL data is transported independently. When you see PSIL, it must include ETL.
4. Local events and unmapped events are in the same category. All those unmapped/local events are routed to the mapping block inside Interrupt aggregator to be converted into global events
5. Other than L2G block, Currently there are only three components generating unmapped events: BCDMA, PktDMA and timer manager. All those unmapped events are routed to the event mapping block inside interrupt aggregator first. All the other components produce global events.
6. After the local/unmapped events are mapped to global events in interrupt aggregator, those global events are sent out by interrupt aggregator and can be transported to different locations ( for example, BCDMA to trigger BCDMA or pktDMA or going back to interrupt aggregator's aggregating global events into interrupts.

**Figure 11-6. DMSS Event Flow**

## 11.2.2 Ring Accelerator (RINGACC)

This chapter describes the RINGACC module, part of the DMSS.

### Note

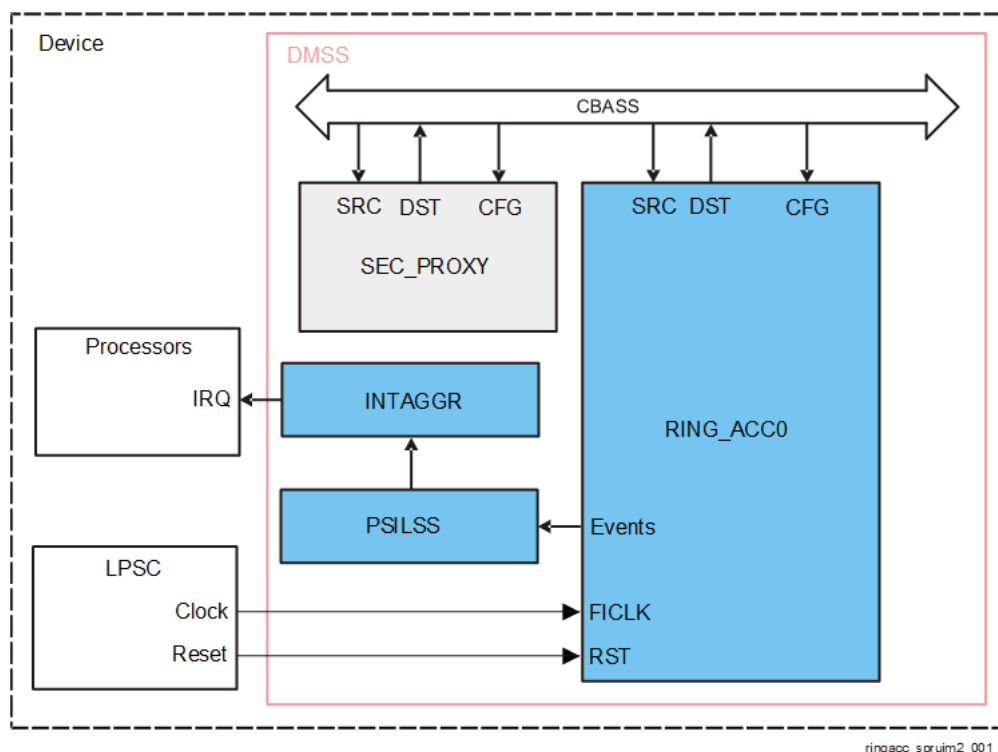

Not all of the RINGACC Functions specified in the document are supported in the device. Updates will be included in the next revision to reflect only supported modes of operation.

### 11.2.2.1 RINGACC Overview

The Ring Accelerator (RINGACC or RA) provides hardware acceleration to enable straightforward passing of work between a producer and a consumer.

**Table 11-64. RINGACC Allocation Within Device Domains**

Module Instance	Domain	
	MCU	MAIN
DMSS0_RINGACC0	-	✓(DMSS)

**Figure 11-7. RINGACC Overview**

#### 11.2.2.1.1 RINGACC Features

- Ring Accelerator implementation
  - Supports up to 32 independent memory mapped ring structure
  - Supports various modes for each ring based on usage and compatibility
  - Provides single word deep shared incoming Transfer Response FIFO
  - Optionally supports dynamic clock gating
  - Provides bit wide source VBUSM read/write target interface for accesses from DMA controller entities
    - Provides 2 word deep command FIFO
    - Provides 2 word deep write data FIFO
    - Provides 2 word deep read data FIFO

- Provides 2 word deep write status FIFO
- Provides bit wide destination VBUSM read/write initiator interface for accesses to ring structures in memory
- Supports up to 16 outstanding writes
- Supports up to 16 outstanding reads
- Provides 2 word deep command FIFO
- Provides 2 word deep write data FIFO
- Provides 2 word deep read data FIFO
- Provides 2 word deep write status FIFO
- Source interface provides an array of 32x512-byte long address windows (four for each ring) which are packed into a single contiguous address range.
  - Read and write addresses which target a specific window are mangled to redirect the read or write transaction to an effective address calculated from the base address for the ring plus current ring offset.
  - Each read or write access presented on VBUSM target interface is modified and bridged onto the VBUSM initiator interface.

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 11.2.2.1.2 RINGACC Parameters

[RINGACC Configuration Parameters](#) shows the RINGACC configuration parameters in this SoC

**Table 11-65. RINGACC Configuration Parameters**

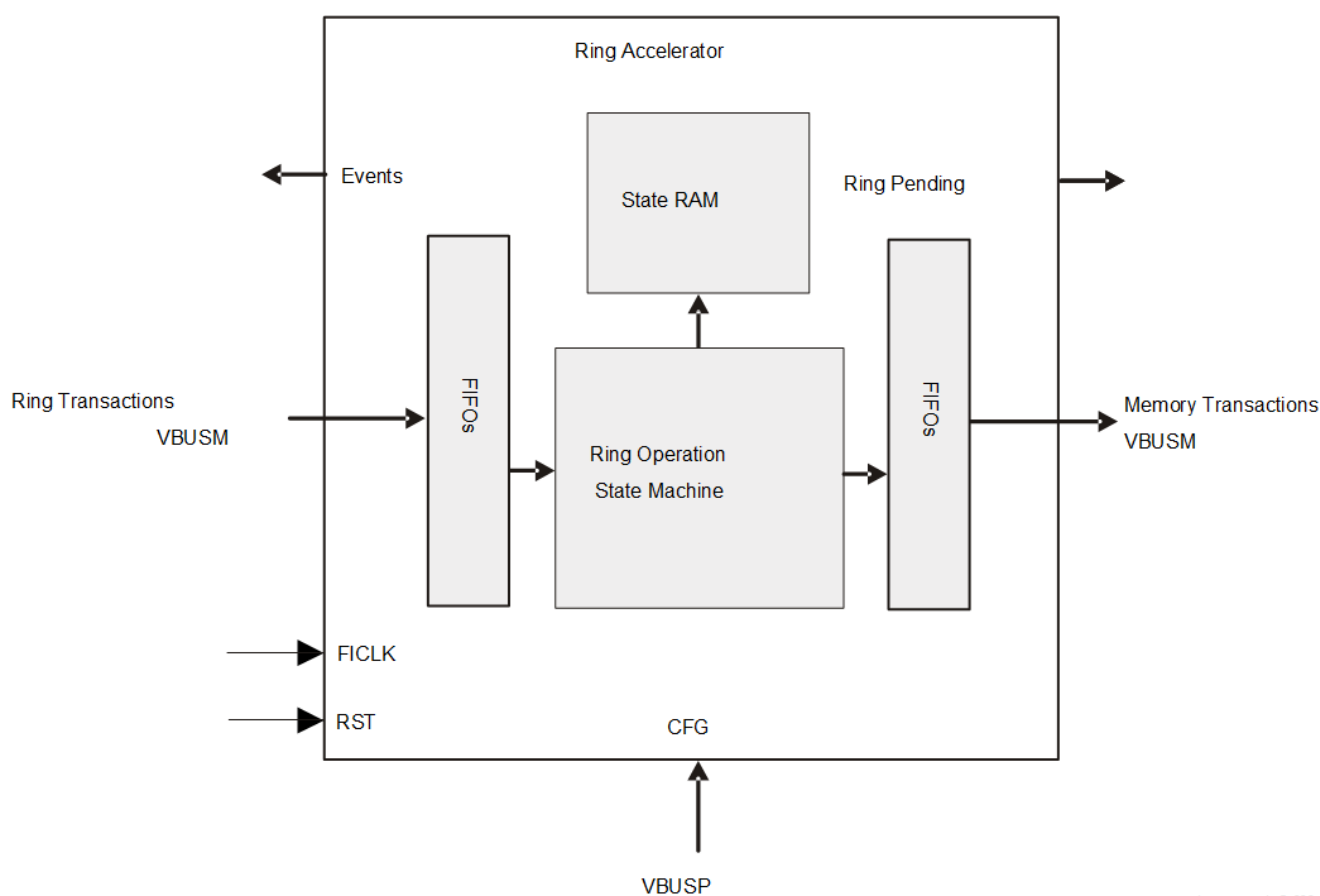

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
DMSS0_RINGACC0	32	0	0x4e000000

### 11.2.2.2 RINGACC Functional Description

The Ring Accelerator (RINGACC) converts constant-address read and write accesses to equivalent read or write accesses to a circular data structure in memory. The RINGACC eliminates the need for each DMA controller which needs to access ring elements from having to know the current state of the ring (base address, current offset). The DMA controller performs a read or write access to a specific address range (which maps to the source interface on the RINGACC) and the RINGACC replaces the address for the transaction with a new address which corresponds to the head or tail element of the ring (head for reads, tail for writes). Since the RINGACC maintains the state, multiple DMA controllers or channels are allowed to coherently share the same rings as applicable. The RINGACC serves a very similar function to the Queue Manager in the earlier SoCs. The RINGACC uses less memory and is able to place data which is destined towards software into cached memory directly.

#### 11.2.2.2.1 Block Diagram

[Ring Accelerator Block-Diagram](#) shows ring accelerator's main internal components.

**Figure 11-8. Ring Accelerator Block-Diagram**

#### 11.2.2.2.1.1 Configuration Registers

The Configuration Registers block is responsible for providing memory mapped registers for configuration of the RINGACC functions. The configuration registers are divided into:

- Static configuration fields , which are typically initialized and then left at specified values for long time periods (or until a reset occurs)
- Real-time (RT) registers , which are modified frequently during runtime. Configuration registers are listed and described in *RINGACC Registers*.

#### **11.2.2.2.1.2 Source Command FIFO**

The Source Command FIFO buffers VBUSM command phases which are accepted from the VBUSM source interface.

#### **11.2.2.2.1.3 Source Write Data FIFO**

The Source Write Data FIFO buffers VBUSM write data phases which are accepted from the VBUSM source interface.

#### **11.2.2.2.1.4 Source Read Data FIFO**

The Source Read Data FIFO buffers VBUSM read data phases which have been returned from the VBUSM destination interface (via the main state machine) and which are to be output on the VBUSM source interface.

#### **11.2.2.2.1.5 Source Write Status FIFO**

The Source Write Status FIFO buffers VBUSM write status data phases which have been returned from the VBUSM destination interface and which are to be output on the VBUSM source interface.

#### **11.2.2.2.1.6 Main State Machine**

The Main State Machine (MSM) block implements all of the control logic which is necessary to accept a command from the source interface, perform a lookup into the ring state RAM, determine the effective address for the destination interface transaction, modify the address (and byte count for reads) for the transaction, and place that modified transaction into the outgoing destination FIFOs. The MSM block is also responsible for updating the ring index and occupancy values and for producing output status to indicate changes to the ring state. The MSM also modifies the ring state whenever the read data or write status for a previous ring transaction return and forwards those responses back to the originating initiator.

#### **11.2.2.2.1.7 Destination Command FIFO**

The Destination Command FIFO stores VBUSM transaction commands which are output from the MSM as modified versions of transactions that were popped from the Source Command FIFO. The Destination command FIFO allocates a new command ID for each read or write command that is pushed to the FIFO. Read IDs are allocated from a scoreboard maintained in the Destination Read Data FIFO. Write IDs are allocated from a scoreboard maintained in the Destination Write Status FIFO. When a new command is allocated, the Destination Command FIFO also pushes the original cid and crouteid values from the source side transaction into a scoreboard in either the Destination Read Data or Destination Write Status FIFOs depending on the applicable transaction direction. The read interface of the Destination Command FIFO directly drives commands onto the destination VBUSM command interface.

#### **11.2.2.2.1.8 Destination Write Data FIFO**

The Destination Write Data FIFO stores write data phases for write commands that are passing through the RINGACC towards memory. The write interface of the Destination Write Data FIFO is directly connected to the read interface of the Source Write Data FIFO and the read interface directly drives write data onto the destination VBUSM write data interface.

#### **11.2.2.2.1.9 Destination Read Data FIFO**

The Destination Read Data FIFO provides a read command translation scoreboard and also stores read data phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Read Data FIFO is directly connected to the destination VBUSM read data interface. As read data passes through the Destination Read Data FIFO, the *rid* and *rrouteid* are changed back to their original values using information which was stored in read command translation scoreboard.

#### **11.2.2.2.1.10 Destination Write Status FIFO**

The Destination Write Status FIFO provides a write command translation scoreboard and also stores write status phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Writes Status FIFO is directly connected to the destination VBUSM write status interface. As write

status words pass through the Destination Write Status FIFO, the *sid* and *srouteid* are changed back to their original values using information which was stored in the write command translation scoreboard.

#### **11.2.2.2.2 RINGACC Functional Operation**

##### **11.2.2.2.2.1 Queue Modes**

Each ring or queue can be in one of four modes that determines how it must be accessed and the compatibility it has with hardware and software.

##### **11.2.2.2.2.1.1 Ring Mode**

Ring mode is used when software owns one side of the ring, and hardware or another software owns the other side. This mode allows the software that owns a side of the ring to control that side including accessing the memory directly rather than going through hardware, and software updates the hardware on any changes through the Doorbell registers. These doorbell accesses indicate when software has pushed or popped entries, allowing the entity on the other side of the ring to know when there are elements ready. The ring mode has limitations that the exposed side of the ring is completely under software control, and any atomicity needed must also be performed by software, which is why the exposed side of a ring is usually owned by a single thread of software. This limitation also means that any hardware configuration that would normally access the same ring for both pushes and pops cannot use ring mode as hardware cannot access the exposed side of the ring, such as free queues that are normally read by hardware but could also be pushed by hardware on an error.

When software is popping from the ring, it must guarantee that it never pops more elements through the Doorbell register (RINGRT[a]\_RT\_DB) than what is valid in the Ring Occupancy (RINGRT[a]\_RT\_OCC) register, which holds how many elements are ready for software consumption. There could be some elements which have data written to memory but have not received status back from memory and those are not considered ready to pop yet as the ring status has not fully updated. Therefore, just reading from memory to determine the number of elements to pop is not sufficient. If software attempts to pop more than the RINGRT[a]\_RT\_OCC register value, then the occupancies could go negative resulting in missed down events and spurious interrupts. An optimization for software is to read the RINGRT[a]\_RT\_OCC register less frequently and keep a local copy which guarantees the maximum number of allowed pops. When the software copy of RINGRT[a]\_RT\_OCC reaches 0, or periodically, the software can read the register to refresh the value. This must reduce the frequency of register reads instead of reading the register for every software pop.

##### **11.2.2.2.2.1.2 Messaging Mode**

Messaging mode requires that all accesses to the queue must go through RINGACC so that all accesses to the memory are controlled and ordered. RINGACC then controls the entire state of the queue, and software has no directly control, such as through doorbells and cannot access the storage memory directly. This is particularly useful when more than one software or hardware entity can be the producer and/or consumer at the same time. Software must access the data through bus accesses to the RINGACC. As with the earlier example, if there are free queues that need the hardware to both push and pop, then they must be configured as at least messaging mode (or a later mode) and not ring mode.

##### **11.2.2.2.2.1.3 Credentials Mode**

Credentials mode adds per element credentials storage to messaging mode. This allows multiple producers with their own credentials to have those credentials stored with the element. This allows the consumer to inherit the credentials of each element rather than a single set for the entire queue, such as for DMA TR credential inheritance. This mode requires each operation to use two elements of storage since the credentials are stored in the second element, so the element count must be scaled appropriately. The credentials field is located in the same location as all modes, the word just before the first word of the message.

##### **11.2.2.2.2.1.4 Peek Support**

All modes except ring mode allow the peek operations so that software can view the next element without actually popping it from the queue. This is done by reading from a different offset from the normal pop operation. All the same fields are read but the element is not actually popped off of the queue. This is useful for algorithms

that need to know about the overall queue and head element to make decisions but have not yet decided to pop from the queue.

#### 11.2.2.2.1.5 Index Register Operation

In ring mode, the Index (RINGRT[a]\_RT\_INDX) register follows the software control of the ring through the doorbell registers, while the hardware index (RINGRT[a]\_RT\_HWINDX) register follows the hardware access of the ring through bus transactions. It works for a ring in either direction as the doorbell register (RINGRT[a]\_RT\_DB) update indicates whether elements were produced or consumed. But in the other queue modes, there is no simple manner to determine which index is for software or hardware since they both use bus transactions which the module cannot differentiate. So for these other queue modes, the index register is always the read index, and the hardware index register is the write index.

#### 11.2.2.2.2 VBUSM Target Ring Operations

Each ring contains four memory spaces on the VBUSM target bus for access, each of which is 512 bytes long, with a total of 4 kB per ring. Each ring space starts immediately after the preceding ring. The allocation per ring is as in [Table 11-66](#).

**Table 11-66. Ring Memory Partition**

Offset	Operation	Supported Ring Modes
0x0 - 0x1FF	Reads pop from head. Writes push to head.	Read supported in all modes, write supported in all modes except Ring mode
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.	Write supported in all modes, read supported in all modes except Ring mode
0x400 - 0x5FF	Reads peek from head. Writes ignored.	All modes except for Ring mode.
0x600 - 0x7FF	Reads peek from tail. Writes ignored.	All modes except for Ring mode.
0x800 - 0xFFFF	Reserved	Reserved

Within each 512-byte (0x200) space, the message data is right justified so that the last byte is always the 511-th byte. The element size of the ring defines which words are valid. The word just before the first valid message word is the credentials field. Access must not be made before the credentials register (CRED[a]\_CRED).

#### 11.2.2.2.3 VBUSM Initiator Interface Command ID Selection

The RINGACC keeps a transaction command scoreboard for reads and writes. Each scoreboard tracks which command indexes are currently outstanding from the RINGACC and which are free to use. When a read or write is requested by the Main State Machine, the scoreboard corresponding to the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*) for the outgoing transaction on the destination interface. 15 is the maximum index value for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

#### 11.2.2.2.4 Ring Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using *ring number*
3. RINGACC calculates effective write address using *ring base + ring\_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments HW index and HW occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *routeid*, *cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
2. RINGACC increments SW index and occupancy for ring
3. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

#### 11.2.2.2.2.5 Ring Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using *ring number*
3. RINGACC calculates effective read address using *ring base + ring\_index*
4. RINGACC increments HW index and decrements HW occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
2. RINGACC increments SW index and decrements SW occupancy for ring
3. RINGACC pushes restored *rrouteid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

#### 11.2.2.2.2.6 Host Doorbell Access

The following sequence will occur for each VBUSP write to the doorbell register (RINGRT[a]\_RT\_DB) for a ring:

1. RINGACC extracts ring number from config address
2. RINGACC looks up ring state using ring number
3. RINGACC adds doorbell ring value to both HW and SW occupancies for ring
4. RINGACC re-evaluates pending bit for ring

#### 11.2.2.2.2.7 Queue Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using *ring number*
3. RINGACC calculates effective write address using *ring base + ring\_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments WR index and RD and WR occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RA pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

#### 11.2.2.2.2.8 Queue Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

- RINGACC extracts ring # from incoming read transaction address
- RINGACC looks up ring state using *ring number*
- RINGACC calculates effective read address using *ring base + ring\_index*
- RINGACC increments RD index and decrements RD and WR occupancy for ring
- RINGACC re-evaluates pending bit for ring
- RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data

- RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)
- 1. At a later time when read data returns:
  - RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
  - RINGACC pushes restored *rroutheid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

#### 11.2.2.2.9 Mismatched Element Size Handling

When less data is written than defined by the element size for the ring for RING or MESSAGE modes, only the written data is stored in the memory and any remaining bytes maintain their old values. The index and occ are still incremented normally, and any special fields that are unwritten are assumed to be 0 (such as the length for QM mode rings).

Writing less data for CREDENTIALS mode is illegal, as those types need the full data to append the additional words to the correct offsets in memory.

When more data is written than defined by the element size for the ring, it will be an error and the write will be ignored and no index or occ increments occur. The only exception is for writes to an 8 byte element size ring, where the additional fields up to another 8 bytes are allowed but not written (for old Queue Manager compatibility).

When less data is read than defined by the element size for the ring, only the read data is fetched from memory, and any remaining bytes are lost. The index and occ are still incremented normally.

When more data is read than defined by the element size for the ring, it will be an error and the read will not affect the ring, the read data will be 0s, and no index or occ decrements occur. Access beyond the credentials word should not be attempted and can result in unpredictable behavior.

All accesses must be for multiples of 32 bit words, and partial bytes are not supported for all ring modes.

#### 11.2.2.2.3 Events

The module outputs events about queue levels that can be used by an external module for statistics or interrupts.

Each queue has:

- an up event when the queue goes from 0 elements to 1 or more elements
- and a down event when the queue goes from 1 or more elements to 0 elements. The event number is programmable per queue in the RING[a]\_EVT register. This event occurs when the state machine updates the final occupancy for the queue. In ring mode this is when the response from the memory access returns, while in other queue modes this is when the operation is processed.

An event number programmed to 0xFFFF indicates to not produce an event for that ring when an event is not necessary. The register event number fields reset to 0xFFFF, so they must be programmed to a valid value before events will be generated. This applies to the monitor event number fields as well.

#### 11.2.2.2.4 Bus Error Handling

If a bus error is detected on a response to a ring memory transaction, an error event is triggered to alert software. Since the ring contents may be corrupted as the push or pop was not completed correctly, software should consider resetting the ring and any software or hardware elements using the ring. A log register (RINGACC\_ERROR\_LOG) captures the ring that had the error and whether it was from a push or pop, and an error up event is sent to the programmed event number. After an error is logged, another will not be captured until the first is read out. When read, if an error is pending an error down event is sent to clear any interrupt, and then the next bus error log can be captured. A read of the RINGACC\_ERROR\_LOG register when there is no error log pending will not produce any down events. The event that is triggered is also programmable. Only

legal push and pop operations will capture this error, and not for any peek, emudbg read, flush command, or any operations that is illegal and causes the resulting memory access to be flushed.

#### **11.2.2.2.5 Monitors**

Monitors can be configured that allow various functions to be tracked of programmed queues. Each monitor is programmed to monitor a particular queue, the function to provide, and the data source to operate on. The supported functions are: to check the queue against programmed thresholds, to keep track of watermarks of the queue, to keep track of starvation occurrences (a read of an empty queue), or statistics capture. The supported data sources are: the queue element count, the head element size value, or the accumulated size value. Each monitor can also be programmed to produce an event should it have a triggering condition.

##### **11.2.2.2.5.1 Threshold Monitor**

A threshold monitor uses a programmed low threshold value and a programmed high threshold value to track the data source in the queue and cause an interrupt or status when a threshold is broken, either below the low value or above the high value. This is useful for software to replenish empty buffers when a queue has too few, or for a queue to accumulate enough elements so that software must start processing them, or for debug. The threshold being broken will cause the up or down event.

##### **11.2.2.2.5.2 Watermark Monitor**

A watermark monitor tracks the low and high values of the data source since the last read of the monitor. After initial setup or clearing, the watermark values will load the current value of the data source as the low and high. Then for successive operations if the resulting data source of the queue is below the low watermark, or above the high watermark, the associated watermark will be updated. When the monitor value registers are read, the value is cleared and starts tracking again using the current data source value. This can be useful for tracking low and high values of queue element counts or sizes for data tracking, debug or future optimizations, such as allocating items to a queue or buffer sizes based on counts.

##### **11.2.2.2.5.3 Starvation Monitor**

A starvation monitor tracks the number of starvation events (a read to an empty queue) that occurred on the queue. The data source is ignored, and the starvation count is always incremented whenever there is a read to the queue and the queue is empty. The count is cleared when the monitor value is read. This can be useful to trigger if any starvation event occurs, or to track how many of these events occur in a timeframe, and can be used for future optimizations or debug.

##### **11.2.2.2.5.4 Statistics Monitor**

The statistics monitor can track some simple statistics on the queue operations. The data source is ignored. The first value is the count of the number of writes to the queue, and the second value is the count of the number of reads from the queue. The counts are cleared when the monitor values are read. This can be useful to track the activity on a queue, and can be used for future optimizations or debug.

##### **11.2.2.2.5.5 Overflow**

RINGACC provides an overflow function where a push to a full ring will result in a push to a special overflow ring, rather than just losing the pushed data. The overflow ring is defined through RINGACC\_OVERFLOW register, and that ring must be defined with a large enough element size to cover the element size of any other ring, as well as enough elements to hold enough overflow data (as an overflow to the overflow ring will be lost). When there is a push to a full ring, there will be two elements written to the overflow ring, first the push data, and then the ring number that was full. A supervisor entity can own the overflow ring and perform what actions are needed from the overflow data. The size of the overflow ring must be an even number since two elements will be pushed for each overflow event. The overflow ring must be configured in ring or message modes.

An overflow queue value of 0xFFFF will disable the overflow function and will not record queue overflows. (SR2.0)

#### 11.2.2.2.5.6 Ring Update Port

To enhance performance for DMAs, the RINGACC provides a bus that indicates when ring updates occur, allowing the DMA to track their own rings and detect updates before the responses arrive. The bus will go valid whenever there is an update to the state of a ring, which can be from a push, pop, or doorbell write. It will not go valid for a peek, an emudbg pop, or a push to a full ring, as those do not update the ring state. When the bus is valid, the other signals are valid and indicate whether the operation was a push or a pop, whether the resulting state of the ring is empty, the ring number, and the number of elements updated to the ring (the push determines whether it is subtracted or added to the current count). One special case is a pop from an empty ring, which indicates an update but the element count is 0 since no items were actually popped, but a DMA using the cnt to add or subtract must handle this correctly by default. The bus will go valid once the operation command has been completed, and not after the response has been received, even for ring mode rings, allowing the DMA to see the update as soon as it is known by the RINGACC even before it is known to software.

#### 11.2.2.2.5.7 Tracing

This module provides a trace output of all operations so that the traffic can be viewed at a later time. The trace uses a simple write-only 32-bit VBUSP bus, with a defined packet header. The msgtype field defines the type of operation, and the message data is simply the data involved in the operation. It is likely the trace output will be read slower than new operations could provide data, so there will be a trace buffer able to hold two complete messages plus trace headers. If a new operation starts while the trace buffer does not have enough space, then that trace message will not be sent. And RINGACC\_TRACE\_CTL register controls whether to enable the trace output, whether to trace a single queue or all queues, and whether to include the message data in the trace output.

Table 11-67 shows the trace message for a push.

**Table 11-67. Trace Message for a Push**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x1	Msgtype for push
1	8:0	0x009	Standard Trace Header
2	31	push_to_head	Push to head flag, 0 = to tail, 1 = to head
2	30:16	0x0	Unused
2	15:0	queue	Queue for push
3-N	31:0	message data	Optional message data for push, length dependent on message size

Table 11-68 shows the trace message for a pop.

**Table 11-68. Trace Message for a Pop**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x2	Msgtype for pop
1	8:0	0x009	Standard Trace Header
2	31	empty	empty pop, 0 = valid message, 1 = empty
2	30:16	0x0	unused

**Table 11-68. Trace Message for a Pop (continued)**

Word	Bits	Data	Comment
2	15:0	queue	queue for pop
3-N	31:0	message data	Optional message Data for pop, length dependent on message size

Table 11-69 shows the trace message for a peek

**Table 11-69. Trace Message for a Peek**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x3	Msgtype for peek
1	8:0	0x009	Standard Trace Header
2	31	empty	empty peek, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for peek
3-N	31:0	message data	Optional message Data for peek, length dependent on message size

### 11.2.3 Secure Proxy (SEC\_PROXY)

This chapter describes the Secure Proxy (SEC\_PROXY) module in the DMSS.

#### 11.2.3.1 Secure Proxy Overview

The Secure Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses.

##### 11.2.3.1.1 Secure Proxy Features

Secure Proxy supports the following features:

- Provides proxy function to store large data bursts that a host can only access in smaller amounts
- Supports a configurable number of threads, where each has their own independent proxy function
- Keeps the large data burst coherent until the complete data has been accessed
- Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
- Supports a configurable target resource. The target has a configurable number of channels, size of each channel and base address
- Supports a programmable fixed queue for each proxy thread
- Supports multiple producers all writing to the same queue
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Supports programmable thresholds for when to generate events
- Optionally supports dynamic clock gating

**Table 11-70. Secure Proxy Allocation Within Device Domains**

Module Instance	Domain	
	MCU	MAIN
DMSS0_SEC_PROXY0	-	✓(DMSS)

##### 11.2.3.1.2 Secure Proxy Parameters

[Secure Proxy Configuration Parameters](#) shows the Secure Proxy configuration parameters set during SoC design.

**Table 11-71. Secure Proxy Configuration Parameters**

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Message Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>
DMSS0_SEC_PROXY0	76	64	DMSS0_RINGACC	20	4096

(1) Number of proxy threads supported. Can be read off from the SEC\_PROXY\_CONFIG read-only register

(2) Number of bytes for message. Can be read off from the SEC\_PROXY\_CONFIG read-only register

(3) Number of channels for the target

(4) Number of bytes per channel supported for the target

#### Note

Some features may not be available. See *Module Integration* for more information.

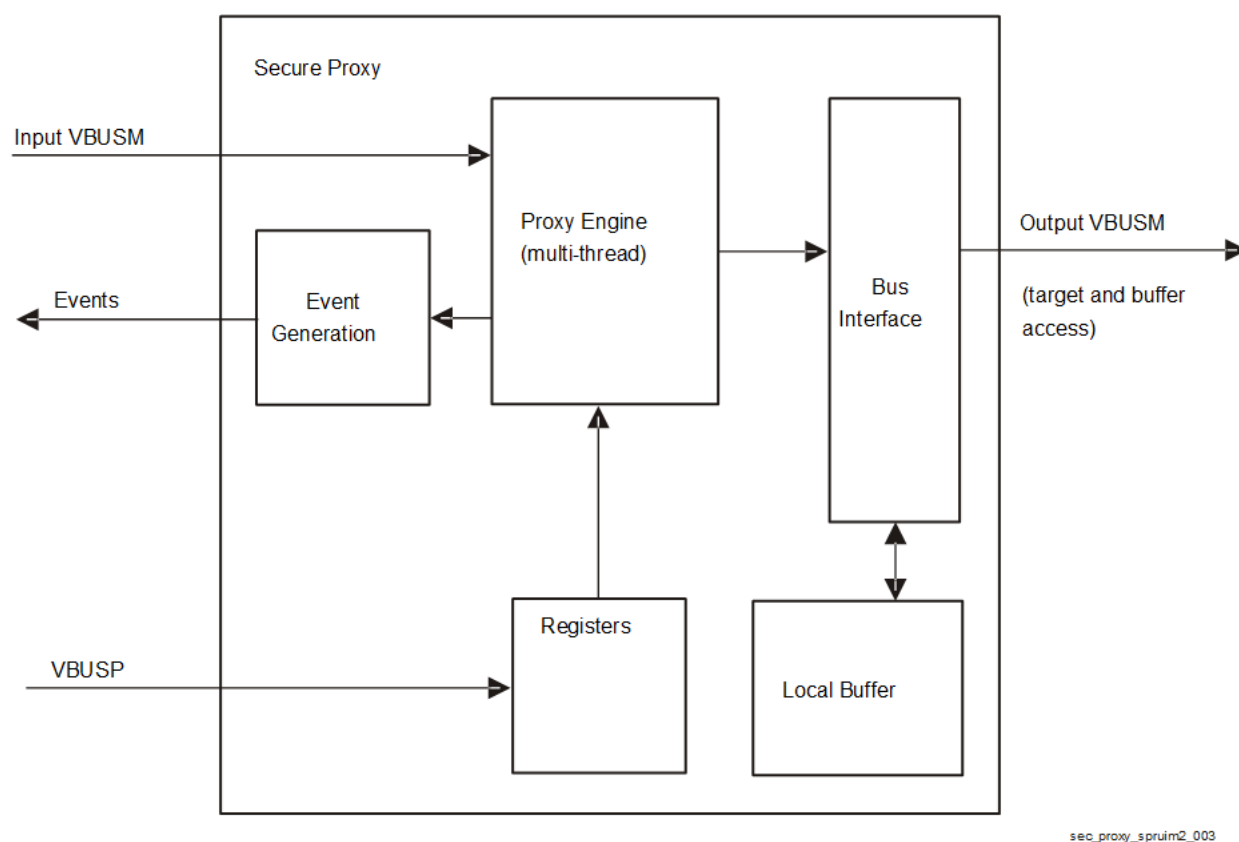

### 11.2.3.2 Secure Proxy Functional Description

This module provides proxy functions for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are:

- large messages (for power control, security control, or IPC)
- data descriptors that are more than a pointer
- DMA Transfer Requests (TR)

All of these require larger data sets, from 12 to 128 bytes, and the storage hardware requires the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as registers, and the largest CPU access is typically 8 bytes. So the proxy provides the ability to access the hardware with a single burst, and at the same time allows the CPU to access the same data in smaller accesses. The proxy itself does not contain the resources, but will front other hardware that do contain the resources. The proxy will access this other hardware with the entire data in a single burst, once the host has completed the data.

[Secure Proxy Block Diagram](#) describes Secure Proxy major building block

**Figure 11-9. Secure Proxy Block Diagram**

#### 11.2.3.2.1 Targets

##### 11.2.3.2.1.1 Ring Accelerator

The RINGACC provides four distinct offsets to use per ring/queue shown in [RINGACC Offset per Ring/Queue](#), totaling 4 KB space per ring/queue.

Secure Proxy always writes to tail, which is the offsets from 0x200 to 0x3FF. Secure Proxy always reads from the head, which is the offsets from 0x000 to 0x1FF. The latter two offsets in RINGACC are not used by this proxy. And if the proxy message size is less than 512 bytes, then it always accesses the upper bytes of those regions, so that the message always ends on the last byte of each region, byte 511.

**Table 11-72. RINGACC Offsets per Ring/Queue**

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored.
0x600 - 0x7FF	Reads peek from tail. Writes ignored.
0x800 - 0xFFFF	Reserved.

This means that target writes will use the following calculation:

target base address + (queue × 4KB) + 0x400 - msg\_size (17), and burst until offset 0x3FF.

And target reads will use the following calculation:

target base address + (queue × 4KB) + 0x200 - msg\_size (18), and burst until offset 0x1FF.

#### 11.2.3.2.2 Buffers

The proxy does not store all the buffers internally. It is programmed with a buffer base address (SEC\_PROXY\_BUFFER\_L, SEC\_PROXY\_BUFFER\_H), and all accesses to the buffer are made through the output VBUSM port using that base. The external buffer must be enough to store one msg\_size per proxy thread. The proxy only includes a small temporary buffer to save one entire message when accessing the target. Otherwise all host accesses are made to the external buffer. This buffer storage must be considered private for the proxy hardware, so any other access can cause unpredictable results.

##### 11.2.3.2.2.1 Proxy Credits

To support outbound proxy limits, the proxy will use internal credits for tracking resource usage. SEC\_PROXY\_THREAD[a]\_CTL register sets the max credits each outbound proxy thread contains. When a proxy thread sends a message, the current credit count (SEC\_PROXY\_THREAD[a]\_STATUS) decrements by 1. If the current credit count is 0, then the proxy thread is not allowed to send any more messages, and they just remain inside the proxy (so that the host can come back later when a credit has become available and quickly send the same message). When a message that was send by this proxy thread is read by an inbound proxy thread then the credit is returned to this proxy thread and the current credit count increments by 1.

For inbound proxy threads, the credits are used to track pending messages. When an outbound proxy thread sends a message that is read by this proxy thread, then the current credit count of this proxy thread is incremented by 1. A current credit count that is non zero indicates a message is pending and can be read. When the proxy thread completes the read of a message the current credit count is decremented by 1. If the current credit count is zero, then the proxy thread will read an empty message where all the data is 0s. The credit count saturates at 255, so if there can be more messages in the system for that proxy thread than 255 then multiple proxy threads should be used, or the count can become mismatched after a saturate.

##### 11.2.3.2.2.2 Proxy Private Word

To support tracking of credits from each proxy thread, the proxy will extract the first word from the total message size for private tracking usage. This will include saving the proxy thread ID used within the proxy. This is necessary so that when a proxy reads a new message from the target it can inspect this word and return the credit to the source proxy thread. This allows the outbound proxy threads to have a set number of message credits, which decrement when a new message is written, and increment when a message from that proxy thread is read, thus keeping the credits in the system coherent. Any data written to this first word of the message will be ignored, so software should not write to the first word of messages through the proxy. Consumer software can use the first word to identify the source proxy thread of the message (SEC\_PROXY\_DATA\_j).

#### **11.2.3.2.3 Completion Byte**

The proxy completes a message when the completion byte is accessed. This completion byte is the final byte in the full size of the message. This byte can be written by any size access, whether byte, 32-bit, or 64-bit word. The write of a message is not complete until this final byte of the message is written, and only then will the message be sent to the target. The read of a message is not complete until this final byte of the message is read by the host, and only then will reading a new message be allowed. Even if the final byte of the message is not needed, it must be accessed to complete the message inside the proxy hardware.

#### **11.2.3.2.3 Proxy Thread Sizes**

There are a configurable number of proxy threads in the module. Each thread has its own address space to the module and determining which proxy thread is being accessed is simply based on the address bits above the final size of each proxy thread space. Since each proxy thread will be programmed to a single resource, the only space requirement is that for using 4 KB to match typically used MMU page sizes. Only the first N bytes, matching the target channel size, is usable.

#### **11.2.3.2.4 Proxy Thread Interleaving**

Each proxy thread must have a single owner, as each proxy thread only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy thread. Then they will have their own buffer and each can access a different resource at the same time. Each proxy thread is completely independent and kept coherent regardless of accesses to other proxy threads or regardless of the order of accesses. So the proxy support interleaving of multiple hosts' accesses.

#### **11.2.3.2.5 Proxy States**

Each proxy thread uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy thread is in use or not, but also for error detection. The proxy thread always starts in idle state, when there is no currently activity. There is a write state for when the proxy thread has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy thread has read data from a resource and that entire data has not been fully read by the host. When a proxy thread access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

#### **11.2.3.2.6 Proxy Host Access**

A proxy thread begins in an idle state, where there is no data in the buffer. In this state the proxy thread will accept an access to the resource.

##### **11.2.3.2.6.1 Proxy Host Writes**

The first write to an idle proxy thread puts the proxy thread into write mode for the selected channel. Further legal writes are stored in the buffer for the enabled bytes and offset within the buffer. A write to a previously written location will overwrite the previous data. The buffer is not cleared initially, so if a byte is not written, the message will include previous buffer data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy thread is then put back into idle state. A write completion when there are no credits available results in the message not being written to the resource and the proxy thread remains in write mode (so that the message can be quickly completed when a credit becomes available).

##### **11.2.3.2.6.2 Proxy Host Reads**

When in idle state, the first read to the proxy thread will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy thread is put back into idle state. If an initial read is made and there are no pending messages, the proxy thread will return an empty message, where the data is all 0s.

#### **11.2.3.2.6.3 Buffer Accesses**

Each read or write will actually trigger a read or write to the external buffer space allocated for that proxy thread, where the real message data is stored. In addition, when a write message completes, the external buffer will be read for the entire message for that proxy thread so that it can then be written to the target. Similarly, after a read causes a read from the target to get a new message, the entire message is written to the external buffer to store the message to the buffer.

#### **11.2.3.2.6.4 Target Access**

After the write has completed and the external buffer read for the entire message, the entire message is then written to the target as a single burst. Similarly, for a read that needs a new message, the target is read for a full message as a single burst.

#### **11.2.3.2.6.5 Error State**

If an error is detected in a proxy thread, the proxy will put that proxy thread into error state, and the current buffer will be lost. A status bit will be set that indicates the proxy thread is in error. All accesses to that proxy thread will be ignored until the status bit is cleared. Once cleared the proxy thread is put back into idle state. Errors are an access to an offset beyond the length of the message, or a mismatch in the direction of access against what was programmed such as reading an outbound thread or writing an inbound thread.

#### **11.2.3.2.7 Permission Inheritance**

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target.

#### **11.2.3.2.8 Resource Association**

Each proxy thread has a register (SEC\_PROXY\_THREAD[a]\_CTL) to define the resource within the target that the proxy thread is mapped to. The host has no ability to access any other resource in the target. This allows the setup of the proxy to determine the resources that all the hosts use.

#### **11.2.3.2.9 Direction**

Each proxy thread has a register (SEC\_PROXY\_THREAD[a]\_CTL) to define the direction for access. It can either be an outbound proxy thread for writing messages to resources. Or it can be an inbound proxy thread for reading messages from resources. The host must match the direction programmed or it will result in a proxy thread error.

#### **11.2.3.2.10 Threshold Events**

Each proxy thread can produce events based on the state of the resource it uses. For outbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to write. For inbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to read. These threshold values are programmed in SEC\_PROXY\_EVT\_MAP\_j, allowing the host to determine how often it gets events. Programming the count values while the threshold is set to 0 will not trigger events, but if the threshold is not 0 then programming the counts will trigger events based on whether the threshold is reached or not. No event is generated if the event is programmed to 0xFFFF.

#### **11.2.3.2.11 Error Events**

Each proxy thread can produce an event when it has detected an error. This error occurs when the host violates the programmed setup of the proxy thread or accesses beyond the message size. There is a separate status bit per proxy thread for these errors. No event is generated if the event is programmed to 0xFFFF.

#### **11.2.3.2.12 Bus Error and Credits**

If a target read for a message returns a bus error, this indicates the read was bad and the data is corrupt and usually 0s. Because the private word is contained in the message, if the private word is corrupted then the source proxy thread is not valid and the credit return will not be correct. Since the data is usually 0, this means the credit would be returned to proxy thread 0 incorrectly most of the time. And the credit will be lost for the

actual source proxy thread of the message that was not read correctly. The hardware has no way to correct for this, as the message from the target is corrupt so it does not know the correct owner of the credit. If software detects that a read message is corrupt, it can attempt to correct the situation by resetting the affected proxy threads using that queue, to restore their credit counts back to the default. Software may also want to reset proxy thread 0 since it may be getting extra credits.

#### **11.2.3.2.13 Debug**

When the transaction has the emudbg set for a read, all side effects will not occur. This means that the read will not cause a target read since that would affect the target, and instead current buffer will be read even if the previous message has completed.

## 11.2.4 Interrupt Aggregator (INTAGGR)

This chapter describes the INTAGGR module, part of DMSS

### 11.2.4.1 INTAGGR Overview

The Interrupt Aggregator (INTAGGR or INTA) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane (ETL) bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

**Table 11-73. INTAGGR Allocation Within Device Domains**

Module Instance	Parameters	
	MCU	MAIN
DMSS0_INTAGGR0	-	✓(DMSS)

#### 11.2.4.1.1 INTAGGR Features

The DMSS0\_INTAGGR0 supports the following features:

- 64-bit VBUSP target using 64-bit registers
- Provides a set of TI Interrupt Architecture compliant interrupt status and mask register sets which are used to pass specific event status to one or more Host blocks.
  - Maps a collection of DMA Messaged Events which are input through an Event Transport Lane into specific bit locations in one or more interrupt cause registers
  - Mapping is performed based on a programmable table which provides a single location for each ordinal input event number (0 through sevt\_cnt-1)
    - Table specifies a specific bit in a specific cause register that the event should set or clear depending on the type of event (up vs down)
    - Tracks a single 'event up' / 'event down' condition. There is no event counting. (The 'cnt' field of the ETL is ignored.)
  - Tracked status interrupts are presented to the user through a standard interrupt register interface.
    - Provides separate 'enable set' and 'enable clear' registers.
    - Provides both masked and unmasked interrupt status.
    - Interrupt status bits can be manually cleared using 'write 1 to clear'.
- Provides an optional set of Unmapped Event (UNMAP) which can take an 'unmapped' event from the ingress ETL and generate a Global event on the egress Event Transport Lane (ETL) interface.
  - Each ingress event can generate an egress Global event on the egress ETL, controllable through a mapping register.
  - Each mapping register has the option of alternatively directly setting an interrupt status bit.
- Provides an optional set of Global Event Input (GEVI) counters which can count events which were delivered via an ingress Event Transport Lane (ETL).
  - Each counted event provides an MMR by which the count can be read and an MMR by which a specified amount can be decremented by the host.
  - Each counted event generates an egress Global event on a zero to non-zero and non-zero to zero transition, controllable through a mapping register.
  - Each mapping register has the option of alternatively directly setting an interrupt status bit.
- Provides an optional set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on the egress ETL interface.
  - Each mapping register has the option of alternatively directly setting an interrupt status bit.

- Provides an optional set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL.
  - Each ingress event index provides a configurable 'pulse' or 'rising edge' bit, plus the configurable index of the generated Global event.
- Supports dynamic clock gating via

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 11.2.4.1.2 INTAGGR Parameters

[Interrupt Aggregators Parameters](#) shows the Interrupt Aggregator 0, parameters set during design time.

**Table 11-74. Interrupt Aggregators Parameters**

Module Instance	Parameters				
	VINTR <sup>1</sup>	SEVI <sup>2</sup>	GEVI <sup>3</sup>	LEVI <sup>4</sup>	MEVI <sup>5</sup>
DMSS0_INTAGGR0	184	1536	256	32	128

(1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTAGGR\_INTCAP register.

(2) SEVI – Number of Main (Steerable) Events. Value can be read from INTAGGR\_INTCAP register.

(3) GEVI – Number of Countable Events. Value can be read from INTAGGR\_AUXCAP register.

(4) LEVI – Number of Local Event inputs. Value can be read from INTAGGR\_AUXCAP register.

(5) MEVI – Number of Multicast Events. Value can be read from INTAGGR\_AUXCAP register.

#### 11.2.4.2 INTAGGR Functional Description

The Interrupt Aggregator (INTAGGR) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the Host(s) in the system. Both the signaling and content of TI system events are incompatible with standard interrupt controllers. The INTAGGR provides mechanisms which convert the TI proprietary system events to standard level sensitive pending bits which can be used by all downstream interrupt infrastructure. Events can be presented to the INTAGGR in two different forms:

- Events may be active high pulses, or clock synchronous rising edges, which are input on separate orthogonal pins. These are called 'Local Events'.
  - Local event signals that are used in pulse counting mode must be sourced by the same clock as the interrupt aggregator.
  - Local event signals that are used in edge counting mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the interrupt aggregator clock, and they must remain high for at least 1 'slow' clock cycle.
- Events may be messages which are input in time division multiplexed sequential order from an Event Transport Lane. These are called 'Global Events'.

In both cases, these events need to be conditioned to transition them from a transient indicator that something occurred to a persistent and reliable indication of the current state of the system. The IA is architected to perform this conversion in an efficient and cost effective manner.

##### 11.2.4.2.1 Submodule Descriptions

###### 11.2.4.2.1.1 Status/Mask Registers

The Status and Mask Registers block is responsible for providing persistent storage for the interrupt status and mask bits and for formatting those in a way that is compliant to the TI Interrupt Architecture requirements. These requirements include the ability to set and clear bits orthogonally and to provide a masked version of the status register that corresponds to the supplied bit mask for each register.

###### 11.2.4.2.1.2 Interrupt Mapping Block

The Interrupt Mapping Block accepts ordinally numbered events (0-N) and converts those ordinal event numbers into a status register number and bit number pair that is then used to manipulate the specified bit in the Status Registers block.

###### 11.2.4.2.1.3 Global Event Input (GEVI) Counters

The GEVI Counters block is responsible for accepting an Event Transport Lane events and summing the total message counts for each received event index. The module creates global egress events for zero to non-zero count up' events and non-zero to zero 'count down' events. The egress global event index is configured via GEVI[a]\_MCMAP register, so count status egress events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

###### 11.2.4.2.1.4 Local Event Input (LEVI) to Global Event Conversion

The Local to Global event block is responsible for accepting an array of input pins and independently counting the number of cycles for which those pins are asserted high, or by counting individual clock synchronous rising edge events. The counting mode is configurable on a 'per pin' basis. The events are converted to egress Global events on an egress ETL. Global events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

###### 11.2.4.2.1.5 Global Event Multicast

The Global event multicast block takes an ingress global event from an ingress ETL, and maps it into two egress Global events on two egress ETL interfaces. Global events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

##### 11.2.4.2.2 General Functionality

#### 11.2.4.2.2.1 Event to Interrupt Bit Steering

Each time an event message is received on the Main Event Transport Lane interface, the interrupt mapping block performs a direct lookup into an SRAM using the event number as the address. The SRAM stores a corresponding interrupt status (INTR\_STATUSM) register and bit number within that register (VINT[a]\_STATUS\_MSKD) which are to be manipulated anytime a message is received indicating something occurred on that specific event. When an up event is received, the specified bit in the [a] Status register will be set. When a down event is received, that same bit will be cleared. This block is what allows flexible aggregation of various system events into an array of bits in the interrupt status registers. It is intended that this mapping is essentially static - set up when a resource is allocated and left untouched until the resource is no longer needed. Note that the 'cnt' field of the ETL is ignored and no interrupt counting is performed here. When 'UpDn=1', the interrupt flag bit is set, and when 'UpDn=0', the flag bit is cleared.

#### 11.2.4.2.2.2 Interrupt Status

The event messages which are generated from the event to interrupt bit steering logic are input to the Interrupt Status registers. Each time an event is received, the interrupt status registers machine will assert or de-assert the specified bit in the specified register. The assertion and de-assertion in the interrupt status register is unaffected by the interrupt enable state. When an up event is received, the corresponding bit is set and when a down event is received, the corresponding bit is cleared. Some sources of input events will not include the ability to send a down event. In these cases, the interrupt router provides the ability to clear the status bits through the Interrupt Source Clear register (VINT[a]\_STATUS). The host will write a one to the specific bit in the register which is to be cleared and the interrupt status machine will clear the bit internally. It is not intended that the Host directly clear bits which are automatically cleared via down events from the source itself.

#### 11.2.4.2.2.3 Interrupt Masked Status

Interrupt enable bits are used in conjunction with the interrupt status bits to create the interrupt masked status register values. The interrupt masked status register (VINT[a]\_STATUS\_MSKD) contains the value of the interrupt status ANDed with the value of the interrupt enable register (VINT[a]\_ENABLE\_SET). Each time a new event message is received from the event to interrupt bit steering logic or the interrupt enable register is modified, the interrupt masked status register is re-evaluated.

#### 11.2.4.2.2.4 Enabling/Disabling Individual Interrupt Source Bits

Separate (VINT[a]\_ENABLE\_SET and VINT[a]\_ENABLE\_CLR) registers are provided to allow individual enable bits to be enabled or disabled without the need for a read-modify-write operation. When the VINT[a]\_ENABLE\_SET register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be set. When the VINT[a]\_ENABLE\_CLEAR register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be cleared.

#### 11.2.4.2.2.5 Global Event Counting

When enabled, the INTAGGR will provide a set of counters which will track how many outstanding messages have been observed for each ingress event index from the ingress Counted Global Event Transport Lane (ETL) interface. For each message received where the 'UpDn' flag is set, the corresponding counter will be incremented by value of the 'cnt' field of ingress message. Events where the 'UpDn' flag is cleared are ignored. The counter is made visible to software in the GEVI[a]\_COUNT register. When software has read the count, it can acknowledge that count has been seen and processed by writing back an integer value specifying the amount by which the counter should be decremented, and the counter will subtract that value from the current count (which may have updated since it was read). The count will saturate at a value of 0xFFFFFFFF. Writing a count 'ack' value higher than the one read is not supported and will produce non-deterministic results.

When a count transitions from zero to a non-zero value, a Global Up 'UpDn=1' event is sent out an egress ETL interface. When a count transitions from a non-zero value to zero, a down 'UpDn=0' event will be sent. The index of the Global event is mappable on a 'per-counter' basis, using the GEVI[a]\_MAP register. The event may be mapped such that it then re-enters INTAGGR's 'Event to Interrupt Bit Steering Block' to generate an interrupt to the host. The event routing is handled by an external event switch fabric. Note that writing a new egress event index via the GEVI[a]\_MAP register does not alter the stored event count for the ingress event register index.

#### **11.2.4.2.2.6 Local Event to Global Event Conversion**

When enabled, the INTAGGR will provide a set of Local to Global event conversion registers. Local events may be discrete clock synchronous pulses or clock synchronous rising edges. The counting mode is configurable on a 'per pin' basis. In pulsed mode, the module will track how many outstanding clock cycle long pulses have been observed on each of the provided LEVI interface pins. For each cycle in which a LEVI input pending bit is asserted the corresponding counter will be incremented by 1. In 'rising edge' mode, the number of rising edge transitions on the pin is counted.

The module will generate egress Global events on its egress ETL, with a different global index configured for each ingress LEVI pin. The LEVI pins numbers (1-N) are converted to arbitrary global event indices via the global event mapping LEVI[a]\_MAP registers. The egress Global events can themselves be mapped to re-enter the INTAGGR's Global Event Counting block, so that the counts can then be made visible to software in the GEVI count registers as described in Section 10.2.7.3.1.3. The event routing is handled by an external event switch fabric.

#### **11.2.4.2.2.7 Global Event Multicast**

In DMSS0\_INTAGGR0, the INTAGGR will provide a set of Global event multicast (GEVI[a]\_MCMAP) registers. These registers allow an ingress Global event on its ingress ETL interface to be mapped into two egress Global events on two separate egress ETL interfaces. A set of registers map the ingress Global event index (1-N) into two arbitrary egress event indices.

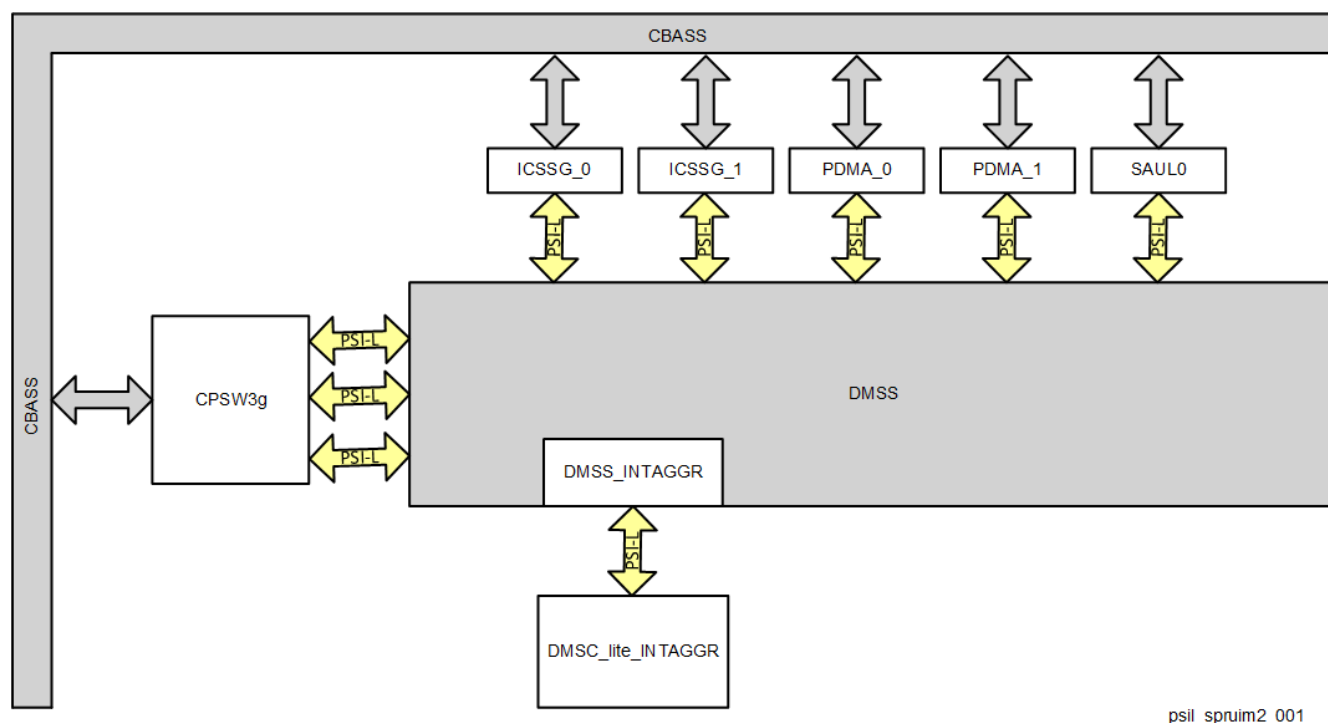

## 11.2.5 Packet Streaming Interface Link (PSI-L)

This section describes the Packet Streaming Interface Link (PSI-L) for the device.

### 11.2.5.1 PSI-L Overview

PSI-L is a packet based protocol used to transfer data between several device modules. Each transaction is routed based on thread ID value instead of physical address. All PSI-L interfaces are point to point direct connections to DMSS0. All switching functions among the PSI-L based interfaces are done inside DMSS0.

The PSI-L also has an event interface referred to as ETL, which is purely used to transfer event information.

**Figure 11-10. PSI-L Overview**

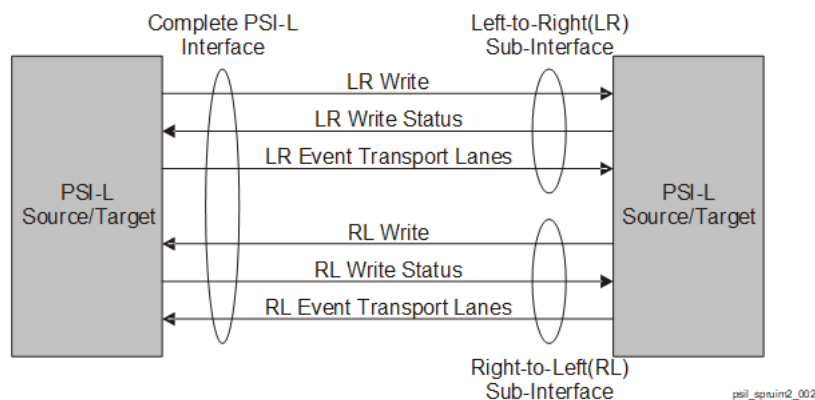

## 11.2.5.2 PSI-L Functional Description

### 11.2.5.2.1 PSI-L Introduction

The PSI-L is used to transfer words of packet data and control information between two peer entities via direct connection. There are credits used for flow control to guarantee that blocking does not occur between threads. Multiple packet transfers can be ongoing simultaneously across a PSI-L interface each on a separate logical thread but all sharing a single data path through time division multiplexing. Each packet which is transferred is accompanied by a destination thread ID which indicates the logical destination thread to which the packet is being sent.

There is low level hardware handshake between PSI-L initiator and target used for transferring data. As it is blocking by nature, a higher level protocol is also used in which credits are maintained for each thread connection. Moments of non-readiness are allowed on the interface but there is no possibility that one thread can block another for an indefinite time since a thread must have credit for the destination before it is allowed to use the interface.

[PSI-L Connection](#) illustrates the point to point PSI-L connection.

**Figure 11-11. PSI-L Connection**

PSI-L is intended to be a versatile interface which can carry various types of communications. The following table describes several types of threads which have been defined.

**Table 11-75. Types of PSI-L Threads**

Type	Description	Example Endpoints
Queue Management (QM) Messaging	Provides transport for queue push, pop, and divert messages to support distributed queue based work passing	Centralized queue manager or message manager and distributed DMA clients
Direct IO	Allows for tunneling CBASS compatible bus transactions through a PSI interconnect	Module which has no CBASS initiator to a remote proxy block
DMA Control Transport	Provides transport for DMA transfer descriptions from a source thread to a destination thread	DMA channel controller to DMA transfer controller
DMA Data Transport	Provides transport for packed data from a source thread to a destination thread	Packet oriented module like networking adapters to or from centralized DMA

Each thread on PSI-L is established between a single thread initiator and a single thread target using a connection oriented transfer mechanism. A thread initiator and a thread target are "paired" to create a logical connection between them referred to as a thread. Pairing is accomplished using a Pair Configuration Message which is valid in all thread types. Pairing can only occur between a thread initiator and a thread target of the same type.

#### 11.2.5.2.2 PSI-L Operation

The PSI-L allows multiple independent streams of packet data (threads) to share a single interface using data phase granularity time division multiplexing. This time division multiplexing is accomplished by dividing each stream into single data transfers. In this way a stream is comprised of a sequence of strongly ordered data transfers but packet transfers between different streams are allowed to be interleaved. Each data phase is qualified with a type identifier which indicates whether the data is packet info, direct IO write or read info, timestamp, software info, control data, payload data, or status.

#### 11.2.5.2.3 Event Transport

PSI-L provides a mechanism by which events can be transported within one or more optional subinterfaces on a link. These sub-interfaces are referred to as event transport lanes (ETLs) and are independent of any PSI-L packet or message transfers which may be ongoing on the other interfaces within the PSI-L. A maximum of one event can be transferred on each event transport lane in each clock cycle. The event transport protocol is a simple request-ready type of hardware handshake.

#### 11.2.5.2.4 Threads

A thread is a complete flow-controlled stream of communication. The PSI-L thread space is divided into a 32K contiguous region representing all of the source threads (0x0000 - 0x7FFF) and a 32K contiguous region representing all of the destination threads (0x8000 - 0xFFFF).

Source threads are responsible for sending request transactions, accepting response transactions, and sending data transfer transactions. Destination threads are responsible for accepting request transactions, sending response transactions, and accepting data transfer transactions. A given thread generally performs only a single class of transactions (see [PSI-L Defined Threads](#)). Both source and destination threads may act as initiators for transfers on one of the PSI-L write sub-interfaces but in this case source threads are actually initiating data transfers while destination threads are only responding to a previous request issued by a source request. Source threads only transfer to destination threads and destination threads only transfer to source threads. Transfers between same thread types do not occur.

The following types of message transfers always originate from source threads and terminate in destination threads:

- Configuration write message
- Configuration read message
- QM push message
- QM pop message
- QM divert message
- Direct read operation message
- Direct write operation message
- DMA transfer request message
- DMA data message

The following types of message transfers always originate in destination threads and terminate in source threads:

- Configuration write response message
- Configuration read response message
- QM push response message
- QM pop response message
- QM divert response message
- DMA transfer response message

#### 11.2.5.2.5 Arbitration Protocol

On each cycle, an arbiter built into the initiator side of each interface decides on which thread to transfer data in the next clock cycle. Both forward (from source threads) and reverse (from destination threads) direction

transfers can occur across the same physical interface so the arbiter must ensure that sustained blocking of any thread can occur.

The decision about which thread to allow using the interface is based on the following factors:

1. Whether data is ready at the source to be sent
2. Whether credit exists for the thread such that it is guaranteed there is a place for the data to land in the destination endpoint. For reverse direction transfers (response messages), it is assumed that credit always exists.
3. The relative priority of the traffic that the thread is carrying for the given packet duration
4. Whether the transfer is for a forward or reverse direction thread (requests versus responses).

No thread can be considered for inclusion in arbitration unless both data is available and credit exists in the destination endpoint. For each thread which can be considered in the current arbitration cycle, the arbiter should then pick the thread with the highest priority. Reverse transfers should be considered higher priority than forward transfers.

#### **11.2.5.2.6 Thread Configuration**

Each source thread has programmable registers for configuring the pairing with a corresponding destination thread and for enabling data flow. Each destination thread has programmable registers for reporting the buffering capability of the thread and for enabling data flow. These registers are accessed using configuration read and write messages from a configuration host.

Each configuration write message sent from a configuration host is acknowledged with a configuration write response message from the addressed endpoint. Each configuration read message sent from a configuration host is acknowledged with a configuration read response message from the addressed endpoint.

##### **11.2.5.2.6.1 Thread Pairing**

Depending on the type of traffic that each source thread carries it may or may not have a fixed pairing with a destination thread.

##### **11.2.5.2.6.1.1 Configuration Transaction Pairing**

Configuration write and read transactions are only initiated by a special module called configuration proxy (PSILCFG\_PROXY). Each configuration proxy in the system uses a single source thread which can initiate configuration write and read transactions to the configuration registers of every other source and destination thread in the PSI-L system. The PSILCFG\_PROXY registers are described in *DMASS\_PSILCFG\_0 Registers*, located in *DMA Controller Registers*.

Each source thread routes to a single target thread and this pairing is specified by programming a required pairing register set for each thread. A source has no ability to change what target thread it talks to. If a source must be able to talk to different targets (or target threads), then it can either have multiple threads or a streaming switch that can be programmed to route the transfers appropriately based on specific packet fields.

##### **11.2.5.2.6.2 Configuration Registers Region**

The configuration registers region contains static configuration information including the settings for linking a thread source to a thread destination. These registers are described in *DMA Controller Registers*. The thread ID mapping is shown in *PSI-L System Thread Map*, located in *Module Integration*.

## 11.3 Peripheral DMA (PDMA)

This chapter describes the PDMA architecture in the device.

### 11.3.1 PDMA Controller

#### 11.3.1.1 PDMA Overview

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals, which perform data transfers using memory mapped registers (MMRs) accessed via a standard non-coherent bus fabric. The PDMA module is located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured transfer request (TR) operations.

The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer DMSS destination channel which then performs the movement of the data into memory. Likewise, a remote DMSS source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The PDMA architecture is intentionally heterogeneous (DMSS + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

The PDMA is linked to the DMSS through a direct PSI-L connection. For more details, refer to *Packet Streaming Interface Link (PSI-L)*.

#### 11.3.1.1.1 PDMA Features

##### 11.3.1.1.1.1 PDMA0 - SPI Features

The PDMA0 - SPI module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit(s)
  - Each unit supports write bursts up to 64 bytes (on selected channel types)
  - Write Unit 0
    - Provides a 32-bit wide VBUSP write-only initiator interface for peripheral accesses
- Provides 1 memory read access unit(s)
  - Supports 1 outstanding read per interface (VBUSP)
  - Supports read burst up to 64 bytes (on selected channel types)
  - Read Unit 0
    - Provides a 32-bit wide VBUSP read-only initiator interface for peripheral accesses
- Supports up to 15 simultaneous destination (Tx) channels
- Supports negative credit monitoring on Tx channels
- Supports up to 15 simultaneous source (Rx) channels
- Supports Static Transfer Requests Only
- Supports X-Y, MCAN, and AASRC transfer modes (as per configuration)
- Provides per-channel buffering:
  - Provides 8 128-bit word deep data FIFO for each destination channel
  - Provides 8 128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to and from DMSS endpoints and remote peripherals

#### 11.3.1.1.1.2 PDMA1 - UART Features

The PDMA1 - UART module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit(s)
  - Each unit supports write bursts up to 64 bytes (on selected channel types)
  - Write Unit 0
    - Provides a 32-bit wide VBUSP write-only initiator interface for peripheral accesses
- Provides 1 memory read access unit(s)
  - Supports 1 outstanding read per interface (VBUSP)
  - Supports read burst up to 64 bytes (on selected channel types)
  - Read Unit 0
    - Provides a 32-bit wide VBUSP read-only initiator interface for peripheral accesses
- Supports up to 7 simultaneous destination (Tx) channels
- Supports negative credit monitoring on Tx channels
- Supports up to 7 simultaneous source (Rx) channels
- Supports Static Transfer Requests Only
- Supports X-Y, MCAN, and AASRC transfer modes (as per configuration)
- Provides per-channel buffering:
  - Provides 8 128-bit word deep data FIFO for each destination channel
  - Provides 8 128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to and from DMSS endpoints and remote peripherals

#### 11.3.1.1.1.3 PDMA2 - McASP Features

The PDMA2 - McASP module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit(s)
  - Each unit supports write bursts up to 64 bytes (X-Y FIFO transfer mode only)
  - Write Unit 0
    - Provides a 32-bit wide VBUSP write-only initiator interface for peripheral accesses
- Provides 1 memory read access unit(s)
  - Supports 1 outstanding read per interface (VBUSP)
  - Supports read burst up to 64 bytes (X-Y FIFO transfer mode only)
  - Read Unit 0
    - Provides a 32-bit wide VBUSP read-only initiator interface for peripheral accesses
- Supports up to 3 simultaneous destination (Tx) channels
- Supports up to 3 simultaneous source (Rx) channels
- Supports Static Transfer Requests Only
- Supports X-Y, MCAN, and AASRC transfer modes (as per configuration)
- Provides per-channel buffering:
  - Provides 8 128-bit word deep data FIFO for each destination channel
  - Provides 8 128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to and from DMSS endpoints and remote peripherals

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 11.3.1.2 Functional Description - SPI

##### 11.3.1.2.1 Compliance to Standards

The PDMA complies fully to all standards listed in the previous section.

### 11.3.1.2.2 Functional Operation

The Peripheral DMA is a simple, low cost implementation of the CPPI 5.0 Unified Transfer Controller. The PDMA module is required to be located close to one or more peripherals (both peripherals and PDMA direct connected to the SCR) which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only the static Transfer Request subset of UTC features which are useful for peripheral type transactions. Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs time division multiplexing between channels in order to share the underlying DMA hardware. A scheduler is provided to control the ordering and rate at which this multiplexing occurs. A block diagram of the PDMA Controller is shown below.

#### 11.3.1.2.2.1 Submodule Descriptions

##### 11.3.1.2.2.1.1 Scheduler

The Scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low level read or write operation.

##### 11.3.1.2.2.1.2 Tx Per Channel Buffers

The Tx Per Channel Buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx Per Channel Buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

##### 11.3.1.2.2.1.3 Tx DMA Unit

The Tx DMA Unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming dma event and then writes data from the Tx Per Channel Data FIFO associated with the channel to an external memory mapped target via a VBUSP controller interface. The number and width of the writes that are performed is in accordance with the parameters which were programmed via PSI-L into the static TR for the channel.

##### 11.3.1.2.2.1.4 Rx Per Channel Buffers

Rx Per Channel Buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte oriented on write so that the data from the Rx DMA units which may not be full words can be packed properly. The buffers are word oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface. The Rx Per Channel Buffer block outputs queue fullness information to the scheduler block which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx Per Channel Buffer will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

##### 11.3.1.2.2.1.5 Rx DMA Unit

The Rx DMA Unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP controller read interface into the Rx Per Channel Data FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters which were programmed via PSI-L into the static TR for the channel.

#### 11.3.1.2.2.2 General Functionality (Applicable to All Functions/Modes)

### 11.3.1.2.2.2.1 Operational States

At any given time, the PDMA can be in one of three different states, as shown in [Table 11-76](#).

**Table 11-76. Operational States**

Operational State	Description
Init	This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the init state, the DMA will de-assert all ready signals on all applicable target interfaces and will de-assert all request signals on all applicable controller interfaces. The PDMA will automatically transition out of the init state into the idle state when all of the RAM initialization has been completed.
Idle	Once the PDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the PDMA interfaces (controller or target). The Idle state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. For clock stop purposes, the module will only report idle if all DMA channels are disabled using the enable bit in PSIL register 2 for each channel.
Active	The PDMA enters the active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the PDMA transitions to the Idle state.

### 11.3.1.2.2.2.2 Clock Stop

The clock stop interface is a request/acknowledge interface used to coordinate the handshaking of properly stopping the main clock to the IP. Before attempting to perform a clock stop operation, software is required to teardown all active channels (via UDMAP 'real time' registers in the UDMAP, or PSIL register 0x408 in PSIL based peripherals), and after this is complete, also clear the global enable bit for all channels (via PSIL register 0x2 in both the UDMAP and PSIL based peripherals). Attempting a clock stop on the IP without first performing the channel teardowns or clearing of global enable bits will result in IP specific behavior that may be UNDEFINED.

The PDMA will not drive clock stop IDLE or clock stop ACK while the global enable (PSIL register 0x2) is set for any channel.

### 11.3.1.2.2.2.3 Emulation Control

The emulation control input (susp\_emususp) and the per channel emulation control 'free' bit allow DMA operation to be suspended on a per channel basis. When the emulation suspend state is entered, the DMA will stop processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. Emulation control is implemented for compatibility with other peripherals. Each source and destination channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is controlled via the 'free' bit in the channel Enable Register. Note the real time emulation suspend request signal is not supported.

### 11.3.1.2.2.2.4 Dynamic Clock Gating

The PDMA includes up to two mid level clock gates using ksdw\_pm\_clkgate(). One is on the main clock of the PDMA while the other is on the interal ecc\_aggr (when RAM is used). These clock gates turn off the clock to their corresponding IP under idle conditions, and then turn the clock back on when work is to be done. Detecting work is done via internal state, or activity on the PSIL or DMA triggers. The DMA triggers are thus always monitored, even when the clocking to the rest of the IP is disabled.

The dynamic clock gating can be disabled through an external port called pwr\_disable\_nogate. No additional signaling is needed to support the dynamic clock gate, although the PDMA supports the 'early wake' pins on PSIL and VBUSP.

### 11.3.1.2.2.3 Events and Flow Control

The following sections describe the simplified mechanism that is provided on the Peripheral DMA for triggering.

### 11.3.1.2.2.3.1 Channel Triggering

Channels must be triggered in order for them to perform work. A local event input bus is provided on the peripheral DMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, etc.). The event inputs for XY mode are triggered either via pulse, or by a clock synchronous rising edge. The counting mode is a design time configuration parameter. In MCAN mode, the inputs are expected to be single cycle pulses, synchronous with the PDMA clock.

- Event signals that are used in pulse mode must be sourced by the same clock as the PDMA.
- Event signals that are used in edge mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the PDMA clock, and they must remain high for at least 1 'slow' clock cycle.

The PDMA provides a 2 bit counter per event input to accommodate startup latency in the channel. (In AASRC mode, the signals are not counted, but latched whenever asserted.)

### 11.3.1.2.2.3.2 Completion Events

All transfers on PDMA are split TR in that they have a UDMA-P half and a (static) PDMA half. Completion events are designed to be triggered from the UDMA-P half of the split TR.

### 11.3.1.2.2.3.3 Channel Types

Each channel in the Peripheral DMA is configured at design time to be either standard X-Y FIFO mode or MCAN channel. The channel type is configured at design time, and can not be changed by software.

#### 11.3.1.2.2.3.3.1 X-Y FIFO Mode

Most peripherals which are serviced by the Peripheral DMA follow the pattern of transferring X bytes from a fixed, non-changing address in a loop Y times for each triggering event that is received. The X parameter is typically 1-16 bytes and the Y parameter can be any integer up to 2048. If a peripheral can be serviced by this basic functionality then it is recommended to use this mode for the peripheral.

#### 11.3.1.2.2.3.3.2 MCAN Mode

The MCANSS subsystem was found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the DMA will start out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, MCAN packet fragmentation requirement to place an 8 byte header on each 64 byte chunk that is transmitted and to remove the header from each 64 byte chunk (other than the first block) that is received.

#### 11.3.1.2.2.3.3.3 AASRC Mode

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOs to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels do not share the same PDMA as do XY and MCAN channels.

The following additional details apply to the PDMA in AASRC mode:

Main Features:

- Up to 16 independent RX channels and 16 TX channels
  - Each channel represents a different data stream to either the UDMA-P-P or a McASP PDMA
- Each channel can be configured to read or write any of the AASRC FIFOs in any order
- Packing support for 1, 2, 3, and 4 byte samples
  - Can directly talk to a McASP using any McASP data format
  - Packing sample size is fixed for a given channel
- Supports both Group and Stream AASRC signaling and FIFO memory maps

- There is a single stream/group mode setting for each PDMA channel

Additional details:

- Each channel has a 'mask' of which DMA requests must fire to activate the channel
  - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
  - In group mode, the mask specifies the one group DMA request that must fire
- Each channel specifies an ordered list of how FIFOs should be accessed
  - All channels use a common list, specifying a range of entry indices within that list. This allows each channel to use a varying number of list elements.
  - The order list can be processed multiple times per DMA request. The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC.
- All FIFOs are specified by index only
  - In the TX ordering table, the indices are assumed to be TX FIFOs
  - In the RX ordering table, the indices are assumed to be RX FIFOs
  - If a DMA channel is in 'Group Mode', the PDMA assumes the indices referenced by that channel represent Group Mode FIFOs; otherwise, it assumes Stream Mode FIFOs.
- The PDMA has configured base addressed and inter-FIFO spans such that it can always convert from a FIFO index to the proper Stream or Group mode FIFO address.

#### 11.3.1.2.2.4 Transmit Operation

##### 11.3.1.2.2.4.1 Destination (Tx) Channel Allocation

A total of 15 destination channels are provided within the DMA for concurrent transfers from Tx per channel buffers to the various attached peripherals. Each Tx channel requires a single PSI-L thread. The Tx channels are allocated as in the following table.

**Table 11-77. Tx Channel Allocation**

Tx DMA Channel	Function	Channel Type	Trigger Mode	Data FIFO Address	Strobe MMR Address	Control FIFO Address
8000	SPI 0 Tx Ch 0	XY	edge	000020100138	000000000000	000000000000
8001	SPI 0 Tx Ch 1	XY	edge	00002010014C	000000000000	000000000000
8002	SPI 0 Tx Ch 2	XY	edge	000020100160	000000000000	000000000000
8003	SPI 0 Tx Ch 3	XY	edge	000020100174	000000000000	000000000000
8004	SPI 1 Tx Ch 0	XY	edge	000020110138	000000000000	000000000000
8005	SPI 1 Tx Ch 1	XY	edge	00002011014C	000000000000	000000000000
8006	SPI 1 Tx Ch 2	XY	edge	000020110160	000000000000	000000000000
8007	SPI 1 Tx Ch 3	XY	edge	000020110174	000000000000	000000000000
8008	SPI 2 Tx Ch 0	XY	edge	000020120138	000000000000	000000000000
8009	SPI 2 Tx Ch 1	XY	edge	00002012014C	000000000000	000000000000
800a	SPI 2 Tx Ch 2	XY	edge	000020120160	000000000000	000000000000
800b	SPI 2 Tx Ch 3	XY	edge	000020120174	000000000000	000000000000
800c	MCAN 0 Tx Ch 0	XY	pulse	000002708000	0000027010D0	000000000000
800d	MCAN 0 Tx Ch 1	XY	pulse	000002708048	0000027010D0	000000000000
800e	MCAN 0 Tx Ch 2	XY	pulse	000002708090	0000027010D0	000000000000

##### 11.3.1.2.2.4.2 Destination (Tx) Channel Out of Band Signals

The following table shows how PSIL signals are handled for destination channels.

**Table 11-78. Tx Channel Out of Band Signals**

PSI-L Signal	XY/AASRC Mode	MCAN Mode
sop	ignored	ignored
eop	ignored	closes current MCAN packet

**Table 11-78. Tx Channel Out of Band Signals (continued)**

PSI-L Signal	XY/AASRC Mode	MCAN Mode
sol	ignored	ignored
eol	ignored	ignored
drop	ignored	ignored
pkt_error	ignored	ignored
tdown	reflect in status, teardown when data marker reached	reflect in status, teardown when data marker reached

#### 11.3.1.2.2.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will need to first pair the channel with a remote data source (normally a UDMA-P channel), set up the static TR for the channel, and enable the thread.

##### 11.3.1.2.2.4.3.1 PSI-L Destination Thread Pairing Registers

###### 11.3.1.2.2.4.3.1.1 Enable Register (PSIL Address 0x002)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the TX channel is disabled. When disabled, the channel discards all ingress data. A one to zero transition on this bit fully resets the channel.
30:0	-	0x0	Reserved.

###### 11.3.1.2.2.4.3.1.2 Local Capabilities Register (PSIL Address 0x040)

Bits	Field	Reset	Description
31:29	-	0x0	Reserved.
28:24	LocalThreadWidth	0x2	Read only element width for the local thread used for pairing purposes. This field is encoded as follows: 0 = 4 bytes, 1 = 8 bytes, 2 = 16 bytes.
23:8	-	0x0	Reserved.
7:0	LocalCreditCnt	0x7	Read only local thread free entry count used for pairing purposes.

##### 11.3.1.2.2.4.3.2 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The Host will pair each destination PDMA channel with (typically) a corresponding source channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the UDMA-P will send all their data to the destination channel in the PDMA and the destination channel in the PDMA will never see any data other than data from the source channel in the UDMA-P.

##### 11.3.1.2.2.4.3.3 PSI-L Destination Thread Realtime Enable/Count Registers

###### 11.3.1.2.2.4.3.3.1 RT Enable Register (PSIL Address 0x408)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the TX channel is disabled. When disabled, it discards all held data. It clears DMA event counts and ignores all future DMA events from the peripheral. It maintains data exchange with the UDMA-P so that credit handshake is not disrupted. A 'hard teardown' can be performed by directly clearing this bit. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	tdown	0x0	When set, the channel will commence a TX channel teardown procedure. To perform a TX teardown, the teardown bit should be set in the UDMA-P and it will automatically propagate to this register bit with the normal flow of peripheral data. Once the channel is fully stopped and ready to be reused (including returning all credits), the enable bit is cleared.
29	pause	0x0	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals, but will not act on them. The pause bit can be cleared and data will resume.
28	flush	0x0	When set, causes all TX channel data to be discarded instead of being written to the peripheral. It essentially allows the TX engine to 'free run' without DMA requests from the peripheral (it will also override 'pause'). This bit should be set only when a channel fails to complete its teardown procedure normally, because a peripheral is no longer functioning or because data flow was halted on a boundary that is not compatible with the static TR configuration.
27:3	-	0x0	Reserved.
2	error	0x0	When set, the channel has encountered a PSIL protocol violation. The error bit can only be set by hardware, and can only be cleared by software. Once this bit is set, the channel should be fully reset and re-initialized via the PSIL pairing registers.
1	idle	0x0	This is a read-only bit that signifies that the disabled channel is also idle. This bit is read only and can only become set if the enable bit in the RT enable register is cleared.
0	free	0x0	When cleared, the channel honors the emudbg suspend signal. When set, the channel will free run, regardless of the value of emudbg suspend.

#### 11.3.1.2.2.4.3.3.2 Destination Thread Byte Count Register (PSIL Address 0x404)

Bits	Field	Reset	Description
31:0	bytes	0x0	This register contains the number of bytes that have been written to the VBUSP mapped peripheral. The register is write to decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

#### 11.3.1.2.2.4.3.4 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of an X, Y, and Z parameter, but the field interpretation varies somewhat.

#### 11.3.1.2.2.4.3.4.1 X-Y FIFO Mode Static TR

In X-Y FIFO mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, 4 = 64 bits, and 5-7 = RESERVED
Y	0x400	11:0	Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.
Z	0x401	23:0	Not used

#### 11.3.1.2.2.4.3.4.2 MCAN Mode Static TR

In MCAN mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the MCAN burst description for more information.
Acc32	0x400	30	Not used
X	0x400	26:24	Not used
Y	0x400	11:0	Buffer Size. This field specifies how many bytes should be written to an MCAN TX buffer. This field includes the 8 byte MCAN header on the initial packet fragment. The PDMA will break up the source packet into fragments of this buffer size, copying the 8 byte MCAN header for the initial fragment, and then skipping it for each additional fragment and thus reusing the header from the first fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.
Z	0x401	23:0	Not used

#### 11.3.1.2.2.4.3.4.3 AASRC Mode Static TR

AASRC mode is similar to X-Y FIFO mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, and 4-7 = RESERVED

Param	PSIL Addr	Field	Description
Y	0x400	11:0	FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer to each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.
Z	0x401	23:0	Not used

#### 11.3.1.2.2.4.3.4.4 AASRC TxFifoConfig (PSIL Address 0x405)

This register describes the FIFO list to be processed for this TX channel.

Bits	Field	Reset	Description
31	GroupMode	0x0	When set, the channel is in 'Group Mode'. It will look for Group Mode DMA requests, and access the Group Mode FIFOs. When clear, the channel is 'Stream Mode'. It will look for Stream FIFO DMA requests, and access the Stream Mode FIFOs.
30	DmaReqReset	0x0	When set, resets any latched DMA request using the DmaReqMask. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
23:20	LastSlot	0x0	This is the index (0-15) of the last slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19:16	FirstSlot	0x0	This is the index (0-15) of the first slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
15:0	DmaReqMask	0x0	This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate.  In Steam Mode, these 16 flags correspond to the 16 DMA requests for each TX FIFO. The flags corresponding to all TX FIFOs involved with the channel should be set to 1.  In Group Mode, these flags indicate which Group Mode DMA requests must fire. In this case, only bits 3:0 are relevant and only one bit should be set to 1 as a DMA channel only services a single group.

#### 11.3.1.2.2.4.3.4.5 AASRC TxOrderTable0 (PSIL Address 0x406)

This table is filled with FIFO index values. TX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all TX threads.

Bits	Field	Reset	Description
31:28	Entry7	7	TX FIFO Index for slot 7
27:24	Entry6	6	TX FIFO Index for slot 6
23:20	Entry5	5	TX FIFO Index for slot 5
19:16	Entry4	4	TX FIFO Index for slot 4

Bits	Field	Reset	Description
15:12	Entry3	3	TX FIFO Index for slot 3
11:8	Entry2	2	TX FIFO Index for slot 2
7:4	Entry1	1	TX FIFO Index for slot 1
3:0	Entry0	0	TX FIFO Index for slot 0

#### 11.3.1.2.2.4.3.4.6 AASRC TxOrderTable1 (PSIL Address 0x407)

This table is filled with FIFO index values. TX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all TX threads.

Bits	Field	Reset	Description
31:28	Entry15	15	TX FIFO Index for slot 15
27:24	Entry14	14	TX FIFO Index for slot 14
23:20	Entry13	13	TX FIFO Index for slot 13
19:16	Entry12	12	TX FIFO Index for slot 12
15:12	Entry11	11	TX FIFO Index for slot 11
11:8	Entry10	10	TX FIFO Index for slot 10
7:4	Entry9	9	TX FIFO Index for slot 9
3:0	Entry8	8	TX FIFO Index for slot 8

#### 11.3.1.2.2.4.3.5 PSI-L Destination Thread Enables

PSI-L destination threads must first be enabled in order to accept data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

#### 11.3.1.2.2.4.4 Data Transfer

Packet transmission is accomplished within the PDMA by unpacking and moving data from the Tx Per Channel FIFOs which were filled via the Transmit PSI-L Interface to specified memory mapped address ranges via the VBUSP controller interfaces. On the Tx side of the PDMA, these transfers are always writes. Each write transfer which is performed by the Tx DMA Unit is to a destination address that is hardcoded in the channel at design time and of a size as specified in the static Transfer Request.

The sequences of logical transactions that are performed by the PDMA on the Memory I/F during transmit is dependent on the channel type. The following sections describe what will happen for the different channel types.

#### 11.3.1.2.2.4.4.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter writes of 'X' parameter bytes to the data\_address specified in the tchan\_info parameter for the channel. Each write that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the Tx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 11.3.1.2.2.4.4.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting bit 31 of the XY register enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2 32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

#### **11.3.1.2.2.4.4.2 MCAN Mode Channel**

The PDMA channel will remain idle until data is received from the UDMA-P over the PSIL interface. At this time, the PDMA will immediately start copying packet bytes into the MCAN TX buffer corresponding the PDMA/MCAN channel. The number of bytes copied is smaller of the remaining bytes in the packet, or the value of the 'Y' parameter. Once a TX buffer has been filled, the PDMA will transfer ownership of the buffer to MCAN by performing an MCAN register write. The PDMA will then wait to regain ownership of the TX buffer by waiting for the corresponding MCAN TX event. At this time, the PDMA will continue with refilling the TX buffer for the next packet fragment. On subsequent fills (until the end of packet is reached), the PDMA will skip over the 8 byte MCAN header, leaving the original contents from the initial fragment copy in place.

##### **11.3.1.2.2.4.4.2.1 MCAN Burst Mode**

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

##### **11.3.1.2.2.4.4.3 AASRC Channel**

The AASRC channel is controlled primarily via the channel's TxFifoConfig register. This register holds 3 basic pieces of information:

- Whether the channel uses AASRC Stream Mode or Group Mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the TxFifoConfig setting. The pulses for the individual events are latched and held by the PDMA until they all arrive.

Once the channel activates, it will start reading FIFO index values from the TxOrderTable, starting at the configured 'First Slot' and ending with the 'Last Slot'. The actual FIFO indices used are obtained from the ordering table. For example, say FirstSlot=3 and LastSlot=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs written for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width written to the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel.

Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

### 11.3.1.2.2.4.5 Transmit PSI-L Interface Transactions

The PDMA will accept data across the Tx PSI-L Interface in accordance with the physical handshaking protocol as defined in the PSI-L Interface specification. The value sources for the output pins on the PSI-L interface are described in the following table.

Pin	Output Value / Source From PDMA
strm_i_link	This signal is asserted high to indicate the PSI-L link is valid.
strm_i_ready	This signal is asserted high anytime there is space in the PSI-L ingress fifo.
strm_i_sreq	This signal is asserted high anytime there is credit return data waiting in the PSI-L status fifo.
strm_i_sthreadid	This is set to the local destination thread that is returning credit.
strm_i_sccnt	This is set to the number of credits being returned, or 0 on a TX teardown acknowledgement.

### 11.3.1.2.2.4.6 Tx Pause

The Host initiates a channel pause by setting the pause bit in the RT enable register. The paused channel can be resumed by clearing the register bit.

### 11.3.1.2.2.4.7 Tx Teardown

The Host initiates a channel teardown by setting the tdown bit in the UDMA-P channel that is paired with the PDMA. The UDMA-P communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous UDMA-P data for the channel has been flushed. At this time, the teardown state will be reflected in the PSI-L RT Enable register of the PDMA. Note that a non-synchronized teardown can also be initiated by directly clearing the enable bit in the PSI-L RT Enable register of the PDMA.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel will be cleared in the PSI-L RT enable register, but the teardown bit will remain high. A teardown completion indication is sent back across the status pins of the PSI-L in the form of a credit response with sccnt=0. Upon completion, no further packet processing will occur until the Host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the UDMA-P transmission stops on a data boundary that is not compatible with the static TR configuration, the flush bit in the RT enable register can be set to guarantee that all data can be properly flushed from the internal pipe.

### 11.3.1.2.2.4.8 Tx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the enable bit in the PSI-L Enable register. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

### 11.3.1.2.2.4.9 Tx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. The registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as in the following table.

Name	PSIL Addr	Field	Description
Y	0x402	15:0	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to write to the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next write offset to use when writing to the CAN TX buffer.
InEvent	0x403	31	When set, the PDMA is in the middle of processing a FIFO event.

Name	PSIL Addr	Field	Description
Flush	0x403	30	When set, the PDMA is processing in a flushing state, where it runs without waiting for DMA requests and without writing data to the peripheral. It is only operating its internal state machine to allow internal data pipes to drain properly.
Pause	0x403	29	When set, the PDMA waiting in a paused state. This bit will clear when data starts flowing again from the UDMA-P.
Data	0x403	28	When set, there is a non-zero amount of data still waiting to be written to the peripheral.
XData	0x403	27	When set, there is enough data still waiting to be written to the peripheral to start servicing a peripheral DMA event.
State	0x403	23:20	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
EventCnt	0x403	19:16	This field holds the number of backlogged DMA events yet to be serviced.

#### 11.3.1.2.2.5 Receive Operation

##### 11.3.1.2.2.5.1 Source (Rx) Channel Allocation

A total of 15 source channels are provided within the DMA for concurrent transfers from the various attached peripherals into the Rx per channel buffers and on to the PSI-L Rx Interface. Each Rx channel requires a single PSI-L thread. The Rx channels are allocated as in [Table 11-79](#).

**Table 11-79. Rx Channel Allocation**

Rx DMA Channel	Function	Channel Type	Trigger Type	Data FIFO Address	Strobe MMR Address	Control FIFO Address
0	SPI 0 Rx Ch 0	XY	edge	00002010013C	000000000000	000000000000
1	SPI 0 Rx Ch 1	XY	edge	000020100150	000000000000	000000000000
2	SPI 0 Rx Ch 2	XY	edge	000020100164	000000000000	000000000000
3	SPI 0 Rx Ch 3	XY	edge	000020100178	000000000000	000000000000
4	SPI 1 Rx Ch 0	XY	edge	00002011013C	000000000000	000000000000
5	SPI 1 Rx Ch 1	XY	edge	000020110150	000000000000	000000000000
6	SPI 1 Rx Ch 2	XY	edge	000020110164	000000000000	000000000000
7	SPI 1 Rx Ch 3	XY	edge	000020110178	000000000000	000000000000
8	SPI 2 Rx Ch 0	XY	edge	00002012013C	000000000000	000000000000
9	SPI 2 Rx Ch 1	XY	edge	000020120150	000000000000	000000000000
10	SPI 2 Rx Ch 2	XY	edge	000020120164	000000000000	000000000000
11	SPI 2 Rx Ch 3	XY	edge	000020120178	000000000000	000000000000
12	MCAN 0 Rx Ch 0	XY	pulse	000002708900	000002701098	000000000000
13	MCAN 0 Rx Ch 1	XY	pulse	000002708990	000002701098	000000000000
14	MCAN 0 Rx Ch 2	XY	pulse	000002708A20	000002701098	000000000000

##### 11.3.1.2.2.5.2 Source Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will need to first pair the channel with a remote data source (normally a UDMA-P channel), set up the static TR for the channel, and enable the thread.

##### 11.3.1.2.2.5.2.1 PSI-L Source Thread Pairing Registers

###### 11.3.1.2.2.5.2.1.1 Peer Thread ID Register (PSIL Address 0x000)

Bits	Field	Reset	Description
31:29	ThreadPriority	0x0	This field is hard coded to 0x0 and is not writable
28:24	PeerThreadWidth	0x0	Datapath width of paired peer destination thread. This field is encoded as follows: 0 = 32-bit, 1 = 64-bit, 2 = 128 bit, 3 = 256 bit, 4 = 512 bit
23:16	-	0x0	Reserved.
15:0	Peer ThreadID	0x0	Thread ID to which all non-Transfer Response, non-Config messages from this thread will be sent.

#### 11.3.1.2.2.5.2.1.2 Peer Credit Register (PSIL Address 0x001)

Bits	Field	Reset	Description
31:8	-	0x0	Reserved.
7:0	CreditCnt	0x0	Free entries in destination thread. Legal range is 0 - 128 in number of elements.

#### 11.3.1.2.2.5.2.1.3 Enable Register (PSIL Address 0x002)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all credit returns, and will not generate egress data. A one to zero transition on this bit fully resets the channel.
30:0	-	0x0	Reserved.

#### 11.3.1.2.2.5.2.2 PSI-L Source Thread Realtime Enable/Count Registers

##### 11.3.1.2.2.5.2.2.1 RT Enable Register (PSIL Address 0x408)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all DMA events from the peripheral. It maintains proper data transfers with the UDMA-P such that the credit handshake is not disrupted. However, unlike teardown, it does not close out the current open packet. Thus the teardown bit should always be used to disable an RX channel instead of manually clearing this bit. Failing to use teardown may result in stale data remaining in the internal RX FIFO, which would also prevent the channel from going idle without a channel reset.  Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.

Bits	Field	Reset	Description
30	tdown	0x0	When set, the channel will commence a RX channel teardown procedure. It will stop on the next FIFO boundary. It then clears the DMA event count and ignores all future DMA events from the peripheral. After stopping peripheral reads, the PDMA sends a teardown message to the UDMA-P that also closes the current packet with an EOP. If no packet is open at the time of the teardown, the message also includes SOP. The EOP teardown message may or may not contain final packet data. Once the channel teardown is complete and ready to be reused, the enable bit is cleared.
29	pause	0x0	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals, but will not act on them. The pause bit can be cleared and data will resume. Pause will not stop teardown from completing.
28:2	-	0x0	Reserved.
1	idle	0x0	This is a read-only bit that signifies that the Paused or Disabled channel is also idle. This bit is read only and can only become set if pause is set or enable is cleared.
0	free	0x0	Free Run: 0 = channel honors the emudbg suspend signal, 1 = channel will free run, regardless of the value of emudbg suspend.

#### 11.3.1.2.2.5.2.2 Source Thread Byte Count Register (PSIL Address 0x404)

Bits	Field	Reset	Description
31:0	bytes	0x0	This register contains the number of bytes that have been read from the VBUSP mapped peripheral. The register is write to decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

#### 11.3.1.2.2.5.2.3 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The Host will pair each source PDMA channel with (typically) a corresponding destination channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA will send all their data to the source channel in the UDMA-P and the destination channel in the UDMA-P will never see any data other than data from the source channel in the PDMA.

#### 11.3.1.2.2.5.2.4 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of an X, Y, and Z parameter, but the field interpretation varies.

#### 11.3.1.2.2.5.2.4.1 X-Y FIFO Mode Static TR

In X-Y FIFO mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, 4 = 64 bits, and 5-7 = RESERVED
Y	0x400	11:0	Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	FIFO count. This field specifies how many full FIFO operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an 'EOP' indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.

#### 11.3.1.2.2.5.2.4.2 MCAN Mode Static TR

In MCAN mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the MCAN burst description for more information.
Acc32	0x400	30	Not used
X	0x400	26:24	Not used
Y	0x400	11:0	Buffer Size. This field specifies how many bytes should be read from an MCAN RX buffer. This field includes the 8 byte MCAN header on the initial packet fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	Buffer Count. This field specifies how many MCAN RX buffers should be read before closing the CPPI packet with an 'EOP' indication. When this count is greater than 1, multiple MCAN RX buffers will be read into a single CPPI packet buffer. The 8 byte MCAN header will be skipped on subsequent MCAN buffer reads. Setting this field to NULL will suppress all packet delineation, and should be avoided.

#### 11.3.1.2.2.5.2.4.3 AASRC Mode Static TR

AASRC mode is similar to X-Y FIFO mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each read which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, and 4-7 = RESERVED
Y	0x400	11:0	FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer from each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	FIFO count. This field specifies how many full DMA request operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an 'EOP' indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.

#### 11.3.1.2.2.5.2.4.4 AASRC RxFifoConfig (PSIL Address 0x405)

This register describes the FIFO list to be processed for this RX channel.

Bits	Field	Reset	Description
31	GroupMode	0x0	When set, the channel is in 'Group Mode'. It will look for Group Mode DMA requests, and access the Group Mode FIFOs. When clear, the channel is 'Stream Mode'. It will look for Stream FIFO DMA requests, and access the Stream Mode FIFOs.
30	DmaReqReset	0x0	When set, resets any latched DMA request using the DmaReqMask. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
23:20	LastSlot	0x0	This is the index (0-15) of the last slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.

Bits	Field	Reset	Description
19:16	FirstSlot	0x0	This is the index (0-15) of the first slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
15:0	DmaReqMask	0x0	<p>This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate.</p> <p>In Steam Mode, these 16 flags correspond to the 16 DMA requests for each RX FIFO. The flags corresponding to all RX FIFOs involved with the channel should be set to 1.</p> <p>In Group Mode, these flags indicate which Group Mode DMA requests must fire. In this case, only bits 3:0 are relevant and only one bit should be set to 1 as a DMA channel only services a single group.</p>

#### 11.3.1.2.2.5.2.4.5 AASRC RxOrderTable0 (PSIL Address 0x406)

This table is filled with FIFO index values. RX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all RX threads.

Bits	Field	Reset	Description
31:28	Entry7	7	RX FIFO Index for slot 7
27:24	Entry6	6	RX FIFO Index for slot 6
23:20	Entry5	5	RX FIFO Index for slot 5
19:16	Entry4	4	RX FIFO Index for slot 4
15:12	Entry3	3	RX FIFO Index for slot 3
11:8	Entry2	2	RX FIFO Index for slot 2
7:4	Entry1	1	RX FIFO Index for slot 1
3:0	Entry0	0	RX FIFO Index for slot 0

#### 11.3.1.2.2.5.2.4.6 AASRC RxOrderTable1 (PSIL Address 0x407)

This table is filled with FIFO index values. RX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all RX threads.

Bits	Field	Reset	Description
31:28	Entry15	15	RX FIFO Index for slot 15
27:24	Entry14	14	RX FIFO Index for slot 14
23:20	Entry13	13	RX FIFO Index for slot 13
19:16	Entry12	12	RX FIFO Index for slot 12
15:12	Entry11	11	RX FIFO Index for slot 11
11:8	Entry10	10	RX FIFO Index for slot 10
7:4	Entry9	9	RX FIFO Index for slot 9
3:0	Entry8	8	RX FIFO Index for slot 8

#### 11.3.1.2.2.5.2.5 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

#### 11.3.1.2.2.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the Receive PSI-L Interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Rx Per Channel FIFO to a remote peer DMA entity via the Rx PSI-L interface

The sequences of logical transactions that are performed by the PDMA on the Memory I/F during receive is dependent on the channel type. The following sections describe what will happen for the different channel types.

#### 11.3.1.2.2.5.3.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data\_address specified in the tchan\_info parameter for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

#### 11.3.1.2.2.5.3.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting bit 31 of the XY register enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2 32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

#### 11.3.1.2.2.5.3.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as follows.

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping/pong buffer for a particular RX packet ID. For example the following two filter entries will setup a ping/pong using RX buffers 0 and 1 for packet ID 5 on CAN RX channel 0:

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

#### 11.3.1.2.2.5.3.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

#### 11.3.1.2.2.5.3.3 AASRC Channel

The AASRC channel is controlled primarily via the channel's RxFifoConfig register. This register holds 3 basic pieces of information:

- Whether the channel uses AASRC Stream Mode or Group Mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the RxFifoConfig setting. The pulses for the individual events are latched and held by the PDMA until they all arrive.

Once the channel activates, it will start reading FIFO index values from the RxOrderTable, starting at the configured 'First Slot' and ending with the 'Last Slot'. The actual FIFO indices used are obtained from the ordering table. For example, say FirstSlot=3 and LastSlot=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel.

Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 11.3.1.2.2.5.4 Receive PSI-L Interface Transactions

When an entire word has been packed into the Rx Per Channel Buffer for a given channel, a one word data phase transfer will be initiated for that channel/thread on the Rx PSI-L interface and the data will be popped from the Rx Per Channel FIFO. The value sources for the output pins on the PSI-L interface are described in the following table.

Pin	Output Value / Source From PDMA
strm_o_req	This signal is asserted when the PDMA determines that there is at least 1 word of data in its TP-CC output FIFO
strm_o_sthread_id	Set equal to the TP-CC DMA channel number which is on the interface for this cycle
strm_o_dthread_id	Set equal to the target thread ID value given in the PSI-L pairing configuration registers for this DMA channel
strm_o_data_type	Will be set to the proper PSI-L data type. The PDMA can send config response, PSI info word 0, and PSI data word.
strm_o_wnum	Set equal to the packing lane for the current word within a contiguous transfer. This value will start at 0 for each new TR and will increment for each subsequent data phase in the TR.
strm_o_lastw	This signal will be asserted coincident with eop.
strm_o_xcnt	The xcnt will be equal to the data path width in bytes.
strm_o_worden	The worden will be modulated to indicate which 32-bit words are valid within each control type data phase.
strm_o_data	The data will be packed/left justified to comply to the big endian data ordering as required in the PSI-L I/F specification.
strm_o_sop	This signal is asserted for 1 data phase at the beginning of each new TR or data transfer packet.
strm_o_eop	This signal is asserted for 1 data phase at the end of each TR or data transfer packet.
strm_o_sol	This signal is set to zero unless the EOL bit is set in PSI-L register 0x401, in which case, it is set for 1 data phase at the start of a new set of transactions designated by the count set in the Z field of PSI-L register 0x401.
strm_o_eol	This signal is set to zero unless the EOL bit is set in PSI-L register 0x401, in which case, it is set for 1 data phase at the end of a set of transactions designated by the count set in the Z field of PSI-L register 0x401.
strm_o_priv	Set to zero.
strm_o_privid	Set to zero.
strm_o_virtid	Set to zero.
strm_o_secure	Set to zero.
strm_o_interest	Set to zero.
strm_o_sready	Always asserted as the PDMA is always able to accept credit returns.

#### 11.3.1.2.2.5.5 Rx Pause

The Host initiates a channel pause by setting the pause bit in RT enable register. The paused channel can be resumed by clearing the register bit.

#### 11.3.1.2.2.5.6 Rx Teardown

The Host initiates a RX channel teardown by setting the tdown bit in the RT enable register for the target RX channel. The PDMA communicates the teardown state to the UDMA-P through the PSI-L data channel, to ensure that the teardown is not seen by the UDMA-P until all the previous PDMA data for the channel has been flushed.

The PDMA will not stop reading peripheral data until it reaches a FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. It will always attempt to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA will then clear the enable bit in the pairing register,

however the teardown bit will remain set. No further packet processing will occur until the Host re-configures the channel. The teardown process will propagate to the UDMA-P and its final status can be checked there.

### 11.3.1.2.2.5.7 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the enable bit in the PSI-L enable register. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

### 11.3.1.2.2.5.8 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. The registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as follows.

Name	PSIL Addr	Field	Description
Z*	0x402	31:16	This field holds the lower 12 bits of the current Z count for legacy purposes. See register 0x40F below for the full width version of Z.
Y	0x402	15:0	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to be read from the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next read offset to use when read to the CAN RX buffer.
InEvent	0x403	31	When set, the PDMA is in the middle of processing a FIFO event.
Tdown	0x403	30	When set, the PDMA is processing a teardown operation. This bit is set simultaneously with the teardown bit in the source (RX) RT enable register. This bit will clear when the teardown is complete, regardless as to if the teardown bit in the pairing register is cleared or not. The teardown will propagate to the UDMA-P and its full completion status can be checked there.
Pause	0x403	29	When set, the PDMA is stopped in a paused state. This bit will clear if the channel is un-paused or disabled.
Space	0x403	28	When set, there is a non-zero amount of internal FIFO space available to hold new read data.
XSpace	0x403	27	When set, there is a enough internal FIFO space available to start servicing a peripheral DMA event.
Buffer	0x403	26	This is the current RX buffer (0/1) for the current MCAN receive operation.
State	0x403	23:20	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
EventCnt	0x403	19:16	This field holds the number of backlogged DMA events yet to be serviced.
Z	0x40F	31:0	This field holds the full width value of the current Z count. In X-Y FIFO mode, this field holds the 1 based FIFO count of the FIFO being currently read, or the number of FIFO completions when the current operation completes. In MCAN mode, this field holds the zero based buffer index of the buffer currently being read, or the number of previously completed buffers.

### 11.3.1.3 Functional Description - UART

#### 11.3.1.3.1 Compliance to Standards

The PDMA complies fully to all standards listed in the previous section.

#### 11.3.1.3.2 Functional Operation

The Peripheral DMA is a simple, low cost implementation of the CPPI 5.0 Unified Transfer Controller. The PDMA module is required to be located close to one or more peripherals (both peripherals and PDMA direct connected to the SCR) which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only the static Transfer Request subset of UTC features which are useful for peripheral type transactions. Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs time division multiplexing between channels in order to share the underlying DMA hardware. A scheduler is provided to control the ordering and rate at which this multiplexing occurs. A block diagram of the PDMA Controller is shown below.

#### 11.3.1.3.2.1 Submodule Descriptions

##### 11.3.1.3.2.1.1 Scheduler

The Scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low level read or write operation.

##### 11.3.1.3.2.1.2 Tx Per Channel Buffers

The Tx Per Channel Buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx Per Channel Buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

##### 11.3.1.3.2.1.3 Tx DMA Unit

The Tx DMA Unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming dma event and then writes data from the Tx Per Channel Data FIFO associated with the channel to an external memory mapped target via a VBUSP controller interface. The number and width of the writes that are performed is in accordance with the parameters which were programmed via PSI-L into the static TR for the channel.

##### 11.3.1.3.2.1.4 Rx Per Channel Buffers

Rx Per Channel Buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte oriented on write so that the data from the Rx DMA units which may not be full words can be packed properly. The buffers are word oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface. The Rx Per Channel Buffer block outputs queue fullness information to the scheduler block which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx Per Channel Buffer will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

##### 11.3.1.3.2.1.5 Rx DMA Unit

The Rx DMA Unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP controller read interface into the Rx Per Channel Data

FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters which were programmed via PSI-L into the static TR for the channel.

### 11.3.1.3.2.2 General Functionality (Applicable to All Functions/Modes)

#### 11.3.1.3.2.2.1 Operational States

At any given time, the PDMA can be in one of three different states, as shown in [Table 11-80](#).

**Table 11-80. Operational States**

Operational State	Description
Init	This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the init state, the DMA will de-assert all ready signals on all applicable target interfaces and will de-assert all request signals on all applicable controller interfaces. The PDMA will automatically transition out of the init state into the idle state when all of the RAM initialization has been completed.
Idle	Once the PDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the PDMA interfaces (controller or target). The Idle state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. For clock stop purposes, the module will only report idle if all DMA channels are disabled using the enable bit in PSIL register 2 for each channel.
Active	The PDMA enters the active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the PDMA transitions to the Idle state.

#### 11.3.1.3.2.2.2 Clock Stop

The clock stop interface is a request/acknowledge interface used to coordinate the handshaking of properly stopping the main clock to the IP. Before attempting to perform a clock stop operation, software is required to teardown all active channels (via UDMAP 'real time' registers in the UDMAP, or PSIL register 0x408 in PSIL based peripherals), and after this is complete, also clear the global enable bit for all channels (via PSIL register 0x2 in both the UDMAP and PSIL based peripherals). Attempting a clock stop on the IP without first performing the channel teardowns or clearing of global enable bits will result in IP specific behavior that may be UNDEFINED.

The PDMA will not drive clock stop IDLE or clock stop ACK while the global enable (PSIL register 0x2) is set for any channel.

#### 11.3.1.3.2.2.3 Emulation Control

The emulation control input (susp\_emususp) and the per channel emulation control 'free' bit allow DMA operation to be suspended on a per channel basis. When the emulation suspend state is entered, the DMA will stop processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. Emulation control is implemented for compatibility with other peripherals. Each source and destination channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is controlled via the 'free' bit in the channel Enable Register. Note the real time emulation suspend request signal is not supported.

#### 11.3.1.3.2.2.4 Dynamic Clock Gating

The PDMA includes up to two mid level clock gates using ksdw\_pm\_clkgate(). One is on the main clock of the PDMA while the other is on the internal ecc\_aggr (when RAM is used). These clock gates turn off the clock to their corresponding IP under idle conditions, and then turn the clock back on when work is to be done. Detecting work is done via internal state, or activity on the PSIL or DMA triggers. The DMA triggers are thus always monitored, even when the clocking to the rest of the IP is disabled.

The dynamic clock gating can be disabled through an external port called `pwr_disable_nogate`. No additional signaling is needed to support the dynamic clock gate, although the PDMA supports the 'early wake' pins on PSIL and VBUSP.

#### **11.3.1.3.2.3 Events and Flow Control**

The following sections describe the simplified mechanism that is provided on the Peripheral DMA for triggering.

##### **11.3.1.3.2.3.1 Channel Triggering**

Channels must be triggered in order for them to perform work. A local event input bus is provided on the peripheral DMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, etc.). The event inputs for XY mode are triggered either via pulse, or by a clock synchronous rising edge. The counting mode is a design time configuration parameter. In MCAN mode, the inputs are expected to be single cycle pulses, synchronous with the PDMA clock.

- Event signals that are used in pulse mode must be sourced by the same clock as the PDMA.
- Event signals that are used in edge mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the PDMA clock, and they must remain high for at least 1 'slow' clock cycle.

The PDMA provides a 2 bit counter per event input to accommodate startup latency in the channel. (In AASRC mode, the signals are not counted, but latched whenever asserted.)

##### **11.3.1.3.2.3.2 Completion Events**

All transfers on PDMA are split TR in that they have a UDMA-P half and a (static) PDMA half. Completion events are designed to be triggered from the UDMA-P half of the split TR.

##### **11.3.1.3.2.3.3 Channel Types**

Each channel in the Peripheral DMA is configured at design time to be either standard X-Y FIFO mode or MCAN channel. The channel type is configured at design time, and can not be changed by software.

###### **11.3.1.3.2.3.3.1 X-Y FIFO Mode**

Most peripherals which are serviced by the Peripheral DMA follow the pattern of transferring X bytes from a fixed, non-changing address in a loop Y times for each triggering event that is received. The X parameter is typically 1-16 bytes and the Y parameter can be any integer up to 2048. If a peripheral can be serviced by this basic functionality then it is recommended to use this mode for the peripheral.

###### **11.3.1.3.2.3.3.2 MCAN Mode**

The MCANSS subsystem was found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the DMA will start out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, MCAN packet fragmentation requirement to place an 8 byte header on each 64 byte chunk that is transmitted and to remove the header from each 64 byte chunk (other than the first block) that is received.

###### **11.3.1.3.2.3.3.3 AASRC Mode**

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOs to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels do not share the same PDMA as do XY and MCAN channels.

The following addition details apply to the PDMA in AASRC mode:

Main Features:

- Up to 16 independent RX channels and 16 TX channels

- Each channel represents a different data stream to either the UDMA-P-P or a McASP PDMA
- Each channel can be configured to read or write any of the AASRC FIFOs in any order
- Packing support for 1, 2, 3, and 4 byte samples
  - Can directly talk to a McASP using any McASP data format
  - Packing sample size is fixed for a given channel
- Supports both Group and Stream AASRC signaling and FIFO memory maps
  - There is a single stream/group mode setting for each PDMA channel

Additional details:

- Each channel has a 'mask' of which DMA requests must fire to activate the channel
  - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
  - In group mode, the mask specifies the one group DMA request that must fire
- Each channel specifies an ordered list of how FIFOs should be accessed
  - All channels use a common list, specifying a range of entry indices within that list. This allows each channel to use a varying number of list elements.
  - The order list can be processed multiple times per DMA request. The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC.
- All FIFOs are specified by index only
  - In the TX ordering table, the indices are assumed to be TX FIFOs
  - In the RX ordering table, the indices are assumed to be RX FIFOs
  - If a DMA channel is in 'Group Mode', the PDMA assumes the indices referenced by that channel represent Group Mode FIFOs; otherwise, it assumes Stream Mode FIFOs.
- The PDMA has configured base addressed and inter-FIFO spans such that it can always convert from a FIFO index to the proper Stream or Group mode FIFO address.

#### 11.3.1.3.2.4 Transmit Operation

##### 11.3.1.3.2.4.1 Destination (Tx) Channel Allocation

A total of 7 destination channels are provided within the DMA for concurrent transfers from Tx per channel buffers to the various attached peripherals. Each Tx channel requires a single PSI-L thread. The Tx channels are allocated as shown in [Table 11-81](#).

**Table 11-81. Tx Channel Allocation**

Tx DMA Channel	Function	Channel Type	Trigger Mode	Data FIFO Address	Strobe MMR Address	Control FIFO Address
8000	USART 0 Tx Ch 0	XY	edge	000002800000	000000000000	000000000000
8001	USART 1 Tx Ch 0	XY	edge	000002810000	000000000000	000000000000
8002	USART 2 Tx Ch 0	XY	edge	000002820000	000000000000	000000000000
8003	USART 3 Tx Ch 0	XY	edge	000002830000	000000000000	000000000000
8004	USART 4 Tx Ch 0	XY	edge	000002840000	000000000000	000000000000
8005	USART 5 Tx Ch 0	XY	edge	000002850000	000000000000	000000000000
8006	USART 6 Tx Ch 0	XY	edge	000002860000	000000000000	000000000000

##### 11.3.1.3.2.4.2 Destination (Tx) Channel Out of Band Signals

The following table shows how PSIL signals are handled for destination channels.

**Table 11-82. Tx Channel Out of Band Signals**

PSI-L Signal	XY/AASRC Mode	MCAN Mode
sop	ignored	ignored
eop	ignored	closes current MCAN packet
sol	ignored	ignored
eol	ignored	ignored

**Table 11-82. Tx Channel Out of Band Signals (continued)**

PSI-L Signal	XY/AASRC Mode	MCAN Mode
drop	ignored	ignored
pkt_error	ignored	ignored
tdown	reflect in status, teardown when data marker reached	reflect in status, teardown when data marker reached

#### 11.3.1.3.2.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will need to first pair the channel with a remote data source (normally a UDMA-P channel), set up the static TR for the channel, and enable the thread.

##### 11.3.1.3.2.4.3.1 PSI-L Destination Thread Pairing Registers

###### 11.3.1.3.2.4.3.1.1 Enable Register (PSIL Address 0x002)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all credit returns, and will not generate egress data. A one to zero transition on this bit fully resets the channel.
30:0	-	0x0	Reserved.

###### 11.3.1.3.2.4.3.1.2 Local Capabilities Register (PSIL Address 0x040)

Bits	Field	Reset	Description
31:29	-	0x0	Reserved.
28:24	LocalThreadWidth	0x2	Read only element width for the local thread used for pairing purposes. This field is encoded as follows: 0 = 4 bytes, 1 = 8 bytes, 2 = 16 bytes.
23:8	-	0x0	Reserved.
7:0	LocalCreditCnt	0x7	Read only local thread free entry count used for pairing purposes.

##### 11.3.1.3.2.4.3.2 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The Host will pair each destination PDMA channel with (typically) a corresponding source channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the UDMA-P will send all their data to the destination channel in the PDMA and the destination channel in the PDMA will never see any data other than data from the source channel in the UDMA-P.

##### 11.3.1.3.2.4.3.3 PSI-L Destination Thread Realtime Enable/Count Registers

###### 11.3.1.3.2.4.3.3.1 RT Enable Register (PSIL Address 0x408)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the TX channel is disabled. When disabled, it discards all held data. It clears DMA event counts and ignores all future DMA events from the peripheral. It maintains data exchange with the UDMA-P so that credit handshake is not disrupted. A 'hard teardown' can be performed by directly clearing this bit. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	tdown	0x0	When set, the channel will commence a TX channel teardown procedure. To perform a TX teardown, the teardown bit should be set in the UDMA-P and it will automatically propagate to this register bit with the normal flow of peripheral data. Once the channel is fully stopped and ready to be reused (including returning all credits), the enable bit is cleared.
29	pause	0x0	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals, but will not act on them. The pause bit can be cleared and data will resume.
28	flush	0x0	When set, causes all TX channel data to be discarded instead of being written to the peripheral. It essentially allows the TX engine to 'free run' without DMA requests from the peripheral (it will also override 'pause'). This bit should be set only when a channel fails to complete its teardown procedure normally, because a peripheral is no longer functioning or because data flow was halted on a boundary that is not compatible with the static TR configuration.
27:3	-	0x0	Reserved.
2	error	0x0	When set, the channel has encountered a PSIL protocol violation. The error bit can only be set by hardware, and can only be cleared by software. Once this bit is set, the channel should be fully reset and re-initialized via the PSIL pairing registers.
1	idle	0x0	This is a read-only bit that signifies that the disabled channel is also idle. This bit is read only and can only become set if the enable bit in the RT enable register is cleared.
0	free	0x0	When cleared, the channel honors the emudbg suspend signal. When set, the channel will free run, regardless of the value of emudbg suspend.

#### 11.3.1.3.2.4.3.2 Destination Thread Byte Count Register (PSIL Address 0x404)

Bits	Field	Reset	Description
31:0	bytes	0x0	This register contains the number of bytes that have been written to the VBUSP mapped peripheral. The register is write to decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

#### 11.3.1.3.2.4.3.4 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of an X, Y, and Z parameter, but the field interpretation varies.

#### 11.3.1.3.2.4.3.4.1 X-Y FIFO Mode Static TR

In X-Y FIFO mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, 4 = 64 bits, and 5-7 = RESERVED
Y	0x400	11:0	Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.
Z	0x401	23:0	Not used

#### 11.3.1.3.2.4.3.4.2 MCAN Mode Static TR

In MCAN mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the MCAN burst description for more information.
Acc32	0x400	30	Not used
X	0x400	26:24	Not used
Y	0x400	11:0	Buffer Size. This field specifies how many bytes should be written to an MCAN TX buffer. This field includes the 8 byte MCAN header on the initial packet fragment. The PDMA will break up the source packet into fragments of this buffer size, copying the 8 byte MCAN header for the initial fragment, and then skipping it for each additional fragment and thus reusing the header from the first fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.
Z	0x401	23:0	Not used

#### 11.3.1.3.2.4.3.4.3 AASRC Mode Static TR

AASRC mode is similar to X-Y FIFO mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, and 4-7 = RESERVED

Param	PSIL Addr	Field	Description
Y	0x400	11:0	FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer to each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.
Z	0x401	23:0	Not used

#### 11.3.1.3.2.4.3.4.4 AASRC TxFifoConfig (PSIL Address 0x405)

This register describes the FIFO list to be processed for this TX channel.

Bits	Field	Reset	Description
31	GroupMode	0x0	When set, the channel is in 'Group Mode'. It will look for Group Mode DMA requests, and access the Group Mode FIFOs. When clear, the channel is 'Stream Mode'. It will look for Stream FIFO DMA requests, and access the Stream Mode FIFOs.
30	DmaReqReset	0x0	When set, resets any latched DMA request using the DmaReqMask. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
23:20	LastSlot	0x0	This is the index (0-15) of the last slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19:16	FirstSlot	0x0	This is the index (0-15) of the first slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
15:0	DmaReqMask	0x0	This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate.  In Stream Mode, these 16 flags correspond to the 16 DMA requests for each TX FIFO. The flags corresponding to all TX FIFOs involved with the channel should be set to 1.  In Group Mode, these flags indicate which Group Mode DMA requests must fire. In this case, only bits 3:0 are relevant and only one bit should be set to 1 as a DMA channel only services a single group.

#### 11.3.1.3.2.4.3.4.5 AASRC TxOrderTable0 (PSIL Address 0x406)

This table is filled with FIFO index values. TX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all TX threads.

Bits	Field	Reset	Description
31:28	Entry7	7	TX FIFO Index for slot 7
27:24	Entry6	6	TX FIFO Index for slot 6
23:20	Entry5	5	TX FIFO Index for slot 5
19:16	Entry4	4	TX FIFO Index for slot 4

Bits	Field	Reset	Description
15:12	Entry3	3	TX FIFO Index for slot 3
11:8	Entry2	2	TX FIFO Index for slot 2
7:4	Entry1	1	TX FIFO Index for slot 1
3:0	Entry0	0	TX FIFO Index for slot 0

#### 11.3.1.3.2.4.3.4.6 AASRC TxOrderTable1 (PSIL Address 0x407)

This table is filled with FIFO index values. TX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all TX threads.

Bits	Field	Reset	Description
31:28	Entry15	15	TX FIFO Index for slot 15
27:24	Entry14	14	TX FIFO Index for slot 14
23:20	Entry13	13	TX FIFO Index for slot 13
19:16	Entry12	12	TX FIFO Index for slot 12
15:12	Entry11	11	TX FIFO Index for slot 11
11:8	Entry10	10	TX FIFO Index for slot 10
7:4	Entry9	9	TX FIFO Index for slot 9
3:0	Entry8	8	TX FIFO Index for slot 8

#### 11.3.1.3.2.4.3.5 PSI-L Destination Thread Enables

PSI-L destination threads must first be enabled in order to accept data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

#### 11.3.1.3.2.4.4 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the Receive PSI-L Interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Rx Per Channel FIFO to a remote peer DMA entity via the Rx PSI-L interface

The sequences of logical transactions that are performed by the PDMA on the Memory I/F during receive is dependent on the channel type. The following sections describe what will happen for the different channel types.

##### 11.3.1.3.2.4.4.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data\_address specified in the tchan\_info parameter for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

##### 11.3.1.3.2.4.4.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting bit 31 of the XY register enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2 32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

#### 11.3.1.3.2.4.4.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as follows.

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping/pong buffer for a particular RX packet ID. For example the following two filter entries will setup a ping/pong using RX buffers 0 and 1 for packet ID 5 on CAN RX channel 0:

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

#### 11.3.1.3.2.4.4.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

#### 11.3.1.3.2.4.4.3 AASRC Channel

The AASRC channel is controlled primarily via the channel's RxFifoConfig register. This register holds 3 basic pieces of information:

- Whether the channel uses AASRC Stream Mode or Group Mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the RxFifoConfig setting. The pulses for the individual events are latched and held by the PDMA until they all arrive.

Once the channel activates, it will start reading FIFO index values from the RxOrderTable, starting at the configured 'First Slot' and ending with the 'Last Slot'. The actual FIFO indices used are obtained from the ordering table. For example, say FirstSlot=3 and LastSlot=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel.

Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 11.3.1.3.2.4.5 Transmit PSI-L Interface Transactions

The PDMA will accept data across the Tx PSI-L Interface in accordance with the physical handshaking protocol as defined in the PSI-L Interface specification. The value sources for the output pins on the PSI-L interface are described in the following table.

Pin	Output Value / Source From PDMA
strm_i_link	This signal is asserted high to indicate the PSI-L link is valid.
strm_i_ready	This signal is asserted high anytime there is space in the PSI-L ingress fifo.
strm_i_sreq	This signal is asserted high anytime there is credit return data waiting in the PSI-L status fifo.
strm_i_sthreadid	This is set to the local destination thread that is returning credit.
strm_i_sccnt	This is set to the number of credits being returned, or 0 on a TX teardown acknowledgement.

#### 11.3.1.3.2.4.6 Tx Pause

The Host initiates a channel pause by setting the pause bit in the RT enable register. The paused channel can be resumed by clearing the register bit.

#### 11.3.1.3.2.4.7 Tx Teardown

The Host initiates a channel teardown by setting the tdown bit in the UDMA-P channel that is paired with the PDMA. The UDMA-P communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous UDMA-P data for the channel has been flushed. At this time, the teardown state will be reflected in the PSI-L RT Enable register of the PDMA. Note that a non-synchronized teardown can also be initiated by directly clearing the enable bit in the PSI-L RT Enable register of the PDMA.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel will be cleared in the PSI-L RT enable register, but the teardown bit will remain high. A teardown completion indication is sent back across the status pins of the PSI-L in the form of a credit response with sccnt=0. Upon completion, no further packet processing will occur until the Host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the UDMA-P transmission stops on a data boundary that is not compatible with the static TR configuration, the flush bit in the RT enable register can be set to guarantee that all data can be properly flushed from the internal pipe.

### 11.3.1.3.2.4.8 Tx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the enable bit in the PSI-L Enable register. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

### 11.3.1.3.2.4.9 Tx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. The registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as in the following table.

Name	PSIL Addr	Field	Description
Y	0x402	15:0	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to write to the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next write offset to use when writing to the CAN TX buffer.
InEvent	0x403	31	When set, the PDMA is in the middle of processing a FIFO event.
Flush	0x403	30	When set, the PDMA is processing in a flushing state, where it runs without waiting for DMA requests and without writing data to the peripheral. It is only operating its internal state machine to allow internal data pipes to drain properly.
Pause	0x403	29	When set, the PDMA waiting in a paused state. This bit will clear when data starts flowing again from the UDMA-P.
Data	0x403	28	When set, there is a non-zero amount of data still waiting to be written to the peripheral.
XData	0x403	27	When set, there is enough data still waiting to be written to the peripheral to start servicing a peripheral DMA event.
State	0x403	23:20	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
EventCnt	0x403	19:16	This field holds the number of backlogged DMA events yet to be serviced.

### 11.3.1.3.2.5 Receive Operation

#### 11.3.1.3.2.5.1 Source (Rx) Channel Allocation

A total of 7 source channels are provided within the DMA for concurrent transfers from the various attached peripherals into the Rx per channel buffers and on to the PSI-L Rx Interface. Each Rx channel requires a single PSI-L thread. The Rx channels are allocated as shown in [Table 11-83](#).

**Table 11-83. Rx Channel Allocation**

Rx DMA Channel	Function	Channel Type	Trigger Type	Data FIFO Address	Strobe MMR Address	Control FIFO Address
0	USART 0 Rx Ch 0	XY	edge	000002800000	000000000000	000000000000
1	USART 1 Rx Ch 0	XY	edge	000002810000	000000000000	000000000000
2	USART 2 Rx Ch 0	XY	edge	000002820000	000000000000	000000000000
3	USART 3 Rx Ch 0	XY	edge	000002830000	000000000000	000000000000
4	USART 4 Rx Ch 0	XY	edge	000002840000	000000000000	000000000000
5	USART 5 Rx Ch 0	XY	edge	000002850000	000000000000	000000000000
6	USART 6 Rx Ch 0	XY	edge	000002860000	000000000000	000000000000

### 11.3.1.3.2.5.2 Source Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will need to first pair the channel with a remote data source (normally a UDMA-P channel), set up the static TR for the channel, and enable the thread.

#### 11.3.1.3.2.5.2.1 PSI-L Source Thread Pairing Registers

##### 11.3.1.3.2.5.2.1.1 Peer Thread ID Register (PSIL Address 0x000)

Bits	Field	Reset	Description
31:29	ThreadPriority	0x0	This field is hard coded to 0x0 and is not writable
28:24	PeerThreadWidth	0x0	Datapath width of paired peer destination thread. This field is encoded as follows: 0 = 32-bit, 1 = 64-bit, 2 = 128 bit, 3 = 256 bit, 4 = 512 bit
23:16	-	0x0	Reserved.
15:0	Peer ThreadID	0x0	Thread ID to which all non-Transfer Response, non-Config messages from this thread will be sent.

##### 11.3.1.3.2.5.2.1.2 Peer Credit Register (PSIL Address 0x001)

Bits	Field	Reset	Description
31:8	-	0x0	Reserved.
7:0	CreditCnt	0x0	Free entries in destination thread. Legal range is 0 - 128 in number of elements.

##### 11.3.1.3.2.5.2.1.3 Enable Register (PSIL Address 0x002)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all credit returns, and will not generate egress data. A one to zero transition on this bit fully resets the channel.
30:0	-	0x0	Reserved.

### 11.3.1.3.2.5.2.2 PSI-L Source Thread Realtime Enable/Count Registers

#### 11.3.1.3.2.5.2.2.1 RT Enable Register (PSIL Address 0x408)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all DMA events from the peripheral. It maintains proper data transfers with the UDMA-P such that the credit handshake is not disrupted. However, unlike teardown, it does not close out the current open packet. Thus the teardown bit should always be used to disable an RX channel instead of manually clearing this bit. Failing to use teardown may result in stale data remaining in the internal RX FIFO, which would also prevent the channel from going idle without a channel reset.  Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	tdown	0x0	When set, the channel will commence a RX channel teardown procedure. It will stop on the next FIFO boundary. It then clears the DMA event count and ignores all future DMA events from the peripheral.  After stopping peripheral reads, the PDMA sends a teardown message to the UDMA-P that also closes the current packet with an EOP. If no packet is open at the time of the teardown, the message also includes SOP. The EOP teardown message may or may not contain final packet data.  Once the channel teardown is complete and ready to be reused, the enable bit is cleared.
29	pause	0x0	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals, but will not act on them. The pause bit can be cleared and data will resume. Pause will not stop teardown from completing.
28:2	-	0x0	Reserved.
1	idle	0x0	This is a read-only bit that signifies that the Paused or Disabled channel is also idle. This bit is read only and can only become set if pause is set or enable is cleared.
0	free	0x0	Free Run: 0 = channel honors the emudbg suspend signal, 1 = channel will free run, regardless of the value of emudbg suspend.

### 11.3.1.3.2.5.2.2.2 Source Thread Byte Count Register (PSIL Address 0x404)

Bits	Field	Reset	Description
31:0	bytes	0x0	This register contains the number of bytes that have been read from the VBUSP mapped peripheral. The register is write to decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

### 11.3.1.3.2.5.2.3 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The Host will pair each source PDMA channel with (typically) a corresponding destination channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA will send all their data to the source channel in the UDMA-P and the destination channel in the UDMA-P will never see any data other than data from the source channel in the PDMA.

### 11.3.1.3.2.5.2.4 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of an X, Y, and Z parameter, but the field interpretation varies.

#### 11.3.1.3.2.5.2.4.1 X-Y FIFO Mode Static TR

In X-Y FIFO mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, 4 = 64 bits, and 5-7 = RESERVED
Y	0x400	11:0	Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	FIFO count. This field specifies how many full FIFO operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an 'EOP' indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.

#### 11.3.1.3.2.5.2.4.2 MCAN Mode Static TR

In MCAN mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the MCAN burst description for more information.
Acc32	0x400	30	Not used
X	0x400	26:24	Not used

Param	PSIL Addr	Field	Description
Y	0x400	11:0	Buffer Size. This field specifies how many bytes should be read from an MCAN RX buffer. This field includes the 8 byte MCAN header on the initial packet fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	Buffer Count. This field specifies how many MCAN RX buffers should be read before closing the CPPI packet with an 'EOP' indication. When this count is greater than 1, multiple MCAN RX buffers will be read into a single CPPI packet buffer. The 8 byte MCAN header will be skipped on subsequent MCAN buffer reads. Setting this field to NULL will suppress all packet delineation, and should be avoided.

#### 11.3.1.3.2.5.2.4.3 AASRC Mode Static TR

AASRC mode is similar to X-Y FIFO mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each read which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, and 4-7 = RESERVED
Y	0x400	11:0	FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer from each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	FIFO count. This field specifies how many full DMA request operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an 'EOP' indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.

#### 11.3.1.3.2.5.2.4.4 AASRC RxFifoConfig (PSIL Address 0x405)

This register describes the FIFO list to be processed for this RX channel.

Bits	Field	Reset	Description
31	GroupMode	0x0	When set, the channel is in 'Group Mode'. It will look for Group Mode DMA requests, and access the Group Mode FIFOs. When clear, the channel is 'Stream Mode'. It will look for Stream FIFO DMA requests, and access the Stream Mode FIFOs.
30	DmaReqReset	0x0	When set, resets any latched DMA request using the DmaReqMask. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
23:20	LastSlot	0x0	This is the index (0-15) of the last slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19:16	FirstSlot	0x0	This is the index (0-15) of the first slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
15:0	DmaReqMask	0x0	This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate.  In Steam Mode, these 16 flags correspond to the 16 DMA requests for each RX FIFO. The flags corresponding to all RX FIFOs involved with the channel should be set to 1.  In Group Mode, these flags indicate which Group Mode DMA requests must fire. In this case, only bits 3:0 are relevant and only one bit should be set to 1 as a DMA channel only services a single group.

#### 11.3.1.3.2.5.2.4.5 AASRC RxOrderTable0 (PSIL Address 0x406)

This table is filled with FIFO index values. RX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all RX threads.

Bits	Field	Reset	Description
31:28	Entry7	7	RX FIFO Index for slot 7
27:24	Entry6	6	RX FIFO Index for slot 6
23:20	Entry5	5	RX FIFO Index for slot 5
19:16	Entry4	4	RX FIFO Index for slot 4
15:12	Entry3	3	RX FIFO Index for slot 3
11:8	Entry2	2	RX FIFO Index for slot 2
7:4	Entry1	1	RX FIFO Index for slot 1
3:0	Entry0	0	RX FIFO Index for slot 0

### 11.3.1.3.2.5.2.4.6 AASRC RxOrderTable1 (PSIL Address 0x407)

This table is filled with FIFO index values. RX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all RX threads.

Bits	Field	Reset	Description
31:28	Entry15	15	RX FIFO Index for slot 15
27:24	Entry14	14	RX FIFO Index for slot 14
23:20	Entry13	13	RX FIFO Index for slot 13
19:16	Entry12	12	RX FIFO Index for slot 12
15:12	Entry11	11	RX FIFO Index for slot 11
11:8	Entry10	10	RX FIFO Index for slot 10
7:4	Entry9	9	RX FIFO Index for slot 9
3:0	Entry8	8	RX FIFO Index for slot 8

### 11.3.1.3.2.5.2.5 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

### 11.3.1.3.2.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the Receive PSI-L Interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Rx Per Channel FIFO to a remote peer DMA entity via the Rx PSI-L interface

The sequences of logical transactions that are performed by the PDMA on the Memory I/F during receive is dependent on the channel type. The following sections describe what will happen for the different channel types.

### 11.3.1.3.2.5.3.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data\_address specified in the tchan\_info parameter for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

### 11.3.1.3.2.5.3.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting bit 31 of the XY register enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase

- Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
- Cannot burst 64-bit samples on a 32-bit bus (configure for 2 32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

#### 11.3.1.3.2.5.3.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as follows.

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping/pong buffer for a particular RX packet ID. For example the following two filter entries will setup a ping/pong using RX buffers 0 and 1 for packet ID 5 on CAN RX channel 0:

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

#### 11.3.1.3.2.5.3.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

#### 11.3.1.3.2.5.3.3 AASRC Channel

The AASRC channel is controlled primarily via the channel's RxFifoConfig register. This register holds 3 basic pieces of information:

- Whether the channel uses AASRC Stream Mode or Group Mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the RxFifoConfig setting. The pulses for the individual events are latched and held by the PDMA until they all arrive.

Once the channel activates, it will start reading FIFO index values from the RxOrderTable, starting at the configured 'First Slot' and ending with the 'Last Slot'. The actual FIFO indices used are obtained from the ordering table. For example, say FirstSlot=3 and LastSlot=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel.

Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 11.3.1.3.2.5.4 Receive PSI-L Interface Transactions

When an entire word has been packed into the Rx Per Channel Buffer for a given channel, a one word data phase transfer will be initiated for that channel/thread on the Rx PSI-L interface and the data will be popped from the Rx Per Channel FIFO. The value sources for the output pins on the PSI-L interface are described in the following table.

Pin	Output Value / Source From PDMA
strm_o_req	This signal is asserted when the PDMA determines that there is at least 1 word of data in its TP-CC output FIFO
strm_o_sthread_id	Set equal to the TP-CC DMA channel number which is on the interface for this cycle
strm_o_dthread_id	Set equal to the target thread ID value given in the PSI-L pairing configuration registers for this DMA channel
strm_o_data_type	Will be set to the proper PSI-L data type. The PDMA can send config response, PSI info word 0, and PSI data word.
strm_o_wnum	Set equal to the packing lane for the current word within a contiguous transfer. This value will start at 0 for each new TR and will increment for each subsequent data phase in the TR.
strm_o_lastw	This signal will be asserted coincident with eop.
strm_o_xcnt	The xcnt will be equal to the data path width in bytes.
strm_o_worden	The worden will be modulated to indicate which 32-bit words are valid within each control type data phase.
strm_o_data	The data will be packed/left justified to comply to the big endian data ordering as required in the PSI-L I/F specification.
strm_o_sop	This signal is asserted for 1 data phase at the beginning of each new TR or data transfer packet.
strm_o_eop	This signal is asserted for 1 data phase at the end of each TR or data transfer packet.
strm_o_sol	This signal is set to zero unless the EOL bit is set in PSI-L register 0x401, in which case, it is set for 1 data phase at the start of a new set of transactions designated by the count set in the Z field of PSI-L register 0x401.
strm_o_eol	This signal is set to zero unless the EOL bit is set in PSI-L register 0x401, in which case, it is set for 1 data phase at the end of a set of transactions designated by the count set in the Z field of PSI-L register 0x401.
strm_o_priv	Set to zero.
strm_o_privid	Set to zero.
strm_o_virtid	Set to zero.
strm_o_secure	Set to zero.
strm_o_interest	Set to zero.

Pin	Output Value / Source From PDMA
strm_o_sready	Always asserted as the PDMA is always able to accept credit returns.

#### 11.3.1.3.2.5.5 Rx Pause

The Host initiates a channel pause by setting the pause bit in RT enable register. The paused channel can be resumed by clearing the register bit.

#### 11.3.1.3.2.5.6 Rx Teardown

The Host initiates a RX channel teardown by setting the tdown bit in the RT enable register for the target RX channel. The PDMA communicates the teardown state to the UDMA-P through the PSI-L data channel, to ensure that the teardown is not seen by the UDMA-P until all the previous PDMA data for the channel has been flushed.

The PDMA will not stop reading peripheral data until it reaches a FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. It will always attempt to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA will then clear the enable bit in the pairing register, however the teardown bit will remain set. No further packet processing will occur until the Host re-configures the channel. The teardown process will propagate to the UDMA-P and its final status can be checked there.

#### 11.3.1.3.2.5.7 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the enable bit in the PSI-L enable register. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

#### 11.3.1.3.2.5.8 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. The registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as follows.

Name	PSIL Addr	Field	Description
Z*	0x402	31:16	This field holds the lower 12 bits of the current Z count for legacy purposes. See register 0x40F below for the full width version of Z.
Y	0x402	15:0	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to be read from the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next read offset to use when read to the CAN RX buffer.
InEvent	0x403	31	When set, the PDMA is in the middle of processing a FIFO event.
Tdown	0x403	30	When set, the PDMA is processing a teardown operation. This bit is set simultaneously with the teardown bit in the source (RX) RT enable register. This bit will clear when the teardown is complete, regardless as to if the teardown bit in the pairing register is cleared or not. The teardown will propagate to the UDMA-P and its full completion status can be checked there.
Pause	0x403	29	When set, the PDMA is stopped in a paused state. This bit will clear if the channel is un-paused or disabled.
Space	0x403	28	When set, there is a non-zero amount of internal FIFO space available to hold new read data.
XSpace	0x403	27	When set, there is a enough internal FIFO space available to start servicing a peripheral DMA event.

Name	PSIL Addr	Field	Description
Buffer	0x403	26	This is the current RX buffer (0/1) for the current MCAN receive operation.
State	0x403	23:20	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
EventCnt	0x403	19:16	This field holds the number of backlogged DMA events yet to be serviced.
Z	0x40F	31:0	This field holds the full width value of the current Z count. In X-Y FIFO mode, this field holds the 1 based FIFO count of the FIFO being currently read, or the number of FIFO completions when the current operation completes. In MCAN mode, this field holds the zero based buffer index of the buffer currently being read, or the number of previously completed buffers.

### 11.3.1.4 Functional Description - McASP

#### 11.3.1.4.1 Compliance to Standards

The PDMA complies fully to all standards listed in the previous section.

#### 11.3.1.4.2 Functional Operation

The Peripheral DMA is a simple, low cost implementation of the CPPI 5.0 Unified Transfer Controller. The PDMA module is required to be located close to one or more peripherals (both peripherals and PDMA direct connected to the SCR) which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only the static Transfer Request subset of UTC features which are useful for peripheral type transactions. Multiple source and destination channels are provided within the PDMA, which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs time division multiplexing between channels to share the underlying DMA hardware. A scheduler is provided to control the ordering and rate at which this multiplexing occurs. A block diagram of the PDMA Controller is shown below:

#### 11.3.1.4.2.1 Submodule Descriptions

##### 11.3.1.4.2.1.1 Scheduler

The Scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low level read or write operation.

##### 11.3.1.4.2.1.2 Tx Per Channel Buffers

The Tx Per Channel Buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx Per Channel Buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

##### 11.3.1.4.2.1.3 Tx DMA Unit

The Tx DMA Unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming dma event and then writes data from the Tx Per Channel Data FIFO associated with the channel to an external memory mapped target via a VBUSP controller interface. The number and width of the writes that are performed is in accordance with the parameters which were programmed via PSI-L into the static TR for the channel.

##### 11.3.1.4.2.1.4 Rx Per Channel Buffers

Rx Per Channel Buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte oriented on write so that the data

from the Rx DMA units which may not be full words can be packed properly. The buffers are word oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface. The Rx Per Channel Buffer block outputs queue fullness information to the scheduler block, which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx Per Channel Buffer initiates transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block simultaneously monitors the status of all of the threads and performs a round robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer is included in the arbitration.

#### 11.3.1.4.2.1.5 Rx DMA Unit

The Rx DMA Unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP controller read interface into the Rx Per Channel Data FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters which were programmed via PSI-L into the static TR for the channel.

#### 11.3.1.4.2.2 General Functionality (Applicable to All Functions/Modes)

##### 11.3.1.4.2.2.1 Operational States

At any given time, the PDMA can be in one of three different states, as shown in [Table 11-84](#).

**Table 11-84. PDMA Operational States**

Operational State	Description
Init	This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the init state, the DMA will de-assert all ready signals on all applicable target interfaces and will de-assert all request signals on all applicable controller interfaces. The PDMA will automatically transition out of the init state into the idle state when all of the RAM initialization has been completed.
Idle	Once the PDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the PDMA interfaces (controller or target). The Idle state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. For clock stop purposes, the module will only report idle if all DMA channels are disabled using the enable bit in PSIL register 2 for each channel.
Active	The PDMA enters the active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the PDMA transitions to the Idle state.

##### 11.3.1.4.2.2.2 Clock Stop

The clock stop interface is used to instruct the PDMA to stop issuing commands on its external interfaces. Note that the PDMA will report a clock stop idle if all its DMA channels have been previously disabled by software using the enable bit in PSIL register 2 for each channel.

##### 11.3.1.4.2.2.3 Emulation Control

The emulation control input (susp\_emususp) and the per channel emulation control 'free' bit allow DMA operation to be suspended on a per channel basis. When the emulation suspend state is entered, the DMA will stop processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. Emulation control is implemented for compatibility with other peripherals. Each source and destination channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is controlled via the 'free' bit in the channel Enable Register. Note the real time emulation suspend request signal is not supported.

##### 11.3.1.4.2.3 Events and Flow Control

The following sections describe the simplified mechanism provided on the Peripheral DMA for triggering.

#### 11.3.1.4.2.3.1 Channel Triggering

Channels must be triggered for them to perform work. A local event input bus is provided on the peripheral DMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, and so forth). The event inputs for XY mode are triggered either via pulse, or by a clock synchronous rising edge. The counting mode is a design time configuration parameter. In MCAN mode, the inputs are expected to be single cycle pulses, synchronous with the PDMA clock.

- Event signals that are used in pulse mode must be sourced by the same clock as the PDMA.
- Event signals that are used in edge mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the PDMA clock, and they must remain high for at least 1 'slow' clock cycle.

The PDMA provides a 2-bit counter per event input to accommodate startup latency in the channel. (In AASRC mode, the signals are not counted, but latched whenever asserted.)

#### 11.3.1.4.2.3.2 Completion Events

All transfers on PDMA are split TR in that they have a UDMA-P half and a (static) PDMA half. Completion events are designed to be triggered from the UDMA-P half of the split TR.

#### 11.3.1.4.2.3.3 Channel Types

Each channel in the Peripheral DMA is configured at design time to be either standard X-Y FIFO mode or MCAN channel. The channel type is configured at design time, and can not be changed by software.

##### 11.3.1.4.2.3.3.1 X-Y FIFO Mode

Most peripherals which are serviced by the Peripheral DMA follow the pattern of transferring X bytes from a fixed, non-changing address in a loop Y times for each triggering event that is received. The X parameter is typically 1-16 bytes and the Y parameter can be any integer up to 2048. If a peripheral can be serviced by this basic functionality then it is recommended to use this mode for the peripheral.

##### 11.3.1.4.2.3.3.2 MCAN Mode

The MCANSS subsystem was found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the DMA starts out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, MCAN packet fragmentation requirement to place an 8-byte header on each 64-byte chunk that is transmitted and to remove the header from each 64-byte chunk (other than the first block) that is received.

##### 11.3.1.4.2.3.3.3 AASRC Mode

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOs to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels do not share the same PDMA as do XY and MCAN channels.

The following additional details apply to the PDMA in AASRC mode.

Main Features:

- Up to 16 independent RX channels and 16 TX channels
  - Each channel represents a different data stream to either the UDMA-P-P or a McASP PDMA
- Each channel can be configured to read or write any of the AASRC FIFOs in any order
- Packing support for 1, 2, 3, and 4 byte samples
  - Can directly talk to a McASP using any McASP data format
  - Packing sample size is fixed for a given channel
- Supports both Group and Stream AASRC signaling and FIFO memory maps

- There is a single stream/group mode setting for each PDMA channel

Additional details:

- Each channel has a 'mask' of which DMA requests must fire to activate the channel
  - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
  - In group mode, the mask specifies the one group DMA request that must fire
- Each channel specifies an ordered list of how FIFOs should be accessed
  - All channels use a common list, specifying a range of entry indices within that list. This lets each channel use a varying number of list elements.
  - The order list can be processed multiple times per DMA request. The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC.
- All FIFOs are specified by index only
  - In the TX ordering table, the indices are assumed to be TX FIFOs
  - In the RX ordering table, the indices are assumed to be RX FIFOs
  - If a DMA channel is in 'Group Mode', the PDMA assumes the indices referenced by that channel represent Group Mode FIFOs; otherwise, it assumes Stream Mode FIFOs.
- The PDMA has configured base addressed and inter-FIFO spans such that it can always convert from a FIFO index to the proper Stream or Group mode FIFO address

#### 11.3.1.4.2.4 Transmit Operation

##### 11.3.1.4.2.4.1 Destination (Tx) Channel Allocation

A total of 3 destination channels are provided within the DMA for concurrent transfers from Tx per channel buffers to the various attached peripherals. Each Tx channel requires a single PSI-L thread. The Tx channels are allocated as follows:

Tx DMA Channel	Function	Channel Type	Trigger Mode	Data FIFO Address	Strobe MMR Address	Control FIFO Address
8000	McASP 0 Tx Ch 0	XY	edge	000002B08000	000000000000	000000000000
8001	McASP 1 Tx Ch 0	XY	edge	000002B18000	000000000000	000000000000
8002	McASP 2 Tx Ch 0	XY	edge	000002B28000	000000000000	000000000000

##### 11.3.1.4.2.4.2 Destination (Tx) Channel Out of Band Signals

The following table shows how PSIL signals are handled for destination channels.

PSI-L Signal	XY/AASRC Mode	MCAN Mode
sop	ignored	ignored
eop	ignored	closes current MCAN packet
sol	ignored	ignored
eol	ignored	ignored
drop	ignored	ignored
pkt_error	ignored	ignored
ttdown	reflect in status, teardown when data marker reached	reflect in status, teardown when data marker reached

##### 11.3.1.4.2.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA is idle and waiting for work to be assigned to them. To initiate PDMA operation, the Host must first pair the channel with a remote data source (normally a UDMA-P channel), set up the static TR for the channel, and enable the thread.

##### 11.3.1.4.2.4.3.1 PSI-L Destination Thread Pairing Registers

###### 11.3.1.4.2.4.3.1.1 Enable Register (PSIL Address 0x002)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the TX channel is disabled. When disabled, the channel discards all ingress data. A one to zero transition on this bit fully resets the channel.
30:0	-	0x0	Reserved.

#### 11.3.1.4.2.4.3.1.2 Peer Credit Register (PSIL Address 0x040)

Bits	Field	Reset	Description
31:29	-	0x0	Reserved.
28:24	LocalThreadWidth	0x2	Read only element width for the local thread used for pairing purposes. This field is encoded as follows: 0 = 4 bytes, 1 = 8 bytes, 2 = 16 bytes.
23:8	-	0x0	Reserved.
7:0	LocalCreditCnt	0x8	Read only local thread free entry count used for pairing purposes.

#### 11.3.1.4.2.4.3.2 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The Host pairs each destination PDMA channel with (typically) a corresponding source channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread, and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the UDMA-P send all their data to the destination channel in the PDMA, and the destination channel in the PDMA never sees any data other than data from the source channel in the UDMA-P.

#### 11.3.1.4.2.4.3.3 PSI-L Destination Thread Realtime Enable/Count Registers

##### 11.3.1.4.2.4.3.3.1 RT Enable Register (PSIL Address 0x408)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the TX channel is disabled. When disabled, it discards all held data. It clears DMA event counts and ignores all future DMA events from the peripheral. It maintains data exchange with the UDMA-P so that credit handshake is not disrupted. A 'hard teardown' can be performed by directly clearing this bit. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	tdown	0x0	When set, the channel will commence a TX channel teardown procedure. To perform a TX teardown, the teardown bit should be set in the UDMA-P and it will automatically propagate to this register bit with the normal flow of peripheral data. Once the channel is fully stopped and ready to be reused (including returning all credits), the enable bit is cleared.
29	pause	0x0	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals, but will not act on them. The pause bit can be cleared and data will resume.

Bits	Field	Reset	Description
28	flush	0x0	When set, causes all TX channel data to be discarded instead of being written to the peripheral. It essentially allows the TX engine to 'free run' without DMA requests from the peripheral (it will also override 'pause'). This bit should be set only when a channel fails to complete its teardown procedure normally, because a peripheral is no longer functioning or because data flow was halted on a boundary that is not compatible with the static TR configuration.
27:3	-	0x0	Reserved.
2	error	0x0	When set, the channel has encountered a PSIL protocol violation. The error bit can only be set by hardware, and can only be cleared by software. Once this bit is set, the channel should be fully reset and re-initialized via the PSIL pairing registers.
1	idle	0x0	This is a read-only bit that signifies that the disabled channel is also idle. This bit is read only and can only become set if the enable bit in the RT enable register is cleared.
0	free	0x0	When cleared, the channel honors the emudbg suspend signal. When set, the channel will free run, regardless of the value of emudbg suspend.

#### 11.3.1.4.2.4.3.3.2 Destination Thread Byte Count Register (PSIL Address 0x404)

Bits	Field	Reset	Description
31:0	bytes	0x0	This register contains the number of bytes that have been written to the VBUSP mapped peripheral. The register is write to decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

#### 11.3.1.4.2.4.3.4 Static Transfer Request Setup

After reset, all channels in the PDMA are idle and waiting for work to be assigned to them. To initiate PDMA operation, the Host sends configuration transactions across PSI-L and sets up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of an X, Y, and Z parameter, but the field interpretation varies somewhat.

##### 11.3.1.4.2.4.3.4.1 X-Y FIFO Mode Static TR

In X-Y FIFO mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, 4 = 64 bits, and 5-7 = RESERVED
Y	0x400	11:0	Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.
Z	0x401	23:0	Not used

#### 11.3.1.4.2.4.3.4.2 MCAN Mode Static TR

In MCAN mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Not used
Y	0x400	11:0	Buffer Size. This field specifies how many bytes should be written to an MCAN TX buffer. This field includes the 8 byte MCAN header on the initial packet fragment. The PDMA will break up the source packet into fragments of this buffer size, copying the 8 byte MCAN header for the initial fragment, and then skipping it for each additional fragment and thus reusing the header from the first fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.
Z	0x401	23:0	Not used

#### 11.3.1.4.2.4.3.4.3 AASRC Mode Static TR

AASRC mode is similar to X-Y FIFO mode, the static TR consists of the following information:

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, and 4-7 = RESERVED
Y	0x400	11:0	FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer to each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.
Z	0x401	23:0	Not used

#### 11.3.1.4.2.4.3.4.4 AASRC TxFifoConfig (PSIL Address 0x405)

This register describes the FIFO list to be processed for this TX channel.

Bits	Field	Reset	Description
31	GroupMode	0x0	When set, the channel is in 'Group Mode'. It will look for Group Mode DMA requests, and access the Group Mode FIFOs. When clear, the channel is 'Stream Mode'. It will look for Stream FIFO DMA requests, and access the Stream Mode FIFOs.

Bits	Field	Reset	Description
30	DmaReqReset	0x0	When set, resets any latched DMA request using the DmaReqMask. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
23:20	LastSlot	0x0	This is the index (0-15) of the last slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19:16	FirstSlot	0x0	This is the index (0-15) of the first slot in the TX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
15:0	DmaReqMask	0x0	This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate. In Steam Mode, these 16 flags correspond to the 16 DMA requests for each TX FIFO. The flags corresponding to all TX FIFOs involved with the channel should be set to 1. In Group Mode, these flags indicate which Group Mode DMA requests must fire. In this case, only bits 3:0 are relevant and only one bit should be set to 1 as a DMA channel only services a single group.

#### 11.3.1.4.2.4.3.4.5 AASRC TxOrderTable0 (PSIL Address 0x406)

This table is filled with FIFO index values. TX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all TX threads.

Bits	Field	Reset	Description
31:28	Entry7	7	TX FIFO Index for slot 7
27:24	Entry6	6	TX FIFO Index for slot 6
23:20	Entry5	5	TX FIFO Index for slot 5
19:16	Entry4	4	TX FIFO Index for slot 4
15:12	Entry3	3	TX FIFO Index for slot 3
11:8	Entry2	2	TX FIFO Index for slot 2
7:4	Entry1	1	TX FIFO Index for slot 1
3:0	Entry0	0	TX FIFO Index for slot 0

#### 11.3.1.4.2.4.3.4.6 AASRC TxOrderTable1 (PSIL Address 0x407)

This table is filled with FIFO index values. TX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all TX threads.

Bits	Field	Reset	Description
31:28	Entry15	15	TX FIFO Index for slot 15
27:24	Entry14	14	TX FIFO Index for slot 14
23:20	Entry13	13	TX FIFO Index for slot 13
19:16	Entry12	12	TX FIFO Index for slot 12
15:12	Entry11	11	TX FIFO Index for slot 11
11:8	Entry10	10	TX FIFO Index for slot 10
7:4	Entry9	9	TX FIFO Index for slot 9

Bits	Field	Reset	Description
3:0	Entry8	8	TX FIFO Index for slot 8

#### 11.3.1.4.2.4.3.5 PSI-L Destination Thread Enables

PSI-L destination threads must first be enabled to accept data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

#### 11.3.1.4.2.4.4 Data Transfer

Packet transmission is accomplished within the PDMA by unpacking and moving data from the Tx Per Channel FIFOs which were filled via the Transmit PSI-L Interface to specified memory mapped address ranges via the VBUSP controller interfaces. On the Tx side of the PDMA, these transfers are always writes. Each write transfer which is performed by the Tx DMA Unit is to a destination address that is hardcoded in the channel at design time and of a size as specified in the static Transfer Request.

The sequences of logical transactions that are performed by the PDMA on the Memory I/F during transmit is dependent on the channel type. The following sections describe what will happen for the different channel types.

#### 11.3.1.4.2.4.4.1 X-Y FIFO Mode Channel

The PDMA channel remains idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA sequentially issues a total of 'Y' parameter writes of 'X' parameter bytes to the data\_address specified in the tchan\_info parameter for the channel. Each write that the DMA performs is a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed, the channel returns to an idle state and waits until it is triggered again. The write transfers that are performed are accomplished as quickly as possible given availability of data in the Tx channelized FIFO, and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 11.3.1.4.2.4.4.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting bit 31 of the XY register enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address increments throughout the burst
- Bursts are sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2 32-bit samples instead)
- PDMA 'gaps' the byte enables on writes as needed

#### 11.3.1.4.2.4.4.2 MCAN Mode Channel

The PDMA channel remains idle until data is received from the UDMA-P over the PSIL interface. At this time, the PDMA immediately starts copying packet bytes into the MCAN TX buffer corresponding the PDMA/MCAN channel. The number of bytes copied is smaller of the remaining bytes in the packet, or the value of the 'Y' parameter. Once a TX buffer has been filled, the PDMA transfers ownership of the buffer to MCAN by performing an MCAN register write. The PDMA then waits to regain ownership of the TX buffer by waiting for the corresponding MCAN TX event. At this time, the PDMA continues with refilling the TX buffer for the next

packet fragment. On subsequent fills (until the end of packet is reached), the PDMA skips over the 8 byte MCAN header, leaving the original contents from the initial fragment copy in place.

#### 11.3.1.4.2.4.4.3 AASRC Channel

The AASRC channel is controlled primarily via the channel's TxFifoConfig register. This register holds 3 basic pieces of information:

- Whether the channel uses AASRC Stream Mode or Group Mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel remains idle until a pulse is detected on ALL associated input DMA request event pins required by the TxFifoConfig setting. The pulses for the individual events are latched and held by the PDMA until they all arrive.

Once the channel activates, it starts reading FIFO index values from the TxOrderTable, starting at the configured 'First Slot' and ending with the 'Last Slot'. The actual FIFO indices used are obtained from the ordering table. For example, say FirstSlot=3 and LastSlot=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs written for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width written to the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel.

Once the total specified number of transactions has been completed, the channel returns to an idle state and waits until it is triggered again. The write transfers that are performed are accomplished as quickly as possible, given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 11.3.1.4.2.4.5 Transmit PSI-L Interface Transactions

The PDMA accepts data across the Tx PSI-L Interface in accordance with the physical handshaking protocol, as defined in the PSI-L Interface specification. The value sources for the output pins on the PSI-L interface are described in the following table.

Pin	Output Value / Source From PDMA
strm_i_link	This signal is asserted high to indicate the PSI-L link is valid.
strm_i_ready	This signal is asserted high anytime there is space in the PSI-L ingress fifo.
strm_i_sreq	This signal is asserted high anytime there is credit return data waiting in the PSI-L status fifo.
strm_i_sthreadid	This is set to the local destination thread that is returning credit.
strm_i_scnt	This is set to the number of credits being returned, or 0 on a TX teardown acknowledgement.

#### 11.3.1.4.2.4.6 Tx Pause

The Host initiates a channel pause by setting the pause bit in the RT enable register. The paused channel can be resumed by clearing the register bit.

#### 11.3.1.4.2.4.7 Tx Teardown

The Host initiates a channel teardown by setting the tdown bit in the UDMA-P channel paired with the PDMA. The UDMA-P communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous UDMA-P data for the channel has been flushed. At this time, the teardown state is reflected in the PSI-L RT Enable register of the PDMA. Note that a non-synchronized teardown can also be initiated by directly clearing the enable bit in the PSI-L RT Enable register of the PDMA.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel is cleared in the PSI-L RT enable register, but the teardown bit remains high. A teardown completion indication is

sent back across the status pins of the PSI-L in the form of a credit response with `scnt=0`. Upon completion, no further packet processing occurs until the Host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the UDMA-P transmission stops on a data boundary that is not compatible with the static TR configuration, the flush bit in the RT enable register can be set to ensure that all data can be properly flushed from the internal pipe.

#### 11.3.1.4.2.4.8 Tx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the enable bit in the PSI-L Enable register. This causes a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

#### 11.3.1.4.2.4.9 Tx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. The registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as in [Table 11-85](#).

**Table 11-85. Tx Debug/State Register**

Name	PSIL Addr	Field	Description
Y	0x402	15:0	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to write to the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next write offset to use when writing to the CAN TX buffer.
InEvent	0x403	31	When set, the PDMA is in the middle of processing a FIFO event.
Flush	0x403	30	When set, the PDMA is processing in a flushing state, where it runs without waiting for DMA requests and without writing data to the peripheral. It is only operating its internal state machine to allow internal data pipes to drain properly.
Pause	0x403	29	When set, the PDMA waiting in a paused state. This bit will clear when data starts flowing again from the UDMA-P.
Data	0x403	28	When set, there is a non-zero amount of data still waiting to be written to the peripheral.
XData	0x403	27	When set, there is enough data still waiting to be written to the peripheral to start servicing a peripheral DMA event.
State	0x403	23:20	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
EventCnt	0x403	19:16	This field holds the number of backlogged DMA events yet to be serviced.

#### 11.3.1.4.2.5 Receive Operation

##### 11.3.1.4.2.5.1 Source (Rx) Channel Allocation

A total of 3 source channels are provided within the DMA for concurrent transfers from the various attached peripherals into the Rx per channel buffers and on to the PSI-L Rx Interface. Each Rx channel requires a single PSI-L thread. The Rx channels are allocated as follows.

Rx DMA Channel	Function	Channel Type	Trigger Type	Data FIFO Address	Strobe MMR Address	Control FIFO Address
0	McASP 0 Rx Ch 0	XY	edge	000002B08000	000000000000	000000000000
1	McASP 1 Rx Ch 0	XY	edge	000002B18000	000000000000	000000000000
2	McASP 2 Rx Ch 0	XY	edge	000002B28000	000000000000	000000000000

#### 11.3.1.4.2.5.2 Source Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. To initiate PDMA operation, the Host must first pair the channel with a remote data source (normally a UDMA-P channel), set up the static TR for the channel, and enable the thread.

##### 11.3.1.4.2.5.2.1 PSI-L Source Thread Pairing Registers

###### 11.3.1.4.2.5.2.1.1 Peer Thread ID Register (PSIL Address 0x000)

Bits	Field	Reset	Description
31:29	ThreadPriority	0x0	This field is hard coded to 0x0 and is not writable
28:24	PeerThreadWidth	0x0	Datapath width of paired peer destination thread. This field is encoded as follows: 0 = 32-bit, 1 = 64-bit, 2 = 128 bit, 3 = 256 bit, 4 = 512 bit
23:16	-	0x0	Reserved.
15:0	Peer ThreadID	0x0	Thread ID to which all non-Transfer Response, non-Config messages from this thread will be sent.

###### 11.3.1.4.2.5.2.1.2 Peer Credit Register (PSIL Address 0x001)

Bits	Field	Reset	Description
31:8	-	0x0	Reserved.
7:0	CreditCnt	0x0	Free entries in destination thread. Legal range is 0 - 128 in number of elements.

###### 11.3.1.4.2.5.2.1.3 Enable Register (PSIL Address 0x002)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all credit returns, and will not generate egress data. A one to zero transition on this bit fully resets the channel.
30:0	-	0x0	Reserved.

##### 11.3.1.4.2.5.2.2 PSI-L Source Thread Realtime Enable/Count Registers

###### 11.3.1.4.2.5.2.2.1 RT Enable Register (PSIL Address 0x408)

Bits	Field	Reset	Description
31	enable	0x0	When set, the channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all DMA events from the peripheral. It maintains proper data transfers with the UDMA-P such that the credit handshake is not disrupted. However, unlike teardown, it does not close out the current open packet. Thus the teardown bit should always be used to disable an RX channel instead of manually clearing this bit. Failing to use teardown may result in stale data remaining in the internal RX FIFO, which would also prevent the channel from going idle without a channel reset. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.

Bits	Field	Reset	Description
30	tdown	0x0	When set, the channel will commence a RX channel teardown procedure. It will stop on the next FIFO boundary. It then clears the DMA event count and ignores all future DMA events from the peripheral.  After stopping peripheral reads, the PDMA sends a teardown message to the UDMA-P that also closes the current packet with an EOP. If no packet is open at the time of the teardown, the message also includes SOP. The EOP teardown message may or may not contain final packet data.  Once the channel teardown is complete and ready to be reused, the enable bit is cleared.
29	pause	0x0	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals, but will not act on them. The pause bit can be cleared and data will resume. Pause will not stop teardown from completing.
28:2	-	0x0	Reserved.
1	idle	0x0	This is a read-only bit that signifies that the Paused or Disabled channel is also idle. This bit is read only and can only become set if pause is set or enable is cleared.
0	free	0x0	Free Run: 0 = channel honors the emudbg suspend signal, 1 = channel will free run, regardless of the value of emudbg suspend.

#### 11.3.1.4.2.5.2.2 Source Thread Byte Count Register (PSIL Address 0x404)

Bits	Field	Reset	Description
31:0	bytes	0x0	This register contains the number of bytes that have been read from the VBUSP mapped peripheral. The register is write to decrement, so running counts can be tracked by reading register and then writing back the value that was read. It will wrap on overflow. It will reset to zero on a channel reset.

#### 11.3.1.4.2.5.2.3 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The Host pairs each source PDMA channel with (typically) a corresponding destination channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread, and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA send all their data to the source channel in the UDMA-P, and the destination channel in the UDMA-P never sees any data other than data from the source channel in the PDMA.

#### 11.3.1.4.2.5.2.4 Static Transfer Request Setup

After reset, all channels in the PDMA are idle and waiting for work to be assigned to them. To initiate PDMA operation, the Host sends configuration transactions across PSI-L and sets up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of an X, Y, and Z parameter, but the field interpretation varies.

#### 11.3.1.4.2.5.2.4.1 X-Y FIFO Mode Static TR

In X-Y FIFO mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	When set, enables VBUSP burst mode on this channel. See the XY burst description for more information.

Param	PSIL Addr	Field	Description
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, 4 = 64 bits, and 5-7 = RESERVED
Y	0x400	11:0	Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	FIFO count. This field specifies how many full FIFO operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an 'EOP' indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.

#### 11.3.1.4.2.5.2.4.2 MCAN Mode Static TR

In MCAN mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.
X	0x400	26:24	Not used
Y	0x400	11:0	Buffer Size. This field specifies how many bytes should be read from an MCAN RX buffer. This field includes the 8 byte MCAN header on the initial packet fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	Buffer Count. This field specifies how many MCAN RX buffers should be read before closing the CPPI packet with an 'EOP' indication. When this count is greater than 1, multiple MCAN RX buffers will be read into a single CPPI packet buffer. The 8 byte MCAN header will be skipped on subsequent MCAN buffer reads. Setting this field to NULL will suppress all packet delineation, and should be avoided.

#### 11.3.1.4.2.5.2.4.3 AASRC Mode Static TR

AASRC mode is similar to X-Y FIFO mode, the static TR consists of the following information.

Param	PSIL Addr	Field	Description
Burst	0x400	31	Not used
Acc32	0x400	30	When set, enables 32-bit access mode. On a 32-bit PDMA, all accesses will have XCNT=4 to support legacy IP that is not fully VBUSP compliant. This bit is ignored if the PDMA VBUSP port is not 32 bits wide.

Param	PSIL Addr	Field	Description
X	0x400	26:24	Element size. This field specifies how much data is transferred in each read which is performed by the DMA. This field is encoded as follows: 0 = 8 bits, 1 = 16 bits, 2 = 24 bits, 3 = 32 bits, and 4-7 = RESERVED
Y	0x400	11:0	FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer from each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.
EOL	0x401	31	EOL Mode. Normally, when the Z count of FIFO operations has been reached, the PDMA will close the packet with an 'EOP' indication. When this flag is set, the PDMA will instead trigger an EOL at the completion of Z.
Z	0x401	23:0	FIFO count. This field specifies how many full DMA request operations comprise a complete packet. When the count has been reached, the PDMA will close the packet with an 'EOP' indication. If this parameter is set to NULL, then no packet delineation is supplied by the PDMA and all framing is controlled via the UDMA-P TR.

#### 11.3.1.4.2.5.2.4.4 AASRC RxFifoConfig (PSIL Address 0x405)

This register describes the FIFO list to be processed for this RX channel.

Bits	Field	Reset	Description
31	GroupMode	0x0	When set, the channel is in 'Group Mode'. It will look for Group Mode DMA requests, and access the Group Mode FIFOs. When clear, the channel is 'Stream Mode'. It will look for Stream FIFO DMA requests, and access the Stream Mode FIFOs.
30	DmaReqReset	0x0	When set, resets any latched DMA request using the DmaReqMask. This bit is self-clearing. It should be used to synchronize the AASRC event status with the PDMA in the event that the AASRC has been previously used and it is not known if the PDMA may have latched, and is holding, previous DMA requests.
23:20	LastSlot	0x0	This is the index (0-15) of the last slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
19:16	FirstSlot	0x0	This is the index (0-15) of the first slot in the RX FIFO ordering table used by this channel. The ordering table is read to get the FIFO index to access for each slot, starting with the first and ending with the last.
15:0	DmaReqMask	0x0	This field holds a set of flags indicating which AASRC DMA requests must fire in order for this channel to activate. In Steam Mode, these 16 flags correspond to the 16 DMA requests for each RX FIFO. The flags corresponding to all RX FIFOs involved with the channel should be set to 1. In Group Mode, these flags indicate which Group Mode DMA requests must fire. In this case, only bits 3:0 are relevant and only one bit should be set to 1 as a DMA channel only services a single group.

#### 11.3.1.4.2.5.2.4.5 AASRC RxOrderTable0 (PSIL Address 0x406)

This table is filled with FIFO index values. RX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all RX threads.

Bits	Field	Reset	Description
31:28	Entry7	7	RX FIFO Index for slot 7
27:24	Entry6	6	RX FIFO Index for slot 6
23:20	Entry5	5	RX FIFO Index for slot 5
19:16	Entry4	4	RX FIFO Index for slot 4
15:12	Entry3	3	RX FIFO Index for slot 3
11:8	Entry2	2	RX FIFO Index for slot 2
7:4	Entry1	1	RX FIFO Index for slot 1
3:0	Entry0	0	RX FIFO Index for slot 0

#### 11.3.1.4.2.5.2.4.6 AASRC RxOrderTable1 (PSIL Address 0x407)

This table is filled with FIFO index values. RX channels reference a starting and ending 'slot' in this table for each transfer. The actual FIFO accessed by the DMA for each slot is determined by the FIFO index stored in this table. Note: This is a single register that is shared by all RX threads.

Bits	Field	Reset	Description
31:28	Entry15	15	RX FIFO Index for slot 15
27:24	Entry14	14	RX FIFO Index for slot 14
23:20	Entry13	13	RX FIFO Index for slot 13
19:16	Entry12	12	RX FIFO Index for slot 12
15:12	Entry11	11	RX FIFO Index for slot 11
11:8	Entry10	10	RX FIFO Index for slot 10
7:4	Entry9	9	RX FIFO Index for slot 9
3:0	Entry8	8	RX FIFO Index for slot 8

#### 11.3.1.4.2.5.2.5 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

#### 11.3.1.4.2.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the Receive PSI-L Interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Rx Per Channel FIFO to a remote peer DMA entity via the Rx PSI-L interface

The sequences of logical transactions that are performed by the PDMA on the Memory I/F during receive is dependent on the channel type. The following sections describe what happens for the different channel types.

#### 11.3.1.4.2.5.3.1 X-Y FIFO Mode Channel

The PDMA channel remains idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA sequentially issues a total of 'Y' parameter reads of 'X' parameter bytes from the data\_address specified in the tchan\_info parameter for the channel. Each read that the DMA performs is a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed,

the channel returns to an idle state and waits until it is triggered again. The read transfers that are performed are accomplished as quickly as possible given availability of data in the Rx channelized FIFO, and given the arbitration that may occur as a result of other channels also using the same read unit.

#### 11.3.1.4.2.5.3.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. For example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting bit 31 of the XY register enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts are sub-divided to fit into a 64-byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2 32-bit samples instead)
- PDMA 'gaps' the byte enables on writes as needed

#### 11.3.1.4.2.5.3.2 MCAN Mode Channel

The PDMA channel remains idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA starts copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN skips the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as follows.

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping/pong buffer for a particular RX packet ID. For example, the following two filter entries set up a ping/pong using RX buffers 0 and 1 for packet ID 5 on CAN RX channel 0.

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

### 11.3.1.4.2.5.3.3 AASRC Channel

The AASRC channel is controlled primarily via the channel's RxFifoConfig register. This register holds 3 basic pieces of information:

- Whether the channel uses AASRC Stream Mode or Group Mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel remains idle until a pulse is detected on ALL associated input DMA request event pins required by the RxFifoConfig setting. The pulses for the individual events are latched and held by the PDMA until they all arrive.

Once the channel activates, it starts reading FIFO index values from the RxOrderTable, starting at the configured 'First Slot' and ending with the 'Last Slot'. The actual FIFO indices used are obtained from the ordering table. For example, say FirstSlot=3 and LastSlot=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel.

Once the total specified number of transactions has been completed, the channel returns to an idle state and waits until it is triggered again. The read transfers that are performed are accomplished as quickly as possible given availability of data in the TX channelized FIFO, and given the arbitration that may occur as a result of other channels also using the same write unit.

### 11.3.1.4.2.5.4 Receive PSI-L Interface Transactions

When an entire word has been packed into the Rx Per Channel Buffer for a given channel, a one word data phase transfer is initiated for that channel/thread on the Rx PSI-L interface, and the data is popped from the Rx Per Channel FIFO. The value sources for the output pins on the PSI-L interface are described in [Table 11-86](#).

**Table 11-86. PSI-L Interface Output Pins**

Pin	Output Value / Source From PDMA
strm_o_req	This signal is asserted when the PDMA determines that there is at least 1 word of data in it's TP-CC output FIFO
strm_o_sthread_id	Set equal to the TP-CC DMA channel number which is on the interface for this cycle
strm_o_dthread_id	Set equal to the target thread ID value given in the PSI-L pairing configuration registers for this DMA channel
strm_o_data_type	Will be set to the proper PSI-L data type. The PDMA can send config response, PSI info word 0, and PSI data word.
strm_o_wnum	Set equal to the packing lane for the current word within a contiguous transfer. This value will start at 0 for each new TR and will increment for each subsequent data phase in the TR.
strm_o_lastw	This signal will be asserted coincident with eop.
strm_o_xcnt	The xcnt will be equal to the data path width in bytes.
strm_o_worden	The worden will be modulated to indicate which 32-bit words are valid within each control type data phase.
strm_o_data	The data will be packed/left justified to comply to the big endian data ordering as required in the PSI-L I/F specification.
strm_o_sop	This signal is asserted for 1 data phase at the beginning of each new TR or data transfer packet.
strm_o_eop	This signal is asserted for 1 data phase at the end of each TR or data transfer packet.
strm_o_sol	This signal is set to zero unless the EOL bit is set in PSI-L register 0x401, in which case, it is set for 1 data phase at the start of a new set of transactions designated by the count set in the Z field of PSI-L register 0x401.

**Table 11-86. PSI-L Interface Output Pins (continued)**

Pin	Output Value / Source From PDMA
strm_o_eol	This signal is set to zero unless the EOL bit is set in PSI-L register 0x401, in which case, it is set for 1 data phase at the end of a set of transactions designated by the count set in the Z field of PSI-L register 0x401.
strm_o_priv	Set to zero.
strm_o_privid	Set to zero.
strm_o_virtid	Set to zero.
strm_o_secure	Set to zero.
strm_o_interest	Set to zero.
strm_o_sready	Always asserted as the PDMA is always able to accept credit returns.

#### 11.3.1.4.2.5.5 Rx Pause

The Host initiates a channel pause by setting the pause bit in RT enable register. The paused channel can be resumed by clearing the register bit.

#### 11.3.1.4.2.5.6 Rx Teardown

The Host initiates a RX channel teardown by setting the tdown bit in the RT enable register for the target RX channel. The PDMA communicates the teardown state to the UDMA-P through the PSI-L data channel, to ensure that the teardown is not seen by the UDMA-P until all the previous PDMA data for the channel has been flushed.

The PDMA does not stop reading peripheral data until it reaches a FIFO boundary, as configured through the 'X' and 'Y' parameters in the static TR. It always attempts to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA then clears the enable bit in the pairing register; however, the teardown bit remains set. No further packet processing occurs until the Host re-configures the channel. The teardown process propagates to the UDMA-P and its final status can be checked there.

#### 11.3.1.4.2.5.7 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the enable bit in the PSI-L enable register. This causes a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

#### 11.3.1.4.2.5.8 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. The registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as in [Table 11-87](#).

**Table 11-87. Rx Debug/State Register**

Name	PSIL Addr	Field	Description
Z*	0x402	31:16	This field holds the lower 12 bits of the current Z count for legacy purposes. See register 0x40F below for the full width version of Z.
Y	0x402	15:0	This field holds the current Y count. In X-Y FIFO mode, this is the number of X sized samples yet to be read from the peripheral for the DMA event being serviced. In MCAN mode, this field holds the next read offset to use when read to the CAN RX buffer.
InEvent	0x403	31	When set, the PDMA is in the middle of processing a FIFO event.

**Table 11-87. Rx Debug/State Register (continued)**

Name	PSIL Addr	Field	Description
Tdown	0x403	30	When set, the PDMA is processing a teardown operation. This bit is set simultaneously with the teardown bit in the source (RX) RT enable register. This bit will clear when the teardown is complete, regardless as to if the teardown bit in the pairing register is cleared or not. The teardown will propagate to the UDMA-P and its full completion status can be checked there.
Pause	0x403	29	When set, the PDMA is stopped in a paused state. This bit will clear if the channel is un-paused or disabled.
Space	0x403	28	When set, there is a non-zero amount of internal FIFO space available to hold new read data.
XSpace	0x403	27	When set, there is a enough internal FIFO space available to start servicing a peripheral DMA event.
Buffer	0x403	26	This is the current RX buffer (0/1) for the current MCAN receive operation.
State	0x403	23:20	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
EventCnt	0x403	19:16	This field holds the number of backlogged DMA events yet to be serviced.
Z	0x40F	31:0	This field holds the full width value of the current Z count. In X-Y FIFO mode, this field holds the 1 based FIFO count of the FIFO being currently read, or the number of FIFO completions when the current operation completes. In MCAN mode, this field holds the zero based buffer index of the buffer currently being read, or the number of previously completed buffers.

## 12.1 General Connectivity Peripherals

## 12.1.1 General-Purpose Interface (GPIO)

This chapter describes the General-Purpose Input/Output (GPIO) for the device.

### 12.1.1.1 GPIO Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, the user can write to an internal register to control the state driven on the output pin. When configured as an input, user can obtain the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce host CPU interrupts and DMA synchronization events in different interrupt/event generation modes.

The device has one or more instances of GPIO modules. The GPIO pins are grouped into banks (16 pins per bank and 9 banks per module), which means that each GPIO module provides up to 144 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 432 (3 instances  $\times$  (9 banks  $\times$  16 pins)) pins. Since MCU\_GPIO0\_[23:143], GPIO0\_[87:143], and GPIO1\_[88:143] are reserved in this device, general purpose interface supports up to 198 pins.

Figure 12-1 presents the GPIO modules overview.

**Figure 12-1. GPIO Modules Overview**

- A. (1): x represents a valid instance of GPIO in a domain.
- B. (2): n represents the maximum number of GPIO signals -1.
- C. (3): CBASS0 represents the connectivity in the domain of the IP.
- D. (4): Some GPIO signals may be uni-directional. Consult the device datasheet for specifics.

#### 12.1.1.1.1 GPIO Features

Each channel in the GPIO modules has the following features:

- Supports 9 banks of 16 GPIO signals
- Supports up to 9 banks of interrupt capable GPIOs
- Interrupts:
  - Can enable interrupts for each bank of 16 GPIO signals
  - Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO signal
- Set/clear functionality:

- Firmware writes 1 to corresponding bit position(s) to set or to clear GPIO signal(s). This allows multiple firmware processes to toggle GPIO output signals without critical section protection (disable interrupts, program GPIO, re-enable interrupts, to prevent context switching to another process during GPIO programming).
- Separate Input/Output registers:
  - If preferred by firmware, some GPIO output signals can be toggled by direct write to the output register(s) in addition to set/clear.
  - Output register, when read in, reflects output drive status. This, in addition to the input register reflecting pin status, allows wired logic be implemented.

#### **12.1.1.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

---

### 12.1.1.2 GPIO Environment

This section describes the GPIO external connections (environment).

The general-purpose interface combines three GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

Figure 12-2 shows a typical application using the general-purpose interface.

#### 12.1.1.2.1 GPIO Interface Signals

Figure 12-2 shows all of the GPIO interface signals.

#### Note

i represents a GPIO instance. See the device datasheet for available domains and GPIO instances.

#### Note

See Module Integration section for signal specifics in GPIO.

**Figure 12-2. GPIO Interface Signals and Typical Application**

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.1.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.1.1.4 GPIO Functional Description

#### 12.1.1.4.1 GPIO Block Diagram

Figure 12-3 shows the general-purpose interface block diagram.

gpio\_005

- A. Some of the GPj pins are muxed with other device signals. For details, see the device-specific Datasheet.
- B. All GPINTj can be used as host CPU interrupts and synchronization events to the DMA.
- C. The RIS\_TRIG and FAL\_TRIG registers are internal to the GPIO module and are not visible to the host CPU.

**Figure 12-3. GPIO Block Diagram**

#### 12.1.1.4.2 GPIO Function

Each GPIO pin (GPj) can be independently configured as either an input or an output using the GPIO direction registers. The GPIO direction register (DIR) specifies the direction of each GPIO signal. Logic 0 indicates the GPIO pin is configured as output, and logic 1 indicates input.

When configured as output, writing a 0x1 to a bit in the set data register drives the corresponding GPj to a logic-high state. Writing a 0x1 to a bit in the clear data register drives the corresponding GPj to a logic-low state. The output state of each GPj can also be directly controlled by writing to the output data register.

For example, to set GP8 to a logic-high state, the software can perform one of the following:

- Write 100h to the GPIO0\_SET\_DATA01 register.
- Write 0h to the GPIO\_DIR01 register to configure as output pin.
- Read in GPIO\_OUT\_DATA01 register, change bit 8 to 0x1, and write the new value back to GPIO\_OUT\_DATA01.

To set GP8 to a logic-low state, the software can perform one of the following:

- Write 100h to the GPIO\_CLR\_DATA01 register.
- Write 0h to the GPIO\_DIR01 register to configure as output pin.
- Read in GPIO\_OUT\_DATA01 register, change bit 8 to 0x0, and write the new value back to GPIO\_OUT\_DATA01.

Note that writing a 0x0 to bits in the set data and clear data registers does not affect the GPIO pin state.

Also, for GPIO pins configured as input, writing to the set data, clear data, or output data registers does not affect the pin state.

For a GPIO pin configured as input, reading the input data register (IN\_DATA) will return the pin state. Reading the SET\_DATA register or the CLR\_DATA data register will return the value in OUT\_DATA, not the actual pin state. The pin state is available by reading the input data register. Note that when the direction is configured as input, the output state is determined by software's programming set/clear/output registers, and may not agree with the pin state, which is driven by an external device.

#### 12.1.1.4.3 Interrupt and Event Generation

Each GPIO pin (GPj) can be configured to generate a host CPU interrupt (GPINTj) or a synchronization event to the DMA (GPINTj). Configuration is on per-bank basis. Each bit of the BINT\_EN parameter dictates YES/NO option for each bank. Bit 0 controls bank 0, bit 1 controls bank 1, and so on.

The interrupt and DMA event can be generated on the rising-edge, falling-edge, or on both edges of the GPIO signal. The edge detection logic is synchronized to the GPIO peripheral clock.

The direction of the GPIO pin does not need to be input when using the pin to generate the interrupt or DMA event. When the GPIO pin is configured as input, transitions on the pin trigger interrupts or DMA events. When the GPIO pin is configured as output, software can toggle the GPIO output register to change the pin state and in turn trigger the interrupt or DMA event.

Note that the direction of the pin need not be input for interrupt generation to work. When the GPINT pin is configured as input, transitions on the pin trigger interrupts. When the GPINT pin is configured as output, firmware can toggle the GPIO output register to change the pin state, and in turn trigger interrupts.

Each interrupt output of GPINT signal are available at the module boundary. Each group of 16 GPINT signals also has their masked interrupt outputs ORed together to generate a per bank interrupt, available at the module boundary. The idea is to either connect individual interrupts or per bank interrupts to the system interrupt controller.

##### 12.1.1.4.3.1 Interrupt Enable (per Bank)

The GPIO\_BINTEN register provides interrupt enable/disable feature for each bank of 16 GPINT signals.

##### 12.1.1.4.3.2 Trigger Configuration (per Bit)

Two internal registers, RIS\_TRIG and FAL\_TRIG, specify which edge of the GPj signal generates an interrupt or DMA event. Each bit in these two registers corresponds to a GPj pin. [Table 12-1](#) describes the host CPU interrupt and DMA event generation of GPj pin based on the bit settings of the RIS\_TRIG and FAL\_TRIG registers.

**Table 12-1. GPIO Interrupt and DMA Event Configuration Options**

Clarifying configuration of GPIO interrupt generation RIS_TRIG Bit n	FAL_TRIG Bit n	Host CPU Interrupt and DMA Event Generation
0	0	GPINTj interrupt and DMA event is disabled
0	1	GPINTj interrupt and DMA event is triggered on falling edge of GPj signal
1	0	GPINTj interrupt and DMA event is triggered on rising edge of GPj signal
1	1	GPINTj interrupt and DMA event is triggered on both rising and falling edge of GPj signal

The RIS\_TRIG and FAL\_TRIG registers are not directly accessible or visible to the host CPU. These registers are accessed indirectly through four registers: SET\_RIS\_TRIG, CLR\_RIS\_TRIG, SET\_FAL\_TRIG, and CLR\_FAL\_TRIG. Writing 1 to a bit on the SET\_RIS\_TRIG register sets the corresponding bit on the RIS\_TRIG register. Writing 1 to a bit of the CLR\_RIS\_TRIG register clears the corresponding bit on the RIS\_TRIG register. Writing to the SET\_FAL\_TRIG and CLR\_FAL\_TRIG registers works the same way on the FAL\_TRIG register.

Reading the SET\_RIS\_TRIG or CLR\_RIS\_TRIG register returns the value of the RIS\_TRIG register. Reading from the SET\_FAL\_TRIG and CLR\_FAL\_TRIG register returns the value of the FAL\_TRIG register.

To use the GPIO pins as sources for host CPU interrupts and DMA events, the associated bank interrupt enable register bit in GPIO\_BINTEN must also be set to 1. For example, to enable GPIO0\_19 (which is in bank 1), GPIO\_BINTEN[1] = 1 should be set to enable interrupts for bank 1.

#### 12.1.1.4.3.3 Interrupt Status and Clear (per Bit)

The INTSTAT registers provide interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding bit position(s). Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

#### Note

The GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

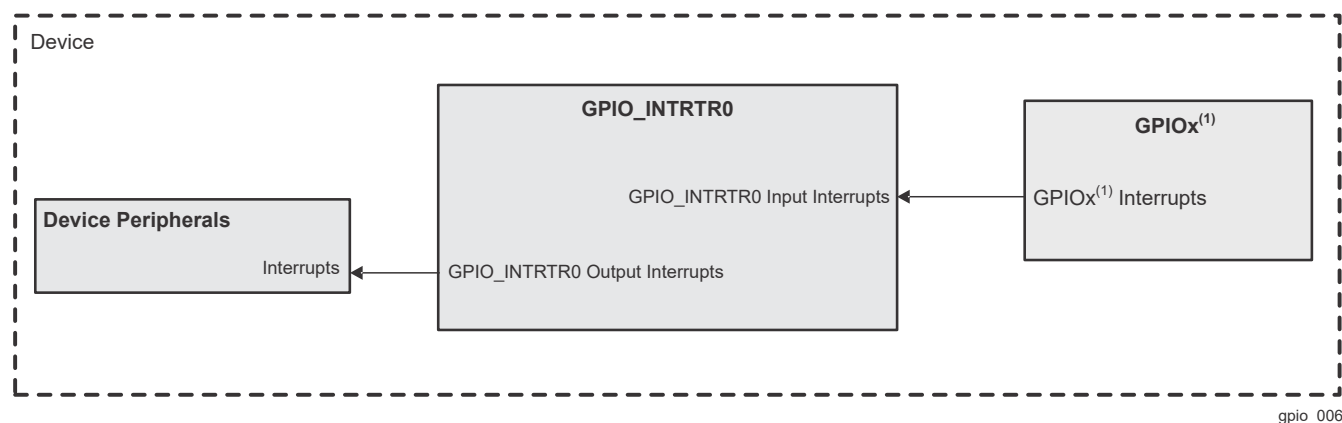

#### 12.1.1.4.4 GPIO Interrupt Connectivity

Because this device muxes GPIO signals with other functional signals, the availability of any particular GPIO and hence the usability of its associated interrupt will change based on the use case pin muxing. The large number of possible GPIO interrupt sources makes it impractical to route all interrupt events to each processing element. Since most applications do not typically require a large number of GPIO interrupts, the interrupt uncertainty is resolved by mapping all GPIO interrupts to a series of event muxes implemented using Interrupt Router (IntRouter) modules. These muxes allow any one of the available GPIO interrupts to be selected and passed on as an event to the various processor interrupt controllers and DMA controllers. Event selection is controlled through associated registers within each IntRouter.

The GPIO bank interrupts already represent a consolidation of the 16 GPIO interrupts associated with each bank and are routed directly to various interrupt controllers rather than through the GPIO IntRouters.

One of the GPIO pins has a potential use case as an Arm reset input and should therefore be routed as highest priority interrupt in the GIC and mapped to nFIQ in software.

Figure 12-4 shows the GPIO Interrupt Routers connectivity. Refer to *Interrupt Routers*, for more details on the GPIO Interrupt Routers connectivity.

gpio\_006

A. (1): x represents a valid instance of GPIO in a domain.

**Figure 12-4. GPIO Interrupt Router Connectivity**

#### 12.1.1.4.5 Emulation Halt Operation

The GPIO peripheral is not affected by emulation halts.

### 12.1.1.5 GPIO Programming Guide

#### 12.1.1.5.1 GPIO Low-Level Programming Models

##### 12.1.1.5.1.1 Global Initialization

##### 12.1.1.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see *GPIO Environment* and *Module Integration*.

**Table 12-2. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC0	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
PLLCTRL0	Interface and functional clocks must be enabled. For more information about the module configuration, see <i>Clocking</i> .
MCU_PLLCTRL0	Interface and functional clocks must be enabled. For more information about the module configuration, see <i>Clocking</i> .
GIOMUX_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling GIOMUX_INTRTR0 interrupts, see <i>Interrupts</i> .
MCU_GIOMUX_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MCU_GIOMUX_INTRTR0 interrupts, see <i>Interrupts</i> .
Interconnects	For information about the MCU_CBASS0, and CBASS0 interconnects configuration, see <i>System Interconnect</i> .

##### 12.1.1.5.1.1.2 GPIO Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

**Table 12-3. GPIO Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Configure GPIO channels as input or output of the corresponding bank	DIR	-h
<b>Interrupt requests configuration</b>		
Configure detection events	SET_RIS_TRIG and/or SET_FAL_TRIG	-h
Clear interrupt status	INTSTAT	FFFFh
Enable interrupts for desired banks [0:8]	GPIO_BINTEN[8-0]	-h

##### 12.1.1.5.1.2 GPIO Operational Modes Configuration

##### 12.1.1.5.1.2.1 GPIO Read Input Register

**Table 12-4. GPIO Read Input Register**

Step	Register/Bit Field/Programming Model	Value
Read interrupt status of the corresponding bank	INTSTAT	-h
Read input register value	IN_DATA	-h
Clear interrupt status	INTSTAT	FFFF FFFFh

##### 12.1.1.5.1.2.2 GPIO Set Bit Function

**Table 12-5. GPIO Set Bit Function**

Step	Register/Bit Field/Programming Model	Value
Write 1h to set desired bit(s) in SET_DATA register.	SET_DATA	-h

### 12.1.1.5.1.2.3 GPIO Clear Bit Function

**Table 12-6. GPIO Clear Bit Function**

Step	Register/Bit Field/Programming Model	Value
Write 1h to clear desired bit(s) in CLR_DATA register.	CLR_DATA	-h

## 12.1.2 Inter-Integrated Circuit (I2C) Interface

This section describes the Inter-Integrated Circuit (I2C) module in the device.

### 12.1.2.1 I2C Overview

The device contains multicontroller Inter-Integrated Circuit (I2C) controllers each of which provides an interface between a local host (LH), such as an Arm and any I<sup>2</sup>C-bus-compatible device that connects via the I<sup>2</sup>C serial bus. External components attached to the I<sup>2</sup>C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I<sup>2</sup>C interface.

Each multicontroller I<sup>2</sup>C module can be configured to act like a target or controller I<sup>2</sup>C-compatible device.

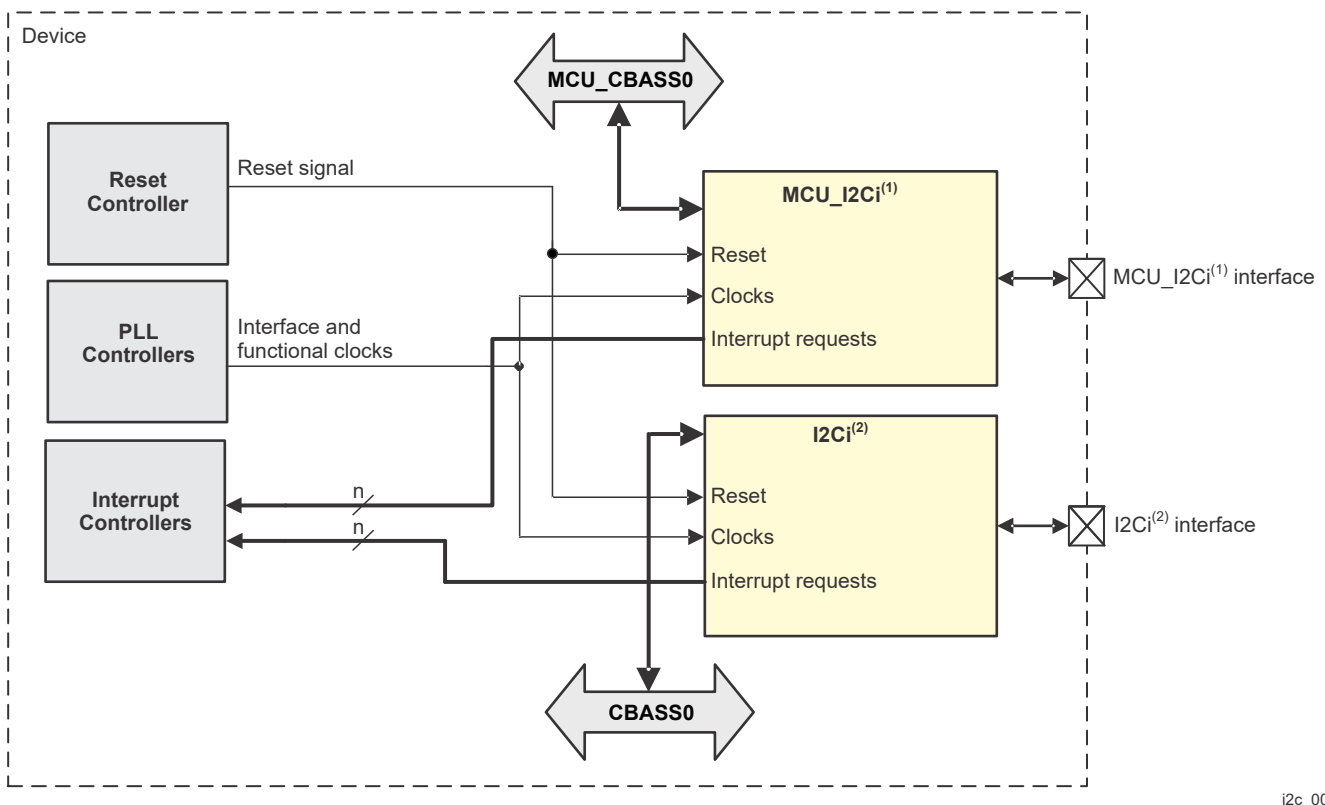

I<sup>2</sup>C instances may be implemented with dedicated, I<sup>2</sup>C compliant, open-drain I/O buffers, or with standard LVCMOS I/O buffers. The I<sup>2</sup>C instances associated with open-drain I/O buffers can support Hs-mode (up to 3.4 Mbps when the I/O buffers are operating at 1.8 V but limited to 400 kbps when the I/O buffers are operating at 3.3 V).

The I<sup>2</sup>C instances associated with standard LVCMOS I/O buffers can support Fast-mode (up to 400 kbps). The LVCMOS I/O buffers being used on these ports are connected such they emulate open-drain outputs. This emulation is achieved by forcing a constant low output and disabling the output buffer to enter the Hi-Z state.

Refer to the device specific datasheet for details on which instances support which buffer type.

For the specific I/O timing characteristics of the different I<sup>2</sup>C instances, see the device-specific Datasheet.

Figure 12-5 shows the I2C modules overview.

i2c\_001

- A. (1): i = 0 to (number of devices - 1) in MCU Domain, if applicable.
- B. (2): i = 0 to (number of devices - 1) in MAIN Domain, if applicable.

**Figure 12-5. I2C Modules Overview**

#### 12.1.2.1.1 I2C Features

Each multicontroller I2C module has the following features:

- Compliant with Philips I<sup>2</sup>C-bus specification version 2.1
- Supports a standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode (up to 3.4 Mbps) only for instances with true open drain buffer and in 1.8 V mode
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multicontroller transmitter/target receiver mode
- Multicontroller receiver/target transmitter mode
- Combined controller transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read
- Module enable/disable capability
- Programmable multitarget channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Low power consumption
- Support Auto Idle mechanism
- Support Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Wide interrupt capability

#### 12.1.2.1.2 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.1.2.1.3 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

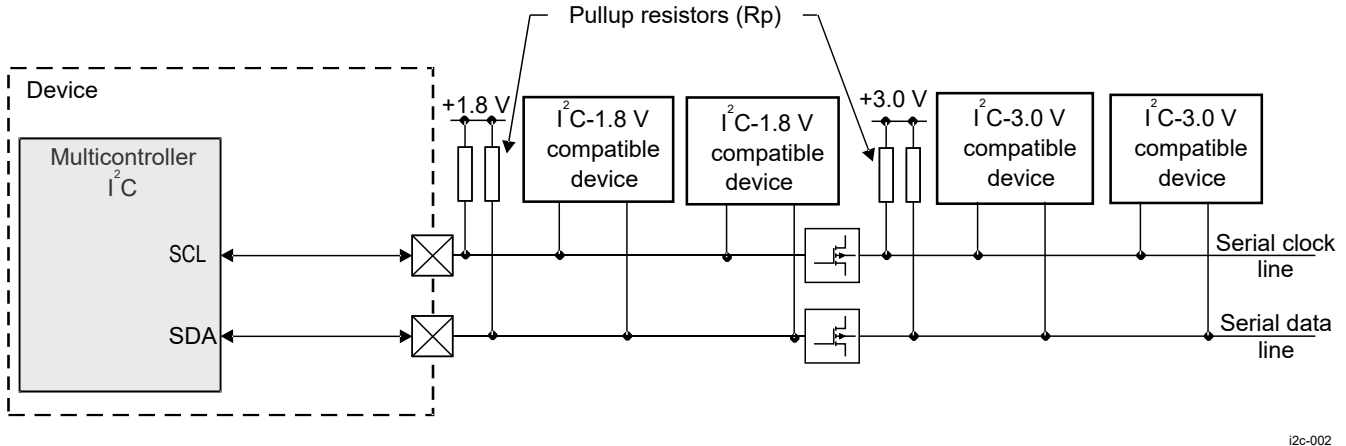

---

### 12.1.2.2 I2C Environment

This section describes the I2C external connections (environment).

#### 12.1.2.2.1 I2C Typical Application

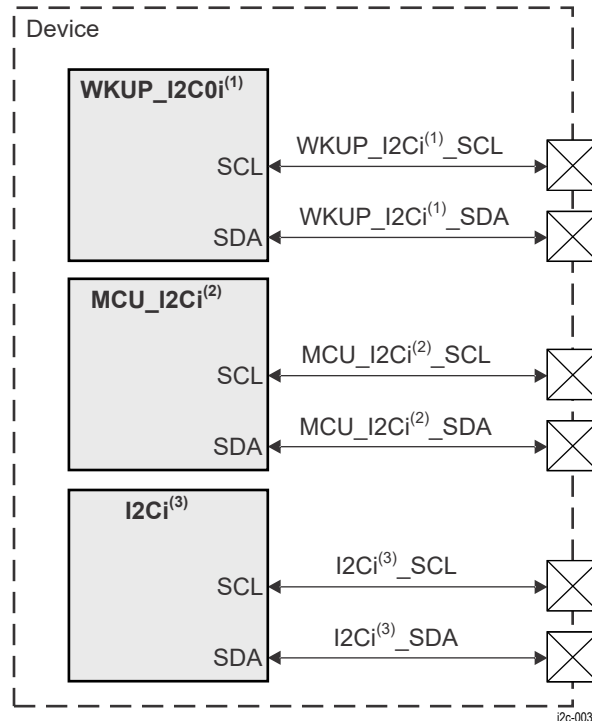

Figure 12-6 shows the multicontroller I2C and their related connections with I2C-compliant devices.

**Figure 12-6. I2C and Typical Connections to I2C Devices**

#### 12.1.2.2.1.1 I2C Pins for Typical Connections in I2C Mode

Figure 12-7 shows the multicontroller I2C pins used for typical connections with I2C devices.

1.  $i = 0$  to (number of devices - 1) in WKUP Domain, if applicable
2.  $i = 0$  to (number of devices - 1) in MCU Domain, if applicable
3.  $i = 0$  to (number of devices - 1) in MAIN Domain, if applicable

**Figure 12-7. I2C Interface Signals**

### 12.1.2.2.1.2 I2C Interface Typical Connections

Table 12-7 describes the I2C I/O signals.

**Table 12-7. I2C I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value
<b>WKUP_I2Ci<sup>(2)</sup></b>				
SCL	WKUP_I2Ci <sup>(2)</sup> _SCL	I/O	I <sup>2</sup> C serial clock line.	1
SDA	WKUP_I2Ci <sup>(2)</sup> _SDA	I/O	I <sup>2</sup> C serial data line.	1
<b>MCU_I2Ci<sup>(2)</sup></b>				
SCL	MCU_I2Ci <sup>(2)</sup> _SCL	I/O	I <sup>2</sup> C serial clock line.	1
SDA	MCU_I2Ci <sup>(2)</sup> _SDA	I/O	I <sup>2</sup> C serial data line.	1
<b>I2Ci<sup>(2)</sup></b>				
SCL	I2Ci <sup>(2)</sup> _SCL	I/O	I <sup>2</sup> C serial clock line.	1
SDA	I2Ci <sup>(2)</sup> _SDA	I/O	I <sup>2</sup> C serial data line.	1

(1) I = Input; O = Output; I/O = Bidirectional

(2) i represents an I2C instance. See the device datasheet for available domains and I2C instances.

#### 12.1.2.2.1.3

#### Note

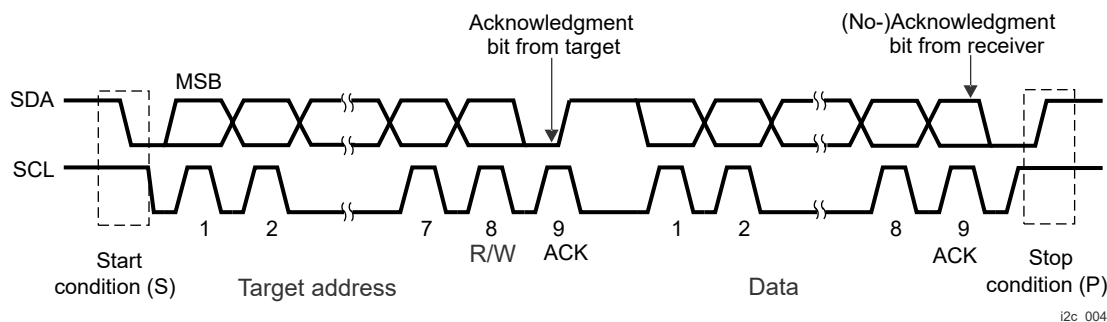

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.2.2.2 I2C Typical Connection Protocol and Data Format

#### 12.1.2.2.2.1 I2C Serial Data Format

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I2C module.

Figure 12-8 shows a typical I<sup>2</sup>C communication format.

**Figure 12-8. I2C Data Transfer**

#### 12.1.2.2.2.2 I2C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 12-9 is an example of data validity requirements.

Figure 12-9. I2C Bit Transfer on the I2C Bus

#### 12.1.2.2.2.3 I2C Start and Stop Conditions

The I2C module generates start (S) and stop (P) conditions when it is configured as a controller.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2C\_IRQSTATUS\_RAW [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2C\_IRQSTATUS\_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 12-10 shows the waveforms that occur during an S and a P condition.

Figure 12-10. I2C S and P Condition Events

#### Note

I2C controller does not support messages non-compliant with I<sup>2</sup>C standard. Void messages are non-standard I<sup>2</sup>C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next controller transfer which would never complete. A soft reset of the controller is recommended for recovery.

#### 12.1.2.2.2.4 I2C Addressing

The I2C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

##### 12.1.2.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 12-11 shows the I2C data transfer formats in F/S mode.

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

## Figure 12-11. I2C Data Transfer Formats in F/S Mode

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB target address bits and 1 least-significant bit (LSB) R/W\_ bit.

The LSB R/W\_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W\_ is 0, the controller writes data to the selected target; if it is 1, the controller reads data from the target.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W\_ bit. If the R/W\_ bit is 0, the next byte contains the last 8 bits of the target address. If the R/W\_ bit is 1, the next byte contains data transmitted from the target to the controller.

### 12.1.2.2.4.2 Data Transfer Format in HS Mode

Figure 12-12 shows the I2C data transfer format in HS mode.

S = Start; Sr = repeated start; P = Stop; F/S = Fast/standard mode; HS = High-speed mode

i2c-008

## Figure 12-12. HS I2C Data Transfer in HS Mode

Each multicontroller I2C can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the controller code address (0x00001XXX, where XXX is the variable portion of the controller code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the target address and the data, as shown in Figure 12-12.

#### 12.1.2.2.2.5 I2C Controller Transmitter

In controller transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

#### 12.1.2.2.2.6 I2C Controller Receiver

Controller receiver mode can be entered only from controller transmitter mode. With any of the address formats (a), (b), or (c) (see [Figure 12-11](#)), if R/W\_ is high, the module enters controller receiver mode after the target address byte and bit R/W\_ are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

#### 12.1.2.2.2.7 I2C Target Transmitter

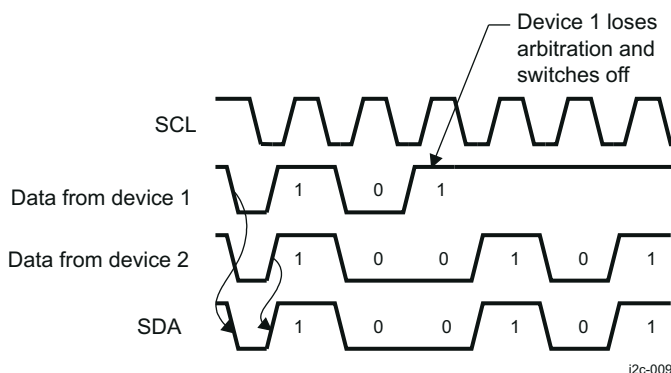

Target transmitter mode can be entered only from target receiver mode. With any of the address formats (a), (b), or (c) (see [Figure 12-11](#)), the target transmitter is entered if the target address byte is the same as its own address and bit R/W\_ is transmitted, if R/W\_ is high. The target transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the controller device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

#### 12.1.2.2.2.8 I2C Target Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the controller device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

#### 12.1.2.2.2.9 I2C Bus Arbitration

If two or more controller transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the target receiver mode, sets the arbitration lost (I2C\_IRQSTATUS\_RAW[0] AL) flag, and generates the arbitration lost interrupt. [I2C Arbitration Between Controller Transmitters](#) shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

**Figure 12-13. I2C Arbitration Between Controller Transmitters**

#### 12.1.2.2.2.10 I2C Clock Generation and Synchronization

Under normal conditions, only one controller device generates the clock signal - SCL. However, there are two or more controller devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device

with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a target can slow down a fast controller and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

### Note

In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if the I<sup>2</sup>C devices have hardware reset inputs. If the I<sup>2</sup>C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the controller should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 12-14 shows clock synchronization.

**Figure 12-14. I2C Clock Generators Synchronization**

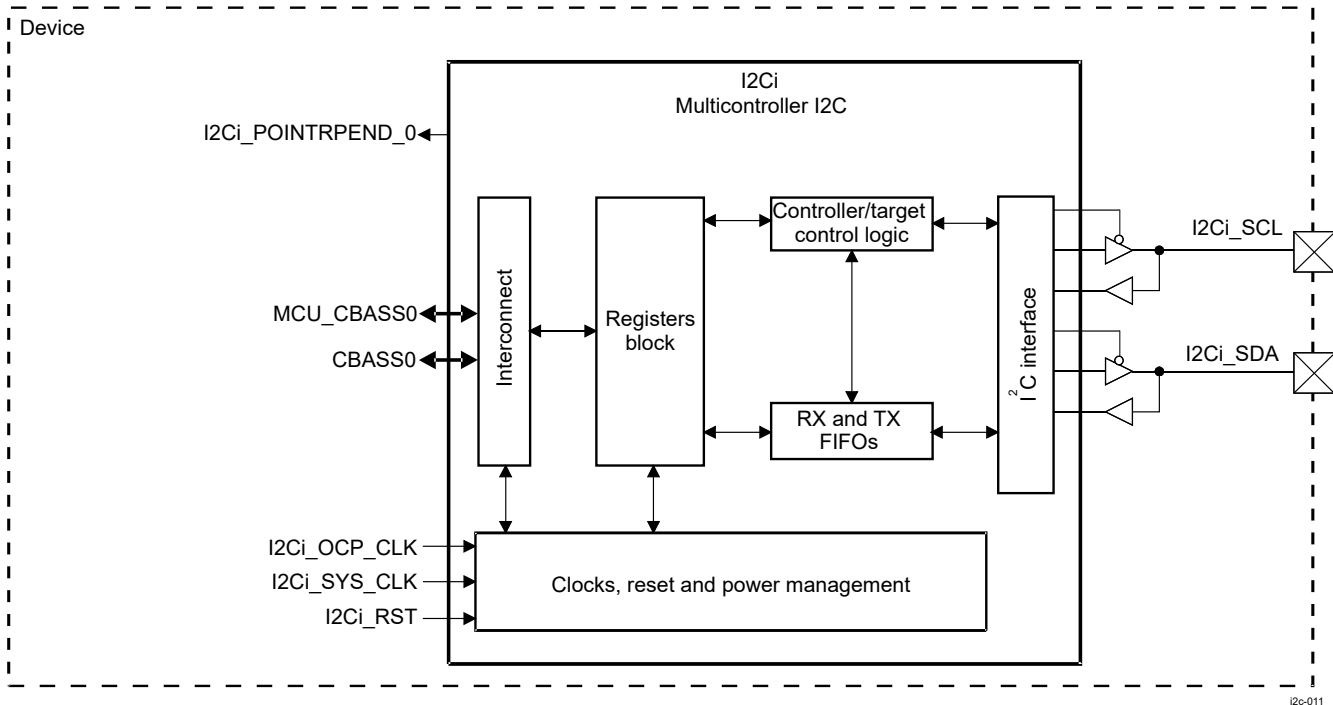

### 12.1.2.3 I2C Functional Description

#### 12.1.2.3.1 I2C Block Diagram

##### Note

DMA mode and SCCB Protocol are not supported on this family of devices.

Figure 12-15 presents the multicontroller I2C block diagram.

- A.  $i = 0$  to number of devices in MCU domain -1.
- B.  $i = 0$  to number of devices in MAIN domain -1.

**Figure 12-15. I2C Block Diagram**

The ten multicontroller I2C can be configured in F/S I2C mode or HS I2C mode. The operation mode is selected by configuring the I2C\_CON[13-12] OPMODE bit field.

Table 12-8 lists the available operation modes.

**Table 12-8. I2C Operation Mode Selection**

Operation Mode	Value of I2C_CON[13-12] OPMODE
F/S I2C	0x0
HS I2C	0x1
SCCB	0x2
Reserved (not used)	0x3

#### 12.1.2.3.2 I2C Clocks

##### 12.1.2.3.2.1 I2C Clocking

Each multicontroller I2C uses the SYS\_CLK functional clock in the Device Configuration section. The internal sampling clock INTERNAL\_CLK is generated by dividing the functional clock by the I2C\_PSC[7-0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the SCLL signal is determined by the I2C\_SCLL[7-0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C\_SCLL[15-8] HSSCLL bit field in the second phase of HS mode.

The high time of the SCLH signal is determined by the I2C\_SCLH[7-0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C\_SCLH[15-8] HSSCLH bit field in the second phase of HS mode.

Table 12-9 lists the  $t_{LOW}$  and  $t_{HIGH}$  values in controller mode only (in target mode, the I2C controller does not generate the I2C clock).

**Table 12-9. I2C  $t_{LOW}$  and  $t_{HIGH}$  Values of the I2C Clock**

Mode	Clock	$t_{LOW}$	$t_{HIGH}$
F/S or HS first phase	$INTERNAL\_CLK = SYS\_CLK / (I2C\_PSC[7-0] \text{ PSC bit field} + 1)$	$(I2C\_SCLL[7-0] \text{ SCLL bit field value} + 7) \times INTERNAL\_CLK \text{ period}$	$(I2C\_SCLH[7-0] \text{ SCLH bit field value} + 5) \times I2Ci\_INTERNAL\_CLK \text{ period}$
HS second phase	$SYS\_CLK$	$(I2C\_SCLL[15-8] \text{ HSSCLL bit field value} + 7) \times SYS\_CLK \text{ period}$	$(I2C\_SCLL[15-8] \text{ HSSCLH bit field value} + 5) \times I2Ci\_SYS\_CLK \text{ period}$

#### Note

For HS mode, the I2C\_SCLL[15-8] HSSCLL and I2C\_SCLL[7-0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C\_SCLH[15-8] HSSCLH and I2C\_SCLH[7-0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

#### Note

The equations in Table 12-9 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I2C controller outputs. Actual  $t_{LOW}$  and  $t_{HIGH}$  periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

#### CAUTION

During active mode (the I2C\_CON[15] I2C\_EN bit is set to 1), make no changes to the I2C\_SCLL and I2C\_SCLH registers. Changes may result in unpredictable behavior.

Table 12-10 lists the register values for obtaining the maximum I2C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

**Table 12-10. I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes <sup>(1)</sup>**

	I2C Mode for			Description
	Standard Mode	Fast Mode	High-Speed Mode <sup>(2)</sup>	
SYS_CLK frequency (MHz)	96			
OCP_CLK frequency (MHz)	133			
I2C_PSC[7-0] PSC	23	9	1	Prescaler value for F/S and HS modes
INTERNAL_CLK frequency (MHz)	4	9.6	96	
I2C_SCLL[7-0] SCLL	13	7	115	Value for F/S mode and first phase of HS mode
I2C_SCLH[7-0] SCLH	15	5	113	Value for F/S mode and first phase of HS mode

**Table 12-10. I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes <sup>(1)</sup> (continued)**

	I <sup>2</sup> C Mode for			Description
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
I2C_SCLL[15-8] HSSCLL			<b>12</b>	Values for second phase of HS mode
I2C_SCLH[15-8] HSSCLH			<b>5</b>	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

(1) Programmable fields are in bold.

(2) HS mode is not supported on this family of devices.

#### Note

This table presents informative values only for the configuration parameters and the I<sup>2</sup>C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

#### Note

For MCU\_I2C[0-1]

For I2C[0-3]

$I2Ci\_INTERNAL\_CLK\ freq = I2Ci\_SYS\_CLK / (PSC + 1)$

$F/S\ filter\ period = 1 / I2Ci\_INTERNAL\_CLK$

$HS\ filter\ period = 1 / I2Ci\_SYS\_CLK\ freq$

$HS\ bit\ rate = I2Ci\_SYS\_CLK\ freq / (HSSCLL + 7 + HSSCLH + 5)$

$FS\ bit\ rate = I2Ci\_INTERNAL\_CLK / (SCLL + 7 + SCLH + 5)$

#### 12.1.2.3.2.2 I2C Automatic Blocking of the I2C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I<sup>2</sup>C clock after the target addressing phase, when the I2C controller is addressed by an external controller device using a certain Own Address.

The release of the I<sup>2</sup>C clock can be performed independently for each Own Address (I2C\_OA, and I2C\_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2C\_SBLOCK register.

#### 12.1.2.3.3 I2C Software Reset

Each multicontroller I2C supports the software reset by accessing the I2C\_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C\_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C\_CON[15] I2C\_EN bit to 0).
2. Set the I2C\_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C\_CON[15] I2C\_EN bit to 1.
4. Check the I2C\_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

### Note

The I2C\_CON[15] I2C\_EN bit can hold the functional clock domain of the multicontroller I2C in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I2C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C\_CON[15] I2C\_EN bit must be set to 1 to enable the functional part of the I2C controller.

The I2C\_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C\_CON[15] I2C\_EN bit to 1.

#### 12.1.2.3.4 I2C Power Management

Table 12-11 describes power-management features available for the multicontroller I2C.

### Note

For information about source clock gating, see *Power* in the *Device Configuration*.

### Note

Some of the I2C features described in this section may not be supported on this family of devices. See the *Module Integration* section for more information about unsupported features..

**Table 12-11. I2C Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Target idle modes	I2C_SYSC[4-3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C_SYSC[9-8] CLOCKACTIVITY	For configuration details, see Table 12-12.
Global wake-up enable	I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

**Table 12-12. I2C Clock Activity Settings**

I2C_SYSC[9-8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	OCP_CLK	SYS_CLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; Functional clock is enabled
01	ON	OFF	Functional clock is disabled; Interface clock is enabled
11	ON	ON	Both clocks are enabled.

#### 12.1.2.3.5 I2C Interrupt Requests

The I2C controller must allocate a minimum of five registers for interrupts.

- Interrupt Raw Status (I2C\_IRQSTATUS\_RAW)
- Interrupt Enabled Status (I2C\_IRQSTATUS)
- Interrupt Enable Set (I2C\_IRQENABLE\_SET)
- Interrupt enable Clear (I2C\_IRQENABLE\_CLR)
- End of interrupt (I2C\_EOI)

End of Interrupt (I2C\_EOI) is used by software to trigger an interrupt service completion.

Table 12-13 lists the event flags, and their mask, that can cause module interrupts.

**Table 12-13. I2C Events**

Event Flag	Event Unmask	Event Mask	Description
I2C_IRQSTATUS[0] AL	I2C_IRQENABLE_SET[0] AL_IE	I2C_IRQENABLE_CLR[0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in controller transmit mode, an interrupt is signaled to the host.
I2C_IRQSTATUS[1] NACK	I2C_IRQENABLE_SET[1] NACK_IE	I2C_IRQENABLE_CLR[1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2C_IRQSTATUS[2] ARDY	I2C_IRQENABLE_SET[2] ARDY_IE	I2C_IRQENABLE_CLR[2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2C_IRQSTATUS[3] RRDY	I2C_IRQENABLE_SET[3] RRDY_IE	I2C_IRQENABLE_CLR[3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2C_IRQSTATUS[4] XRDY	I2C_IRQENABLE_SET[4] XRDY_IE	I2C_IRQENABLE_CLR[4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2C_IRQSTATUS[5] GC	I2C_IRQENABLE_SET[5] GC_IE	I2C_IRQENABLE_CLR[5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[6] STC	I2C_IRQENABLE_SET[6] STC_IE	I2C_IRQENABLE_CLR[6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[7] AERR	I2C_IRQENABLE_SET[7] AERR_IE	I2C_IRQENABLE_CLR[7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2C_IRQSTATUS[8] BF	I2C_IRQENABLE_SET[8] BF_IE	I2C_IRQENABLE_CLR[8] BF_IE	Bus free. An interrupt is signaled to the host.
I2C_IRQSTATUS[9] AAS	I2C_IRQENABLE_SET[9] AAS_IE	I2C_IRQENABLE_CLR[9] AAS_IE	Address recognized as target. An interrupt is signaled to the host.
I2C_IRQSTATUS[10] XUDF	I2C_IRQENABLE_SET[10] XUDF_IE	I2C_IRQENABLE_CLR[10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2C_IRQSTATUS[11] ROVR	I2C_IRQENABLE_SET[11] ROVR_IE	I2C_IRQENABLE_CLR[11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2C_IRQSTATUS[13] RDR	I2C_IRQENABLE_SET[13] RDR_IE	I2C_IRQENABLE_CLR[13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2C_IRQSTATUS[14] XDR	I2C_IRQENABLE_SET[14] XDR_IE	I2C_IRQENABLE_CLR[14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

#### 12.1.2.3.6 I2C Programmable Multitarget Channel Feature

This feature allows each multicontroller I2C to be addressed using four separate Own Addresses configured in the I2C\_OA and I2C\_OAx registers (where x = 1, 2, 3). An additional register (I2C\_ACTOA) is used to indicate to the LH which address is used by the external controller to communicate with the I2C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C\_CON[7] XOA0, I2C\_CON[6] XOA1, I2C\_CON[5] XOA2, or I2C\_CON[4] XOA3).

#### 12.1.2.3.7 I2C FIFO Management

The depth of the RX and TX FIFOs can be checked by reading the I2C\_BUFSTAT[15-14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

### 12.1.2.3.7.1 I2C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C\_IRQENABLE\_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX FIFO or the I2C\_BUF[5-0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I2C controller in receive mode and/or from any source to the I2C controller FIFO in transmit mode).

Figure 12-16 and Figure 12-17 show receive and transmit operations, respectively, from a FIFO management point of view.

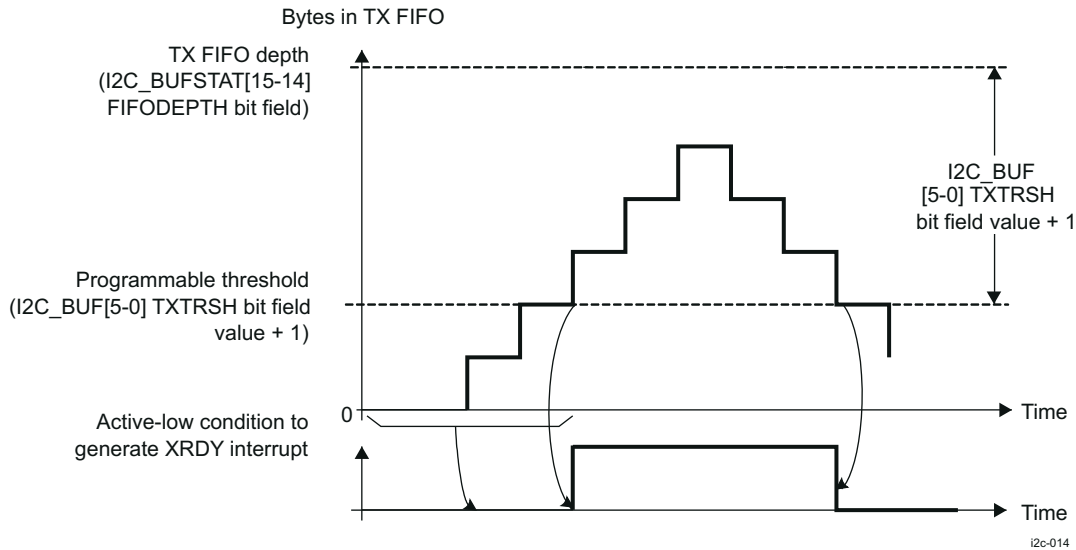

i2c-013

**Figure 12-16. I2C Receive FIFO Interrupt Request Generation**

In Figure 12-16, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C\_BUF[13-8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

**Figure 12-17. I2C Transmit FIFO Interrupt Request Generation**

In [Figure 12-17](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C\_IRQENABLE\_CLR[4] XRDY\_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C\_BUF[5-0] TXTRSH + 1 or I2C\_BUF[5-0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 12.1.2.3.7.3, Draining Feature \[I2C Mode Only\]](#)).

#### Note

In target transmit mode (the I2C\_CON[10] MST bit is cleared and the I2C\_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external controller can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in target transmit mode, data can remain in the TX FIFO without being transmitted over the I<sup>2</sup>C bus. In this case, the TX FIFO must be cleared by setting the I2C\_BUF[6] TXFIFO\_CLR bit.

#### 12.1.2.3.7.2 I2C FIFO Polling Mode

In FIFO polling mode (the I2C\_IRQENABLE\_SET[4] XRDY\_IE and I2C\_IRQENABLE\_SET[3] RRDY\_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C\_IRQSTATUS\_RAW[4] XRDY and the I2C\_IRQSTATUS\_RAW[3] RRDY bits (the I2C\_IRQSTATUS\_RAW[13] RDR and I2C\_IRQSTATUS\_RAW[14] XDR bits can also be polled if the draining feature is enabled). The I2C\_IRQSTATUS\_RAW[4] XRDY and I2C\_IRQSTATUS\_RAW[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

### 12.1.2.3.7.3 I2C Draining Feature

#### Note

DMA mode and SCCB Protocol are not supported on this family of devices.

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold and the I2C\_BUF[5-0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C\_IRQSTATUS\_RAW[7] AERR bit.

The draining mechanism generates an interrupt using the I2C\_IRQSTATUS\_RAW[13] RDR or I2C\_IRQSTATUS\_RAW[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C\_BUFSTAT[13-8] RXSTAT or I2C\_BUFSTAT[5-0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (controller or target), if the RX FIFO threshold (the I2C\_BUF[13-8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I<sup>2</sup>C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C\_IRQSTATUS\_RAW[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C\_BUFSTAT[13-8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C\_BUFSTAT[13-8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In controller transmit mode, if the TX FIFO threshold (the I2C\_BUF[5-0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C\_IRQSTATUS\_RAW[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C\_BUFSTAT[5-0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C\_BUFSTAT[5-0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In controller mode, the LH can alternately not check the values of the I2C\_BUFSTAT[5-0] TXSTAT and I2C\_BUFSTAT[13-8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C\_CNT[15-0] DATACOUNT bit field value modulo I2C\_BUF[13-8] RXTRSH or I2C\_BUF[5-0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C\_IRQENABLE\_SET[14] XDR\_IE or I2C\_IRQENABLE\_SET[13] RDR\_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C\_BUF[5-0] TXTRSH bit field value + 1 for the TX threshold or the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold).

### 12.1.2.3.8 I2C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the INTERNAL\_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C\_PSC[7-0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2C\_I2C\_PSC[7-0] PSC bit field.

### 12.1.2.3.9 I2C System Test Mode

A system test mode is available for multicontroller I2C module testing. This mode is enabled by setting the I2C\_SYSTEST[15] ST\_EN bit to 1. When this bit is cleared to 0, the I2C controller is configured in normal operation mode.

In system test mode, the I2C\_SYSTEST[13-12] TMODE bit field selects the type of test. [Table 12-14](#) lists the tests available for the multicontroller HS I2C.

**Table 12-14. I2C List of Tests**

I2C_SYSTEST[13-12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of SCL serial clock line	The SCL line is driven with a permanent clock as if controlled with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.
11	Loop-back mode + SCL/SDA I/O	In controll transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register through an internal path through the FIFO buffers. The interrupt request is normally generated if it is enabled. Moreover, the SCL and SDA are controlled with the I2C_SYSTEST[3-0] bits.

#### Note

When the I2C\_SYSTEST[13-12] TMODE bit field is set to 11, the I2C controller must be configured in I<sup>2</sup>C F/S (I2C\_CON[13-12] OPMODE set to 00) or I<sup>2</sup>C HS mode (I2C\_CON[13-12] OPMODE set to 01).

#### Note

In normal operation mode (the I2C\_SYSTEST[15] ST\_EN bit cleared to 0), the I2C\_SYSTEST[3-0] bits that control the SCL, SDA lines in system test mode are read-only bits.

In system test mode (the I2C\_SYSTEST[15] ST\_EN bit set to 1), the I2C\_IRQSTATUS\_RAW[4] XRDY, I2C\_IRQSTATUS\_RAW[3] RRDY, I2C\_IRQSTATUS\_RAW[10] XUDEF, I2C\_IRQSTATUS\_RAW[11] ROVR, I2C\_IRQSTATUS\_RAW[2] ARDY and I2C\_IRQSTATUS\_RAW[1] NACK status bits can be set to 1 when the I2C\_SYSTEST[11] SSB bit is set to 1. Clearing the I2C\_SYSTEST[11] SSB bit to 0 does not clear the I2C\_IRQSTATUS\_RAW bits to 0. The I2C\_IRQSTATUS\_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

## 12.1.2.4 I2C Programming Guide

### 12.1.2.4.1 I2C Low-Level Programming Models

#### 12.1.2.4.1.1 I2C Programming Model

This section describes the programming model of the multicontroller I2C configured in I<sup>2</sup>C mode.

##### 12.1.2.4.1.1.1 Main Program

##### 12.1.2.4.1.1.1.1 Configure the Module Before Enabling the I2C Controller

Before enabling the I2C controller, perform the following steps:

1. Enable the functional and interface clocks (see *MCU\_I2C[0-1] Clocks*, and *I2C[0-3] Clocks*).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C\_PSC[7-0] PSC bit field. This value depends on the frequency of the functional clock (SYS\_CLK).
3. Program the I2C\_SCLL[7-0] SCLL and I2C\_SCLH[7-0] SCLH bit fields to obtain a bit rate of 100 kbps or 400 kbps. These values depend on the internal sampling clock frequency (see [Table 12-9](#)).
4. (Optional) Program the I2C\_SCLL[15-8] HSSCLL and I2C\_SCLH[15-8] HSSCLH bit fields to obtain a bit rate of 400 kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 12-9](#)).
5. Configure the Own Address of the I2C controller by storing it in the I2C\_OA register. Up to four Own Addresses can be programmed in the I2C\_OA and I2C\_OAx registers (where x = 1, 2, 3) for each I2C controller.

#### Note

For a 10-bit address, set the corresponding expand Own Address bit in the I2C\_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C\_BUF[5-0] TXTRSH bit field to (TX threshold – 1) and the I2C\_BUF[13-8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I2C controller out of reset by setting the I2C\_CON[15] I2C\_EN bit to 1.

##### 12.1.2.4.1.1.1.2 Initialize the I2C Controller

To initialize the I2C controller, perform the following steps:

1. Configure the I2C\_CON register:
  - For controller or target mode, set the I2C\_CON[10] MST bit (0: target; 1: controller).
  - For transmitter or receiver mode, set the I2C\_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C\_IRQENABLE\_SET register to 1 (the I2C\_IRQENABLE\_SET[4] XRDY\_IE bit for the transmit interrupt, the I2C\_IRQENABLE\_SET[3] RRDY bit for the receive interrupt).

##### 12.1.2.4.1.1.1.3 Configure Target Address and the Data Control Register

In controller mode, configure the target address register by programming the I2C\_SA[9-0] SA bit field and the number of data bytes (I<sup>2</sup>C data payload) associated with the transfer by programming the I2C\_CNT[15-0] DCOUNT bit field.

#### Note

For a 10-bit address, set the I2C\_CON[8] XSA bit to 1.

##### 12.1.2.4.1.1.1.4 Initiate a Transfer

Poll the I2C\_IRQSTATUS\_RAW[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C\_CON[0] STT and I2C\_CON[1] STP bits. To initiate a transfer, the I2C\_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C\_CON[1] STP bit to 1.

#### 12.1.2.4.1.1.5 Receive Data

Poll the I2C\_IRQSTATUS\_RAW[3] RRDY bit, or use the RRDY interrupt (the I2C\_IRQENABLE\_SET[3] RRDY\_IE bit must be set to 1) to read the receive data in the I2C\_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C\_BUF[13-8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C\_IRQENABLE\_SET[13] RDR\_IE bit to 1).

#### Note

In receive mode only, the I2C\_IRQSTATUS\_RAW[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I2C controller simply holds SCL to low to prevent other bytes from being received.

The I2C\_IRQSTATUS\_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C\_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C\_IRQENABLE\_SET[7] AERR\_IE bit to 1.

#### 12.1.2.4.1.1.6 Transmit Data

Poll the I2C\_IRQSTATUS\_RAW[4] XRDY bit, or use the XRDY interrupt (the I2C\_IRQENABLE\_SET[4] XRDY\_IE bit must be set to 1) to write data to the I2C\_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C\_BUF[5-0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C\_IRQENABLE\_SET[14] XDR\_IE bit to 1).

#### Note

In transmit mode only, the I2C\_IRQSTATUS\_RAW[10] XUDF bit indicates whether the transmitter has experienced underflow.

In controller transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C\_CNT[15-0] DCOUNT bit field is not 0).

In target transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I<sup>2</sup>C controller device still requests data bytes to be read.

The I2C\_IRQSTATUS\_RAW[7] AERR bit is set to 1 when a write access is performed in the I2C\_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C\_IRQENABLE\_SET[7] AERR\_IE bit to 1.

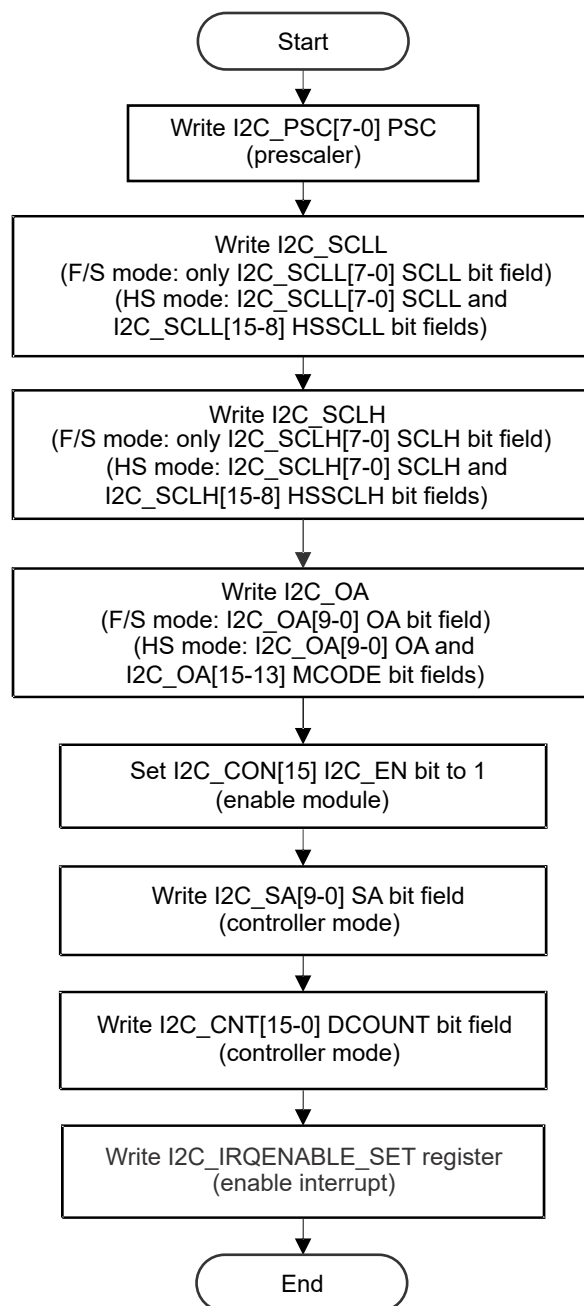

#### 12.1.2.4.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C\_IRQSTATUS\_RAW[0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C\_IRQSTATUS\_RAW[1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C\_IRQSTATUS\_RAW[2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C\_IRQSTATUS\_RAW[3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C\_IRQSTATUS\_RAW[4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C\_IRQSTATUS\_RAW[5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C\_IRQSTATUS\_RAW[6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C\_IRQSTATUS\_RAW[7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C\_IRQSTATUS\_RAW[8] BF bit) and resolve accordingly.

#### 12.1.2.4.1.1.3 Programming Flow-Diagrams

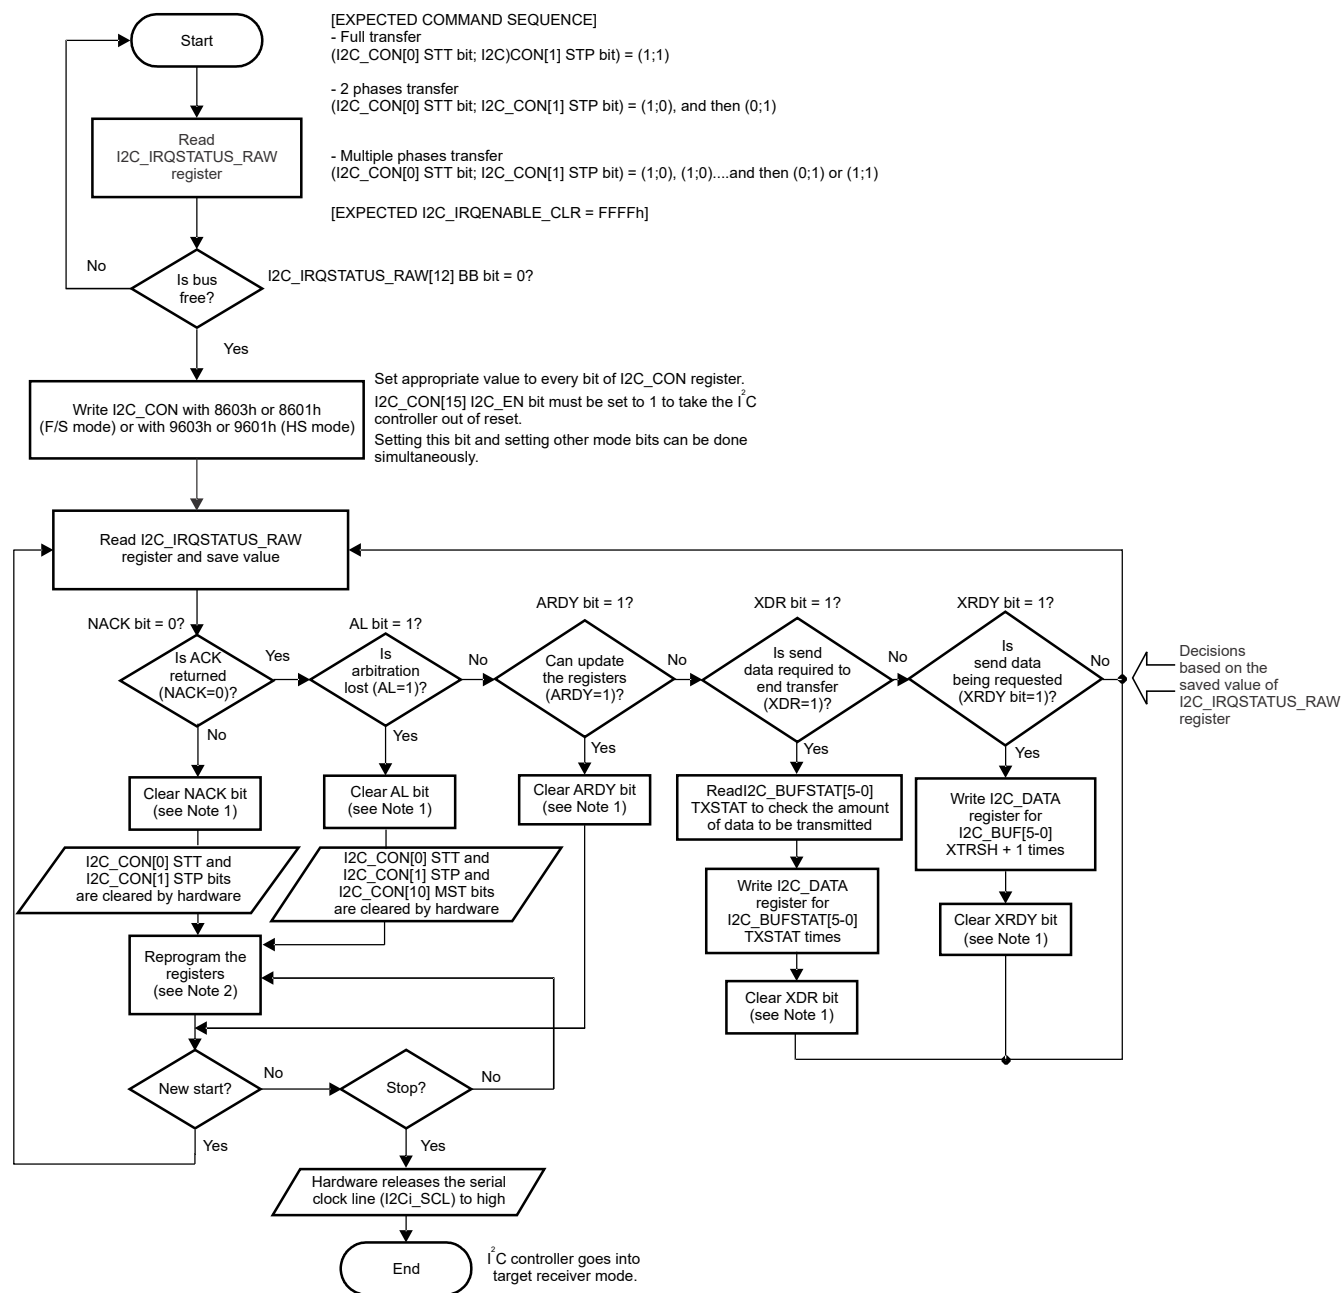

Figure 12-18 through Figure 12-24 are procedure flow charts for programming the F/S and HS I<sup>2</sup>C modes.

i2c-018

**Figure 12-18. I2C Setup Procedure**

i2c-019

- The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram the registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

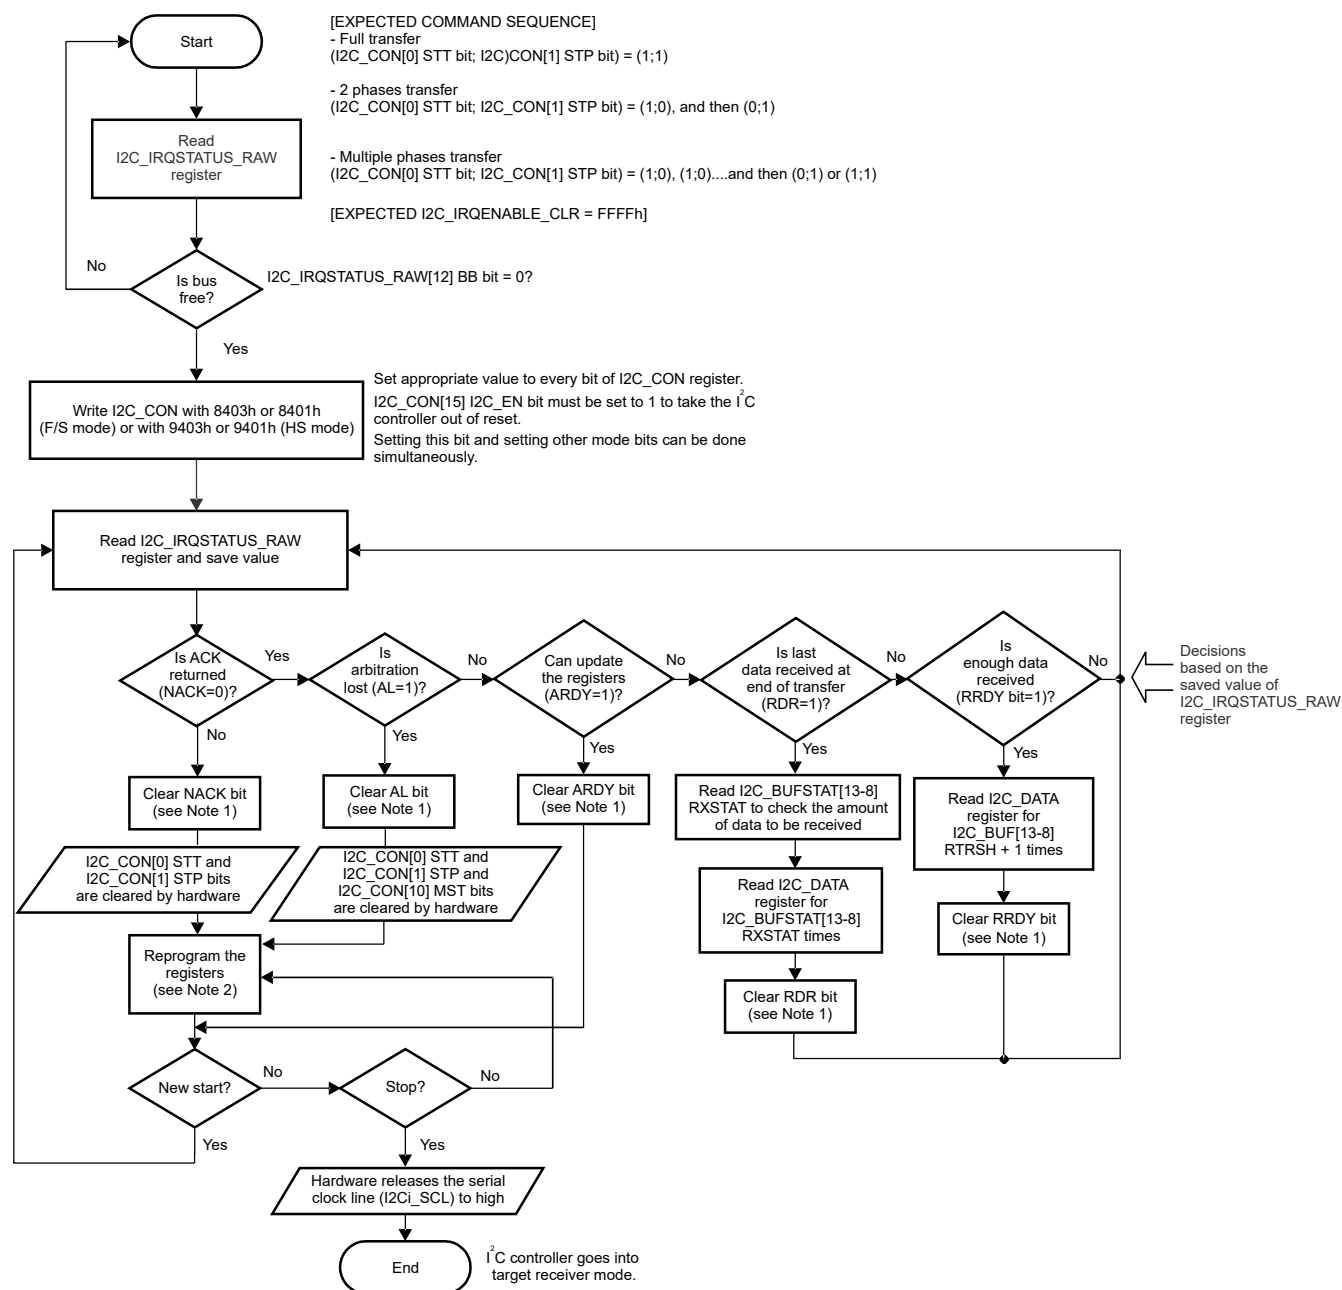

**Figure 12-19. I2C Controller Transmitter Mode, Polling Method, in F/S and HS Modes**

### Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

## Note

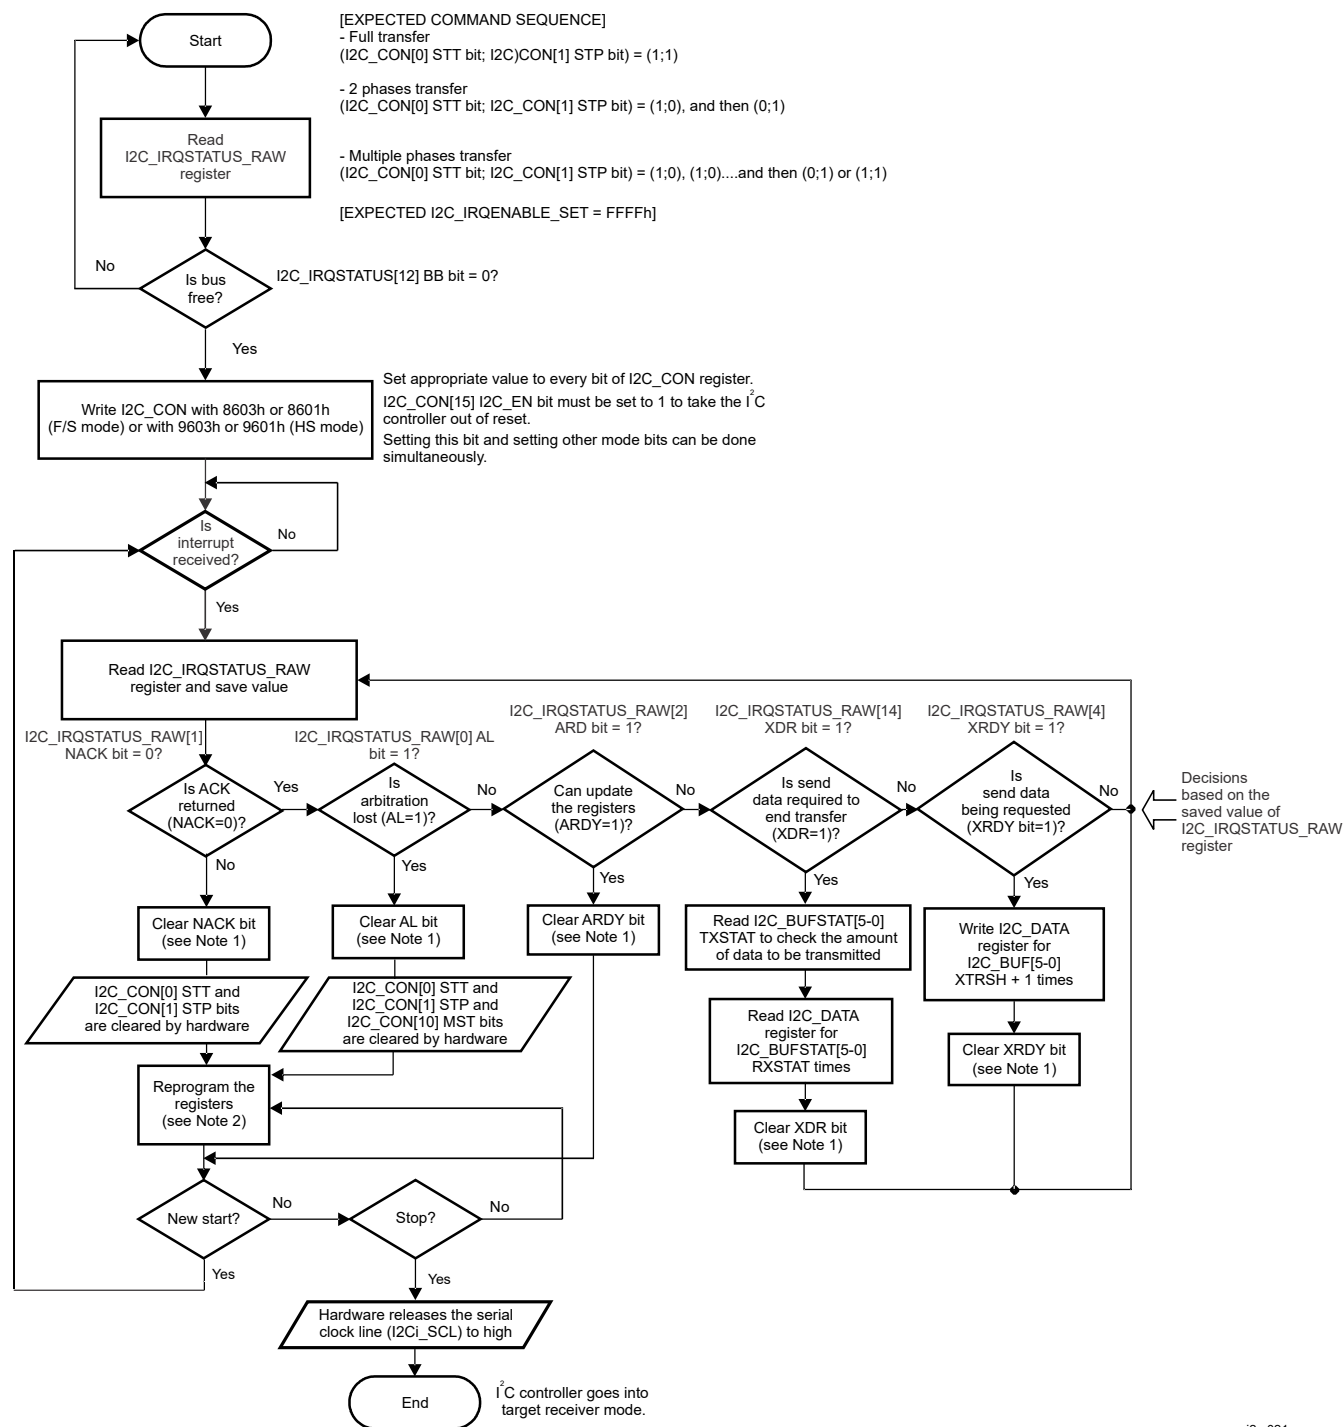

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

### 12.1.3 Multichannel Serial Peripheral Interface (MCSPi)

This section describes the Multichannel Serial Peripheral Interface (MCSPi) modules for the device.

#### 12.1.3.1 MCSPi Overview

The MCSPi module is a multichannel transmit/receive, controller/peripheral synchronous serial bus.

Figure 12-25 shows the MCSPi overview.

**Figure 12-25. MCSPi Overview**

n represents a valid instance of MCSPi in a domain.

#### 12.1.3.1.1 MCSPi Features

The MCSPi modules include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPi word lengths, ranging from 4 to 32 bits
- Up to four controller channels, or single channel in peripheral mode
- Controller multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - MCSPi configuration per channel. This means, clock definition, polarity enabling and word width
- Single interrupt line for multiple interrupt source events
- Enable the addition of a programmable start-bit for MCSPi transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable shift operations (1-32 bits)
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel.

#### 12.1.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

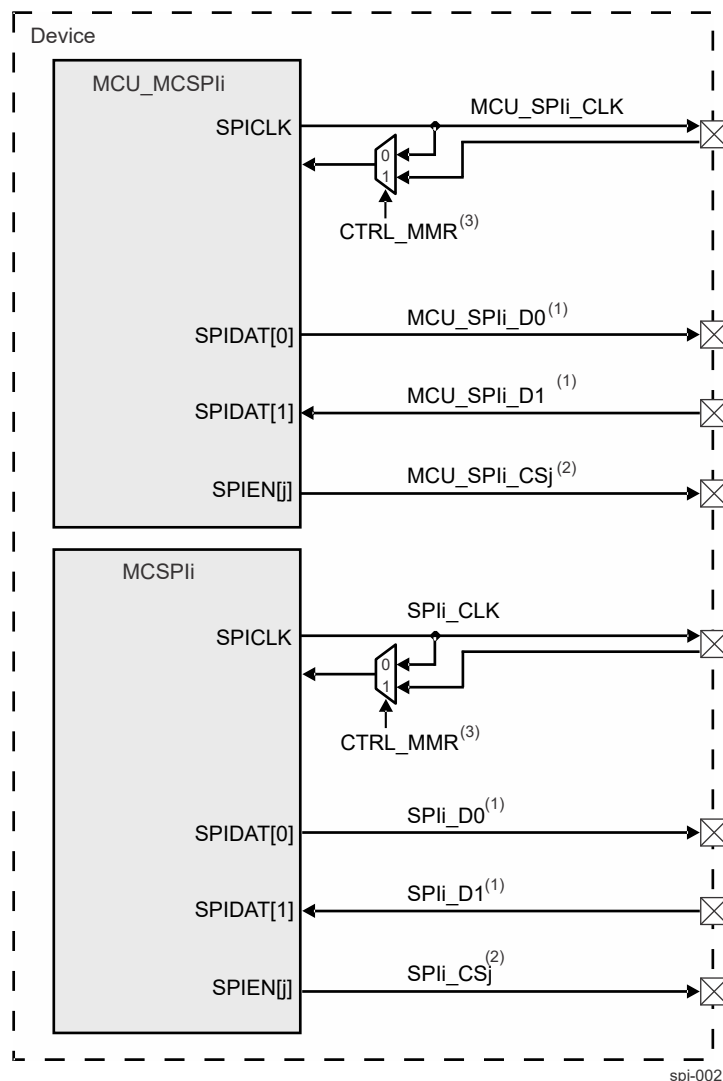

---

### 12.1.3.2 MCSPI Environment

This section describes the MCSPI external connections (environment).

#### 12.1.3.2.1 Basic MCSPI Pins for Controller Mode

Figure 12-26 shows all of the MCSPI interface signals in controller mode.

- A. Direction depends on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits
- B.  $j = 0$  to 3
- C. The source of the loopback clock is defined by CTRLMMR\_MCU\_SPI0\_CLKSEL[16] MSTR\_LB\_CLKSEL bit (and the respective register for MCU\_MCSPI1) and CTRLMMR\_SPI0\_CLKSEL[16] MSTR\_LB\_CLKSEL bit (and the respective for MCSPIi) in *Control Module (CTRL\_MMR)*.

#### Note

$i$  represents a MCSPI instance. See the device datasheet for available domains and MCSPI instances.

**Figure 12-26. MCSPI Interface Signals in Controller Mode**

Table 12-15 describes the MCSPI I/O signals in controller mode.

**Table 12-15. MCSPI I/O Signals (Controller Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCU_MCSPI<sup>(5)</sup></b>

- (1) HiZ = High Impedance
- (2) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHiCONF[18] IS and MCSPI\_CHiCONF[16] DPE0.
- (3) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHiCONF[18] IS and MCSPI\_CHiCONF[17] DPE1.
- (4) The chip-select input in peripheral mode can be selected through the MCSPI\_CHiCONF[22-21] SPIENSLV bit field.

#### Note

For SPI[4-0]\_CLK and MCU\_SPI[1-0]\_CLK signals to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_MCU\_PADCONFIGx/ CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.3.2.3 MCSPI Protocol and Data Format

The synchronous MCSPI protocol allows a controller device to initiate serial data transfers to a peripheral device. A peripheral select line (SPIEN\_[n]) allows selection of an individual peripheral MCSPI device. Peripheral devices that are not selected do not interfere with MCSPI bus activities.

MCSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

MCSPI supports any MCSPI word ranging from 4 bits to 32 bits long (the MCSPI\_CHiCONF[11-7] WL bit field).

MCSPI word length can be changed between transmissions to allow the controller device to communicate with peripheral devices that have different requirements.

- MCSPI enable (SPIEN\_[n], for channel i)

The polarity of the MCSPI enable signals is programmable (the MCSPI\_CHiCONF[6] EPOL bit). SPIEN\_[n] signals can be active high or low.

Assertion of the SPIEN\_[n] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single controller mode only. SPIEN\_[n] can be kept active between words with the MCSPI\_CHiCONF[20] FORCE bit.

Two consecutive words for two different peripheral devices can go along with active SPIEN\_[n] signals with different polarity.

- Programmable start-bit

In start-bit mode a start-bit is added before the MCSPI word length to indicate how the next MCSPI word must be handled. The start-bit is enabled by setting the MCSPI\_CHiCONF[23] SBE bit to 1. The MCSPI\_CHiCONF[24] SBPOL bit defines the polarity of the start-bit.

- Programmable MCSPI clock

- Bit rate

In controller mode, the baud rate of the MCSPI serial clock is programmable using the 50-MHz reference clock (from the device clock management module). [Table 12-17](#) lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the MCSPI\_CHiCONF[5-2] CLKD bit field).

**Table 12-17. MCSPI Controller Clock Rates**

Divider	Clock Rate
1	50 MHz <sup>(1)</sup>
2	25 MHz <sup>(1)</sup>
4	12.5 MHz
8	6.25 MHz
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz
128	390.625 kHz
256	~195 kHz
512	~97.7 kHz
1024	~48.8 kHz
2048	~24.4 kHz

**Table 12-17. MCSPI Controller Clock Rates  
(continued)**

Divider	Clock Rate
4096	~12.2 kHz

- (1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Datasheet.

– Polarity and phase

The polarity (the MCSPI\_CHiCONF[1] POL bit) and the phase (the MCSPI\_CHiCONF[0] PHA bit) of the MCSPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 12-18](#) and [Figure 12-28](#).

**Table 12-18. Phase and Polarity Combinations**

Polarity (POL)	Phase (PHA)	MCSPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

**Figure 12-28. Phase and Polarity Combinations**

#### 12.1.3.2.3.1 Transfer Format

In controller and peripheral modes, the MCSPI drives the data lines when SPIEN<sub>[n]</sub> is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

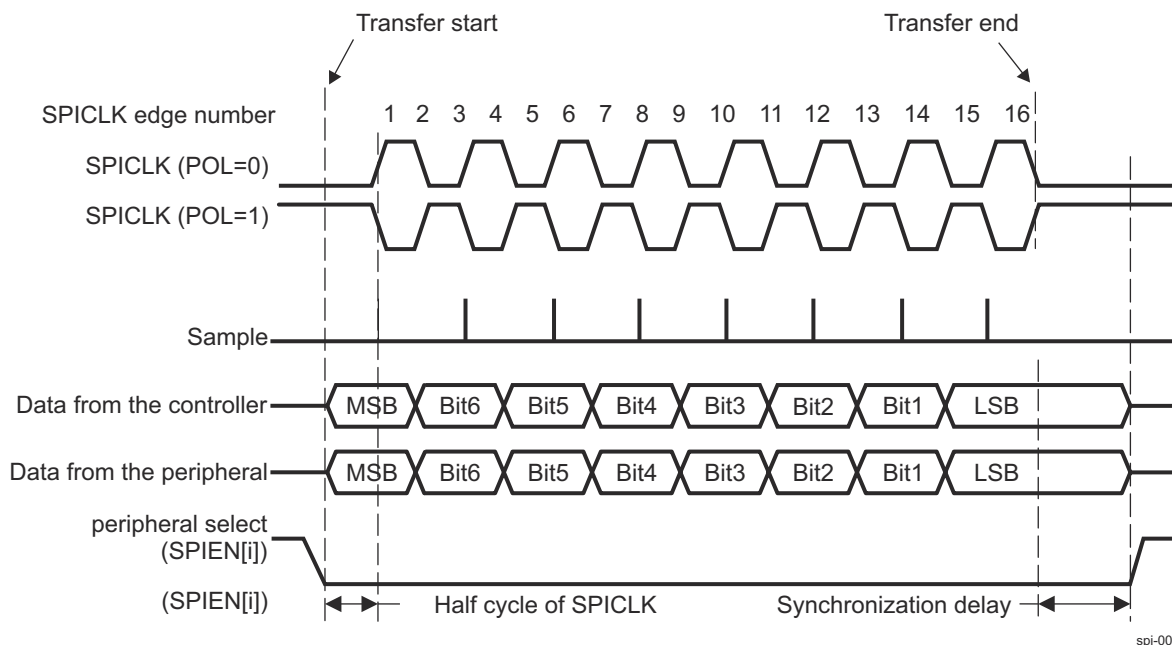

When PHA = 0, the first bit of the MCSPI word to transmit (on the controller or the peripheral data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN<sub>[n]</sub>.

Therefore, the first edge of the SPICLK line is used by the controller to sample the first data bit sent by the peripheral. On the same edge, the first data bit sent by the controller is sampled by the peripheral.

On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the SPICLK line defined by the MCSPI word length programmed in the controller device, with data being latched on odd-numbered edges and shifted on even-numbered edges, see [Figure 12-29](#).

**Figure 12-29. Full-Duplex Transfer Format With PHA = 0**

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the MCSPI word to transmit (on the controller or the peripheral data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the controller and peripheral. A synchronization delay is added between the activation of SPIEN\_[n] and the first SPICLK edge.

The received data bit is shifted into the shift register on the third SPICLK edge.

This process continues for a number of pulses on the SPICLK line defined by the MCSPI word length programmed in the controller device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

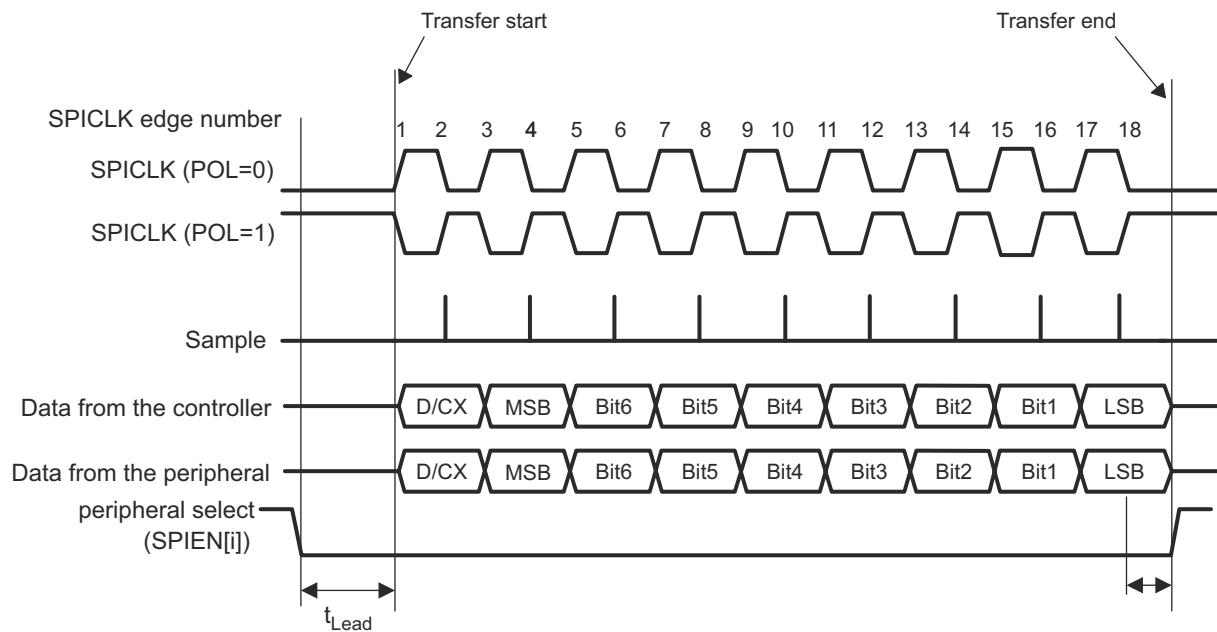

#### Note

The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of MCSPI\_FCLK (MCSPI functional clock) in controller mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of MCSPI\_FCLK in the controller and peripheral modes.

- Transmission with a start-bit (SBE = 1)

When the MCSPI\_CHCONF[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next MCSPI word must be handled as a command or as data.

[Figure 12-30](#) shows an example of a data transfer with an extra start-bit.

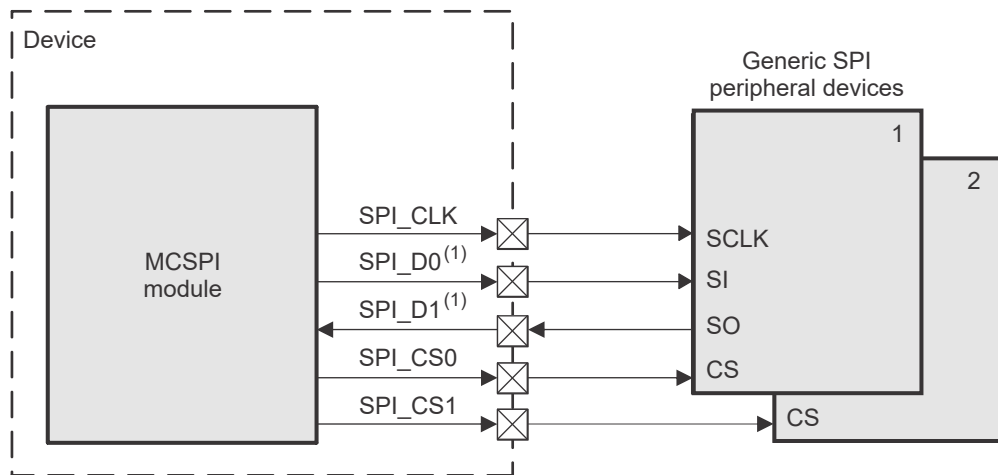

spi-006

**Figure 12-30. Extended MCSPI Transfer With a Start-Bit (SBE = 1)**

#### 12.1.3.2.4 MCSPI in Controller Mode

Figure 12-31 shows a case in controller mode (full-duplex) where the MCSPI module is connected with two peripheral devices.

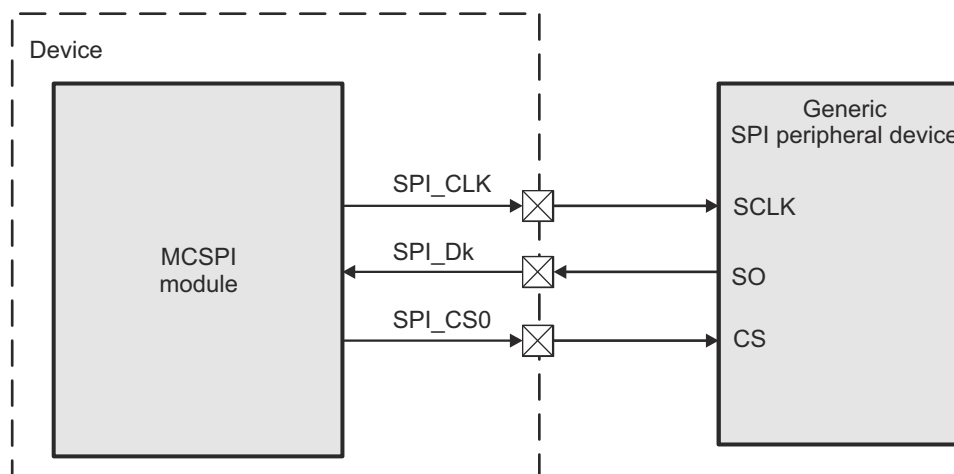

spi-007

A. Direction depends on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

**Figure 12-31. MCSPI Controller Mode (Full Duplex)**

Figure 12-32 shows the controller single mode, which can also be configured in receive-only mode.

spi-008

k = 0 or 1 depending on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

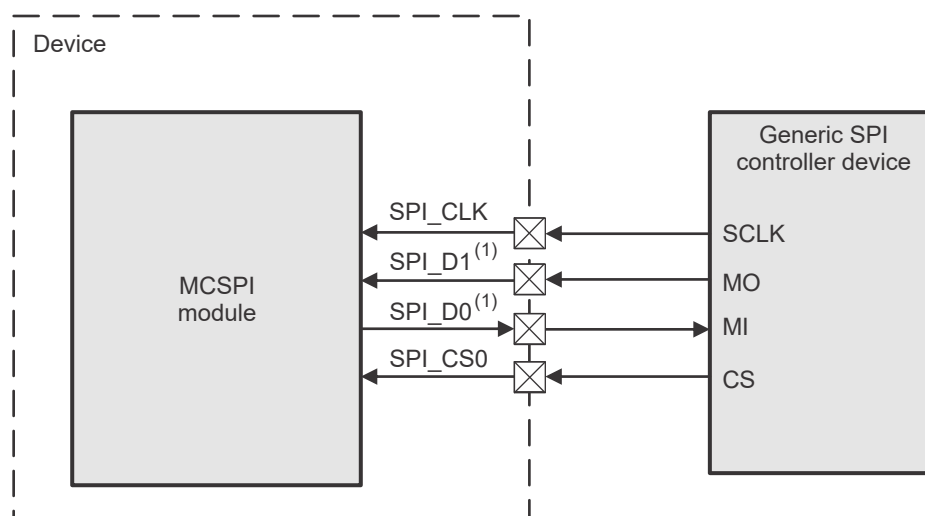

**Figure 12-32. MCSPI Controller Single Mode (Receive Only)**

#### 12.1.3.2.5 MCSPI in Peripheral Mode

Figure 12-33 shows a case in peripheral mode (full-duplex).

#### Note

Only channel 0 can be configured as peripheral, but the chip-enable signal can be connected to any SPIEN\_[n] pin and then rerouted internally to channel 0 (the MCSPI\_CH0CONF[22-21] SPIENSLV bit field). For more information, see [Section 12.1.3.4.4, MCSPI Peripheral Mode](#).

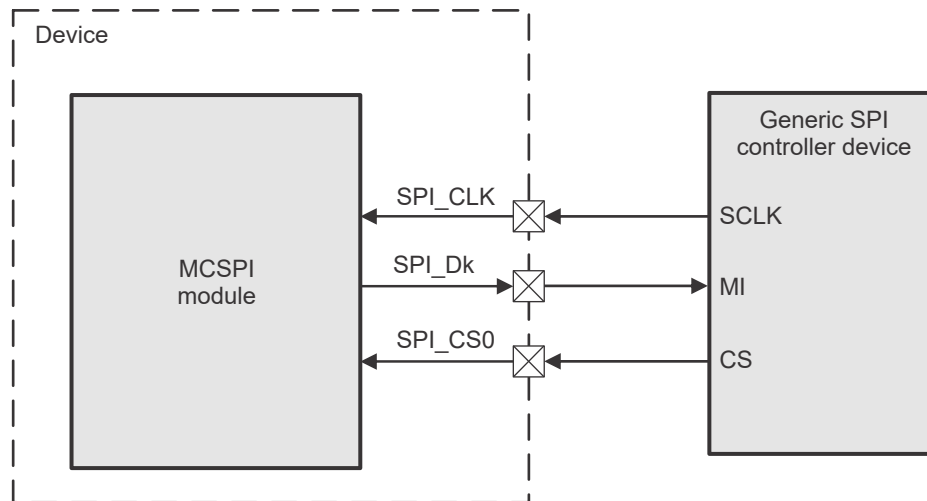

spi-009

A. Direction depends on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

**Figure 12-33. MCSPI Peripheral Mode (Full Duplex)**

Figure 12-34 shows the peripheral single mode, which can also be configured in transmit-only mode.

spi-010

k = 0 or 1 depending on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

**Figure 12-34. MCSPI Peripheral Single Mode (Transmit Only)**

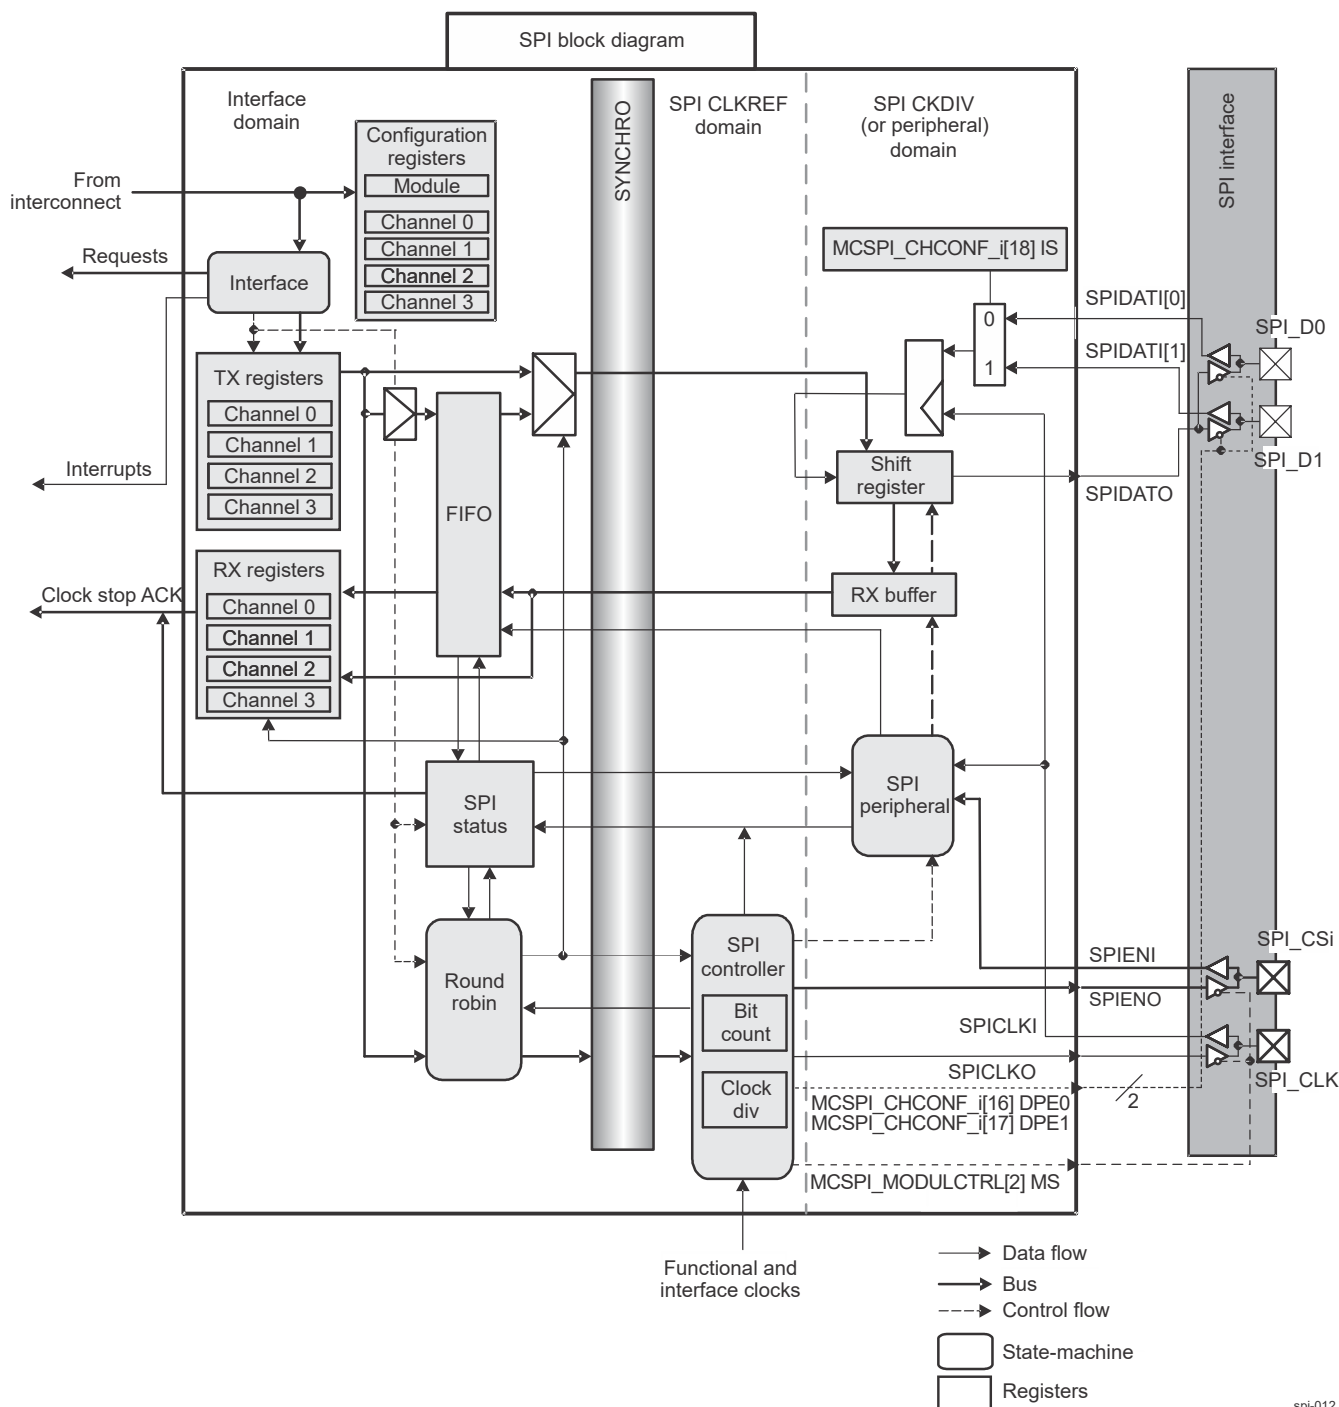

### 12.1.3.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.1.3.4 MCSPI Functional Description

#### 12.1.3.4.1 MCSPI Block Diagram

Figure 12-35 shows the MCSPI module.

spi-012

**Figure 12-35. MCSPI Block Diagram**

#### 12.1.3.4.2 MCSPI Reset

The MCSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI\_RST). MCSPI can be reset by software through the

MCSPi\_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPi\_SYSCONFIG register is not affected by that software reset.

#### 12.1.3.4.3 MCSPi Controller Mode

##### 12.1.3.4.3.1 Controller Mode Features

The MCSPi controller mode supports multichannel communication with up to four independent MCSPi communication channel contexts. The MCSPi initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN\_[n]) signals.

Connected to multiple external devices, the MCSPi exchanges data with one MCSPi device at a time through two main modes (available in peripheral mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

#### Note

There is a fixed chip select line allocation in multichannel controller mode. Channel *i* is mapped to SPIEN\_[*n*].

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPi.

Three interrupt events can be used for data transmission and reception in controller mode (for more information about interrupts, see [Section 12.1.3.4.7.1, Interrupt Events in Controller Mode](#)).

##### 12.1.3.4.3.2 Controller Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The controller transmit-and-receive mode is programmable per channel (the MCSPi\_CHiCONF[13-12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPi\_TXi transmitter register state, the MCSPi\_RXi receiver register state, and round-robin arbitration.

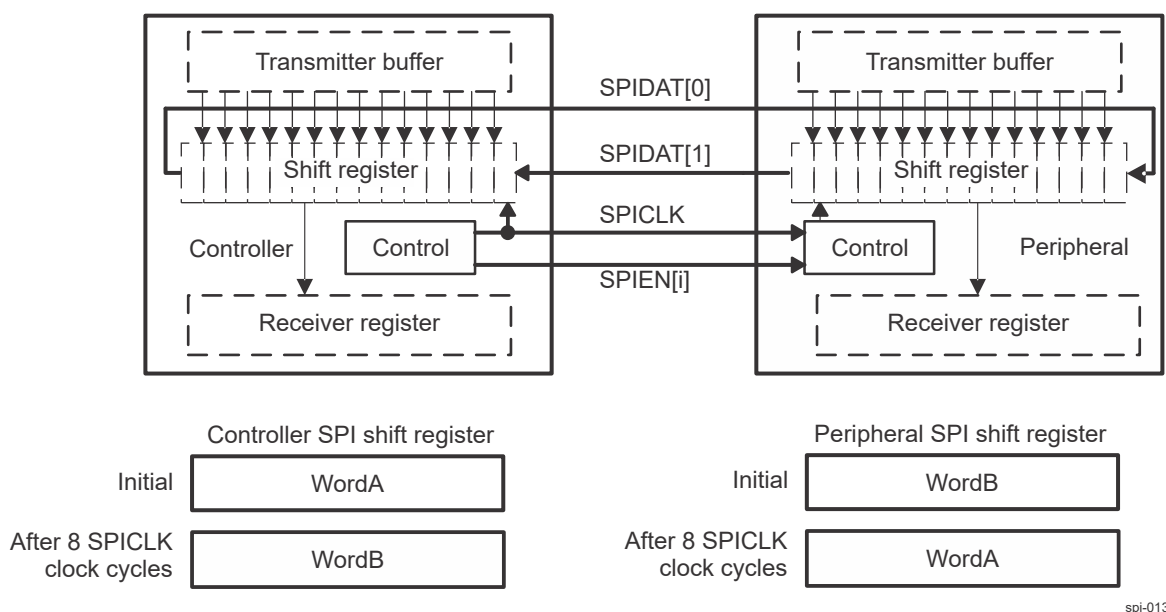

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the MCSPi\_CHiCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPi\_TXi transmitter register is not empty (the MCSPi\_CHiSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPi\_TXi register is empty when the shift register is assigned, the TXx\_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the MCSPi\_CHiSTAT[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPi\_RXi register cannot be overwritten. The MCSPi\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set to this mode.

When MCSPi word transfer completes (the MCSPi\_CHiSTAT[2] EOT bit is set), the updated MCSPi\_TXi register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral.

Figure 12-36 shows an example of a full-duplex system with a controller device on the left and a peripheral device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral. At the same time, WordB transfers from the peripheral to the controller.

**Figure 12-36. MCSPI Full-Duplex Transmission (Example)**

#### 12.1.3.4.3.3 Controller Transmit-Only Mode (Half Duplex)

The controller transmit-only mode prevents the processor from reading the MCSPI\_RXi register (minimizing data movement) when only transmission is meaningful.

The controller transmit-only mode is programmable per channel (the MCSPI\_CHiCONF[13-12] TRM bit field). Transmission starts only after data is loaded into the MCSPI\_TXi register.

Rule 1 and Rule 2, defined in Section 12.1.3.4.3.2, apply in this mode.

Rule 3, defined in Section 12.1.3.4.3.2, does not apply.

In controller transmit-only mode, the MCSPI\_RXi register state FULL does not prevent transmission and the MCSPI\_RXi register is always overwritten with the new MCSPI word. This event is not significant when only transmission is meaningful. Thus, the RX0\_OVERFLOW bit in the MCSPI\_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX\_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI\_CHiSTAT[2] EOT bit.

#### 12.1.3.4.3.4 Controller Receive-Only Mode (Half Duplex)

The controller receive mode prevents the processor from refilling the MCSPI\_TXi register (minimizing data movement) when only reception is meaningful.

The controller receive mode is programmable per channel (the MCSPI\_CHiCONF[13-12] TRM bit field).

The controller receive-only mode enables channel scheduling only on the empty state of the MCSPI\_RXi register.

Rule 1 and Rule 3, defined in Section 12.1.3.4.3.2, apply in this mode.

Rule 2, defined in Section 12.1.3.4.3.2, does not apply.

In the controller receive-only mode, software must write dummy data to the MCSPI\_TXi register. Only one dummy write is enough to receive any number of words from the peripheral. Software must ensure that the MCSPI\_TXi register is always full (the TXi\_EMPTY bits of MCSPI\_IRQSTATUS) when receiving. The content of the MCSPI\_TXi register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI\_TXi register, the TXi\_EMPTY and TXi\_UNDERFLOW bits in the MCSPI\_IRQSTATUS register are never set in receive-only mode.

The MCSPI\_CHiSTAT[2] EOT bit gives the status of serialization. The RXi\_FULL bits of the MCSPI\_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI\_RXi register. The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 12.1.3.4.3.5 Single-Channel Controller Mode

When the MCSPI is configured as a controller device with a single enabled channel (MCSPI\_MODULCTRL[2] MS = 0 and MCSPI\_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN\_[n] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI\_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI\_TXi register or the FIFO is performed. In 4-pin mode (MCSPI\_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN\_[n] is controlled by software using the MCSPI\_CHiCONF[20] FORCE bit.

##### 12.1.3.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the MCSPI word transfer to complete (wait until the MCSPI\_CHiSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

##### 12.1.3.4.3.5.2 Force SPIEN\_[n] Mode

Continuous transfers are allowed manually by keeping the SPIEN\_[n] signal active for successive MCSPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN\_[n] line. This mode is supported by all channels and any controller sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN\_[n] active mode is supported when:

- A single channel is used (with the MCSPI\_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI\_CHiCONF).

The state of the SPIEN\_[n] signal is programmable:

- Writing 1 to the MCSPI\_CHiCONF[20] FORCE bit drives the SPIEN\_[n] line high when the MCSPI\_CHiCONF[6] EPOL bit is set to 0. SPIEN\_[n] is driven low when the MCSPI\_CHiCONF[6] EPOL bit is set to 1.
- Writing 0 to the MCSPI\_CHiCONF[20] FORCE bit drives the SPIEN\_[n] line low when the MCSPI\_CHiCONF[6] EPOL bit is set to 0. SPIEN\_[n] is driven high when the MCSPI\_CHiCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI\_CHiCTRL[0] EN bit is set to 1). The first enabled channel activates the SPIEN\_[n] line.

When the channel is enabled, the SPIEN\_[n] signal activates with the programmed polarity. As in the multichannel controller mode, the transfer start depends on the status of the MCSPI\_TXi register (the MCSPI\_CHiSTAT[1] TXS bit), the status of the MCSPI\_RXi register (the MCSPI\_CHiSTAT[1] RXS bit), and the defined mode (the MCSPI\_CHiCONF[13-12] TRM bit field) of the channel enabled.

The MCSPI\_CHiSTAT[2] EOT bit gives the transfer status of each MCSPI word. The RXx\_FULL bit in the MCSPI\_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI\_RXi register.

A change in the configuration parameters is propagated directly on the MCSPI interface. If the SPIEN<sub>[n]</sub> signal is activated, ensure that the configuration is changed only between MCSPI words to avoid corrupting the current transfer.

### Note

To avoid data corruption, SPIEN<sub>[n]</sub> polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN<sub>[n]</sub> signal is activated.

A delay between MCSPI words that requires the connected MCSPI peripheral device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last MCSPI word, the channel must be deactivated (the MCSPI\_CHICTRL[0] EN bit set to 0) and SPIEN<sub>[n]</sub> can be forced to its INACTIVE state using the MCSPI\_CHICONF[20] FORCE bit.

Figure 12-37 and Figure 12-38 show successive transfers with SPIEN<sub>[n]</sub> maintained active low with a different configuration for each MCSPI word in single-data-pin and dual-data-pin interface modes, respectively.

**Figure 12-37. Continuous Transfers With SPIEN<sub>[n]</sub> Maintained Active (Single-Data-Pin Interface Mode)**

**Figure 12-38. Continuous Transfers With SPIEN<sub>[n]</sub> Maintained Active (Dual-Data-Pin Interface Mode)**

### Note

The SPIEN<sub>[n]</sub> signal can be maintained active via software using the MCSPI\_CHICONF[20] FORCE bit only when the MCSPI\_MODULCTRL[0] SINGLE bit is set to 0x1.

#### 12.1.3.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the MCSPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI\_RXi register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the MCSPI\_CHICONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see [Section 12.1.3.4.3.2, Controller Transmit-and-Receive Mode \(Full Duplex\)](#)). An enabled channel can be scheduled if its receive register is full (the MCSPI\_CHiSTAT[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI\_RXi register cannot be overwritten in turbo mode. Consequently, the MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 12.1.3.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the MCSPI word to indicate whether the next MCSPI word must be handled as a command or as data. This feature is available only in controller mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN<sub>[n]</sub> mode. In this case, only one channel can be used; round-robin arbitration is not possible.

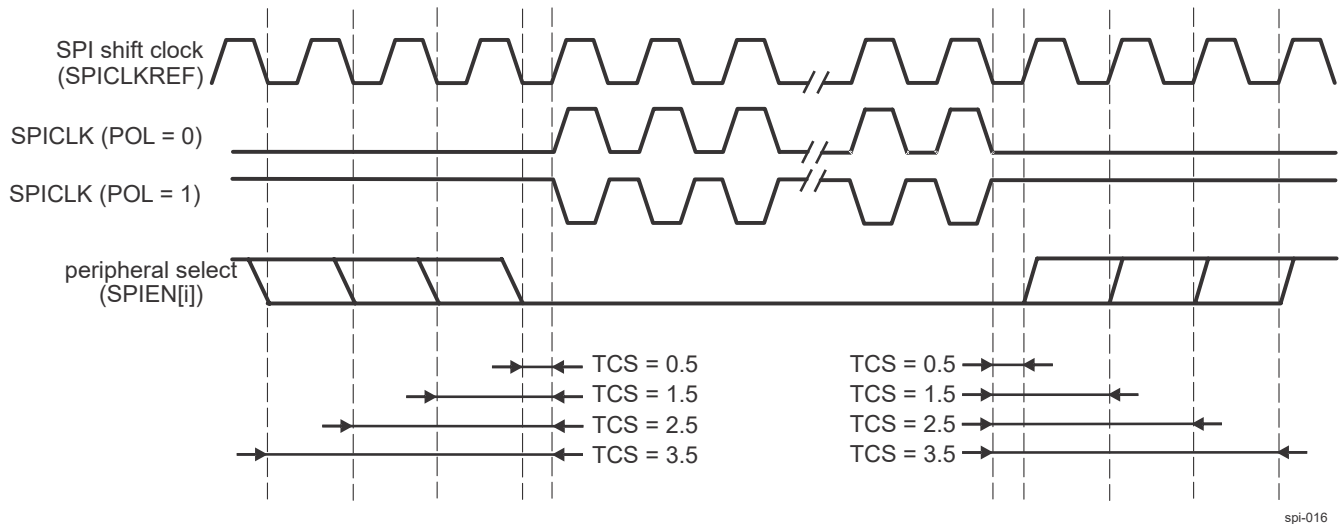

This mode is programmable per channel by setting the MCSPI\_CHiCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI\_CHiCONF[24] SBPOL bit is set to 0, the MCSPI word must be handled as a command. When the MCSPI\_CHiCONF[24] SBPOL bit is set to 1, the MCSPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI\_CHiCONF[24] SBPOL bit before writing the MCSPI word to be transmitted to the TX register.

#### 12.1.3.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in controller mode with automatic CS generation (the MCSPI\_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI\_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI\_CHiCONF[26-25] TCS0 bit field.

[Figure 12-39](#) shows the CS SPIEN timing controls.

**Figure 12-39. CS SPIEN Timing Controls**

#### Note

Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

### 12.1.3.4.3.8 Programmable MCSPI Clock (SPICLK)

In controller mode, the baud rate of the MCSPI serial clock is programmable.

An internal reference clock, SPICLKREF, is used as input of a programmable divider (the MCSPI\_CHiCONF[5-2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. [Table 12-19](#) summarizes the supported divisor values.

**Table 12-19. MCSPI Controller Clock Rates**

Divider	Clock Rate
1	50 MHz <sup>(1)</sup>
2	25 MHz <sup>(1)</sup>
4	12.5 MHz
8	6.25 MHz
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz
128	~390 kHz
256	~195 kHz
512	~97.7 kHz
1024	~48.8 kHz
2048	~24.4 kHz
4096	~12.2 kHz
8192 and higher: Division not supported	—

- (1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Datasheet.

#### 12.1.3.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI\_CHiCONF[5-2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI\_CHiCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI\_CHiCTRL[15-8] EXTCLK bit field is concatenated with the MCSPI\_CHiCONF[5-2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI\_CHiCONF[1] POL and MCSPI\_CHiCONF[0] PHA bits (see [Table 12-20](#)).

**Table 12-20. CLKSPiO High/Low Time Computation**

Clock Ratio $F_{RATIO}$	CLKSPiO High Time	CLKSPiO Low Time
1	$T_{HIGH\_REF}$	$T_{LOW\_REF}$
Even $\geq 2$	$T_{ref} * (F_{RATIO}/2)$	$T_{ref} * (F_{RATIO}/2)$
Odd $\geq (POL = PHA)$	$T_{ref} * (F_{RATIO} - 1)/2$	$T_{ref} * (F_{RATIO} + 1)/2$
Odd $\geq (POL \neq PHA)$	$T_{ref} * (F_{RATIO} + 1)/2$	$T_{ref} * (F_{RATIO} - 1)/2$

#### Note

$F_{RATIO}$  = SPICLK frequency ( $F_{OUT}$ ) division ratio  
 $T_{HIGH}$  = SPICLK high time period  
 $T_{LOW}$  = SPICLK low time period  
 $T_{ref}$  = MCSPI\_FCLK period  
 $T_{HIGH\_REF}$  = MCSPI\_FCLK high time period  
 $T_{LOW\_REF}$  = MCSPI\_FCLK low time period

If the CLKG bit is set to 1;  $F_{\text{RATIO}} = \text{EXTCLK concatenated with CLKD} + 1$ .

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty\_cycle} = (1 - 1/F_{\text{RATIO}})/2$$

Table 12-21 shows examples of clock granularity with a clock source frequency of 50 MHz.

**Table 12-21. Clock Granularity Examples**

EXTCLK	CLKD	CLKG	F <sub>RATIO</sub>	PHA	POL	T <sub>HIGH</sub> (ns)	T <sub>LOW</sub> (ns)	T <sub>PERIOD</sub> (ns)	Duty Cycle	F <sub>OUT</sub> (MHz)
X	0	0	1	X	X	10.0	10.0	20.0	50–50	50
X	1	0	2	X	X	20.0	20.0	40.0	50–50	25
X	2	0	4	X	X	40.0	40.0	80.0	50–50	12.5
X	3	0	8	X	X	80.0	80.0	160.0	50–50	6.2
0	0	1	1	X	X	10.0	10.0	20.0	50–50	50
0	1	1	2	X	X	20.0	20.0	40.0	50–50	25
0	2	1	3	1	0	40.0	20.0	60.0	66–33	16.6
0	2	1	3	1	1	20.0	40.0	60.0	33–66	16.6
0	3	1	4	X	X	40.0	40.0	80.0	50–50	12.5
5	0	1	81	1	0	820.0	800.0	1620.0	50.6–49.4	0.617
5	7	1	88	X	X	880.0	880.0	1760.0	50–50	0.568

#### 12.1.3.4.4 MCSPI Peripheral Mode

To select the MCSPI peripheral mode, set the MCSPI\_MODULCTRL[2] MS bit.

A MCSPI peripheral device can be connected to up to four external MCSPI controller devices but handles transactions with one MCSPI controller device at a time.

In peripheral mode, the MCSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN\_[n]) and receives an MCSPI clock (SPICLK) from the external MCSPI controller device. Only channel 0 can be configured as a peripheral but through the MCSPI\_CH0CONF\_0[22-21] SPIENSLV bit field any of the SPIEN\_[n] signals can be used to select the MCSPI module. In peripheral mode and when the MCSPI\_MODULCTRL[1] PIN34 is set to 0x0 (default behaviour), the MCSPI uses the edge of SPIEN\_[n] to detect word length. For this reason, SPIEN\_[n] must become inactive between each word.

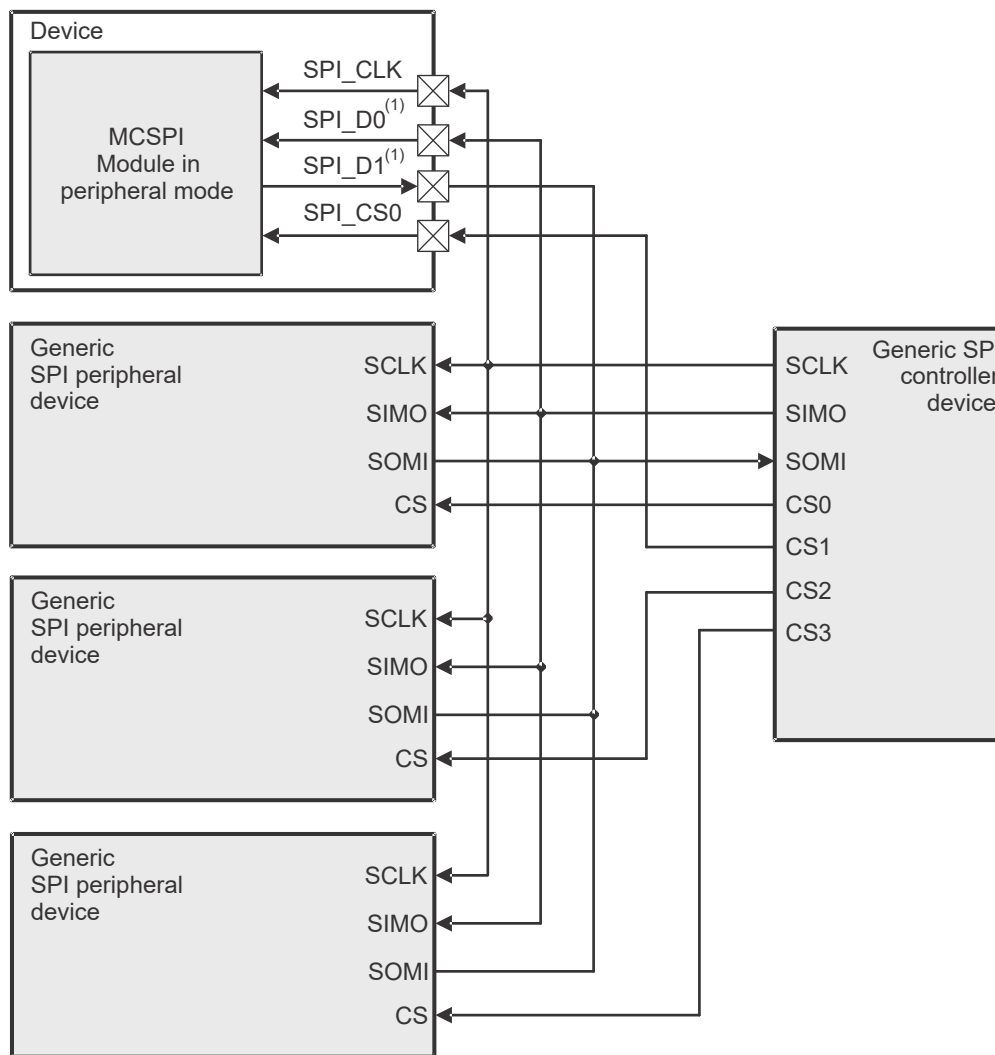

When the MCSPI\_MODULCTRL[1] PIN34 is set to 0x0, the MCSPI does not support SPIEN\_[n] active between MCSPI words. In this case, the MCSPI uses the edge to detect word length.

When the MCSPI\_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external MCSPI controller to deactivate SPIEN\_[n] between each word as in this case the MCSPI module works in 3-pin peripheral mode and SPIEN\_[n] is not needed.

##### 12.1.3.4.4.1 Dedicated Resources

Only channel 0 can be enabled in peripheral mode.

Figure 12-40 shows an example of four peripherals wired on a single controller device.

spi-017

A. Direction depends on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

**Figure 12-40. Example of MCSPI Peripheral With One Controller and Multiple Peripheral Devices on Channel 0**

Channel 0 in peripheral mode has the following resources:

- Its own channel enable, programmable with the MCSPI\_CH0CTRL[0] EN bit. This channel must be enabled before transmission and reception.
- For this mode, the peripheral-select signal can be detected on any of the SPIEN\_[n] ports. This is programmable with the MCSPI\_CH0CONF[22-21] SPIENSLV bit field.
- Its own transmitter register, MCSPI\_TX0, on top of the common transmit shift register. If the MCSPI\_TX0 register is empty, the MCSPI\_CH0STAT[1] TXS bit is set. If MCSPI is selected by an external controller (the active signal on the SPIEN\_[n] port assigned to channel 0), the MCSPI\_TX0 register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI\_TX0 register must be loaded before MCSPI is selected by a controller.
- Its own receiver register, MCSPI\_RX0, on top of the common receive shift register. If the MCSPI\_RX0 register is full, the MCSPI\_CH0STAT[0] RXS bit is set.

### Note

The MCSPI\_TXi and MCSPI\_RXi registers are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI\_CH0CONF:
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The MCSPI modules are in peripheral mode after reset and must be properly configured for the modules to act in controller mode.)
  - MCSPI word length, programmable with the WL bit
  - SPIEN\_[n] polarity, programmable with the EPOL bit
  - SPICLK polarity, programmable with the POL bit
  - SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external MCSPI controller connected to the MCSPI peripheral device. The MCSPI\_CH0CONF[5-2] CLKD bit field is not used in peripheral mode.

### Note

The configuration of the channel can be loaded in the MCSPI\_CH0CONF only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the MCSPI\_CH0CONF[15] DMAR bit for reading and the MCSPI\_CH0CONF[14] DMAW bit for writing.
- Four interrupt events (see [Section 12.1.3.4.7.2, Interrupt Events in Peripheral Mode](#)).

#### 12.1.3.4.4.2 Peripheral Transmit-and-Receive Mode

The peripheral receive mode is programmable (set the MCSPI\_CH0CONF[13-12] TRM bit field to 0x0).

In peripheral transmit-and-receive mode, the MCSPI\_TX0 register must be loaded before MCSPI is selected by an external MCSPI controller device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI\_TX0 register content is always loaded in the shift register whether it is updated or not. The event TX0\_UNDERFLOW is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI\_CH0STAT[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a peripheral transmit-only device, the RX0\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI\_RX0 register (see [Section 12.1.3.4.7.2, Interrupt Events in Peripheral Mode](#)).

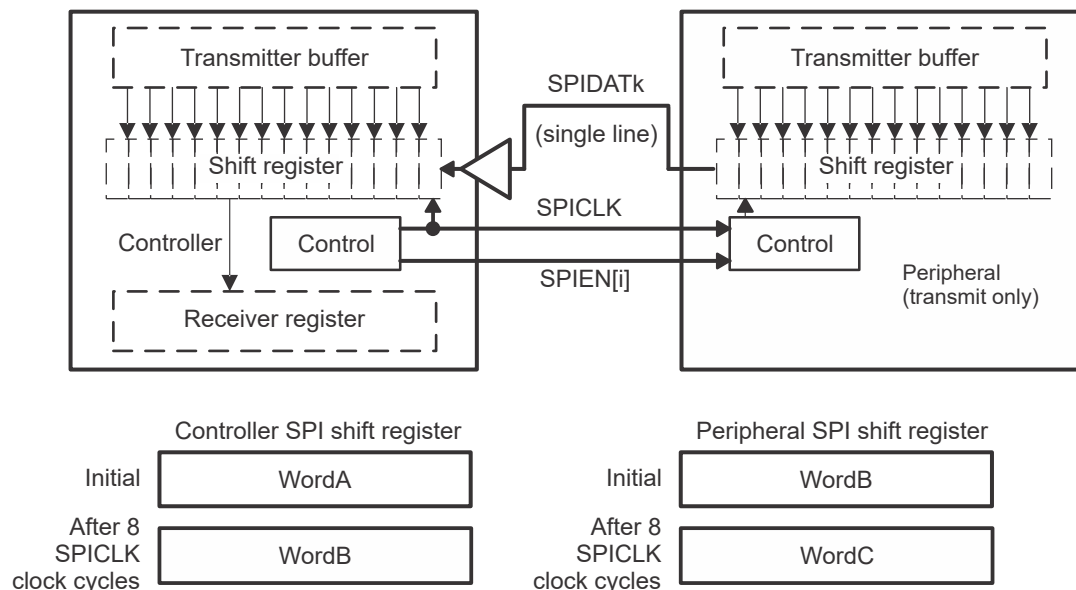

#### 12.1.3.4.4.3 Peripheral Transmit-Only Mode

The peripheral transmit-only mode is programmable (set the MCSPI\_CH0CONF[13-12] TRM bit field to 0x2) and avoids the requirement for the processor to read the MCSPI\_RX0 register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a peripheral transmit-only device, the RX0\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI\_RX0 register.

When the MCSPI word transfer completes, the MCSPI\_CH0STAT[2] EOT bit is set.

[Figure 12-41](#) shows a half-duplex system with a controller device on the left and a transmit-only peripheral device on the right. Each time a bit transfers out from the peripheral, 1 bit transfers in the controller. After eight cycles of the serial clock SPICLK, WordB transfers from the peripheral to the controller.

spi-018

k = 0 or 1 depending on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

**Figure 12-41. MCSPI Half-Duplex Transmission (Transmit-Only Peripheral)**

#### 12.1.3.4.4.4 Peripheral Receive-Only Mode

The peripheral receive mode is programmable (set the MCSPI\_CH0CONF[13-12] TRM bit field to 0x1).

In receive-only mode, the MCSPI\_TX0 register must be loaded before the MCSPI is selected by an external MCSPI controller device. The MCSPI\_TX0 register content is always loaded into the shift register whether it is updated or not. The TX0\_UNDERFLOW event is activated accordingly and does not prevent transmission.

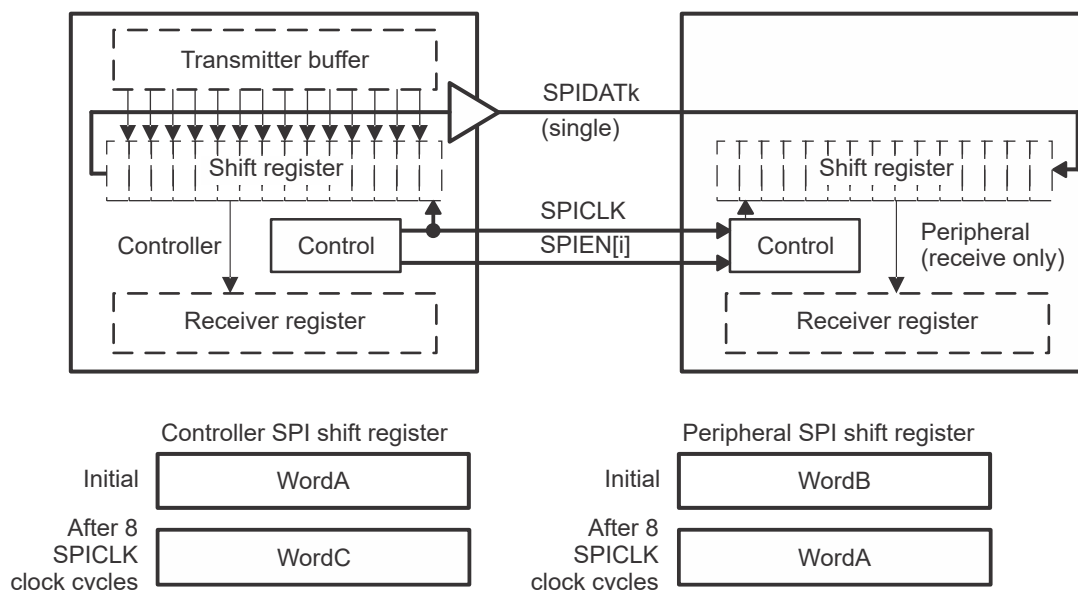

When the MCSPI word transfer completes (the MCSPI\_CH0STAT[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a peripheral receive-only device, the TX0\_EMPTY and TX0\_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI\_TX0 register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 12-42 shows a half-duplex system with a controller device on the left and a receive-only peripheral device on the right. Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral.

spl-019

k = 0 or 1 depending on MCSPI\_CHiCONF[16] DPE0, MCSPI\_CHiCONF[17] DPE1 and MCSPI\_CHiCONF[18] IS bits

**Figure 12-42. MCSPI Half-Duplex Transmission (Receive-Only Peripheral)**

#### 12.1.3.4.5 MCSPI 3-Pin or 4-Pin Mode

Depending on targeted application the MCSPI interface can be configured to use 3 or 4 pins through the MCSPI\_MODULCTRL[1] PIN34 bit. If this bit is set to 0, MCSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN<sub>[n]</sub> signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN<sub>[n]</sub> is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI\_CHiCONF). 3-pin and 4-pin operation applies to both controller and peripheral modes.

#### 12.1.3.4.6 MCSPI FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI\_CHiCONF[28] FFER or MCSPI\_CHiCONF[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Controller or peripheral mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI\_CHiCONF[11-7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 12-43](#)) or receive (see [Figure 12-44](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 12-45](#)).

spi-020

**Figure 12-43. Buffer Used in Transmit Direction Only**

spi-021

**Figure 12-44. Buffer Used in Receive Direction Only**

spi-022

**Figure 12-45. Buffer Used for Transmit and Receive Directions**

Two levels (MCSPi\_XFERLEVEL[5-0] AEL and MCSPi\_XFERLEVEL[13-8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the MCSPi word length. The driver must set these values as a multiple of the MCSPi word length defined in WL. [Table 12-22](#) lists the number of bytes written in the FIFO, depending on the word length.

**Table 12-22. FIFO Writes, Word Length Relationship**

	MCSPi Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

#### 12.1.3.4.6.1 Buffer Almost Full

The MCSPI\_XFERLEVEL[15-8] AFL bit field is needed when the buffer is used to receive an MCSPI word from a peripheral (the MCSPI\_CHiCONF[28] FFER bit must be set to 1). It defines the almost-full buffer status. See [Figure 12-46](#).

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the processor to enable the system to read AFL + 1 bytes from the receive register.

#### Note

AFL + 1 must correspond to a multiple value of the MCSPI\_CHiCONF[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

**Figure 12-46. Buffer Almost Full Level (AFL)**

#### Note

The MCSPI\_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI\_IRQSTATUS RXi\_FULL flag.

#### 12.1.3.4.6.2 Buffer Almost Empty

The MCSPI\_XFERLEVEL[7-0] AEL bit field is needed when the buffer is used to transmit an MCSPI word to a peripheral (the MCSPI\_CHiCONF[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See [Figure 12-47](#).

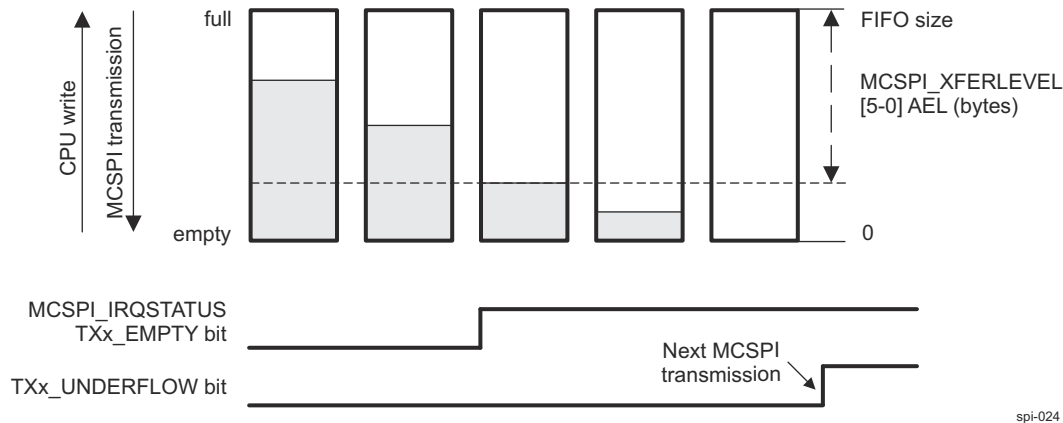

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the processor to enable the system to write AEL + 1 bytes to the transmit register.

#### Note

AEL + 1 must correspond to a multiple value of the MCSPI\_CHiCONF[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

**Figure 12-47. Buffer Almost Empty Level (AEL)**

### Note

The MCSPi\_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPi\_IRQSTATUS TXi\_EMPTY flag.

#### 12.1.3.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPi\_XFERLEVEL register the AEL and AFL levels and especially the MCSPi\_XFERLEVEL[31-16] WCNT bit field to define the number of MCSPi words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of MCSPi word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many MCSPi transfers have been done. For received words, software must poll the MCSPi\_CHiSTAT[5] RXFFE bit and read the MCSPi\_RXi receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPi\_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPi\_CHiSTAT[5] RXFFE bit to know the last MCSPi words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

#### 12.1.3.4.6.4 Multiple MCSPi Word Access

The processor has the ability to perform multiple MCSPi word access to the receive or transmit registers within a single 32-bit interface access by setting the MCSPi\_MODULCTRL[7] MOA to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- MCSPi\_MODULCTRL[7] MOA is set to 1.
- Only 32-bit interface access and data width can be performed to receive or transmit registers, for other kind of access the processor must de-assert MCSPi\_MODULCTRL[7] MOA bit.
- The level MCSPi\_XFERLEVEL[7-0] AEL and MCSPi\_XFERLEVEL[15-8] AFL must be 32-bit aligned, it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPi\_XFERLEVEL[31-16] WCNT is used it must be configured according to MCSPi word length.
- The word length of MCSPi words allows to perform multiple MCSPi access, that means that MCSPi\_CHiCONF[11-7] WL is <16.

The number of MCSPi word access depends on MCSPi word length:

- $3 \leq WL \leq 7$ , MCSPI word length smaller or equal to byte length, 4 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI\_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = WCNT[1] = 0.
- $8 \leq WL \leq 15$ , MCSPI word length greater than byte or equal to 16-bit length, 2 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI\_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = 0.
- $16 \leq WL$  Multiple MCSPI word access is not applicable.

#### 12.1.3.4.6.5 First MCSPI Word Delay

Figure 12-48 shows the MCSPI controller ability to delay the first MCSPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first MCSPI word after MCSPI channel enabled and first write in transmit register. It is based on output clock frequency.

This option is meaningful in controller mode and single channel mode asserted through MCSPI\_MODULCTRL[0] SINGLE.

spi-016a

**Figure 12-48. Controller Single Channel Initial Delay**

Few delay values are available: No delay, 4/8/16/32 MCSPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

#### 12.1.3.4.7 MCSPI Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI\_IRQSTATUS register (RXi\_FULL, TXi\_UNDERFLOW, TXi\_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI\_IRQENABLE register (RXi\_FULL\_ENABLE, TXi\_UNDERFLOW\_ENABLE, TXi\_EMPTY\_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

##### 12.1.3.4.7.1 Interrupt Events in Controller Mode

In controller mode, the interrupt events related to the state of the MCSPI\_TXi register are TXi\_EMPTY and TXi\_UNDERFLOW. The interrupt event related to the state of the MCSPI\_RXi register is RXi\_FULL.

#### 12.1.3.4.7.1.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TXi register is empty (transient event). Enabling a channel automatically triggers this event, except in controller receive-only mode (see [Section 12.1.3.4.3.4, Controller Receive-Only Mode](#)). When the FIFO buffer is enabled (the MCSPI\_CHiCONF[27] FFEW bit is set to 1), the MCSPI\_IRQSTATUS TXi\_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field.

The MCSPI\_TXi register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXi\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXi\_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI\_TXi register defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

#### 12.1.3.4.7.1.2 TXx\_UNDERFLOW

The event TXx\_UNDERFLOW is activated when the channel is enabled and if the MCSPI\_TXi register or the FIFO is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

The TXi\_UNDERFLOW is a harmless warning in controller mode.

To avoid having a TXi\_UNDERFLOW event at the beginning of a transmission, the TXi\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TXi register, because the channel is enabled. To avoid having a TXx\_UNDERFLOW event, the MCSPI\_TXi register must seldom be loaded.

The MCSPI\_IRQSTATUS TXi\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.3.4.7.1.3 RXx\_FULL

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RXi register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHiCONF[28] FFER bit is set to 1), RXi\_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI\_XFERLEVEL[13-8] AFL threshold.

The MCSPI\_RXi register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXi\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXi\_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI\_RXi. The processor must perform the correct number of reads.

#### 12.1.3.4.7.1.4 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI\_XFERLEVEL[31-16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.3.4.7.2 Interrupt Events in Peripheral Mode

In peripheral mode, the interrupt events related to the state of the MCSPI\_TXi register are TX0\_EMPTY and TX0\_UNDERFLOW. The interrupt events related to the state of the MCSPI\_RXi are RX0\_FULL

and RX0\_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI\_IRQSTATUS register.

#### 12.1.3.4.7.2.1 TXx\_EMPTY

The TXi\_EMPTY event is activated when a channel is enabled and its MCSPI\_TXi register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI\_CHiCONF[27] FFEW bit is set to 1), the TXx\_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field.

The MCSPI\_TXi register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXi\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXi\_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI\_TXi register defined by MCSPI\_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

#### 12.1.3.4.7.2.2 TXx\_UNDERFLOW

The TXx\_UNDERFLOW event is activated when a channel is enabled and if the MCSPI\_TXi register is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx\_UNDERFLOW indicates an error (data loss) in peripheral mode.

To avoid having a TXi\_UNDERFLOW event at the beginning of a transmission, the TXi\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TXi register because the channel is enabled.

The MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.3.4.7.2.3 RXx\_FULL

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RXi register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHiCONF[28] FFER bit is set to 1), RXi\_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI\_XFERLEVEL[13-8] AFL bit field.

The MCSPI\_RXi register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXi\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXi\_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI\_RXi. The processor must perform the correct number of reads.

#### 12.1.3.4.7.2.4 RX0\_OVERFLOW

The RX0\_OVERFLOW event is activated in peripheral mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI\_RXi register or FIFO is full when a h MCSPI word is received. The MCSPI\_RXi register is always overwritten with the new MCSPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0\_OVERFLOW event should not appear in peripheral mode using the FIFO.

The RX0\_OVERFLOW event indicates an error (data loss) in peripheral mode.

The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.3.4.7.2.5 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.3.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI\_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the processor must:

1. Read the MCSPI\_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI\_RXi register that corresponds to the event to remove the source of an RXi\_FULL event or write into the MCSPI\_TXi register that corresponds to the event to remove the source of a TXi\_EMPTY event. No action is required to remove the source of the TXi\_UNDERFLOW and RX0\_OVERFLOW events.
3. Set the corresponding bit of the MCSPI\_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

#### 12.1.3.4.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI\_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI\_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx\_FULL: To remove the source of the event, the processor must read the corresponding MCSPI\_RXi register.
- TXx\_EMPTY: To remove the source of the event, the processor must write into the corresponding MCSPI\_TXi register.
- TXx\_UNDERFLOW and RX0\_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI\_IRQSTATUS register to 1. This does not affect the interrupt line state.

#### 12.1.3.4.8 MCSPI DMA Requests

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the MCSPI\_CHiCONF[15] DMAR bit. The DMA read request line is de-asserted when reading of the MCSPI\_RXi register of the MCSPI channel completes.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI\_TXi register of the MCSPI channel is empty. A DMA write request can be individually masked with the MCSPI\_CHiCONF[14] DMAW bit. The DMA write request line is de-asserted when loading of the MCSPI\_TXi register of the channel completes.

#### 12.1.3.4.9 MCSPI Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity.

##### 12.1.3.4.9.1 Normal Mode

In normal mode, internal MCSPI module clocks are automatically switched off (autogated) when there is no activity in peripheral or controller mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI\_SYSCONFIG[0] AUTOIDLE bit is set.
- In controller mode, there is no data to transmit or receive in all channels.
- In peripheral mode, the MCSPI is not selected by the external controller and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In controller mode, an internal access occurs.
- In peripheral mode, an internal access occurs or the MCSPI is selected by the external controller.

##### 12.1.3.4.9.2 Idle Mode

#### Note

Some of the MCSPI features described in this section may not be supported on this family of devices. For more information, see *MCSPI Not Supported Features*.

At the power management level, when all conditions to shut off the MCSPI\_FCLK or MCSPI\_ICLK clocks are met, the corresponding LPSC asserts a clock stop request to the MCSPI. Although this procedure is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the clock stop request can be configured through the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgement modes are:

- Force-idle mode (the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the clock stop request, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The MCSPI never acknowledges the clock stop request and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow shut off of MCSPI\_FCLK and MCSPI\_ICLK.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The MCSPI acknowledges the clock stop request, depending on its internal activity. MCSPI acknowledges the shut off of MCSPI\_FCLK and MCSPI\_ICLK only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional feature to control gating of MCSPI\_FCLK or MCSPI\_ICLK. The MCSPI\_SYSCONFIG[9-8] CLOCKACTIVITY bit field determines which clock shuts down (MCSPI\_FCLK, MCSPI\_ICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the clock stop request are tested. For example, if MCSPI\_FCLK is not shut off on clock stop request, the MCSPI considers only MCSPI\_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with MCSPI\_ICLK and others with MCSPI\_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if MCSPI acknowledges the clock stop request.

##### 12.1.3.4.9.2.1 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the MCSPI responds unconditionally to the clock stop request by de-asserting unconditionally the interrupt and DMA request lines, if asserted.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI\_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely de-asserted. The interface clock and MCSPI clock provided to the MCSPI can be switched off.
  - A clock stop request during an MCSPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.

### 12.1.3.5 MCSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

#### 12.1.3.5.1 MCSPI Global Initialization

##### 12.1.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the MCSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MCSPI. For further information, see *MCSPI Integration* and *MCSPI Environment*.

[Table 12-23](#) lists the information on the global initialization of the surrounding modules.

**Table 12-23. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
MCU_M4FSS0_CORE0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MCU_M4FSS0_CORE0 interrupts, see <i>Interrupts</i> .
R5FSS0/1_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0/1_CORE0/1 interrupts, see <i>Interrupts</i> .
PRUSS	Device INTCs must be configured to enable the interrupt request generation. For information about enabling PRUSS interrupts, see <i>Interrupts</i> .
PDMA0 and PDMA1	Device INTCs must be configured to enable the interrupt request generation.
MCU_PLLCTRL0 and PLLCTRL0	PLL controller's configuration must be done to enable the module clocks. For more information, see <i>Clocking</i> .

#### 12.1.3.5.1.2 MCSPI Global Initialization

##### 12.1.3.5.1.2.1 Main Sequence – MCSPI Global Initialization

The procedure in [Table 12-24](#) can be used to initialize MCSPI when performing software reset.

**Table 12-24. MCSPI Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPi_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	MCSPi_SYSSTATUS[0] RESETDONE	=1
Configure static settings (such as SPI controller or peripheral) as required.	MCSPi_MODULCTRL[8-0]	0x-
Write MCSPi_SYSCONFIG	MCSPi_SYSCONFIG	0x-

#### 12.1.3.5.2 MCSPI Operational Mode Configuration

##### 12.1.3.5.2.1 MCSPI Operational Modes

The selection of the working mode is done with the MCSPi\_CHiCONF register.

**Table 12-25. MCSPI Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPi_CHiCONF[13-12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPi_CHiCONF	0x-
Reset the status bits.	MCSPi_IRQSTATUS	0x0

**Table 12-26. MCSPI Transmit Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPi_CHiCONF[13-12] TRM	0x2

**Table 12-26. MCSPI Transmit Mode Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPi_CHiCONF	0x-
Reset the status bits.	MCSPi_IRQSTATUS	0x0

**Table 12-27. MCSPI Transmit-and-Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPi_CHiCONF[13-12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPi_CHiCONF	0x-
Reset the status bits.	MCSPi_IRQSTATUS	0x0

#### 12.1.3.5.2.1.1 Common Transfer Sequence

MCSPi module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN<sub>[n]</sub> lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

[Table 12-28](#) represents the main sequence which is common to all transfers.

In multi-channel controller mode, the sequences of different channels can be run simultaneously.

**Table 12-28. Common Transfer Sequence (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
Write MCSPi_IRQENABLE to enable interrupts	MCSPi_IRQENABLE	0x-
Write MCSPi_CHiCONF to configure the channel	MCSPi_CHiCONF	0x-
Start the channel	MCSPi_CHiCTRL[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPi_TXi	0x-
Wait for the host event for end of transfer		
Stop the channel	MCSPi_CHiCTRL[0] EN	0

#### 12.1.3.5.2.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. [Table 12-29](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 12-29. End of Transfer Sequences**

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
<b>CONTROL LER Normal</b>	End of transfer sequence	See <a href="#">Section 12.1.3.5.2.1.3</a>		See <a href="#">Section 12.1.3.5.2.1.4.1</a>	See <a href="#">Section 12.1.3.5.2.1.4.2</a>	See <a href="#">Section 12.1.3.5.2.1.5.1</a>	See <a href="#">Section 12.1.3.5.2.1.5.2</a>
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1

**Table 12-29. End of Transfer Sequences (continued)**

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
<b>CONTROL LER Turbo</b>	End of transfer sequence	See <a href="#">Section 12.1.3.5.2.1.3</a>		See <a href="#">Section 12.1.3.5.2.1.4.1</a>	See <a href="#">Section 12.1.3.5.2.1.4.2</a>	See <a href="#">Section 12.1.3.5.2.1.6.1</a>	See <a href="#">Section 12.1.3.5.2.1.6.2</a>
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
<b>PERIPHER AL</b>	End of transfer sequence	See <a href="#">Section 12.1.3.5.2.1.3</a>		See <a href="#">Section 12.1.3.5.2.1.4.1</a>	See <a href="#">Section 12.1.3.5.2.1.4.2</a>	See <a href="#">Section 12.1.3.5.2.1.7</a>	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write\_count = 0
- read\_count = 0
- channel\_enable = FALSE
- last\_transfer = FALSE
- last\_request = FALSE

They are initialized before starting the channel.

#### 12.1.3.5.2.1.3 Transmit-and-Receive (Controller and Peripheral)

If the requests are configured in DMA, write\_count and read\_count are assigned with 'N' when the DMA handlers have completed their 'N' CBASS0 accesses.

**Table 12-30. Transmit-and-Receive (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHiCTRL[0] EN	1
Wait for write_count = N AND read_count = N		
Stop the channel	MCSPi_CHiCTRL[0] EN	0

**Table 12-31. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXi_EMPTY</b>		
Write the transmitter register with data	MCSPi_TXi	0x-
Increment write_count +1		
<b>IF: RXi_FULL</b>		
Read the receiver register	MCSPi_RXi	
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.4 Transmit-Only (Controller and Peripheral)

##### 12.1.3.5.2.1.4.1 Based on Interrupt Requests

**Table 12-32. Transmit-Only With Interrupts (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHICTRL[0] EN	1
Wait until last transfer = TRUE		
Wait for end of transfer	MCSPi_CHISTAT[2] EOT	=1
Stop the channel	MCSPi_CHICTRL[0] EN	0

**Table 12-33. Transmit-Only With Interrupts (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXx_EMPTY AND write_count &lt; N</b>		
Write the transmitter register with data	MCSPi_TXi	0x-
Increment write_count +1		
<b>ELSEIF: write_count ≥ N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

##### 12.1.3.5.2.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its 'N' CBASS0 accesses, write\_count is assigned with 'N'.

**Table 12-34. Transmit-Only With DMA (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHICTRL[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPi_CHICONF[14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHISTAT[2] EOT	=1
Stop the channel	MCSPi_CHICTRL[0] EN	0

**Table 12-35. Transmit-Only With DMA (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXi_EMPTY AND write_count = N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.5 Controller Normal Receive-Only

##### 12.1.3.5.2.1.5.1 Based on Interrupt Requests

**Table 12-36. Receive-Only With Interrupt (Controller Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHICTRL[0] EN	1
Wait until last_request = TRUE		
Stop the channel	MCSPi_CHICTRL[0] EN	0
Read the receiver register	MCSPi_RXi	0x-

**Table 12-36. Receive-Only With Interrupt (Controller Normal) (Main Process) (continued)**

Step	Register/Bit Field/Programming Model	Value
Increment read_count +1		

**Table 12-37. Receive-Only With Interrupt (Controller Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXi_FULL AND read_count = N - 1</b>		
last_request = TRUE		
<b>ELSEIF: read_count ≠ N - 1</b>		
Read the receiver register	MCSPI_RXi	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.5.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-1' CBASS0 accesses, read\_count is assigned with 'N-1'.

**Table 12-38. Receive-Only With DMA (Controller Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHICTRL[0] EN	1
Wait until read_count = N - 1		
Disable DMA read request	MCSPI_CHICNF[15] DMAR	0
Wait until last_transfer = TRUE		
Stop the channel	MCSPI_CHICTRL[0] EN	0
Read the receiver register	MCSPI_RXi	0x-
Increment read_count +1		

**Table 12-39. Receive-Only With DMA (Controller Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXi_FULL AND read_count = N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.6 Controller Turbo Receive-Only

##### 12.1.3.5.2.1.6.1 Based on Interrupt Requests

**Table 12-40. Receive-Only With Interrupt (Controller Turbo) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHICTRL[0] EN	1
Wait until channel_enable = TRUE		
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHISTAT[2] EOT	=1
Stop the channel	MCSPI_CHICTRL[0] EN	0
Wait until channel_enable = FALSE		

**Table 12-41. Receive-Only With Interrupt (Controller Turbo) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXi_FULL</b>		
<b>IF: read_count = N - 2</b>		
last_transfer = TRUE		
Wait until channel_enable = FALSE		
<b>ENDIF</b>		
<b>IF: read_count &lt; N</b>		
Read the receiver register	MCSPI_RXi	0x-
Increment read_count +1		
<b>ENDIF</b>		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.6.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-2' CBASS0 accesses read\_count is assigned with 'N-2'.

**Table 12-42. Receive-Only With DMA (Controller Turbo) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHICTRL[0] EN	1
Wait until channel_enable = TRUE		
Wait until read_count = TRUE		
Disable DMA read request	MCSPI_CHiCONF[15] DMAR	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHiSTAT[2] EOT	=1
Stop the channel	MCSPI_CHICTRL[0] EN	0
Wait until channel_enable = FALSE		

**Table 12-43. Receive-Only With DMA (Controller Turbo) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXi_FULL</b>		
<b>IF: read_count = N - 2</b>		
last_transfer = TRUE		
Wait until channel_enable = FALSE		
<b>ENDIF</b>		
<b>IF: read_count &lt; N</b>		
Read the receiver register	MCSPI_RXi	0x-
Increment read_count +1		
<b>ENDIF</b>		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.7 Peripheral Receive-Only

If the requests are configured in DMA, read\_count is assigned with 'N' when the DMA handler has completed its 'N' CBASS0 accesses.

**Table 12-44. Receive-Only (Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHiCTRL[0] EN	1
Wait until read_count = N		
Stop the channel	MCSPi_CHiCTRL[0] EN	0

**Table 12-45. Receive-Only (Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXi_FULL</b>		
Read the receiver register	MCSPi_RXi	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.3.5.2.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The MCSPi module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see [Section 12.1.3.4.6, MCSPi FIFO Buffer Management](#).

**Table 12-46. FIFO Mode Common Sequence (Controller) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS	1
Write MCSPi_IRQENABLE to enable interrupts	MCSPi_IRQENABLE	1
Write MCSPi_CHiCONF to configure the channel	MCSPi_CHiCONF	0x-
Write MCSPi_XFERLEVEL	MCSPi_XFERLEVEL	0x-
Start the channel	MCSPi_CHiCTRL[0] EN	1
<b>IF: Receive only</b>		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPi_TXi	0x-
<b>ENDIF</b>		
Wait for the host event for end of transfer		
Stop the channel	MCSPi_CHiCTRL[0] EN	0

#### 12.1.3.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in [Section 12.1.3.5.2.1.8, Transfer Procedures With FIFO](#).

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPi\_CHiCONF[28] FFER and MCSPi\_CHiCONF[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Peripheral mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI\_CH0CONF[22-21] SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request has been released by writing the MCSPI\_TXi register, even in receive-only mode (only one write request occurs in this case).

#### 12.1.3.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

[Table 12-47](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 12-47. End of Transfer Sequences in FIFO Mode**

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See <a href="#">Figure 12-49</a>	See <a href="#">Figure 12-51</a>	See <a href="#">Figure 12-52</a>
No	See <a href="#">Figure 12-50</a>	See <a href="#">Figure 12-51</a>	See <a href="#">Figure 12-53</a>

The end of transfer sequences are described from the start of the channel.

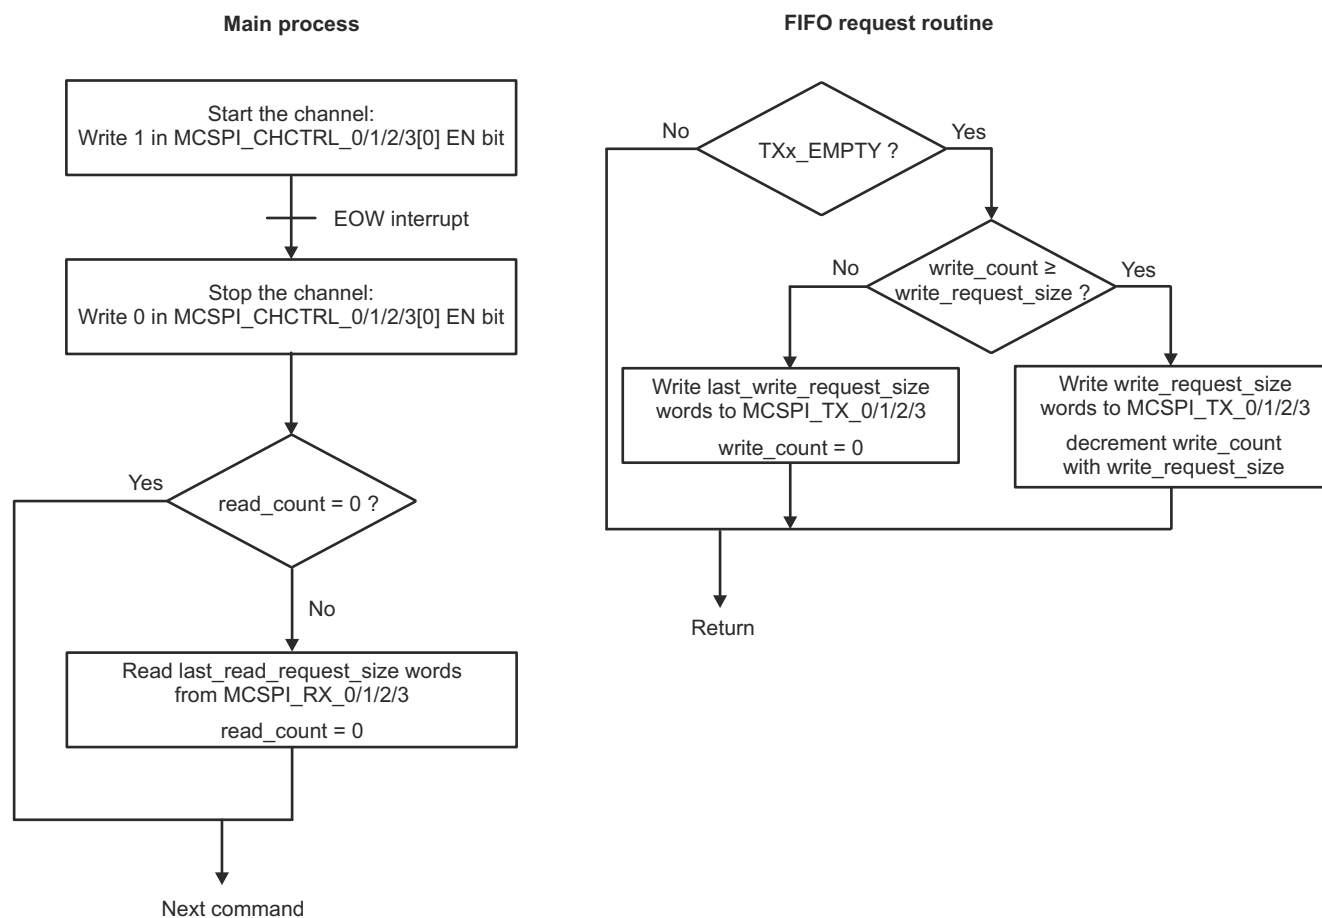

In these sequences, some soft variables are used:

- write\_count = N
- read\_count = N
- last\_request = FALSE

They are initialized before starting the channel.

#### 12.1.3.5.2.1.8.3 Transmit-and-Receive With Word Count

[Figure 12-49](#) shows the flow of a transfer in transmit-and-receive mode, with word count.

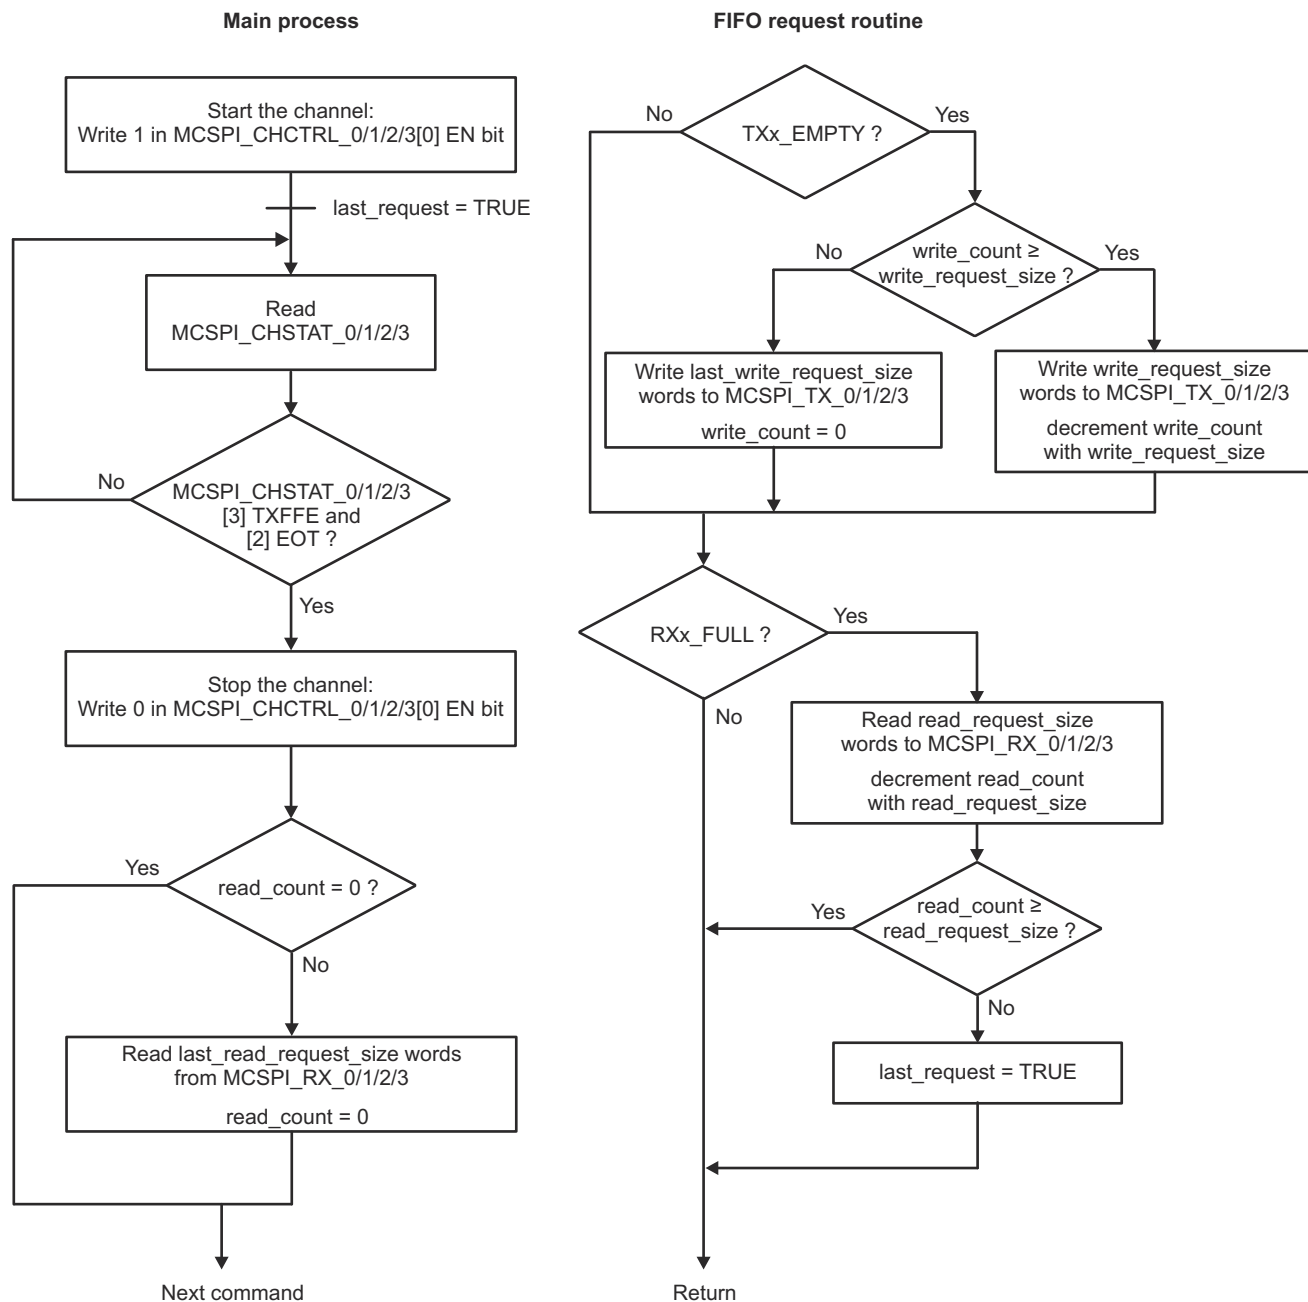

mcspi\_025

**Figure 12-49. FIFO Mode Transmit-and-Receive With Word Count (Controller)**

#### 12.1.3.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 12-50 shows the flow of a transfer in transmit-and-receive mode, without word count.

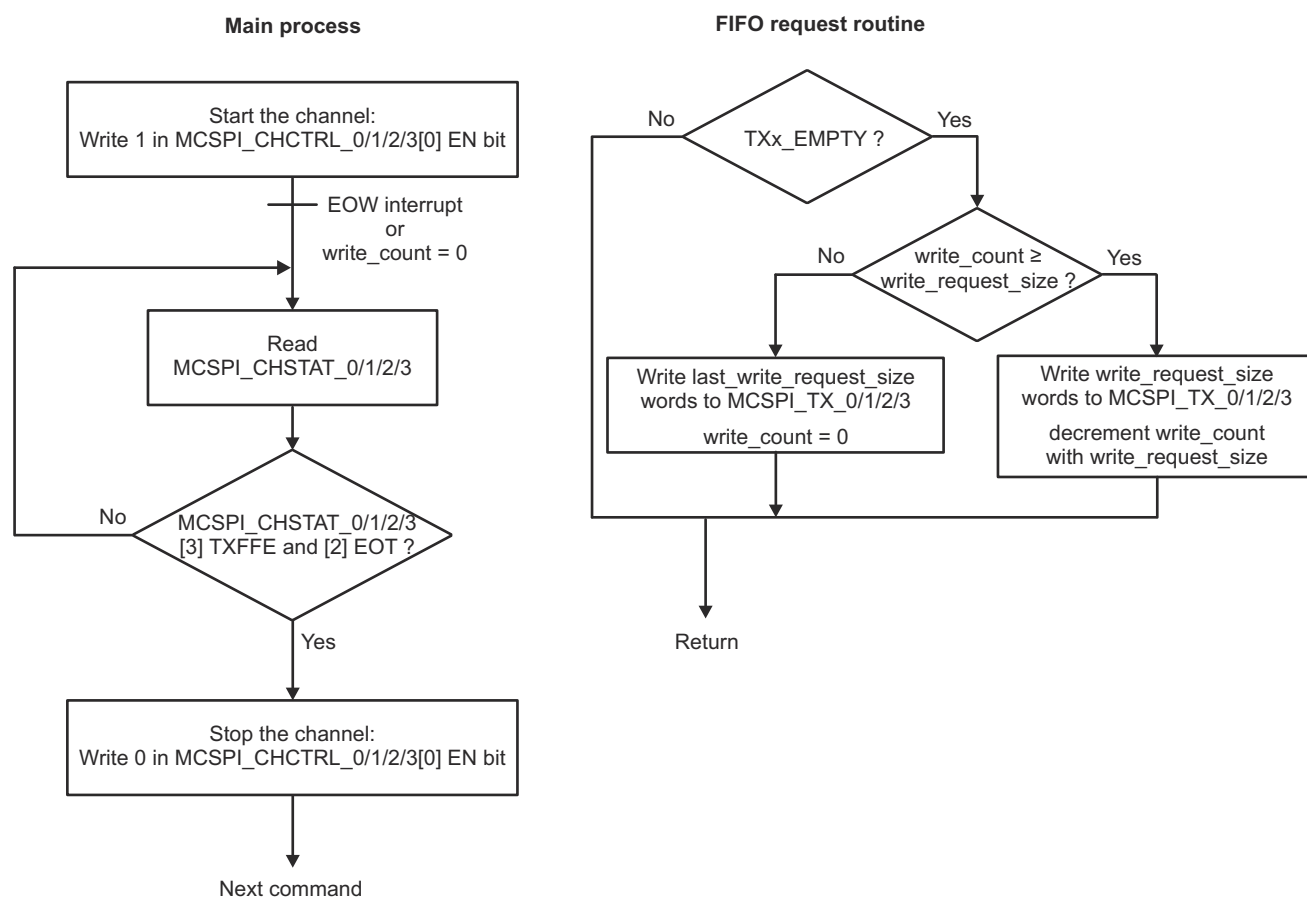

mcspi\_026

**Figure 12-50. FIFO Mode Transmit-and-Receive Without Word Count (Controller)**

#### 12.1.3.5.2.1.8.5 Transmit-Only

Figure 12-51 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write\_count = 0

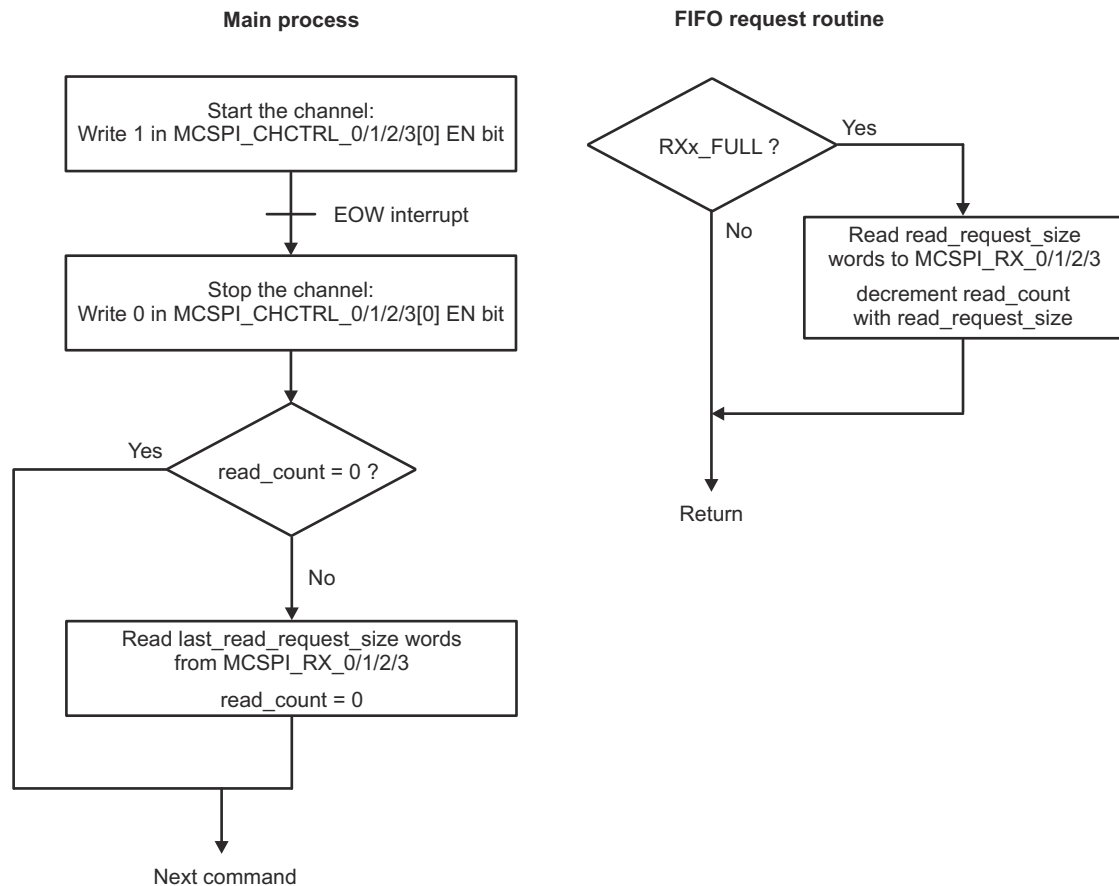

mcspi\_027

**Figure 12-51. FIFO Mode Transmit-Only (Controller)**

#### 12.1.3.5.2.1.8.6 Receive-Only With Word Count

Figure 12-52 shows the flow of a transfer in receive-only mode, with word count.

mcspi\_028

**Figure 12-52. FIFO Mode Receive-Only With Word Count (Controller)**

#### 12.1.3.5.2.1.8.7 Receive-Only Without Word Count

Figure 12-53 shows the flow of a transfer in receive-only mode, with word count.

mcspi\_029

#### 12.1.3.5.2.1.9 Common Transfer Procedures Without FIFO – Polling Method

##### 12.1.3.5.2.1.9.1 Receive-Only Procedure – Polling Method

Table 12-48 lists the receive-only procedure using the polling method.

**Table 12-48. Receive-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-25.	
Start the channel.	MCSPI_CHCTRL[0] EN	1
Wait for end-of-transfer.	MCSPI_CHSTAT[2] EOT	=1
Read the receiver register.	MCSPI_RXi	0x-

**Table 12-48. Receive-Only Procedure – Polling Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Stop the channel if no more data is expected.	MCSPi_CHICTRL[0] EN	0

#### 12.1.3.5.2.1.9.2 Receive-Only Procedure – Interrupt Method

Table 12-49 lists the receive-only procedure using the interrupt method.

**Table 12-49. Receive-Only Procedure – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-25.	
Start the channel.	MCSPi_CHICTRL[0] EN	1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPi_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPi_CHICTRL[0] EN	0
Read the receiver register.	MCSPi_RXi	0x-

#### 12.1.3.5.2.1.9.3 Transmit-Only Procedure – Polling Method

Table 12-50 lists the transmit-only procedure using the polling method.

**Table 12-50. Transmit-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-26.	
Start the channel.	MCSPi_CHICTRL[0] EN	1
Write the transmitter register with data.	MCSPi_TXi	0x-
Wait until end of transfer?	MCSPi_CHISTAT[2] EOT	=1
Stop the channel.	MCSPi_CHICTRL[0] EN	0

#### 12.1.3.5.2.1.9.4 Transmit-and-Receive Procedure – Polling Method

Table 12-51 lists the transmit-and-receive procedure using the polling method.

**Table 12-51. Transmit-and-Receive Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-27.	
Start the channel.	MCSPi_CHICTRL[0] EN	1
Write the transmitter register with data.	MCSPi_TXi	0x-
Wait until transmit/receive word?	MCSPi_CHISTAT[2] EOT	=1
Stop the channel.	MCSPi_CHICTRL[0] EN	0
Read the receiver register.	MCSPi_RXi	0x-

#### 12.1.3.5.3 Common Transfer Procedures Without FIFO – Polling Method

##### 12.1.3.5.3.1 Receive-Only Procedure – Polling Method

Table 12-52 lists the receive-only procedure using the polling method.

**Table 12-52. Receive-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-25.	
Start the channel.	MCSPi_CHICTRL[0] EN	1
Wait for end-of-transfer.	MCSPi_CHISTAT[2] EOT	=1

**Table 12-52. Receive-Only Procedure – Polling Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Read the receiver register.	MCSPi_RXi	0x-
Stop the channel if no more data is expected.	MCSPi_CHiCTRL[0] EN	0

#### 12.1.3.5.3.2 Receive-Only Procedure – Interrupt Method

Table 12-53 lists the receive-only procedure using the interrupt method.

**Table 12-53. Receive-Only Procedure – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-25.	
Start the channel.	MCSPi_CHiCTRL[0] EN	1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPi_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPi_CHiCTRL[0] EN	0
Read the receiver register.	MCSPi_RXi	0x-

#### 12.1.3.5.3.3 Transmit-Only Procedure – Polling Method

Table 12-54 lists the transmit-only procedure using the polling method.

**Table 12-54. Transmit-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-26.	
Start the channel.	MCSPi_CHiCTRL[0] EN	1
Write the transmitter register with data.	MCSPi_TXi	0x-
Wait until end of transfer?	MCSPi_CHiSTAT[2] EOT	=1
Stop the channel.	MCSPi_CHiCTRL[0] EN	0

#### 12.1.3.5.3.4 Transmit-and-Receive Procedure – Polling Method

Table 12-55 lists the transmit-and-receive procedure using the polling method.

**Table 12-55. Transmit-and-Receive Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-27.	
Start the channel.	MCSPi_CHiCTRL[0] EN	1
Write the transmitter register with data.	MCSPi_TXi	0x-
Wait until transmit/receive word?	MCSPi_CHiSTAT[2] EOT	=1
Stop the channel.	MCSPi_CHiCTRL[0] EN	0
Read the receiver register.	MCSPi_RXi	0x-

### 12.1.4 Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the function, operation, and configuration of the Universal Asynchronous Receiver/Transmitter (UART)/RS-485/Infrared Data Association (IrDA)/Consumer Infrared (CIR) module in the device.

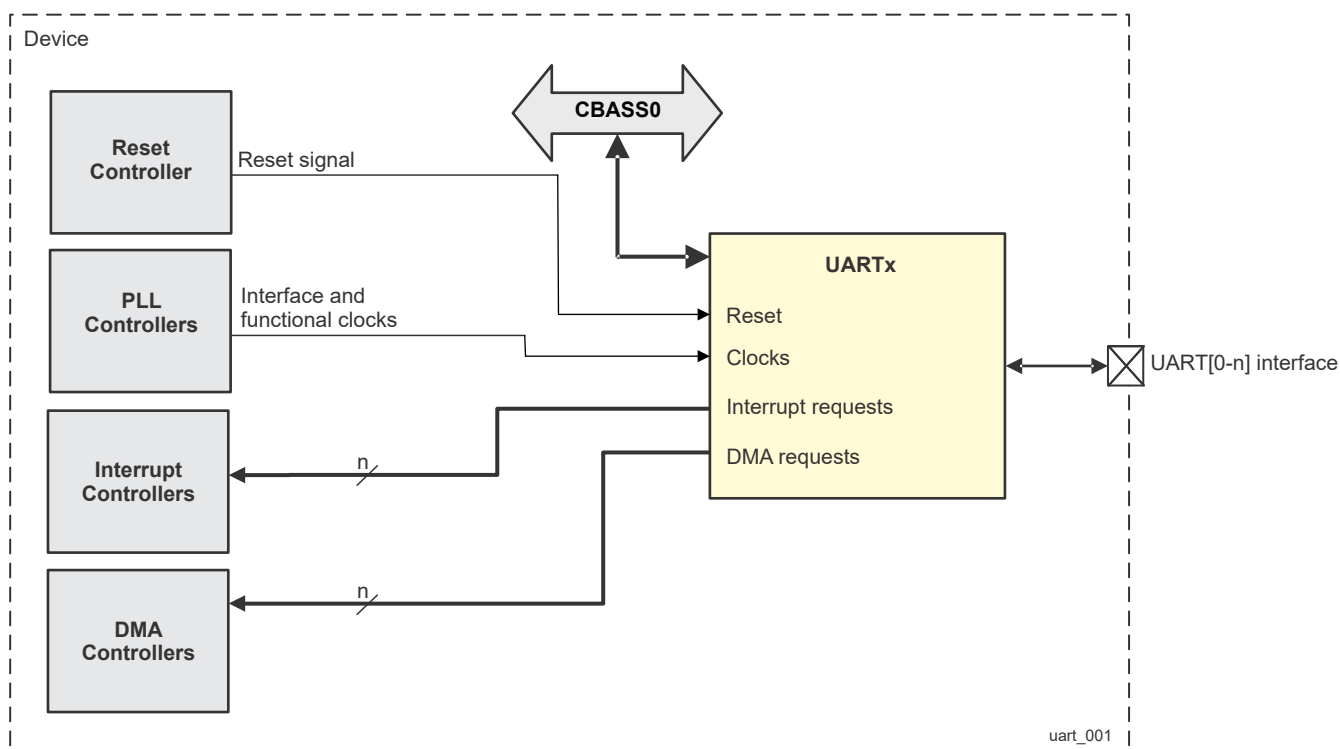

#### Note

UART and USART acronyms are used interchangeably in this section.

#### 12.1.4.1 UART Overview

The UART is a peripheral that utilizes the DMA for data transfer or interrupt polling via host CPU. All UART modules support IrDA and CIR modes when 48 MHz function clock is used. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 12-54 shows the UART modules overview.

- A. x represents a valid instance of UART in a domain. See the device datasheet for specifics.  
B. n represents the maximum number of available UART signals -1.

**Figure 12-54. UART Modules Overview**

#### 12.1.4.1.1 UART Features

The UART includes the following features:

- 16C750-compatible
- RS-485 external transceiver auto flow control support
- 64-byte FIFO buffer for receiver and 64-byte FIFO buffer for transmitter
- Programmable interrupt trigger levels for FIFOs
- Programmable sleep mode
- The 48 MHz functional clock is default option and allows baud rates up to 3.6 Mbps
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Optional multi-drop transmission

- Configurable time-guard feature
- Configurable data format:
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions (CTS, RTS)
- UART0 module in MAIN domain has extended modem control signals (DCD, RI, DTR, DSR)

#### 12.1.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

#### 12.1.4.1.3 IrDA Features

The IrDA includes the following features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
  - Frame formatting: addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection
- IrDA mode when 48 MHz function clock is used

#### 12.1.4.1.4 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following features to provide CIR support for remote-control applications:

- Transmit and receive mode
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle
- CIR mode when 48 MHz function clock is used

### 12.1.4.2 UART Environment

The , modules are hereinafter referred to as UART module.

This section describes the UART/RS-485/IrDA/CIR external connections (environment).

- The UART interface is described in [Section 12.1.4.2.1, UART Functional Interfaces](#).
- The RS-485 interface is described in [Section 12.1.4.2.2, RS-485 Functional Interfaces](#).
- The IrDA interface is described in [Section 12.1.4.2.3, IrDA Functional Interfaces](#).
- The CIR interface is described in [Section 12.1.4.2.4, CIR Functional Interfaces](#).

#### 12.1.4.2.1 UART Functional Interfaces

##### 12.1.4.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see [Figure 12-55](#) ).

uart-002

A. i represents a valid instance of UART in a domain. See the device datasheet for valid domains and instances.

**Figure 12-55. UART Mode Interface Signals**

### 12.1.4.2.1.2 UART Interface Description

Table 12-56 lists the UART interface input/output (I/O) signals.

**Table 12-56. UART I/O Signals**

Module Pin Name	Device Level Signal Name	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>WKUP_UARTi<sup>(10)</sup></b>				
RX	WKUP_UARTi <sup>(10)</sup> _RXD	I	Serial data input	HiZ
TX	WKUP_UARTi <sup>(10)</sup> _TXD	O	Serial data output <sup>(3)</sup>	1
CTS	WKUP_UARTi <sup>(10)</sup> _CTS	I	Clear to send <sup>(4)</sup>	HiZ
RTS	WKUP_UARTi <sup>(10)</sup> _RTS	O	Request to send <sup>(5)</sup>	1
<b>MCU_UARTi<sup>(10)</sup></b>				
RX	MCU_UARTi <sup>(10)</sup> _RXD	I	Serial data input	HiZ
TX	MCU_UARTi <sup>(10)</sup> _TXD	O	Serial data output <sup>(3)</sup>	1
CTS	MCU_UARTi <sup>(10)</sup> _CTS	I	Clear to send <sup>(4)</sup>	HiZ
RTS	MCU_UARTi <sup>(10)</sup> _RTS	O	Request to send <sup>(5)</sup>	1
<b>UARTi<sup>(10)</sup> Modem Signals</b>				
DCD	UARTi <sup>(10)</sup> _DCDn	I	Data Carrier Detect <sup>(6)</sup>	HiZ
DSR	UARTi <sup>(10)</sup> _DSRn	I	Data Set Ready <sup>(7)</sup>	HiZ
DTR	UARTi <sup>(10)</sup> _DTRn	O	Data Terminal Ready <sup>(8)</sup>	1
RIN	UARTi <sup>(10)</sup> _RIN	I	Ring Indicator <sup>(9)</sup>	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UART\_MDR1[2-0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UART\_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).

(4) Active-low modem status signal. Reading the UART\_MSR[4] NCTS\_STS bit checks the condition of CTS. Reading the UART\_MSR[0] CTS\_STS bit checks a change of state of CTS since the last read of the modem status register. The auto-CTS mode uses CTS to control the transmitter.

(5) When active (low), the module is ready to receive data. Setting the UART\_MCR[1] RTS bit activates RTS signal, which becomes inactive as the result of a module reset, loopback mode, or clearing the UART\_MCR[1] RTS bit. In auto-RTS mode, RTS signal becomes inactive as a result of the receiver threshold logic.

(6) Active-low modem status signal. The condition of DCD can be checked by reading the UART\_MSR[7] NCD\_STS bit. Any change in its state can be detected by reading the UART\_MSR[3] DCD\_STS bit.

(7) Active-low modem status signal. Reading the UART\_MSR[5] NDSR\_STS bit checks the condition of DSR. Reading the UART\_MSR[1] DSR\_STS bit checks a change of state of DSR since the last read of the UART\_MSR register.

(8) When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting the UART\_MCR[0] DTR bit.

(9) Active-low modem status signal. The condition of RIN can be checked by reading the UART\_MSR[6] NRI\_STS bit. Any change in its state can be detected by reading the UART\_MSR[2] RI\_STS bit.

(10) i represents a UART instance. See the device datasheet for available domains and UART instances.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.4.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16× (<= 230.4 kbps)
- UART 16× with autobauding (>= 1200 bps and <= 115.2 kbps)
- UART 13× (>= 460.8 kbps)

### CAUTION

To be used as a UART, the operating mode must be programmed appropriately in the UART\_MDR1[2-0] MODE\_SELECT bit field to select UART, IrDA, or CIR mode, and the UART\_MDR3[4] DIR\_EN bit field to select RS-485 mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 12-56 shows the UART frame data format.

Figure 12-56. UART Frame Data Format

#### 12.1.4.2.2 RS-485 Functional Interfaces

##### 12.1.4.2.2.1 System Using RS-485 Communication

The RS-485 network physical layer consists of two-wire differential bus, usually twisted pair. External RS-485 transceiver IC is needed to access a RS-485 bus by the RS-485 mode. Figure 12-57 shows an example connection of MCU\_UART0 in RS-485 mode.

A. i represents a valid instance of UART in a domain. See the device datasheet for valid domains and instances.

Figure 12-57. RS-485 Mode Interface Signals

##### 12.1.4.2.2.2 RS-485 Interface Description

Table 12-57 lists the RS-485 interface input/output (I/O) signals.

Table 12-57. UART I/O Signals (RS-485 Mode)

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>WKUP_UARTi<sup>(3)</sup></b>				
RX	WKUP_UARTi <sup>(3)</sup> _RXD	I	Serial data input	HiZ
TX	WKUP_UARTi <sup>(3)</sup> _TXD	O	Serial data output	1

**Table 12-57. UART I/O Signals (RS-485 Mode) (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
DIR	WKUP_UARTi <sup>(3)</sup> _RTSn	O	RS-485 Direction	1
<b>MCU_UARTi<sup>(3)</sup></b>				
RX	MCU_UARTi <sup>(3)</sup> _RXD	I	Serial data input	HiZ
TX	MCU_UARTi <sup>(3)</sup> _TXD	O	Serial data output	1
DIR	MCU_UARTi <sup>(3)</sup> _RTSn	O	RS-485 Direction	1
<b>UARTi<sup>(3)</sup></b>				
RX	UARTi <sup>(3)</sup> _RXD	I	Serial data input	HiZ
TX	UARTi <sup>(3)</sup> _TXD	O	Serial data output	1
DIR	UARTi <sup>(3)</sup> _RTSn	O	RS-485 Direction	1

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) i represents a valid UART instance. See the device datasheet for available domains and UART instances.

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.1.4.2.3 IrDA Functional Interfaces

##### 12.1.4.2.3.1 System Using IrDA Communication Protocol

Figure 12-58 shows an example connection of MCU\_UART0 to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

uart-003

A. i represents a valid instance of UART in a domain. See the device datasheet for valid domains and instances.

**Figure 12-58. IrDA Mode Interface Signals**

### 12.1.4.2.3.2 IrDA Interface Description

Table 12-58 lists the IrDA interface I/O signals.

**Table 12-58. UART I/O Signals (IrDA Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
RX		I	Serial data input	HiZ
TX		O	Serial data output in IrDA modes (SIR, MIR, and FIR). <sup>(3)</sup>	0
SD		O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1
RX		I	Serial data input	HiZ
TX		O	Serial data output in IrDA modes (SIR, MIR, and FIR). <sup>(3)</sup>	0
SD		O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) In other modes, this pin is set to the reset value (inactive state).

(4) The SD pinout (see UART\_ACREG[6] SD\_MOD bit).

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.4.2.3.3 IrDA Protocol and Data Format

#### 12.1.4.2.3.3.1 SIR Mode

In SIR mode, data is transferred between the Host CPU and peripheral devices at speeds of up to 115.2 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART\_LCR register.

The UART\_BLR[6] XBOF\_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

The SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine sends an escape character (0x7D), inverts the fifth bit of the real data to be sent, and then sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the Host CPU reads the line status register (UART\_LSR\_IRDA) to find possible errors of the received frame.

#### Note

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART\_ACREG[5] DIS\_IR\_RX bit. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be 1.6- $\mu$ s or 3/16 encoding, selected by the UART\_ACREG[7] PULSE\_TYPE bit. In 1.6- $\mu$ s encoding, the infrared pulse width is 1.6  $\mu$ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

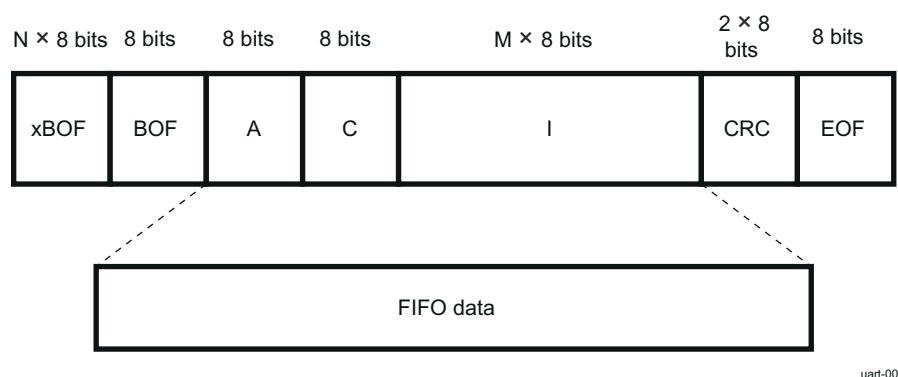

For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

### Note

Reception supports variable-length stop-bits.

#### 12.1.4.2.3.3.1.1 Frame Format

Figure 12-59 shows the IrDA SIR frame format.

uart-006

**Figure 12-59. IrDA SIR Frame Format**

The CRC is applied on the address (A), control (C), and information (I) bytes.

### Note

The two words of CRC are written to the FIFO in reception.

#### 12.1.4.2.3.3.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

- In reception:

For the A, C, I, and CRC fields:

- Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
- If the byte is equal to the CE byte, discards the CE byte
- Complements bit 5 of the byte following the CE
- Sends the complemented byte to the CRC detector and stores it in the RX FIFO

#### 12.1.4.2.3.3.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

#### 12.1.4.2.3.3.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6- $\mu$ s pulse duration methods. The UART\_ACREG[7] PULSE\_TYPE bit selects the pulse-width method in transmit mode.

#### 12.1.4.2.3.3.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the TX line is always low, and the counter used to form a pulse on TX is cleared continuously.

After the TX FIFO output resets to 0, TX rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, TX falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh clock to the tenth clock of each 16-clock bit cycle.

Figure 12-60 shows the IrDA SIR encoding mechanism.

**Figure 12-60. IrDA SIR Encoding Mechanism**

#### 12.1.4.2.3.3.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 12-61 shows the IrDA SIR decoding mechanism.

uart-008

**Figure 12-61. IrDA SIR Decoding Mechanism**

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the RX input can be disabled using the UART\_ACREG[5] DIS\_IR\_RX bit. The UART\_MDR2[6] IRRXINVERT bit can invert the signal from the transceiver (RX) pin to the IR RX logic in the UART. This inversion is performed by default.

#### 12.1.4.2.3.3.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the UART\_EFR[1-0] bit field (see [Table 12-59](#)), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UARTi receives in IrDA mode, use the UART\_XON1\_ADDR1[7-0] and UART\_XON2\_ADDR2[7-0] bit fields.

**Table 12-59. UART\_EFR[1-0] IR Address Checking Options**

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

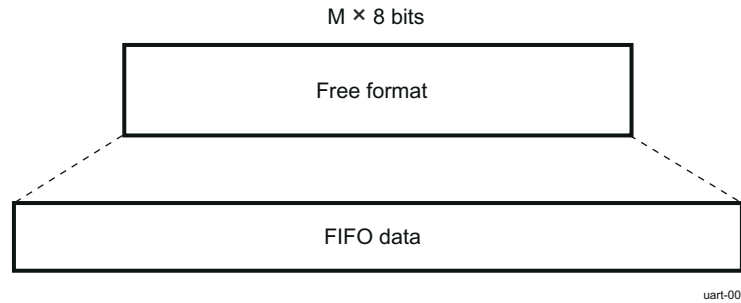

#### 12.1.4.2.3.3.2 SIR Free-Format Mode

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

[Figure 12-62](#) shows SIR FF mode.

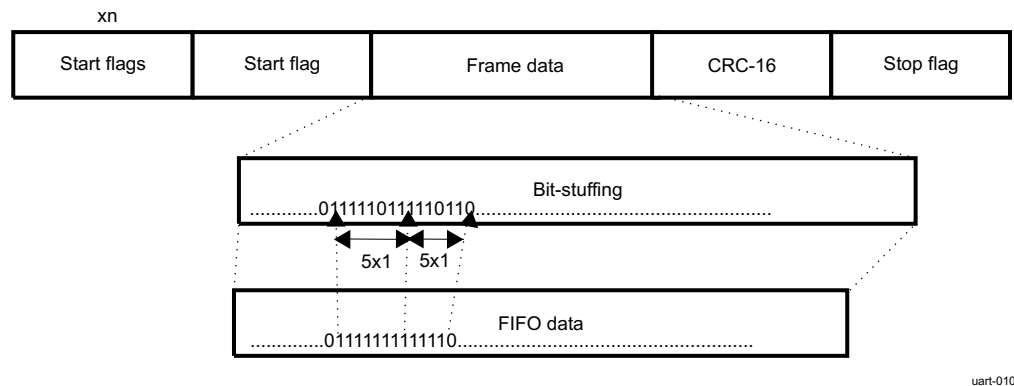

**Figure 12-62. SIR FF Mode**

In SIR FF mode, the Host CPU software must construct (that is, encode and decode) the entire FIFO data packet.

#### 12.1.4.2.3.3.3 MIR Mode

In MIR mode, data is transferred between the Host CPU and the peripheral devices at 0.576 Mbps or 1.152 Mbps. A MIR transmit frame starts with at least two start flags, followed by a frame data and a CRC-16, and ends with a stop flag (see [Figure 12-63](#)).

**Figure 12-63. MIR Transmit Frame Format**

On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the Host CPU reads the line status register (UART\_LSR\_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

### 12.1.4.2.3.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 12-64 shows the MIR baud rate adjustment mechanism.

**Figure 12-64. MIR Baud Rate Adjustment Mechanism**

### 12.1.4.2.3.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 12-65 shows the SIP.

**Figure 12-65. SIP**

### 12.1.4.2.3.3.4 FIR Mode

In FIR mode, data is transferred between the Host CPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 12-66 shows the FIR transmit frame format.

**Figure 12-66. FIR Transmit Frame Format**

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
----------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see [Table 12-60](#)) and generates the SIP (see [Section 12.1.4.2.3.3.3.2, SIP Generation](#)).

**Table 12-60. 4-PPM Format**

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in [Table 12-60](#) are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 12-61](#)).

**Table 12-61. FIR Preamble, Start Flag, and Stop Flag**

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted LSBs of each byte first (see [Table 12-62](#)).

**Table 12-62. FIR Data Byte Transmission Order Example**

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the Host CPU reads the line status register (UART\_LSR\_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

#### 12.1.4.2.4 CIR Functional Interfaces

##### 12.1.4.2.4.1 System Using CIR Communication Protocol With Remote Control

All UART modules can be connected to an external infrared transceiver in CIR mode. [Figure 12-67](#) shows an example connection of MCU\_UART0 in CIR mode.

A. i represents a valid instance of UART in a domain. See the device datasheet for valid domains.

**Figure 12-67. CIR Mode Interface Signals**

#### 12.1.4.2.4.2 CIR Interface Description

Table 12-63 lists the CIR interface I/O signals.

**Table 12-63. UART I/O Signals (CIR Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
RX		I	Serial data input	HiZ
TX		O	Serial data output in CIR mode. <sup>(3)</sup>	0
SD		O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1
<b>UART[0-9]</b>				
RX		I	Serial data input	HiZ
TX		O	Serial data output in CIR mode. <sup>(3)</sup>	0
SD		O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) In other modes, this pin is set to the reset value (inactive state).

(4) The SD pinout is an inverted value of the UART\_ACREG[6] SD\_MOD bit.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.1.4.2.4.3 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

##### 12.1.4.2.4.3.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 12-68).

**Figure 12-68. CIR Pulse Modulation**

#### 12.1.4.2.4.3.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART\_MDR2[5-4] CIR\_PULSE\_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 12-69 shows the CIR modulation duty cycles.

**Figure 12-69. CIR Modulation Duty Cycle**

The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

### 12.1.4.2.4.3.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration  $t$ .

Similarly, 0 is transmitted as a blank duration  $T$ . The Host CPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see [Figure 12-70](#)).

**Figure 12-70. UART RC-5 Bit Encoding**

Because CIR mode logic does not impose a fixed format for infrared packets of data, the Host CPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the Host CPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of  $t$ ) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

[Figure 12-71](#) shows SIRC bit encoding.

**Figure 12-71. UART SIRC Bit Encoding**

To construct comprehensive packets constituting remote-control commands, the Host CPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 12-72 shows a standard RC-5 frame as detected by UART in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two  $t$  pulses (digital bits) from the TX FIFO.

**Figure 12-72. UART RC-5 Standard Packet Format**

Where:

- S1, S2: Start-bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the Host CPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

The SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 12-73 shows the packet format and bit encoding. As Figure 12-74 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

**Figure 12-73. UART SIRC Packet Format**

### Note

The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

**Figure 12-74. UART SIRC Bit Transmission Example**

### Note

This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

#### 12.1.4.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.1.4.4 UART Functional Description

##### 12.1.4.4.1 UART Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, RS-485, IrDA, or CIR) and enables the mechanism corresponding to the chosen function.
- Register mode: Enables conditional access to registers.

For more information about mode configuration, see [Section 12.1.4.4.7, Mode Selection](#).

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the UART\_IIR\_UART register indicates the interrupt type.
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

[Figure 12-75](#) is the UART block diagram.

uart-022

A. i represents a valid instance of UART in a domain. See the device datasheet for valid domains and instances.

**Figure 12-75. UART Functional Block Diagram**

#### 12.1.4.4.2 UART Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses.

#### 12.1.4.4.3 UART Software Reset

The UART\_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

##### 12.1.4.4.3.1 Independent TX/RX

The receiver and transmitter are enabled by default after reset. Software can choose to disable, re-enable or to reset either the RX or the TX side independently of the other through the UART\_ECR register.

#### 12.1.4.4.4 UART Power Management

##### 12.1.4.4.4.1 UART Mode Power Management

##### 12.1.4.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UART\_IER\_UART[4] SLEEP\_MODE bit to 1 (when the UART\_EFR[4] ENHANCED\_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RX, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the RX line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UART\_SCR[4] RX\_CTS\_WU\_EN bit to 1. To understand how to manage the interrupt, see [Section 12.1.4.4.5.1.2, Wake-Up Interrupt](#).

---

#### Note

There must be no writing to the divisor latches, UART\_DLL and UART\_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UART\_IER\_UART[4] SLEEP\_MODE bit before writing to the UART\_DLL or UART\_DLH register.

---

##### 12.1.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UART\_SYSC[2] ENAWAKEUP bit and the UART\_WER register).

For more information, see *Power* in the *Device Configuration*.

##### 12.1.4.4.2 IrDA Mode Power Management

###### 12.1.4.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART\_MDR1[3] IR\_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

###### 12.1.4.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see [Section 12.1.4.4.1.2, System Power Saving](#)).

##### 12.1.4.4.3 CIR Mode Power Management

###### 12.1.4.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see [Section 12.1.4.4.2.1, Module Power Saving](#)).

###### 12.1.4.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see [Section 12.1.4.4.1.2, System Power Saving](#)).

##### 12.1.4.4.4 Local Power Management

[Table 12-64](#) describes power-management features available for the UART.

### Note

For information about source clock gating and the sleep/wake-up transitions description, see *Power* in the *Device Configuration*.

**Table 12-64. UART Local Power-Management Features**

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the clock on interface activity or gating the UARTI_FCLK clock on internal activity.
Peripheral idle modes	UART_SYSC[4-3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Controller standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

#### 12.1.4.4.5 UART Interrupt Requests

##### 12.1.4.4.5.1 UART Mode Interrupt Management

###### 12.1.4.4.5.1.1 UART Interrupts

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UART\_IIR\_UART) sets the UART\_IIR\_UART[0] IT\_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UART\_IIR\_UART[5-1] bit field. [Table 12-65](#) summarizes the interrupt control functions.

**Table 12-65. UART Mode Interrupts**

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR_UART register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears
000000	4	Modem status	See the UART_MSR register.	Read the MSR register
010000	5	XOFF interrupt/ special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR_UART register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the UART_IIR_UART register

For the receiver-line status interrupt, the UART\_LSR\_UART[7] RX\_FIFO\_STS bit generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UART\_IIR\_UART register.

#### 12.1.4.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UART\_SCR[4] RX\_CTS\_WU\_EN bit is set to 1. The UART\_IIR\_UART register is not modified when this occurs; the UART\_SSR[1] RX\_CTS\_WU\_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UART\_SCR[4] RX\_CTS\_WU\_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

#### 12.1.4.4.5.2 IrDA Mode Interrupt Management

##### 12.1.4.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART\_IER\_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART\_IIR\_IRDA).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART\_IER\_IRDA and UART\_IIR\_IRDA mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 12-66](#)). The interrupt line is activated when any interrupt is generated (there is no priority).

**Table 12-66. IrDA Mode Interrupts**

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the UART_RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the UART_RESUME register OR Read the UART_IIR_IRDA register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR_IRDA register.

##### 12.1.4.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 12.1.4.4.5.1.2, Wake-Up Interrupt](#)).

#### 12.1.4.4.5.3 CIR Mode Interrupt Management

##### 12.1.4.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART\_IER\_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART\_IIR\_CIR).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART\_IER\_CIR and UART\_IIR\_CIR mappings, depending on the selected mode.

Table 12-67 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART\_IIR\_CIR[5] TX\_STATUS\_IT bit is to indicate that the last bit of infrared data was passed to the TX pin.

**Table 12-67. CIR Mode Interrupts**

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR register until the interrupt condition disappears
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully	Read the UART_IIR_CIR register
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

#### 12.1.4.4.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see Section 12.1.4.4.5.1.2, *Wake-Up Interrupt*).

#### 12.1.4.4.6 UART FIFO Management

The FIFO is accessed by reading and writing the UART\_RHR and UART\_THR registers. Parameters are controlled using the FIFO control register (UART\_FCR) and supplementary control register (UART\_SCR). Reading the UART\_SSR[0] TX\_FIFO\_FULL bit at 1 means the FIFO is full.

The UART\_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 12-76 shows the FIFO management registers.

#### Note

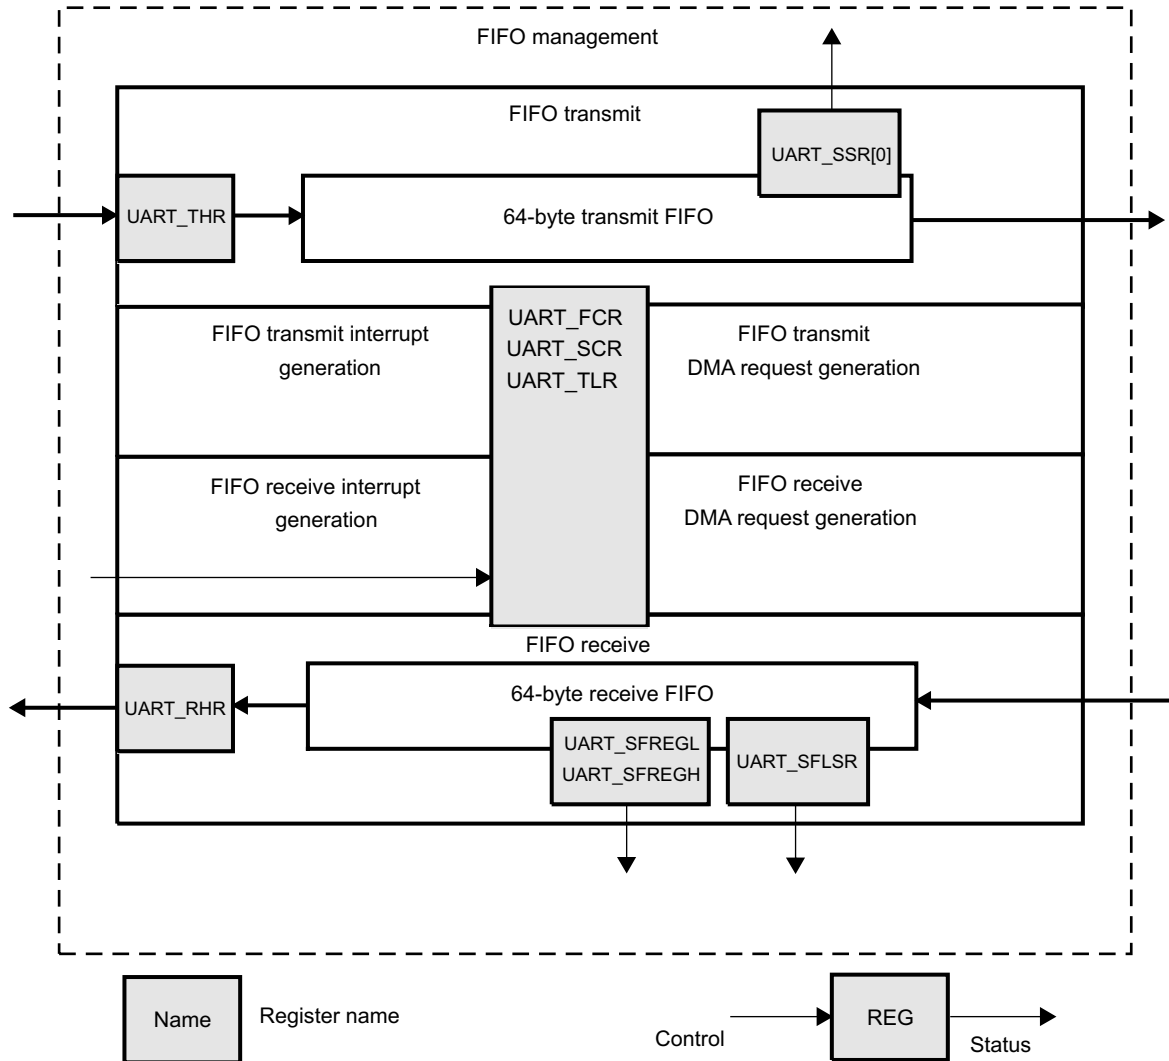

Data in the UART\_RHR register is not overwritten when an overflow occurs.

#### Note

The UART\_SFLSR, UART\_SFREGL, and UART\_SFREGH status registers are used in IrDA mode only. For information about their use, see Section 12.1.4.4.8.3.3, *IrDA Data Formatting*.

#### Note

Bits UART\_FCR[2] TX\_FIFO\_CLEAR and UART\_FCR[1] RX\_FIFO\_CLEAR are automatically cleared by hardware after  $4 \times + 5 \times \text{UARTi\_FCLK}$  clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

uart-023

Figure 12-76. UART FIFO Management Registers

#### 12.1.4.4.6.1 FIFO Trigger

##### 12.1.4.4.6.1.1 Transmit FIFO Trigger

Table 12-68 lists the TX FIFO trigger level settings.

Table 12-68. UART TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[5-4] TX_FIFO_TRIG bit field (8, 16, 32, or 56 spaces)
0	!= 0x0	Defined by the UART_TLR[3-0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space)

**Note:** The combination of TX\_FIFO\_TRIG\_DMA = 0x0 and TX\_FIFO\_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

##### 12.1.4.4.6.1.2 Receive FIFO Trigger

Table 12-69 lists the RX FIFO trigger-level settings.

**Table 12-69. UART RX FIFO Trigger-Level Setting Summary**

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[7-6] RX_FIFO_TRIG bit field (8, 16, 56, or 60 characters)
0	!= 0x0	Defined by the UART_TLR[7-4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character)  <b>Note:</b> The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START and UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX\_FIFO\_TRIG\_HALT > RX\_FIFO\_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR\_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud\_rate} + 4 \times \text{FCLK}$$

#### Note

The RTS signal is deasserted after the UART module receives the data over RX\_FIFO\_TRIG\_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX\_FIFO\_TRIG\_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START bit field or the UART\_FCR[7-6] RX\_FIFO\_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

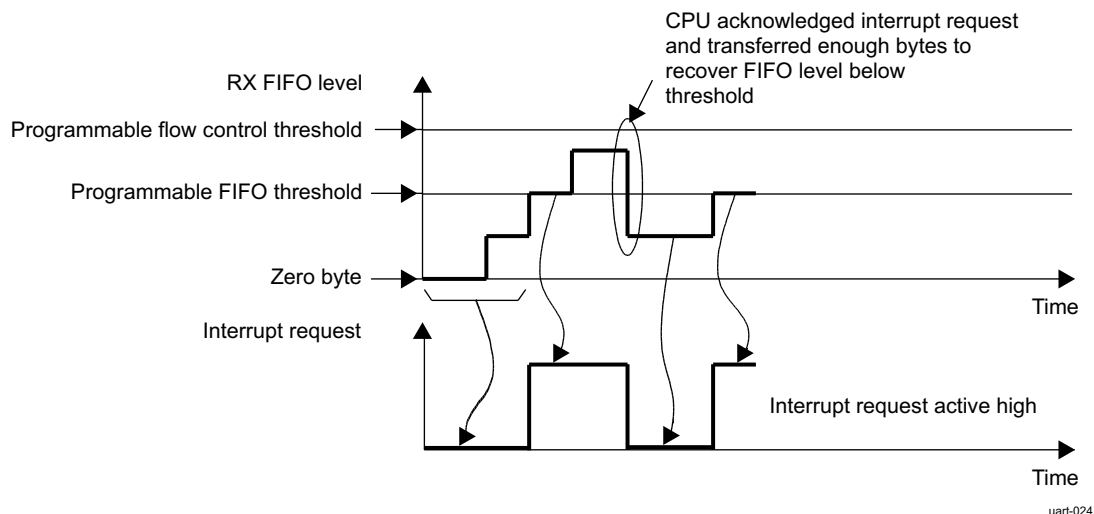

#### 12.1.4.4.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UART\_FCR[0] FIFO\_EN bit is set to 1 and relevant interrupts are enabled by the UART\_IER\_UART register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UART\_TLR[7-4] RX\_FIFO\_TRIG\_DMA and UART\_TLR[3-0] TX\_FIFO\_TRIG\_DMA bit fields or the UART\_FCR[7-6] RX\_FIFO\_TRIG and UART\_FCR[5-4] TX\_FIFO\_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the Host CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit field) must be greater than or equal to the RX FIFO threshold.

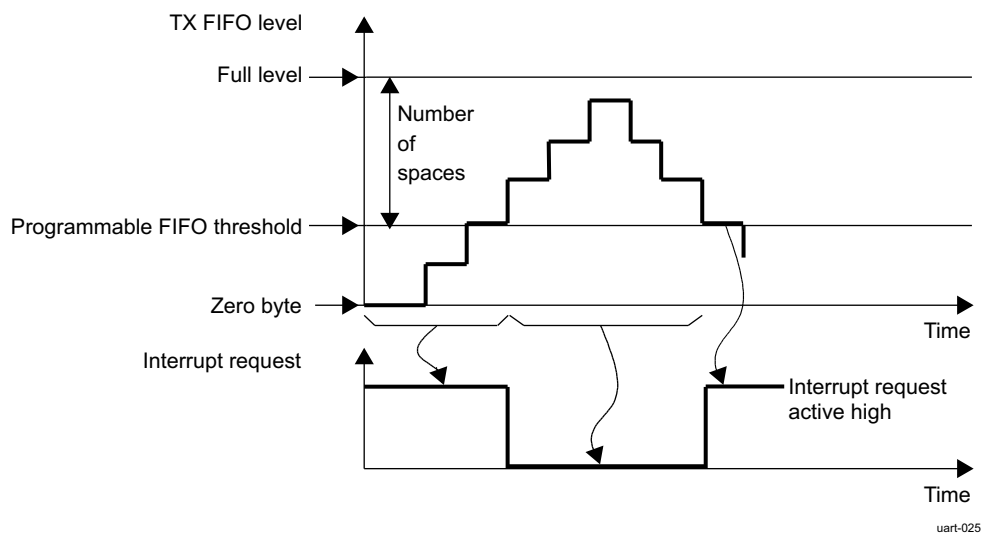

Figure 12-77 shows the generation of the RX FIFO interrupt request.

**Figure 12-77. UART RX FIFO Interrupt Request Generation**

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the Host CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 12-78 shows the generation of the TX FIFO interrupt request.

**Figure 12-78. UART TX FIFO Interrupt Request Generation**

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

#### 12.1.4.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UART\_FCR[0] FIFO\_EN bit is set to 0 and the relevant interrupts are disabled by the UART\_IER\_UART register), the status of the receiver and transmitter can be checked by polling the line status register (UART\_LSR\_UART).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the Host CPU.

#### 12.1.4.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in *UART Hardware Requests*, assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the signals (where i = 0 to ).

signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the UART\_SCR[0] DMA\_MODE\_CTL bit is set to 0, setting the UART\_FCR[3] DMA\_MODE bit to 0 enables DMA mode 0. Setting the UART\_FCR[3] DMA\_MODE bit to 1 enables DMA mode 1.
- When the UART\_SCR[0] DMA\_MODE\_CTL bit is set to 1, the UART\_SCR[2-1] DMA\_MODE\_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART\_SCR) description.

For example:

- If no DMA operation is desired, set the UART\_SCR[0] DMA\_MODE\_CTL bit to 1 and the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 0x0. (The DMA\_MODE bit is discarded.)
- If DMA mode 1 is desired, set the UART\_SCR[0] DMA\_MODE\_CTL bit to 0 and the UART\_FCR[3] DMA\_MODE bit to 1, or set the UART\_SCR[0] DMA\_MODE\_CTL bit to 1 and the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 01. (The UART\_FCR[3] DMA\_MODE bit is discarded.)

If the FIFOs are disabled (the UART\_FCR[0] FIFO\_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART\_MDR3[2] SET\_DMA\_TX\_THRESHOLD, the threshold can be programmed different ways:

- SET\_TX\_DMA\_THRESHOLD = 1:  
The threshold value will be the value of the UART\_TX\_DMA\_THRESHOLD register. If SET\_TX\_DMA\_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET\_TX\_DMA\_THRESHOLD = 0:  
The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

##### 12.1.4.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UART\_SCR[0] DMA\_MODE\_CTL = 0 and UART\_FCR[3] DMA\_MODE = 1:
  - a. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit fields to 01 (DMA mode 1)
  - b. Set the UART\_SCR[0] DMA\_MODE\_CTL bit to 1 (this setting of UART\_SCR[0] DMA\_MODE-CTL will ignores UART\_FCR[3] DMA\_MODE\_CTL bit)

#### Note

It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- c. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON

protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- f. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- g. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
2. DMA mode 1 is set (both TX/RX DMA) by registers UART\_FCR[3] DMA\_MODE = 0 and UART\_SCR[0] DMA\_MODE\_CTL = 1, UART\_SCR[2-1] DMA\_MODE\_2 = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:
  - a. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UART\_FCR[3] DMA\_MODE = 0 and UART\_SCR[0] DMA\_MODE\_CTL = 1, UART\_SCR[2-1] DMA\_MODE\_2 = 11. It is the same as above:
  - a. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

#### 12.1.4.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 12-79 through Figure 12-82 show the supported DMA operations.

uart-026

**Figure 12-79. UART Receive FIFO DMA Request Generation (32 Characters)**

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UART\_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UART\_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

uart-027

**Figure 12-80. UART Transmit FIFO DMA Request Generation (56 Spaces)**

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UART\_TLR register.

The threshold can be programmed in a number of ways. [Figure 12-80](#) shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UART\_FCR[5-4] TX\_FIFO\_TRIG bit field or the UART\_TLR[3-0] TX\_FIFO\_TRIG\_DMA bit field concatenated with the TX\_FIFO\_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

Figure 12-81 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

**Figure 12-81. UART Transmit FIFO DMA Request Generation (8 Spaces)**

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 12-82). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART\_DLL and UART\_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

**Figure 12-82. UART Transmit FIFO DMA Request Generation (1 Space)**

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART\_MDR3[1] NONDEFAULT\_FREQ bit and UART\_TX\_DMA\_THRESHOLD register (see [Figure 12-83](#)). In the example, the UART\_TX\_DMA\_THRESHOLD[5-0] TX\_DMA\_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART\_DLL and UART\_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART\_MDR3[1] NONDEFAULT\_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

uart-036

**Figure 12-83. UART Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)**

#### 12.1.4.4.6.4.3 DMA Transmission

Figure 12-84 shows DMA transmission.

uart-030

**Figure 12-84. DMA Transmission**

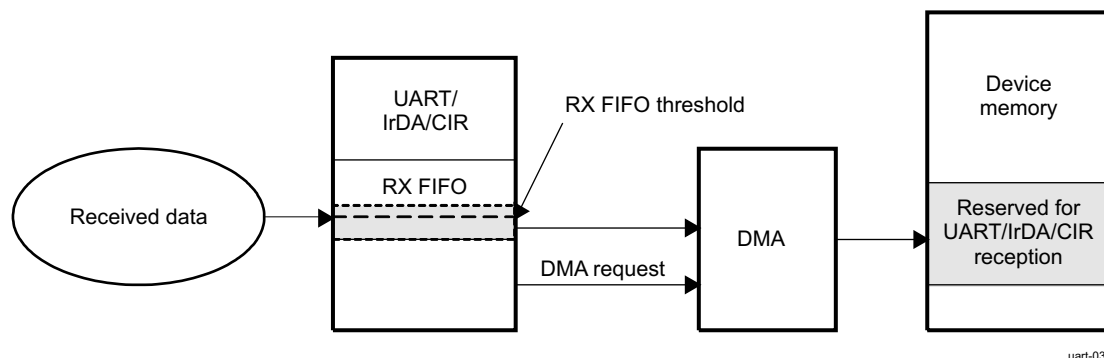

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:
  - a. Until the TX FIFO trigger level is not reached, a DMA request is generated
  - b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UART\_THR empty (TX FIFO empty).

#### Note

In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UART\_THR register empties.

#### 12.1.4.4.6.4.4 DMA Reception

Figure 12-85 shows DMA reception.

**Figure 12-85. DMA Reception**

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
  - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
  - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

#### 12.1.4.4.7 UART Mode Selection

##### 12.1.4.4.7.1 Register Access Modes

##### 12.1.4.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UART\_LCR register determines the register access mode (see [Table 12-70](#)).

**Table 12-70. UART Register Access Mode Programming (Using UART\_LCR)**

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

#### 12.1.4.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR\_SPR, TCR\_TLR, and XOFF). These registers are identified in [Table 12-93](#), *UART Load FIFO Triggers Defined by the Concatenated Value*.

[Table 12-71](#) through [Table 12-73](#) summarize the register access submodes.

**Table 12-71. UART Subconfiguration Mode A Summary**

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

**Table 12-72. UART Subconfiguration Mode B Summary**

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

**Table 12-73. UART Suboperational Mode Summary**

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

#### 12.1.4.4.7.1.3 Registers Available for the Register Access Modes

[Table 12-74](#) lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

**Table 12-74. UART Register Access Mode Overview**

Address Offset	Registers

#### 12.1.4.4.7.2 UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UART\_MDR1[2:0] MODE\_SELECT bit field (see [Table 12-75](#)).

**Table 12-75. UART Mode Selection**

Value	Mode
0x0:	UART 16× mode
0x1:	SIR mode
0x2:	UART 16× auto-baud
0x3:	UART 13× mode
0x4:	MIR mode
0x5:	FIR mode
0x6:	CIR mode

MODE\_SELECT is effective when the module is in operational mode (see [Section 12.1.4.4.7.1, Register Access Modes](#)).

To select a RS-485 mode, set the UART\_MDR3[4] DIR\_EN bit field to 0x1.

#### 12.1.4.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 12-76](#) are used for the UART function.

**Table 12-76. UART Mode Register Overview**

Address Offset	Registers <sup>(1) (2)</sup>

(1) REGISTER\_NAME(CIR) notation indicates that the register exists for other functions (IrDA or UART), but fields have different meanings for other functions (described separately in *UART Registers*).

(2) REGISTER\_NAME[m:n] notation indicates that only register bits numbered m to n apply to the CIR function.

### 12.1.4.4.8 UART Protocol Formatting

#### 12.1.4.4.8.1 UART Mode

##### 12.1.4.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed divisors that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-86 shows the baud rate generator and associated controls.

uart-032

**Figure 12-86. UART Baud Rate Generation**

#### CAUTION

Before initializing or modifying clock parameter controls (UART\_DLH, UART\_DLL), UART\_MDR1[2-0] MODE\_SELECT = DISABLE must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

##### 12.1.4.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16× mode: Divisor value = Operating frequency / (16× baud rate)
- UART 13× mode: Divisor value = Operating frequency / (13× baud rate)

Table 12-79 describes the UART baud rate settings.

**Table 12-79. UART Baud Rate Settings (48MHz, 160MHz, 192MHz Clock)**

Baud Rate	Baud Multiple	Source Clock(MHz)	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)

#### 12.1.4.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

##### 12.1.4.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UART\_LCR register.

Character length is specified using the UART\_LCR[1-0] CHAR\_LENGTH bit field.

The number of stop-bits is specified using the UART\_LCR[2] NB\_STOP bit.

The parity bit is programmed using the UART\_LCR[5-3] PARITY\_EN, UART\_LCR[5-3] PARITY\_TYPE\_1, and UART\_LCR[5-3] PARITY\_TYPE\_2 bit fields (see [Table 12-80](#)).

**Table 12-80. UART Parity Bit Encoding**

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

##### 12.1.4.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UART\_EFR[7] AUTO\_CTS\_EN and UART\_EFR[6] AUTO\_RTS\_EN bit fields, respectively.

With auto-CTS, CTS signal must be active before the module can transmit data.

Auto-RTS activates the RTS output only when there is enough room in the RX FIFO to receive data. It deactivates the RTS output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UART\_TCR register determine the levels at which RTS is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UART\_TCR register. RTS is active if the RX FIFO level is below the HALT trigger level in the UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit field. When the RX FIFO HALT trigger level is reached, RTS is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

RTS is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START bit field. This reassertion requests the sending device to resume transmission.

In this case, RTS is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks CTS before sending the next data byte. When CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, CTS must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the CTS state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, CTS is an active-low signal.

#### 12.1.4.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UART\_EFR) and the modem control register (UART\_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UART\_EFR[3-0] bit field (see [Table 12-81](#)).

Two other enhanced features relate to software flow control:

- XON-any function (UART\_MCR[5] XON\_EN): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

#### Note

The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UART\_EFR[5] SPECIAL\_CHAR\_DETECT): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UART\_IIR\_UART) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UART\_IIR\_UART. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

**Table 12-81. UART\_EFR[3:0] Software Flow Control Options**

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>

- (1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.  
XON1 is defined in the UART\_XON1\_ADDR1[7-0] XON\_WORD1 bit field. XON2 is defined in the UART\_XON2\_ADDR2[7-0] XON\_WORD2 bit field.

XOFF1 is defined in the UART\_XOFF1[7-0] XOFF\_WORD1 bit field. XOFF2 is defined in the UART\_XOFF2[7-0] XOFF\_WORD2 bit field.

#### 12.1.4.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UART\_IIR\_UART[4] bit (if enabled by UART\_IER\_UART[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UART\_IIR\_UART[4] bit is cleared and the XOFF interrupt disappears.

---

#### Note

When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

---

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UART\_EFR[1-0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UART\_EFR[1-0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

#### 12.1.4.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT. As soon as the RX FIFO reaches the trigger level programmed by UART\_TCR[7-4] RX\_FIFO\_TRIG\_START, two XON1 characters are sent, so the data transfer recovers.

---

#### Note

If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

---

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

#### 12.1.4.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UART\_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

---

#### Note

The combination of 7-bit character plus space parity is not supported.

---

Autobauding mode is selected when the UART\_MDR1[2-0] MODE\_SELECT bit field is set to 0x2. In UART autobauding mode, UART\_DLL, UART\_DLH, and UART\_LCR[5-0] bit field settings are not used; instead, the UART\_UASR register is updated with the configuration detected by the autobauding logic.

### UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UART\_LCR, UART\_DLL, and UART\_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UART\_MDR1[2-0] MODE\_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115.2 bps (10 possibilities)

#### 12.1.4.4.8.1.3.5 Error Detection

When the UART\_LSR\_UART register is read, the UART\_LSR\_UART[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UART\_LSR\_UART register and then reading the UART\_RHR register identifies errors in a character.

Reading the UART\_RHR register updates the BI, FE, and PE bits (see [Table 12-65](#) for the UART mode interrupts).

The UART\_LSR\_UART[7] RX\_FIFO\_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

---

#### Note

Reading the UART\_LSR\_UART register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UART\_RHR register.

---

Reading the UART\_LSR\_UART register clears the OE bit if it is set (see [Table 12-65](#) for the UART mode interrupts).

#### 12.1.4.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the Host CPU with the UART\_IIR\_UART[5-1] IT\_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the Host CPU must:

- Reset the RX FIFO.
- Read the UART\_RESUME register, which clears the internal flag.

#### 12.1.4.4.8.1.3.7 Time-Out and Break Conditions

##### 12.1.4.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (RX) is high for a time that equals 4x the programmed word length + 12 bits or manually configured amount of baud clocks, if a value other zero is set in the timeout register. RX is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on RX.

There are two modes of operation:

- In default operation on the UART\_EFR2[6] TIMEOUT\_BEHAVE is set to 0. For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on RX or when the UART\_RHR register is read.
- Optionally, for choose to enable the timeout counter even if no character has been received by setting UART\_EFR2[6] TIMEOUT\_BEHAVE bit. This will generate periodic interrupts if the RX line remains idle. In this mode the counter will auto-reset when a timeout has been reached. Reading the UART\_IIR\_UART will clear the interrupt, but not the counter.

##### 12.1.4.4.8.1.3.7.2 Break Condition

When a break condition occurs, TX is pulled low. A break condition is activated by setting the UART\_LCR[6] BREAK\_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UART\_LSR\_UART[6] TX\_SR\_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK\_EN bit to 1.

The break condition is asserted while the BREAK\_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

### 12.1.4.4.8.2 RS-485 Mode

#### 12.1.4.4.8.2.1 RS-485 External Transceiver Direction Control

The UART\_MDR3[4] DIR\_EN bit enables hardware control over an external transceiver to support RS-485. The direction signal comes across the DIR port. The direction polarity is controlled by the UART\_MDR3[3] DIR\_POL bit. The direction is determined by the hardware monitoring the TX FIFO and the TX shift register. When both are empty the transceiver is set to RX. There is a guard band delay counter of 3 bit clock cycles after the TX shift register is going empty to allow time for the stop bit to transition through the transceiver before a direction change to receive might be applied.

Figure 12-87 shows the direction control.

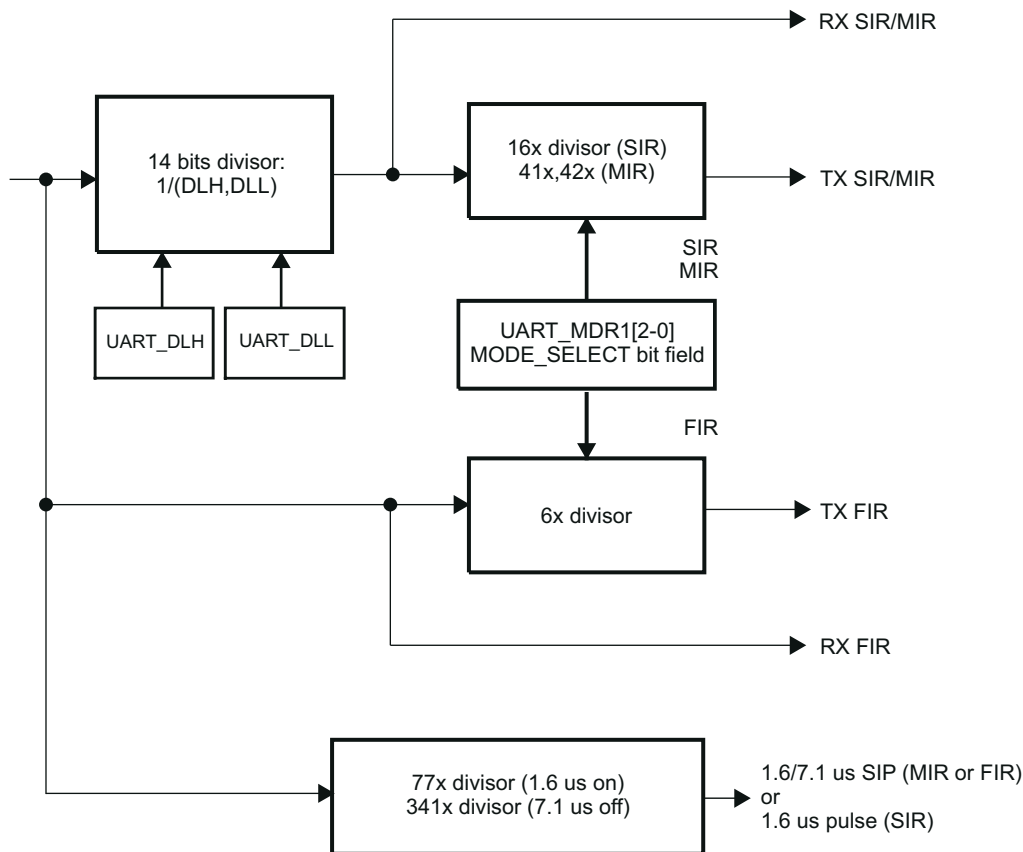

**Figure 12-87. RS-485 External Transceiver Direction Control**

### 12.1.4.4.8.3 IrDA Mode

#### 12.1.4.4.8.3.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-88 shows the baud rate generator and associated controls.

uart-033

Figure 12-88. IrDA Baud Rate Generator

### CAUTION

Before initializing or modifying clock parameter controls (UART\_DLH, UART\_DLL), MODE\_SELECT=DISABLE (UART\_MDR1[2-0] MODE\_SELECT) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

#### 12.1.4.8.3.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16× baud rate)
- MIR mode: Divisor value = Operating frequency/(41×/42× baud rate)
- FIR mode: Divisor value = None

Table 12-82 lists the IrDA baud rate settings.

Table 12-82. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 μs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 μs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 μs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 μs
57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 μs
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 μs

**Table 12-82. IrDA Baud Rate Settings (continued)**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
0.576 Mbps	MIR	41×/42×	1/4	2	0.5756 Mbps <sup>(1)</sup>	0	+1.63/-0.80	416 ns
1.152 Mbps	MIR	41×/42×	1/4	1	1.1511 Mbps <sup>(1)</sup>	0	+1.63/-0.80	208 ns
4 Mbps	FIR	6×	4 PPM	–	4 Mbps	0	0	125 ns

(1) Average value

### Note

Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

#### 12.1.4.4.8.3.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

##### 12.1.4.4.8.3.3.1 IR RX Polarity Control

The UART\_MDR2[6] IRRXINVERT bit provides the flexibility to invert the RX pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.

##### 12.1.4.4.8.3.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the RX input can be disabled by the UART\_ACREG[5] DIS\_IR\_RX bit.

##### 12.1.4.4.8.3.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART\_XON1\_ADDR1[7-0] XON\_WORD1 and UART\_XON2\_ADDR2[7-0] XON\_WORD2 bit fields.

Setting the UART\_EFR[0] bit to 1 selects address1 checking. Setting the UART\_EFR[1] bit to 1 selects address2 checking. Setting the UART\_EFR[1-0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

##### 12.1.4.4.8.3.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART\_MDR1[7] FRAME\_END\_MODE bit to 0. The Host CPU writes the value of the frame length to the UART\_TXFLH and UART\_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the UART\_MDR1[7] FRAME\_END\_MODE bit to 1. The Host CPU writes 1 to the UART\_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the Host CPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

##### 12.1.4.4.8.3.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the Host CPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the Host CPU writes 1 to the UART\_ACREG[2] SCTX\_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART\_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

#### **12.1.4.4.8.3.3.6 Error Detection**

When the UART\_LSR\_UART register is read, the UART\_LSR\_UART[4-2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see [Table 12-66](#)). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

#### **12.1.4.4.8.3.3.7 Underrun During Transmission**

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the Host CPU must:

- Reset the TX FIFO.
- Read the UART\_RESUME register, which clears the internal flag.

This function can be disabled by the UART\_ACREG[4] DIS\_TX\_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

#### **12.1.4.4.8.3.3.8 Overrun During Receive**

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 12.1.4.4.8.1.3.6, Overrun During Receive](#)).

#### **12.1.4.4.8.3.3.9 Status FIFO**

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART\_SFREGH[3-0] MSB and UART\_SFREGL[3-0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART\_SFLSR register. Reading the UART\_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The Host CPU uses the frame-length information to locate the frame boundary in the received frame data. The Host CPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the Host CPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

#### **12.1.4.4.8.3.3.10 Multi-drop Parity Mode with Address Match**

Multi-drop mode is enabled in the UART\_EFR2 register.

Address matching mode is only available with 8 bit character length setting. UART\_LCR[1-0] CHAR\_LENGTH bit fields should always be set to 0x11 (8 bits) prior to enabling the feature.

This mode allows the transmitter to send data on a line where multiple receivers are connected, when supported. In this mode, a set parity bit is used to mark an address, and a parity of 0 denotes data.

This setting affects how the parity is generated. Writing a 0x1 into the UART\_ECR[0] A\_MULTIDROP bit will set the parity bit for the next byte to be sent, which will then be considered an address, for sending a data frame, the UART\_ECR[0] A\_MULTIDROP bit has to be cleared.

On reception if the feature is enabled by setting the UART\_EFR2[2] MULTIDROP bit to 0x1 incoming frames with parity set to 0x1 are treated as address frames and with parity set to 0x0 as data frames. The receiver will drop all data frames until a matching address frame was found.

The matching address is determined by the values set in UART\_MAR, UART\_MMR and UART\_MBR registers and the value set in UART\_EFR2[7] BROADCAST bit.

Table 12-83 summarizes the operation of address matching based on the mentioned values.

**Table 12-83. Details of address matching**

Received frame	Received parity	Frame type	UART_MAR	UART_MMR	UART_MBR	UART_EFR2[7] BROADCAST	Operation of receiver	Address matching
0xXX <sup>(2)</sup>	0	DATA	X <sup>(1)</sup>	X <sup>(1)</sup>	0xXX <sup>(2)</sup>	X <sup>(1)</sup>	Drops data until matching address found	N/A
0xXX <sup>(2)</sup>	1	ADDRESS	0xXX <sup>(2)</sup>	0x00	0xXX <sup>(2)</sup>	0	Matches any address	Yes
0xEF	1	ADDRESS	0xXX <sup>(2)</sup>	0xXX <sup>(2)</sup>	0xEF	1	Matches broadcast address	Yes
0x1A	1	ADDRESS	0x1A	0xFF	0xXX <sup>(2)</sup>	0	Single address match	Yes
0xF5	1	ADDRESS	0xF3	0xF9	0xXX <sup>(2)</sup>	0	Group address match	Yes

(1) X indicates a do not care bit value

(2) 0xXX indicates a do not care 8 bit hexadecimal value

The possible values for matching address can be calculated in the following way:

- Single and Group addresses can be formed by masking the UART\_MAR registers value with the value set in the UART\_MMR register, bits set to 0x0 in the UART\_MMR register result in do not care values.
- Broadcast addresses can be set in the UART\_MBR register if broadcast address is enabled in the UART\_EFR2[7] BROADCAST bit, the module will match on received address frames containing the broadcast address.
- For more details, see example below:
  - UART\_MAR: 0xF3, UART\_MMR: 0xF9, UART\_MBR: 0xFF
  - Single and Group addresses: 0xF1, 0xF3, 0xF5, 0xF7
  - Broadcast addresses: 0xFF

If an address match occurred the matching address value can be obtained from the UART\_RHR register in the following way:

- If the FIFO is disabled or the threshold is set to 0x1, the matching address can be directly read from UART\_RHR as the FIFO will not be overwritten.
- If the FIFO is enabled or the threshold is greater than 0x1, the matching address will be the latest frame in the FIFO with a parity error bit set.

For received data, the parity error bit in the UART\_LSR\_UART register is set when a bit with a parity of 0x1 is received indicating an address frame and the received address matches based on the values of UART\_MAR, UART\_MMR, UART\_MBR and UART\_EFR2[2] MULTIDROP bit.

In Multi-drop mode no parity is used, as the parity bit is used to differentiate address and data frames. The parity error bit is used for indicating an address match.

For enabling the interrupt generation for address matching UART\_IER\_UART[2] LINE\_STS\_IT bit has to be set to 0x1.

An interrupt for the matching address can be identified by reading the UART\_IIR\_UART[5-1] IT\_TYPE bit fields, a value of 0x00011 indicates a receiver line status error. After the UART\_LSR\_UART[2] RX\_PE bit has to be read, a value of 0x1 indicates that an address match occurred. The reception of a frame is indicated with a value

of 0x1 in the UART\_LSR\_UART[0] RX\_FIFO\_E bit as the matching value is written into the FIFO regardless of the frame type (data or address). UART\_LSR\_UART[7] RX\_FIFO\_STS bit will also be set to 0x1 as the parity error bit is used to indicate a matching address.

Note that the operation of the UART\_LSR\_UART[2] RX\_PE bit depends on the value set in UART\_EFR2[2] MULTIDROP bit. If UART\_EFR2[2] MULTIDROP bit is set to 0x0, UART\_LSR\_UART[2] RX\_PE bit is used to indicate a received parity error. If UART\_EFR2[2] MULTIDROP bit is set to 0x1, the receiver is in Multi-drop Address Match mode, thus the value in UART\_LSR\_UART[2] RX\_PE bit is used to indicate an address match.

The interrupt is cleared the same way in both operation modes: reading the UART\_LSR\_UART register updates the values.

#### 12.1.4.4.8.3.3.11 Time-guard

The time-guard feature enables the UART interface to operate with slow remote devices.

When set, it will insert a number of idle states between transmitting two characters, the length of which can be set in the UART\_TIMEGUARD register. The value in the register defines the number of baud clocks of idle period to insert.

This idle state essentially acts like a long stop bit.

#### 12.1.4.4.8.3.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

##### 12.1.4.4.8.3.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART\_ACREG[1] ABORT\_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

#### CAUTION

When the TX FIFO is not empty and the UART\_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

##### 12.1.4.4.8.3.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-μs pulse duration methods. The UART\_ACREG[7] PULSE\_TYPE bit selects the pulse width method in the transmit mode.

##### 12.1.4.4.8.3.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART\_MDR1[2-0] MODE\_SELECT = 0x0) and the UART\_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART\_LCR[1-0] CHAR\_LENGTH bit field = 0x3 (8 data bits)
- UART\_LCR[2] NB\_STOP bit = 0x0 (1 stop-bit)
- UART\_LCR[3] PARITY\_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

#### 12.1.4.4.8.3.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the CPU reads the line status register (UART\_LSR\_UART) to detect errors in the received frame.

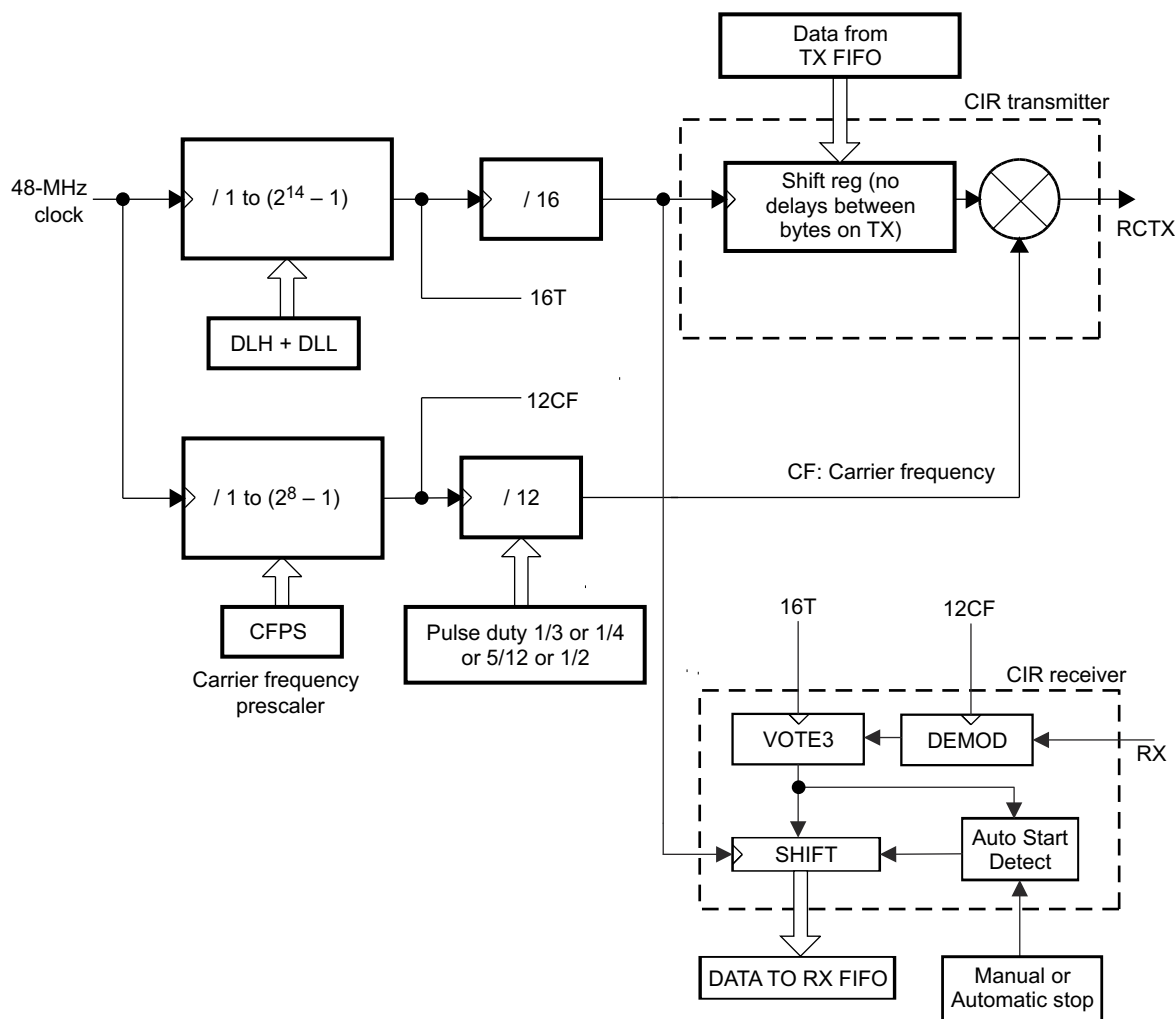

When the UART\_MDR1[6] SIP\_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP\_MODE bit is set to 0, SIP transmission depends on the UART\_ACREG[3] SEND\_SIP bit.

The CPU can set the SEND\_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

#### 12.1.4.4.8.4 CIR Mode

##### 12.1.4.4.8.4.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the Host CPU must develop a data structure that combines 1 and 0 with a  $t$  period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 12-89.

uart-034

Figure 12-89. CIR Mode Block Components

Based on the requested modulation frequency, the UART\_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

Dividing value = (FCLK / 12) / MODfreq

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

#### Note

The UART\_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART\_MDR2 register. [Table 12-84](#) shows the duty cycle.

**Table 12-84. CIR Duty Cycle**

UART_MDR2[5-4] CIR_PULSE_MODE	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

#### 12.1.4.4.8.4.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

##### 12.1.4.4.8.4.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 12.1.4.4.8.3.3.1, IR RX Polarity Control](#)).

##### 12.1.4.4.8.4.2.2 CIR Transmission

In transmission, the Host CPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a  $t$  period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART\_MDR1[5] SCT bit and the UART\_ACREG[2] SCTX\_EN bit, depending on the timer status
  - Using the UART\_IIR\_UART[5] TX\_STATUS\_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

##### 12.1.4.4.8.4.2.3 CIR Reception

In reception, there are 2 ways to stop it

- The Host CPU can disable the reception by setting the UART\_ACREG[5] DIS\_IR\_RX bit to 1. When it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the UART\_ACREG[5] DIS\_IR\_RX bit must be set to 0.
- Using a specific mechanism, depending on the value set in the BOF length register (UART\_EBLR), allows stopping automatically the reception. If the value set in the UART\_EBLR register is different than 0, this feature is enabled and counts a number of bits received at 0. When the counter achieves the value defined in the UART\_EBLR register, the reception is automatically stopped and UART\_IIR\_CIR[2] RX\_STOP\_IT bit is set. When a 1 is detected on the RX pin, the reception is automatically enabled.

There is a limitation when receiving data in UART CIR mode. The IrDA transceivers on the market have a common characteristic that shrinks the hold time of the received modulation pulse. The UART filtering schema on receiving is based on the same encoding mechanism used in transmission.

For the following scenario:

- shift register period: 0.9us
- modulation frequency: 36kHz
- duty cycle: 1/4 of a modulation frequency period

So the data sent in those conditions would look like 7us pulses within 28us period. The UART expects to receive similar incoming data on receive, but available transceiver timing characteristics typically send 2us modulated pulses. Those will be filtered out and RX FIFO will not receive any data.

This does not affect UART CIR mode in transmission.

---

#### Note

The CIR RX demodulation can be bypassed by setting the UART\_MDR3[0] DISABLE\_CIR\_RX\_DEMOD bit.

---

#### 12.1.4.5 UART Programming Guide

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

#### Note

Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 12.1.4.4.7.1, Register Access Modes](#).

#### 12.1.4.5.1 UART Global Initialization

##### 12.1.4.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART.

For more information, see , *UART Integration*.

##### 12.1.4.5.1.2 UART Module Global Initialization

The procedure in [Table 12-85](#) can be used to initialize UART when performing software reset.

**Table 12-85. UART Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	=1

#### 12.1.4.5.2 UART Mode selection

[Table 12-86](#) describes how to set different register access mode.

**Table 12-86. UART Configure Register Access Mode**

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7-0]	#0xBF
Set the register access mode B	UART_LCR[7-0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

#### 12.1.4.5.3 UART Submode selection

This section describes how to set different register access submode.

**Table 12-87. UART Configure Register Access Submode TCR\_TLR**

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see <a href="#">Table 12-86</a>	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see <a href="#">Table 12-86</a>	0x1

**Table 12-87. UART Configure Register Access Submode TCR\_TLR (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

**Table 12-88. UART Configure Register Access Submode MSR\_SPR**

Step	Register/Bit Field/Programming Model	Value
First option: configure the submode MSR_SPR		
Configure mode B	see <a href="#">Table 12-86</a>	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
Second option: configure the submode MSR_SPR		
Configure mode B	see <a href="#">Table 12-86</a>	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

**Table 12-89. UART Configure Register Access Submode XOFF**

Step	Register/Bit Field/Programming Model	Value
Configure of the XOFF		
Configure B	see <a href="#">Table 12-86</a>	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

#### 12.1.4.5.4 UART Load FIFO trigger and DMA mode settings

##### 12.1.4.5.4.1 DMA mode Settings

To enable and configure program the DMA mode, perform the following steps:

**Table 12-90. DMA Mode Settings**

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0
Select the DMA mode, for more information see <a href="#">Section 12.1.4.4.6.4</a>	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see <a href="#">Section 12.1.4.4.6.4</a>	UART_SCR[2-1] DMA_MODE_2	-

##### 12.1.4.5.4.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

**Table 12-91. Load FIFO Triggers Defined by the FCR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-87</a>	0x-
Set the desire RX FIFO trigger level	UART_FCR[5-4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7-6] RX_FIFO_TRIG	0x-

**Table 12-92. Load FIFO Triggers Defined by the TLR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-87</a>	0x-
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA	0x-

**Table 12-93. Load FIFO Triggers Defined by the Concatenated Value**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-87</a>	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA UART_FCR[7-6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA UART_FCR[5-4] TX_FIFO_TRIG	0x-

#### 12.1.4.5.5 UART Protocol, Baud rate and interrupt settings

##### 12.1.4.5.5.1 Baud rate settings

**Table 12-94. UART Baud Rate Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Switch to register configuration mode B	see <a href="#">Table 12-86</a>	
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 12-86</a>	
Disable sleep mode	UART_IER_UART[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see <a href="#">Table 12-86</a>	
Set the appropriate divisor value	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x-

##### 12.1.4.5.5.2 Interrupt settings

**Table 12-95. UART Interrupt Settings**

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see <a href="#">Table 12-86</a>	0x7
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 12-86</a>	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER_UART[7] CTS_IT UART_IER_UART[6] RTS_IT UART_IER_UART[5] XOFF_IT UART_IER_UART[4] SLEEP_MODE UART_IER_UART[3] MODEM_STS_IT UART_IER_UART[2] LINE_STS_IT UART_IER_UART[1] THR_IT UART_IER_UART[0] RHR_IT	0x-

##### 12.1.4.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

**Table 12-96. UART Protocol Settings**

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see <a href="#">Section 12.1.4.4.8.1.3.1</a> , <i>Frame Formatting</i>	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1-0] PARITY_LENGTH	0x-

**Table 12-96. UART Protocol Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Switch to register operational mode	UART_LCR[7] DIV_EN	0
	UART_LCR[6] BREAK_EN	

#### 12.1.4.5.5.4 UART/RS-485/IrDA(SIR/MIR/FIR)/CIR

**Table 12-97. UART Mode Selection**

Step	Register/Bit Field/Programming Model	Value
Load the desired UART/IrDA (SIR, MIR, FIR)/CIR modes, see <a href="#">Section 12.1.4.4.7.2, UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</a>	UART_MDR1[2-0] MODE_SELECT	0x-
Load the desired RS-485 mode, see <a href="#">Section 12.1.4.4.7.2, UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</a>	UART_MDR3[4] DIR_EN	0x1

#### 12.1.4.5.5.5 UART Multi-drop Parity Address Match Mode Configuration

**Table 12-98. UART Multi-drop Parity Address Match Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Disable receive mode	UART_ECR[3] RX_EN	0
Enable Multi-drop parity Address match mode	UART_EFR2[2] MULTIDROP	1
Set the matching device address	UART_MAR[7-0] ADDRESS	0x-
Set the address match masking	UART_MMR[7-0] MASK	0x-
Set the broadcast address match	UART_MBR[7-0] BROADCAST_ADDRESS	0x-
Enable broadcast address matching if needed	UART_EFR2[7] BROADCAST	1
Enable receive mode	UART_ECR[3] RX_EN	1

#### 12.1.4.5.6 UART Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

##### 12.1.4.5.6.1 Hardware Flow Control Configuration

**Table 12-99. UART Hardware Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-87</a>	0x7
Load the start and halt trigger value.	UART_TCR[7-4] AUTO_RTS_START	0x-
	UART_TCR[3-0] AUTO_RTS_HALT	
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN	0x-
	UART_EFR[6] AUTO_RTS_EN	

##### 12.1.4.5.6.2 Software Flow Control Configuration

**Table 12-100. UART Software Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see <a href="#">Table 12-89</a>	
Load the software control characters	UART_XON1_ADDR1[7-0] XON_WORD1	0x-
	UART_XON2_ADDR2[7-0] XON_WORD2	
	UART_XOFF1[7-0] XOFF_WORD1	
	UART_XOFF2[7-0] XOFF_WORD2	
Set the register access submode TCR_TLR	see <a href="#">Table 12-87</a>	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	--

**Table 12-100. UART Software Flow Control Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Load start and halt trigger value for software flow control	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable special character function (0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3-0] SW_FLOW_CONTROL	0x-

#### 12.1.4.5.7 IrDA Programming Model

##### 12.1.4.5.7.1 SIR mode

###### 12.1.4.5.7.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

**Table 12-101. SIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate(115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x1A 0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

###### 12.1.4.5.7.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

**Table 12-102. SIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x1A 0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 6 bytes	UART_TXFLL[7-0] TXFLL	0x06
Set the seven starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
Set SIR pulse width to be 1.6 $\mu$ s	UART_ACREG[7] PULSE_TYPE	1

##### 12.1.4.5.7.2 MIR mode

###### 12.1.4.5.7.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 12-103. MIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (1.152 bps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set MIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force outputs DTR and RTS to active	UART_MCR[1-0]	0x3
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

#### 12.1.4.5.7.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 12-104. MIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7-0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

#### 12.1.4.5.7.3 FIR mode

##### 12.1.4.5.7.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

**Table 12-105. FIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB	0x0
	UART_DLH[7-0] CLOCK_MSB	
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see <a href="#">Section 12.1.4.5.4</a> , Load FIFO trigger and DMA mode settings	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7-0] RXFLL	0xA
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00

**Table 12-105. FIR Mode Receive Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

#### 12.1.4.5.7.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

**Table 12-106. FIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see <a href="#">Section 12.1.4.5.4, Load FIFO trigger and DMA mode settings</a>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Set FIR mode and enable auto-SIP mode	UART_MDR1[7-0]	0x45
Set frame length	UART_TXFLL[7-0] TXFLL UART_TXFLH[7-0] TXFLH	0x4 0x0
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	1
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

## 12.2 High-speed Serial Interfaces

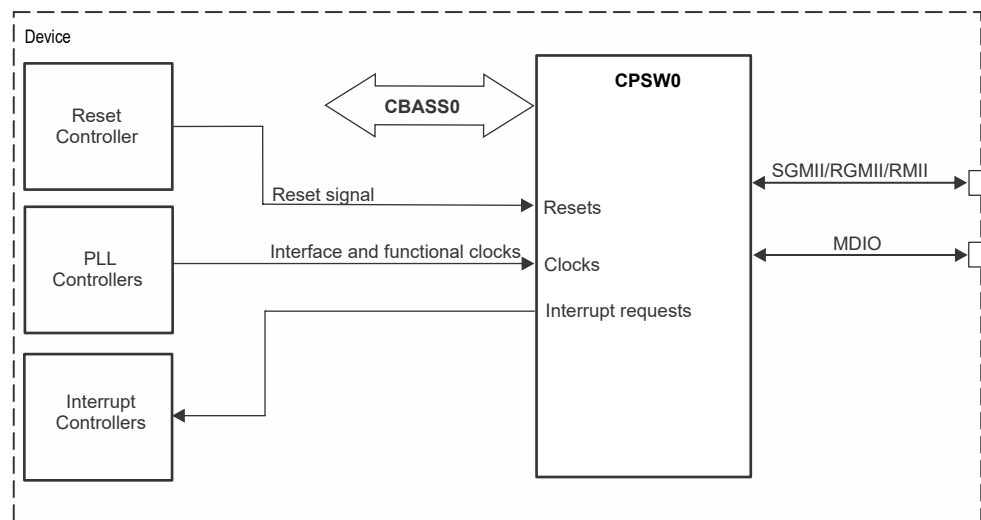

## 12.2.1 Gigabit Ethernet Switch (CPSW3G)

This chapter describes the Gigabit Ethernet Switch (CPSW3G) subsystem in the device.

### 12.2.1.1 CPSW0 Overview

The 3-port Gigabit Ethernet Switch (CPSW0) subsystem provides Ethernet packet communication for the device and can be configured as an Ethernet switch.

Figure 12-90 shows the CPSW0 module overview.

**Figure 12-90. CPSW0 Overview**

#### 12.2.1.1.1 CPSW0 Features

The 3-port CPSW0 subsystem provides the following features:

- Two Ethernet ports (port 1 and 2) with selectable SGMII, RGMII and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port (port 0)
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Cut through switch support
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
  - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
  - CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Wire rate switching (802.1d)
- Non-Blocking switch fabric
- Time Sensitive Network Support
  - IEEE P802.3br Interspersing Express Traffic
  - IEEE 802.1Qbv Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
  - 512 ALE table entries
  - Configurable number of addresses plus VLANs

- Wire rate lookup
- Host controlled time-based aging and/or auto-aging
- Spanning tree support
- L2 address lock and L2 filtering support
- MAC authentication (802.1x)
- Receive-based or destination-based Multicast and Broadcast rate limits
- MAC address blocking
- Source port locking
- OUI (Vendor ID) host accept/deny feature
- Configurable number of classifier/policers (32)
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- EtherStats and 802.3Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Ethernet Mac transmit to Ethernet Mac receive Loopback mode (digital loopback) supported
- CPSGMII Loopback Modes (transmit to receive)
- Maximum frame size of 2024 bytes
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Host port CPPI Streaming Packet Interface (CPPI\_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCDED)

#### **12.2.1.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

---

#### **12.2.1.1.3 CPSW Terminology**

**Terminology:**

<b>AVB</b>	Audio Video Bridging
<b>AVBTP</b>	Audio Video Bridging Transport Protocol
<b>BCCA</b>	Best Controller Clock Algorithm
<b>CFI</b>	Canonical Format Indicator
<b>CPPI</b>	Communications Port Programming Interface
<b>CPSW</b>	Common Platform Switch
<b>DLR</b>	Device Level Ring
<b>DSCP</b>	Differentiated Services Code Point
<b>EEE</b>	Energy Efficient Ethernet
<b>EMAC</b>	Ethernet Media Access Control
<b>EOP</b>	End of Packet
<b>EOQ</b>	End of Queue
<b>IPG</b>	Inter-Packet Gap
<b>LPI</b>	Low Power Indicator
<b>MDIO</b>	Management Data Input/Output
<b>MOF</b>	Middle of Frame
<b>OUI</b>	Organizationally Unique Identifier
<b>PFC</b>	Priority based Flow Control
<b>PTP</b>	Precision Time Protocol
<b>RMON</b>	Remote Monitoring
<b>RTCP</b>	RTP Control Protocol
<b>RTP</b>	Real-time Transport Protocol
<b>SCR</b>	Switched Central Resource
<b>SRP</b>	Stream Reservation Protocol
<b>TOS</b>	Type of Service
<b>VLAN</b>	Virtual Local Area Network

### 12.2.1.2 CPSW0 Environment

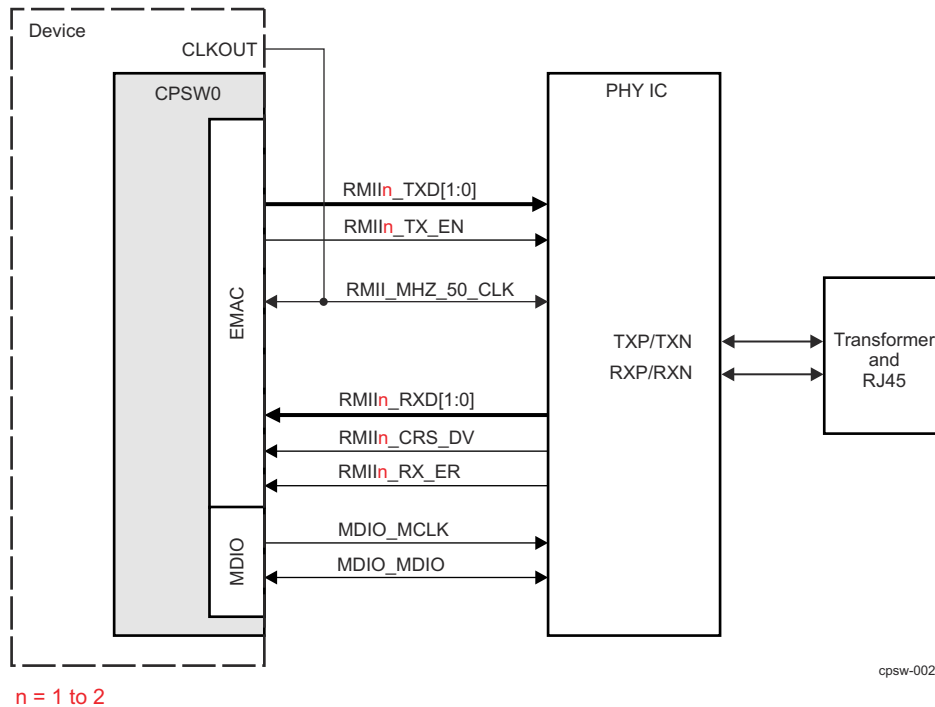

This section describes the CPSW0 external connections (environment).

#### 12.2.1.2.1 CPSW0 RMII Interface

Figure 12-91 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system. The individual CPSW0 and MDIO signals for the RMII interface are summarized in Table 12-107.

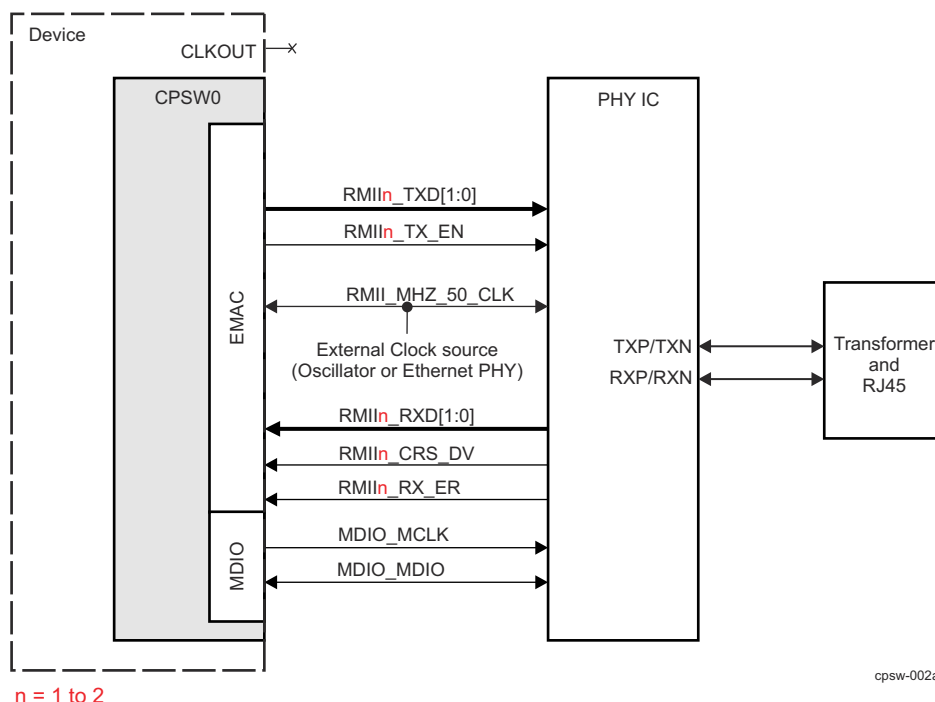

The CPSW0 module integrated in the device supports internal and external clock sources in RMII mode. Figure 12-91 shows the internal clock source for RMII\_MHZ\_50\_CLK clock. It is 50 MHz clock source that is provided on the CLKOUT0 device pin. This clock has to be routed on the PCB to the RMII\_REF\_CLK device pin and the external PHY, RMII clock input.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 12-91. RMII Interface Typical Application (Internal Clock Source)**

Figure 12-92 shows the external clock source for RMII\_MHZ\_50\_CLK clock. In this case a 50 MHz clock is available on the PCB and it can be sourced from an oscillator or from the Ethernet PHY. This externally generated clock should be routed to both RMII\_REF\_CLK device pin and the external PHY, RMII clock input.

**Figure 12-92. RMII Interface Typical Application (External Clock Source)**
**Table 12-107. RMII I/O Description**

Signal <sup>(2)</sup>	Device Pin(s)	I/O <sup>(1)</sup>	Description
RMIIin_TXD[1:0]	RMIIin_TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMIIin_TX_EN is asserted.
RMIIin_TX_EN	RMIIin_TX_EN	O	RMII transmit enable. The transmit enable signal indicates that the RMIIin_TXD[1:0] pins are generating data for use by the PHY. RMIIin_TX_EN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	RMII_REF_CLK	I	RMII 50MHz reference clock.  The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RMIIin_RXD[1:0]	RMIIin_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMIIin_CRS_DV is asserted and RMIIin_RX_ER is de-asserted.
RMIIin_CRS_DV	RMIIin_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMIIin_RX_ER	RMIIin_RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MCLK	MDIO0_MDC	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO0_MDIO data pin.
MDIO_MDIO	MDIO0_MDIO	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

(2) n 1 to 2

### 12.2.1.2.2 CPSW0 RGMII Interface

Figure 12-93 shows a device with integrated EMAC and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW0 and MDIO signals for the RGMII interface are summarized in Table 12-108.

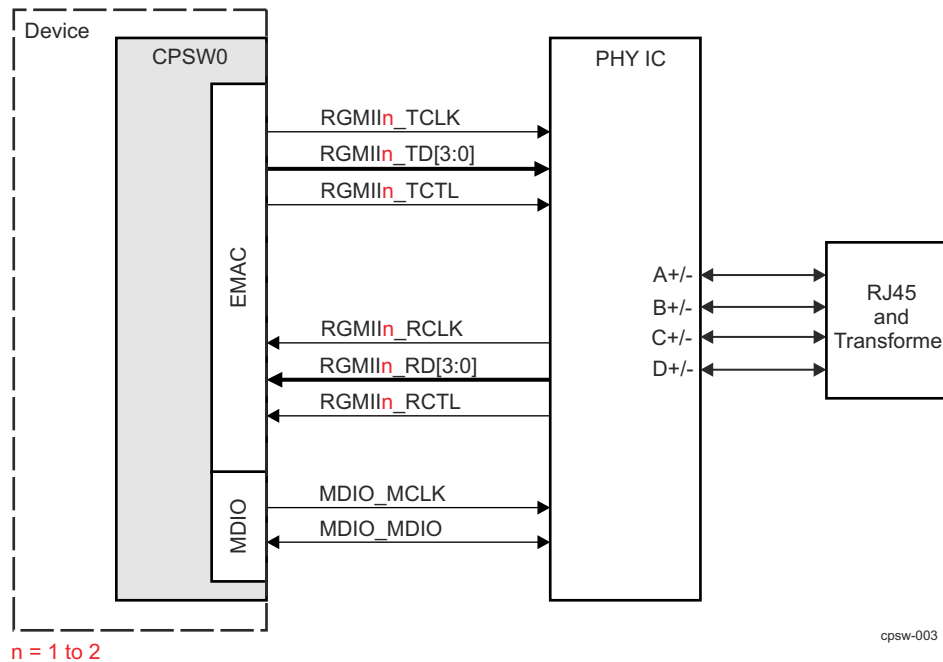

Figure 12-93. RGMII Interface Typical Application

Table 12-108. RGMII I/O Description

Signal <sup>(2)</sup>	Device Pin(s)	I/O <sup>(1)</sup>	Description
RGMII <sub>n</sub> _TD[3:0]	RGMII <sub>n</sub> _TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII <sub>n</sub> _TCTL is asserted.
RGMII <sub>n</sub> _TCTL	RGMII <sub>n</sub> _TX_CTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII <sub>n</sub> _TCLK	RGMII <sub>n</sub> _TxC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RGMII <sub>n</sub> _RD[3:0]	RGMII <sub>n</sub> _RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII <sub>n</sub> _RX_CTL is asserted
RGMII <sub>n</sub> _RCTL	RGMII <sub>n</sub> _RX_CTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII <sub>n</sub> _RCLK	RGMII <sub>n</sub> _RxC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MCLK	MDIO0_MDC	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO0_MDIO pin.
MDIO_MDIO	MDIO0_MDIO	I/O	The MDIO0_MDIO pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

(2) n 1 to 2

---

**Note**

The Control Module registers assign the specific function to the device pads. For more information on Control Module settings, see *Pad Configuration Registers* in *Control Module (CTRL\_MMR)* and the device-specific Datasheet.

---

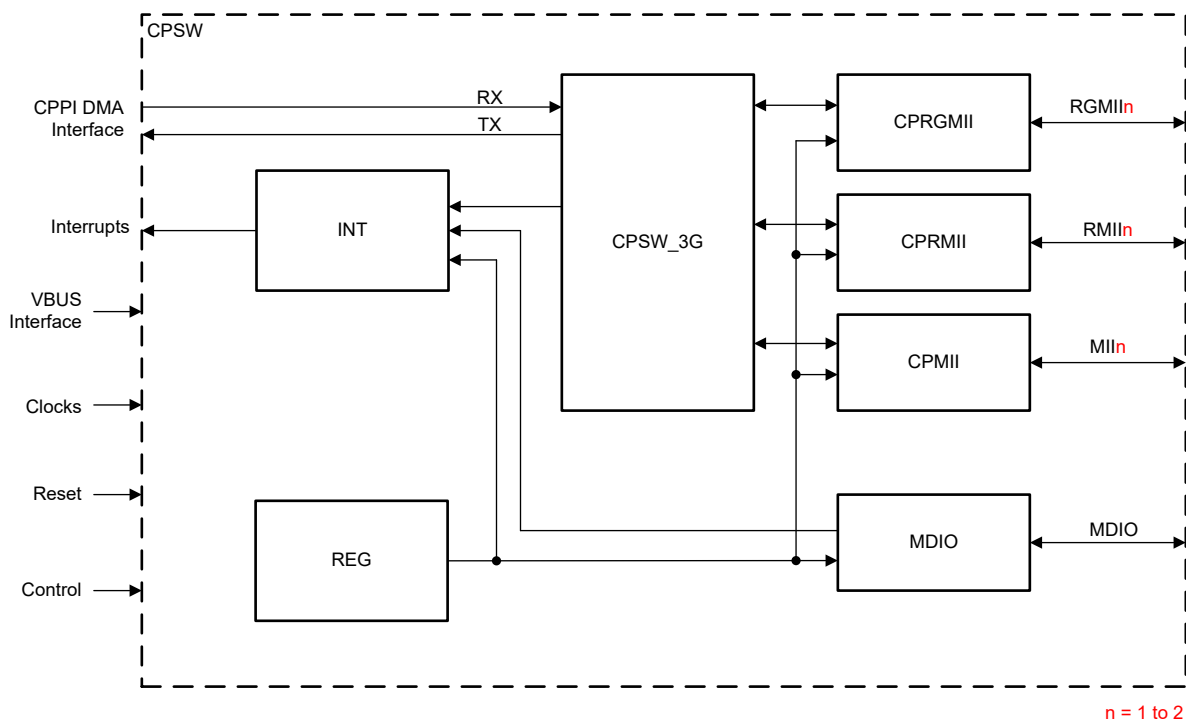

**12.2.1.3 Integration**

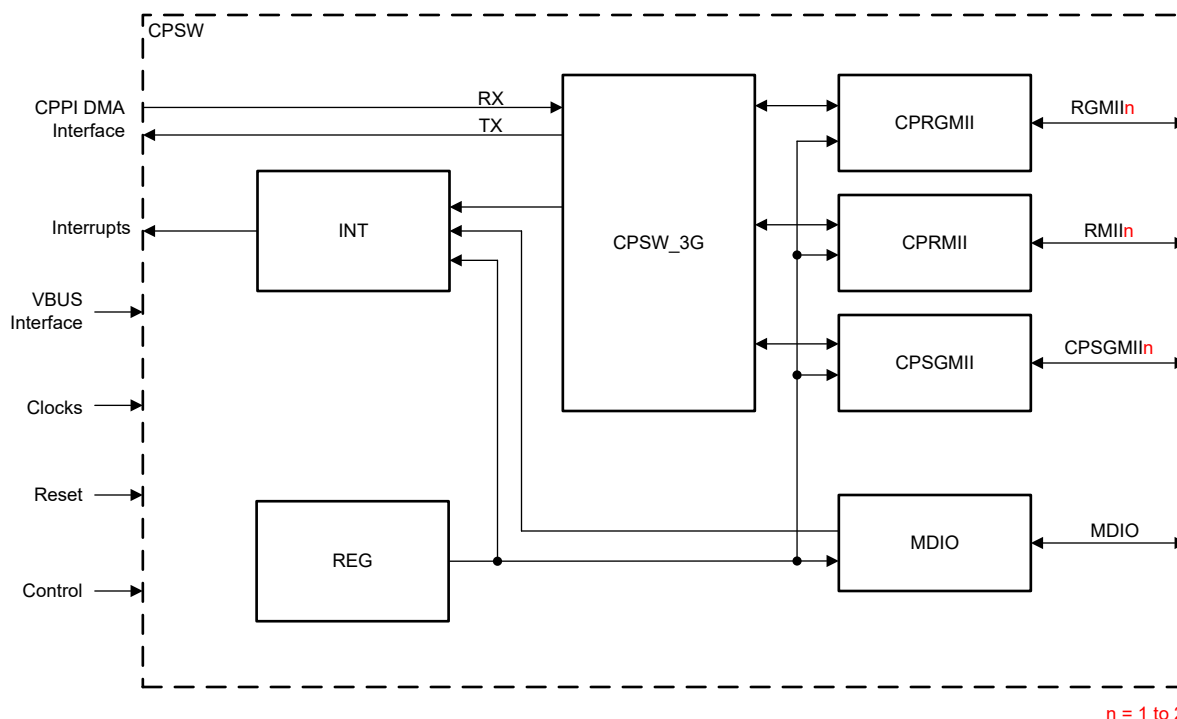

See the *Module Integration* section for information about clocks, resets and hardware requests.

The three-port switch Ethernet subsystem module (CPSW) is compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in [Figure 12-94](#).

The three-port Ethernet subsystem consists of:

- CPSW\_3G
- One SGMII<sub>n</sub> (where n = 1 to 2) interface module
- One RGMII<sub>n</sub> (where n = 1 to 2) interface module
- One RMII<sub>n</sub> (where n = 1 to 2) interface module
- One MII<sub>n</sub> (where n = 1 to 2) interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

**Figure 12-94. CPSW Top Level Block Diagram**

#### 12.2.1.4.2 CPSW Ports

The Ethernet Subsystem has three ports. Port 0 is the Host port (internal to the Subsystem). Port 1 and 2 are the external ports connected to SGMII, RGMII, RMII, MII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI Host Port
- Port1 and 2 are referred to the interfaces SGMII/RGMII/RMII/MII

##### 12.2.1.4.2.1 Interface Mode Selection

The three-port switch (CPSW) Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable SGMII, RMII, RGMII, and MII interfaces.

The interface modes for all 2 Ethernet ports are selected by configuring the Ethernet interface mode selection bitfield (PORT\_MODE\_SEL) in the CTRLMMR\_ENET1\_CTRL and CTRLMMR\_ENET2\_CTRL registers.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

#### 12.2.1.4.3 Clocking

##### 12.2.1.4.3.1 Subsystem Clocking

CPSW clocking summary is shown in *CPSW Integration*.

##### 12.2.1.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

##### 12.2.1.4.3.2.1 RGMII Interface Clocking

RGMII\_RXC, RGMII\_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

#### 12.2.1.4.3.2.2 RMII Interface Clocking

RMII interface clock RMII\_50MHZ\_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

For more details on RMII clocking, please see *CPSW0 Integration*

CTRLMMR\_CLKOUT\_CTRL[4]CLK\_EN and CTRLMMR\_CLKOUT\_CTRL[0]CLK\_SEL bits are used to enable and select the clock source for CLKOUT device pin.

#### 12.2.1.4.3.2.3 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (CPPI\_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW3\_MDIO\_CONTROL\_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

#### 12.2.1.4.4 Software IDLE

The submodule software idle register bits enable CPSW operation to be completely or partially suspended by software control. There are two CPSW submodules that contain software idle register bits. Each of the two submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW module enters the idle state when all two submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the two submodule idle bits. The CPSW\_3G is in the idle state when all two submodules are in the idle state. The CPSW3\_CPSW\_NU\_SOFT\_IDLE\_REG[0] SOFT\_IDLE bit may be set if desired after the submodules are in the idle state. The SOFT\_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

#### 12.2.1.4.5 Interrupt Functionality

CPSW Ethernet Subsystem has six interrupt outputs:

- Cn\_FH\_PEND\_INTR - FHost (from host to Ethernet) level interrupt
- Cn\_TH\_PEND\_INTR - THost (from Ethernet to host) level interrupt
- Cn\_TH\_THRESH\_PEND\_INTR - THost (from Ethernet to host) non-paced level interrupt
- Cn\_MISC\_PEND\_INTR - Miscellaneous non-paced pending interrupt
- ECC\_SEC\_PEND\_INTR: ECC SEC pending interrupt - from CPSW ECC module. This interrupt is also included in the C0\_MISC\_PEND\_INTR if enabled or can be used separately if desired.
- ECC\_DED\_PEND\_INTR: ECC DED pending interrupt - from CPSW ECC module. This interrupt is also included in the C0\_MISC\_PEND\_INTR if enabled or can be used separately.

#### Note

n = 0 to \$num\_cores-1

#### 12.2.1.4.5.1 EVNT\_PEND Interrupt

See [Section 12.2.1.4.7](#), *Common Platform Time Sync (CPTS)* for more details on this interrupt.

#### 12.2.1.4.5.2 Statistics Interrupt (STAT\_PEND0)

The statistics level interrupt (STAT\_PEND0) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement any statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The statistics are mapped into internal memory space and are 32-bits wide. The raw and masked statistics interrupt status may be read by reading the CPSW3\_CPSW\_NU\_CPTS\_INTSTAT\_RAW\_REG and CPSW3\_CPSW\_NU\_CPTS\_INTSTAT\_MASKED\_REG registers, respectively.

The statistics interrupt is enabled by setting to 1h the TS\_PEND\_EN bit in the CPSW3\_CPSW\_NU\_CPTS\_INT\_ENABLE\_REG register.

#### 12.2.1.4.5.3 ECC DED Level Interrupt (ECC\_DED\_INT)

Level interrupt (ECC\_DED\_INT) indicating an ECC double error has been detected.

#### 12.2.1.4.5.4 ECC SEC Level Interrupt (ECC\_SEC\_INT)

Level interrupt (ECC\_SEC\_INT) indicating an ECC single error has been detected and corrected.

#### 12.2.1.4.5.5 MDIO Interrupts

**Normal Mode:** (CPSW3\_MDIO\_POLL\_REG[30] STATECHANGEMODE = 0h)

MDIO\_LINKINT event is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR\_MON field of the CPSW3\_MDIO\_USER\_GROUP\_USER\_PHY\_SEL\_REG\_k register and the corresponding LINKINT\_ENABLE bit is set. The MDIO\_LINKINT event is also captured in the MDIO CPSW3\_MDIO\_LINK\_INT\_MASKED\_REG register. When the GO bit in the CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the CPSW3\_MDIO\_USER\_INT\_MASK\_SET\_REG register is set, the MDIO\_USERINT signal is asserted. The MDIO\_USERINT event is also captured in the CPSW3\_MDIO\_USER\_INT\_MASKED\_REG register.

**State Change Mode:** (CPSW3\_MDIO\_POLL\_REG[30] STATECHANGEMODE = 1h)

In State Change Mode, the MDIO will assert MDIO\_LINKINT[0] when any bit in the MDIO CPSW3\_MDIO\_ALIVE\_REG or CPSW3\_MDIO\_LINK\_REG registers changes due to MDIO operations. The MDIO\_LINKINT event is also captured in the CPSW3\_MDIO\_LINK\_INT\_MASKED\_REG register. MDIO\_LINKINT[1] output is unused in State Change Mode. The CPSW3\_MDIO\_USER\_GROUP\_USER\_PHY\_SEL\_REG\_k registers are unused in state change mode.

**Manual Mode:** (CPSW3\_MDIO\_POLL\_REG[31] MANUALMODE = 1h)

Manual Mode allows software to directly control the MDIO serial clock output (CPSW3\_MDIO\_MANUAL\_IF\_REG[2] MDIO\_MDCLK\_O) and the MDIO serial data output enable (CPSW3\_MDIO\_MANUAL\_IF\_REG[1] MDIO\_OE). Manual Interface Mode is enabled when the MANUALMODE bit is set in the CPSW3\_MDIO\_POLL\_REG register. Manual Mode is intended to be used by software for slow speed general purpose IO operations and not for MDIO PHY operations.

#### 12.2.1.4.6 CPSW\_3G

The CPSW\_3G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW\_3G contains two Ethernet port interfaces (Ethernet port 1 and 2), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW\_3G is shown in [Figure 12-95](#).

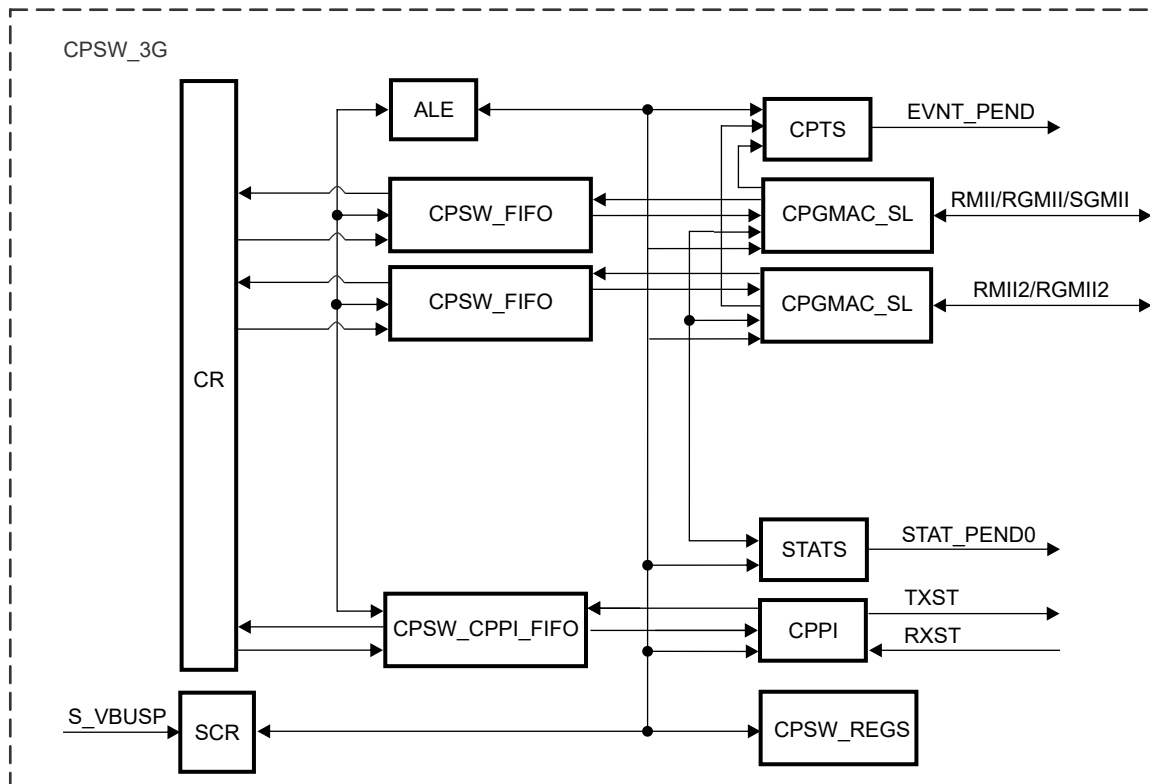

Figure 12-95. CPSW\_3G Block Diagram

#### 12.2.1.4.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines to which port(s) the packet should be forwarded. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the `ENABLE_ALE` bit in the `CPSW3_CPSW_NU_ALE_ALE_CONTROL` register is set. All packets are dropped when the `ENABLE` bit is cleared to 0.

##### 12.2.1.4.6.1.1 Error Handling

In normal operation, the Ethernet port modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the `CPSW3_CPSW_NU_CPSW_NU_ETH_MAC_i_PN_MAC_CONTROL_REG` configuration bit(s) `RX_CEF_EN`, `RX_CSF_EN`, or `RX_CMF_EN` are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

##### 12.2.1.4.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the `ENABLE_BYPASS` bit in the `CPSW3_CPSW_NU_ALE_ALE_CONTROL` register. When in bypass mode, all Ethernet port received packets

are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

#### 12.2.1.4.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the ENABLE\_OUI\_DENY bit in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the SUPER bit set. When ENABLE\_OUI\_DENY bit is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. Broadcast packets will be dropped unless the broadcast address is entered into the table with the SUPER bit set. Unicast packets will be dropped unless the unicast address is in the table with BLOCK and SECURE both set (supervisory unicast packet).

#### 12.2.1.4.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. There are many reasons to drop frames the below drop events are individually counted in CPSW per port statistics counters.

**Table 12-109. Learned Address Control Bits**

Abbreviation	Description
vddc	Dual VLAN or Double VLAN drop counter.
frdc	IPv4 fragmented drop counter.
nldc	IPv4 Protocol or IPv6 Next Header drops due to next header limit drop counter.
etdc	Ether Type field is $\leq 1500$ and the frame size is too small drop counter.
smdc	The Source Address has bit 40 set drop counter.
badc	The Source or Destination Address blocked drop counter.
svdc	The Source Address is locked to a different port drop counter.
des	The Source and Destination are equal and the Source Address is not in the table drop counter.
adc	The Source Address is not in the table in authentication mode drop counter.
vicdc	The VLAN ingress check failed drop counter.
rldc	Rate Limit Drop Counter.
over	Lookup Overflow, the rate of the ALE clock is not sufficient to handle the incoming frame rate (Should never happen).
drop	Packet is dropped and not forwarded.

#### 12.2.1.4.6.1.5 Automotive Security Features

The ALE has many automotive security features that most enterprise switches do not require.

- VLANs can be configured to not allow fragmented IPv4 frames. That is a VLAN can be configured to not allow fragmented IPv4 traffic.
- VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6. Next Header values, for example a VLAN can be configured to only allow TCP traffic in both IPv4 and IPv6 packets.
- Drop invalid Source Addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)

- IEEE802.3 Length Check, drop frames that the IEEE802.3 Length is not contained within the frame. (Ether Types 0-1500)
- Any Source Address can be secured to a port dropping any attempts from other ports to masquerade as a service.
- Any source or destination address can be blocked.
- Per Port or Per VLAN ingress checking, dropping traffic from non-member ports.
- Classification, Policing on L2 and L3 information.

#### **12.2.1.4.6.1.6 CPSW Switching Solutions**

The host port can operate in many different modes as well depending on the functionality of the host. It is important to understand the modes and configure them properly.

The ALE Table is designed to maximize the modes without compromise of the system functionality as well.

##### **12.2.1.4.6.1.6.1 Basics of 3-port Switch Type**

The 3-port switch has a host port, and that port can operate in two fundamental modes. Bridge mode allows the host to extend the switched domain to another network like Wi-Fi or another multi-port switch. In this case the host must be able to see unknown unicast addresses so they can be broadcast to the other network. In Port mode the host need not see any unknown unicast traffic. The CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL[8] EN\_HOST\_UNI\_FLOOD bit determines the host mode for unknown unicast traffic. This bit should only be set if the user is bridging two or more networks together.

The 3-port switch can operate like a two-port switch using the ALE table just for the host info, the only adder is now other VLANs need to be supported for transit traffic between the external ports. This can easily be done using the default VLAN rules so no ALE table entries are used.

The 3-port switch can also operate in a fully authenticated environment where all network nodes are registered via the 802.1x based protocols. In this case the ALE table is filled with network node addresses that have been authenticated

##### **12.2.1.4.6.1.7 VLAN Routing and OAM Operations**

###### **12.2.1.4.6.1.7.1 InterVLAN Routing**

The CPSW module supports wire rate InterVLAN routing for a small number of routes, that is the host will setup an ALE classifier with and associated egress operation that will cause the CPSW to perform particular egress operations. The ALE can optionally check time to live validity as well.

The ALE uses the classifier along with an egress opcode, destination port mask and TTL check field to tell the CPSW to manipulate the packet on the egress. The CPSW will use the opcode along with a per port operation table to process the packet. By setting up the CPSW egress operation table you can replace the DA, SA and VLAN along with optionally updating the time to live IP header field. This allows the CPSW to perform the routing function for a small set of routes without getting the local host/CPU involved.

The Egress opcode will only be use for a classifier match and the packet would normally be sent only to the host. That is the host would have routed the packet but the CPSW has been configured to do the work instead. In the event that the time-to-live check feature is enabled and the time-to-live is either 0 or 1, the packet will not get the egress opcode and instead be sent to the host as if the route is not setup. This allows the host to deal with invalid TTL fields.

###### **12.2.1.4.6.1.7.2 OAM Operations**

The ALE supports OAM loopback on ports so that a remote link can be tested. That is a port placed in OAM loopback will echo packets received on a port back to the port with an egress op of 0xFF which will swap the SA and DA on egress in the CPSW.

Any supervisory packet will not be affected, so the spanning tree and other bridging functions are not affected.

Packets will only be echoed if the port is in OAM loopback mode, the received packet in not a supervisor packet. The port is in a forwarding state and the packet received DA!=SA and there are no errors in the packet.

When a port is in OAM loopback the port will not egress traffic from other ports, no address for loop backed traffic will be learned if enabled. Any packet received on the OAM loopback port with an error will be process as if the port is not in OAM. That is if the host has enabled copy errored frames the errored frames will be sent to the host instead.

#### 12.2.1.4.6.1.8 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwarded for special purposes.

#### 12.2.1.4.6.1.9 Address Table Entry

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 12-110. Learned Address Control Bits**

Bit(s)	Value
Ageable	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

#### Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

#### 12.2.1.4.6.1.9.1 Multicast Address Table Entry

**Table 12-111. Multicast Address Table Entry Bit Values**

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Port Mask(1:0) (PORT\_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Multicast Forward State (MCAST\_FWD\_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT\_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 12.2.1.4.6.1.9.2 OUI Unicast Address Table Entry

**Table 12-112. OUI Unicast Address Table Entry Bit Values**

70:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE (10)	ENTRY_TYPE (01)	Reserved	UNICAST_OUI	Reserved

#### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

#### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (UNICAST\_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

### 12.2.1.4.6.1.9.3 Unicast Address Table Entry (Bit 40 == 0)

**Table 12-113. Unicast Address Table Entry Bit Values**

70:69	68	67:66	65	64	63	62	61:60	59:48	47:0
RESERVED	TRUNK	PORT_NUMBER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TYPE (3h)	RESERVED	UNICAST_ADDRESS

#### Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk number

#### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

#### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

#### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT\_NUMBER.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

#### Touch Indicator (TOUCH)

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

#### Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

#### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

## Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

### 12.2.1.4.6.1.9.4 Multicast Address Table Entry (Bit 40==1)

**Table 12-114. Multicast Address Table Entry Bit Values**

70:69	68:66	65	64	63:62	61:60	59:48	47:0
RESERVED	PORT_MASK	SUPER	IGNMBITS	FWDSTLVL	ENTRY_TYPE (1h)	RESERVED	MULTICAST_A DDRESS

## Port Mask(2:0) (PORT\_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

## Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

## Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

## Forward State Level (FWDSTLVL)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s).

A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

0h = Forwarding

1h = Blocking/Forwarding/Learning

2h = Forwarding/Learning

3h = Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

## Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

## Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### 12.2.1.4.6.1.9.5 VLAN/Unicast Address Table Entry (Bit 40 == 0)

**Table 12-115. Unicast Address Table Entry Bit Values**

70:69	68	67:66	65	64	63	62	61:60	59:48	47:0
RESERVED	TRUNK	PORT_NUM MBER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TY PE (3h)	VLAN_ID	UNICAST_ ADDRESS

**Trunk Indicator (TRUNK)**

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk number

**Port Number (PORT\_NUMBER)**

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

**Block (BLOCK)**

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

**Secure (SECURE)**

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT\_NUMBER.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

**Touch Indicator (TOUCH)**

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

**Ageable (AGEABLE)**

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

**Table Entry Type (ENTRY\_TYPE)**

Address entry. Unicast or multicast determined by address bit 40.

3h: VLAN address entry. Unicast or multicast determined by address bit 40.

**VLAN ID (VLAN\_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Packet Address (UNICAST\_ADDRESS)**

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

### 12.2.1.4.6.1.9.6 VLAN/Multicast Address Table Entry (Bit 40==1)

**Table 12-116. VLAN/Multicast Address Table Entry Bit Values**

70:69	68:66	65	64	63:62	61:60	59:48	47:0
RESERVED	PORT_MASK	SUPER	IGNMBITS	FWDSTLVL	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_AD DRESS

#### Port Mask(2:0) (PORT\_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

#### Forward State Level (FWDSTLVL)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s).

A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

0h = Forwarding

1h = Blocking/Forwarding/Learning

2h = Forwarding/Learning

3h = Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

#### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

#### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### 12.2.1.4.6.1.9.7 Inner VLAN Table Entry

**Table 12-117. Inner VLAN Table Entry**

70:69	68:66	65	64:62	61:60	59:48	47	46:39	38:36
RESERVED	NO_LEARN_M ASK	VLAN_FORCE INGRESS_C HECK	0h	ENTRY_TYPE (1h)	VLAN_ID	NOFRAG	RESERVED	REG_MCAST_F LOOD_INDEX

35:27	26:24	23	22:15	14:12	11:3	2:0
RESERVED	FORCE_UNTAGGED_EGRESS	LMTNXTHDR	RESERVED	UREGMSK	RESERVED	VLAN_MEMBER_LIST

### No Learn Mask (NO\_LEARN\_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

### VLAN Force Ingress Check (VLAN\_FORCE\_INGRESS\_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the ly\_REG\_Py\_VID\_INGRESS\_CHECK bit in the CPSW3\_CPSW\_NU\_ALE\_I0\_ALE\_PORTCTL0 register except this check is for this VLAN only (not all VLANs).

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

### (NOFRAG)

VLAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

### Registered Multicast Flood Index (REG\_MCAST\_FLOOD\_INDEX)

This field indicates which port(s) are the registered multicast flood mask.

### Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)

This field causes the packet VLAN tag to be removed on egress for the specified port(s) (except on port 0).

### VLAN Limit Next Header Control (LMTNXTHDR)

This bit causes frames to be dropped if the Protocol/Nxt Header does not match the CPSW3\_CPSW\_NU\_ALE\_ALE\_NXT\_HDR register values.

### VLAN Unregister Multicast Mask (UREGMSK)

This field indicates which port(s) are the unregistered multicast flood mask.

### VLAN Member List (VLAN\_MEMBER\_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

#### 12.2.1.4.6.1.9.8 Outer VLAN Table Entry

**Table 12-118. Outer VLAN Table Entry**

70:69	68:66	65	64:62	61:60	59:48	47	46:39	38:36
RESERVED	NO_LEARN_MASK	VLAN_FORCE_INGRESS_CHECK	2h	ENTRY_TYPE (2h)	VLAN_ID	NOFRAG	RESERVED	REG_MCAST_FLOOD_INDEX

35:27	26:24	23	22:15	14:12	11:3	2:0
RESERVED	FORCE_UNTAGGED_EGRESS	LMTNXTHDR	RESERVED	UREGMSK	RESERVED	VLAN_MEMBER_LIST

### No Learn Mask (NO\_LEARN\_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

### VLAN Force Ingress Check (VLAN\_FORCE\_INGRESS\_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the ly\_REG\_Py\_VID\_INGRESS\_CHECK bit in the CPSW3\_CPSW\_NU\_ALE\_I0\_ALE\_PORTCTL0 register except this check is for this VLAN only (not all VLANs).

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

### (NOFRAG)

VLAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

### Registered Multicast Flood Index (REG\_MCAST\_FLOOD\_INDEX)

Index into CPSW\_ALE\_MSK\_MUX0 to CPSW\_Ix\_ALE\_MSK\_MUXx register array that is used to create the registered multicast flood mask.

### Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)

This field causes the packet VLAN tag to be removed on egress for the specified port(s) (except on port 0).

### VLAN Limit Next Header Control (LMTNXTHDR)

This bit causes frames to be dropped if the Protocol/Nxt Header does not match the CPSW3\_CPSW\_NU\_ALE\_ALE\_NXT\_HDR register values.

### VLAN Unregister Multicast Mask (UREGMSK)

This field indicates which port(s) are the unregistered multicast flood mask.

### VLAN Member List (VLAN\_MEMBER\_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

#### 12.2.1.4.6.1.9.9 EtherType Table Entry

**Table 12-119. EtherType Table Entry**

70:65	64:62	61:60	59:16	15:0
RESERVED	4h	ENTRY_TYPE (2h)	RESERVED	ETHERTYPE

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### Ether Type (ETHERTYPE)

16-bits Ether Type field.

#### 12.2.1.4.6.1.9.10 IPv4 Table Entry

**Table 12-120. IPv4 Table Entry**

70	69:65	64:62	61:60	59:32	31:0
RESERVED	IGNMBITS	6h	ENTRY_TYPE (2h)	RESERVED	IPV4ADR

### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### IPv4 Address (IPv4ADR)

32-bit IPv4 Address. Any ignored bits must be zero value in the table entry.

#### 12.2.1.4.6.1.9.11 IPv6 Table Entry High

**Table 12-121. IPv6 Table Entry High**

70:64	63	62	61:60	59:0
IGNMBITS	RESERVED	(1h)	ENTRY_TYPE (2h)	IPv6ADR[127:68]

### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### IPv6 Address - upper 64 bits (IPv6ADR[127:68])

This address is split into three fields in the IPv6 High and IPv6 Low table entry. Any ignored bits must be zero in the table entry(s).

#### 12.2.1.4.6.1.9.12 IPv6 Table Entry Low

**Table 12-122. IPv6 Table Entry Low**

70:63	62	61:60	59:0
IPv6ADR[67:60]	1h	ENTRY_TYPE (2h)	IPv6ADR[59:0]

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### IPv6 Address - upper 8 bits (IPv6ADR[67:60])

### IPv6 Address - upper 60 bits (IPv6ADR[59:0])

This address is split into three fields in the IPv6 High and IPv6 Low table entry. Any ignored bits must be zero in the table entry(s).

Note: IPv6 table address entries operate differently than all other table entry types. IPv6 table entries have a high entry concatenated with a low entry. The high entry must have an entry\_pointer value of the low entry\_pointer plus 0x40. Bit six of the entry\_pointer must be set for the high entry and must be zero for the low entry.

#### 12.2.1.4.6.1.10 Multicast Address

Multicast addresses are addresses with bit 40 set. Only destination addresses can be Multicast addresses. The group bit (bit 40) of the source address is reserved in the IEEE standard.

A multicast address of all ones is the broadcast address which can be added to the lookup table if forwarding of broadcast packets need be modified.

#### 12.2.1.4.6.1.10.1 Multicast Ranges

Added IgnMbits to indicate at least one bit of the multicast address is ignored. Up to 10 bits of the multicast address can be ignored to provide the ability to create multiple multicast address ranges.

if ((IgnMbits)&(MultiCastAddress[0] == 0x000)) { MultiCastAddress[0] is ignored in compare }

if ((IgnMbits)&(MultiCastAddress[1:0] == 0x001)) { MultiCastAddress[1:0] is ignored in compare }

if ((IgnMbits)&(MultiCastAddress[2:0] == 0x003)) { MultiCastAddress[2:0] is ignored in compare }

```

if ((IgnMbits)&(MultiCastAddress[3:0]==0x007)) { MultiCastAddress[3:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[4:0]==0x00F)) { MultiCastAddress[4:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[5:0]==0x01F)) { MultiCastAddress[5:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[6:0]==0x03F)) { MultiCastAddress[6:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[7:0]==0x07F)) { MultiCastAddress[7:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[8:0]==0x0FF)) { MultiCastAddress[8:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[9:0]==0x1FF)) { MultiCastAddress[9:0] is ignored in compare}

```

Below is 'C' code to modify ALE MultiCastAddress and IgnMbits when iNumOfBitsToIgnore is greater than zero. Where fGenMask(iOffset,iBitsToMask) creates a Mask for the value provided. For example fGenMask(0,5) will return 0x1F.

```

if(iNumOfBitsToIgnore)
{
    int iIgnClrMsk,iIgnSetMsk;
    iIgnClrMsk=fGenMask(0, iNumOfBitsToIgnore);
    iIgnSetMsk=fGenMask(0, iNumOfBitsToIgnore -1);
    MultiCastAddress &= ~iIgnClrMsk;
    MultiCastAddress |= iIgnSetMsk;
    IgnMbits = 1;
}
else
{
    IgnMbits = 0;
}

```

Multicast Addresses or Ranges can overlap, in the event of an overlap; the higher ALE index will be used.

#### **12.2.1.4.6.1.11 Aging and Auto Aging**

The ALE supports software control or automatic aging of agable addresses.

Any time an agable address is seen as a source address entering from a port the source address entry will be marked as touched.

If the aging timer expires or the software sets the [29] AGE\_OUT\_NOW bit in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL, the aging process will be started.

The aging process will read each ALE entry and for all entries that are an address with or without VLAN that is also agable, the touch check process will be done.

The touch check process will test the TOUCH bit and if clear, the entry will be marked as free, else the TOUCH bit will be cleared.

What this means is that if the aging interval was programmed as one second, any unused entry could stay in the ALE table for 1.000001 to 1.999999 seconds

#### **12.2.1.4.6.1.12 ALE Policing and Classification**

The ALE has a number of configurable classifier engines (policers) that can be used for classification. Classification is a subset of the policing function and uses a policer without the color marking or rate

limiting functions. A policer is a hardware engine that is used for policing. The POLCNTDIV8 field in the CPSW3\_CPSW\_NU\_ALE\_ALE\_STATUS register indicates the number of policers available to be used for classification. Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

- Port Number
- Priority extracted from VLAN, mapped from DSCP if enabled, or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- Outer VLANID -S-VLANID
- Inner VLANID -C-VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking for IPv4 and IPv6
- IP Destination Address - IPSA with full CIDR masking for IPv4 and IPv6
- Support Host Thread/Flow ID mapping based on any packet classification above

#### 12.2.1.4.6.1.12.1 ALE Policing

The policing function on each policer engine is implemented as dual-counter three-color marking engine as described in the IETF RFC2698. The first counter is the Committed Information Rate (CIR) counter and the second counter is the Peak Information Rate (PIR) counter. The policing function can use either or both counters. Based on the counter values the packet color is determined. The color is used to determine whether the packet is dropped or forwarded. The ALE has a local feature that can drop packets regardless of queue state.

The policing rates are determined by the below equations:

CIR policing rate in Mbit/s = ((ALE frequency in Mhz) \* CPSW3\_CPSW\_NU\_ALE\_POLICECFG7[31-0]  
CIR\_IDLE\_INC\_VAL) / 32768

PIR policing rate in Mbit/s = ((ALE frequency in Mhz) \* CPSW3\_CPSW\_NU\_ALE\_POLICECFG6[31-0]  
PIR\_IDLE\_INC\_VAL) / 32768

Each policer has 10 different match operations (see [Section 12.2.1.4.6.1.12](#)). Since multiple policing entries can be hit on a single packet this provides the ability to create precise traffic stream control.

Packets are colored at ALE lookup time. Packets can be colored RED, YELLOW, or GREEN. If multiple policers are configured for a packet stream then the packet color is merged from all matching (hit) policers. If any policer is RED then the packet is marked RED. Else if any policer is YELLOW then the packet is marked YELLOW. Otherwise the packet is marked GREEN.

The Policing engine supports several modes such that packets that don't hit a policing/classifier match can be treated as RED, YELLOW, GREEN or policer 0 color. Using policer 0 allows for a system to regulate unregulated traffic.

#### 12.2.1.4.6.1.12.2 Classifier to Host Thread Mapping

The ALE module allows Host Thread mapping based on any packet classification. That is the ALE can generate a thread ID used by the host based on ALE classifier matches.

When enabled the highest classifier match can map to a particular thread ID value.

The ALE also supports an optional default Thread ID value in the event that no classifier match.

Each Thread ID, including the default thread ID, has an enable functionality such that, if no classifier matches occur the default value is used, if the default is not enabled, the switch will use the {port,priority} value instead. If multiple classifier matches occur, the highest matching entry with a thread enable bit set will be used.

Three registers are used for ALE classification thread mapping configuration  
(CPSW3\_CPSW\_NU\_ALE\_THREADMAPDEF, CPSW3\_CPSW\_NU\_ALE\_THREADMAPCTL and

CPSW3\_CPSW\_NU\_ALE\_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW3\_CPSW\_NU\_ALE\_THREADMAPCTL register allows the CPSW3\_CPSW\_NU\_ALE\_THREADMAPVAL register contents to be written to the selected classifier. There is a CPSW3\_CPSW\_NU\_ALE\_THREADMAPDEF register that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

#### 12.2.1.4.6.1.12.3 ALE Classification

When the policers are configured as classifiers, the color marking and policing functions of the policing/classifier engines are not used. One or multiple classifiers can be configured to match on a single packet. For example, a classifier can be enabled to match on priority while another classifier could match IP address.

##### 12.2.1.4.6.1.12.3.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST\_THREAD\_MREADY) but there are 6-bits of FLOW\_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_FLOW\_ID\_OFFSET\_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW3\_CPSW\_NU\_ALE\_THREADMAPDEF, CPSW3\_CPSW\_NU\_ALE\_THREADMAPCTL and CPSW3\_CPSW\_NU\_ALE\_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW3\_CPSW\_NU\_ALE\_THREADMAPCTL register allows the CPSW3\_CPSW\_NU\_ALE\_THREADMAPVAL register contents to be written to the selected classifier. There is a single CPSW3\_CPSW\_NU\_ALE\_THREADMAPDEF that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

#### 12.2.1.4.6.1.13 Mirroring

The ALE supports three mirroring modes: destination port, source port and or table entry.

**Destination port mirroring** allows packets from any ingress port or trunk which ends up switching to a particular egress destination port or trunk to be mirrored to yet another egress destination port or trunk. For example any traffic from any port that is switched to port 'A' can be also mirrored to port 'B'. (MIRROR\_DP=A, MIRROR\_DEN=1h, MIRROR\_TOP=B in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).

**Source port mirroring** allows packets received on any enabled ingress source port or trunk to be switched to the mirror egress port as well as the actual egress destination ports. For example traffic received on ingress port 'A' can be switched to egress port 'B' as well as the intended egress destination port. (ly\_REG\_Py\_MIRROR\_SP=1h in the CPSW3\_CPSW\_NU\_ALE\_I0\_ALE\_PORTCTL0 register, MIRROR\_SEN=1h, MIRROR\_TOP=B in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).

**Table entry mirroring** allows for any MAC Address, MAC Address with VLAN, ONU Address or VLAN entry that matches on ingress to be switched to the egress destination as well as the actual egress destination. For example all traffic for VLAN ID of 35 can be mirrored to port 'B'. That is any traffic switched on VLAN ID of 35 will be mirrored. ({VLAN ID of 35 in ALE Table entry index=C}, MIRROR\_MIDX=C, MIRROR\_MEN=1h, MIRROR\_TOP=B)

In the event that mirrored packets are mirrored to or from a port that is also the mirror port the packet will not be duplicated or marked as a mirror packet since the packet has already been on the port as ingress or egress. The packet sent to the mirror port may have modified VLAN info based on the port and VLAN lookup table entries. The mirror port need not be a member of the VLAN ID it is mirroring, the ALE will forward traffic to the mirror port after ingress and egress filters are applied.

The switch may decide to drop any mirror traffic based on switch buffer thresholds as to prevent required traffic from becoming congested.

Port mirroring is controlled by register fields in CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL, CPSW3\_CPSW\_NU\_ALE\_ALE\_CTRL2 and the port control registers.

- MIRROR\_DP - The destination port that will have its traffic mirrored (CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).
- MIRROR\_TOP - The port to which mirrored traffic is sent (CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).
- MIRROR\_MEN - The enable for mirroring traffic that matches a supported lookup table entry (CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).
- MIRROR\_DEN - The Enable for destination port mirroring (CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).
- MIRROR\_SEN - The Enable for source port mirroring (CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register).
- MIRROR\_MIDX - The index of a lookup table entry that will be mirrored (CPSW3\_CPSW\_NU\_ALE\_ALE\_CTRL2 register).
- ly\_REG\_Py\_MIRROR\_SP - The enable for the Source port to be mirrored. Although multiple source ports can be mirrored concurrently, a mirror traffic bandwidth issue may occur on the mirror egress port (CPSW3\_CPSW\_NU\_ALE\_I0\_ALE\_PORTCTL0 register).

#### 12.2.1.4.6.1.14 Trunking

The ALE supports port trunking of any port in any of four trunk groups. That is, four trunk groups can be supported with up to eight ports in each trunk group. There are no port adjacency rules for trunk groups. When ports are a member of a trunk group, addresses added and used in the lookup table will refer to the trunk group rather than port as indicated in the lookup table entries. If ports are removed from a trunk group, the ALE will redistribute the traffic based on the crc polynomial of enabled fields and the remaining ports within the trunk group. A trunk group may contain only one port. Packet priority, DA, SA, C-VLAN ID, IPv4SA, IPv4DA, IPv6SA, and/or IPv6DA can be used in the hash to generate destination port within the trunk group. If all hash enables are disabled, the packet can be directed to a particular port within the trunk group which allows for testing paths etc. A host directed frame is directed to the directed port regardless of trunk group settings.

Trunking is controlled through fields in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CTRL2 register and in each ALE CPSW3\_CPSW\_NU\_ALE\_I0\_ALE\_PORTCTL0 register:

- TRK\_EN\_DST - Enable destination address hashing for trunk port calculation.
- TRK\_EN\_SRC - Enable source address hashing for trunk port calculation.
- TRK\_EN\_PRI - Enable priority hashing for trunk port calculation.
- TRK\_EN\_IVLAN - Enable inner C-VLAN ID hashing for trunk port calculation.
- TRK\_EN\_SIP - Enable source IP address hashing for trunk port calculation.
- TRK\_EN\_DIP - Enable destination IP address hashing for trunk port calculation.
- TRK\_BASE - Hashing formula starting value and test port offset.
- ly\_REG\_Py\_TRUNKEN - Enable this port as a trunk group
- ly\_REG\_Py\_TRUNKNUM - Trunk group number defines this port as a member of a particular trunk group.

#### 12.2.1.4.6.1.15 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_RX\_DSCP\_MAP\_REG\_y and

CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_DSCP\_MAP\_REG registers in the Register Manual section for DSCP mapping.

#### 12.2.1.4.6.1.16 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN\_Aware Lookup*, and *Egress*.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST\_FWD\_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port port, if the port has the RX\_CMF\_EN, RX\_CEF\_EN, or RX\_CSF\_EN bit(s) set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG registers. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG registers:

- [22] RX\_CEF\_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX\_CSF\_EN - enables short frames to be forwarded
- [24] RX\_CMF\_EN - enables MAC control frames to be forwarded.

#### 12.2.1.4.6.1.16.1 Ingress Filtering Process

Condition and action
If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process
if (directed packet) then use directed port number and go to Egress process
If (Rx ly_REG_Py_PORTSTATE is Disabled) then discard the packet
if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet

if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not BCAST_MCAST_CTL)) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> <li>Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.</li> </ul>
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (not block) and (receive port number != port_number)) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet
If (VLAN_Unaware) CPSW3_CPSW_NU_ALE_ALE_UVLAN_UNTAG = "000000" CPSW3_CPSW_NU_ALE_ALE_UVLAN_URCAST = "111111" CPSW3_CPSW_NU_ALE_ALE_UVLAN_URCAST = "111111" UVLAN_MEMBER_LIST = "111111" else if (VLAN not found) CPSW3_CPSW_NU_ALE_ALE_UVLAN_UNTAG = CPSW3_CPSW_NU_ALE_ALE_UVLAN_UNTAG CPSW3_CPSW_NU_ALE_ALE_UVLAN_RMCAST = CPSW3_CPSW_NU_ALE_ALE_UVLAN_RMCAST CPSW3_CPSW_NU_ALE_ALE_UVLAN_RMCAST = CPSW3_CPSW_NU_ALE_ALE_UVLAN_RMCAST CPSW3_CPSW_NU_ALE_ALE_UVLAN_MEMBER = CPSW3_CPSW_NU_ALE_ALE_UVLAN_MEMBER else CPSW3_CPSW_NU_ALE_ALE_UVLAN_UNTAG = found CPSW3_CPSW_NU_ALE_ALE_UVLAN_UNTAG CPSW3_CPSW_NU_ALE_ALE_UVLAN_URCAST = found CPSW3_CPSW_NU_ALE_ALE_UVLAN_URCAST CPSW3_CPSW_NU_ALE_ALE_UVLAN_RMCAST = found CPSW3_CPSW_NU_ALE_ALE_UVLAN_RMCAST UVLAN_MEMBER_LIST = found UVLAN_MEMBER_LIST
if ((not SUPER) and (ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member)) then discard the packet
if ((ENABLE_AUTH_MODE) and (source address not found) and not(destination address found and (SUPER))) then discard the packet
if (destination address equals source address) then discard the packet
if (VLAN_AWARE) goto VLAN_Aware_Lookup process else goto VLAN_Unaware_Lookup process

#### 12.2.1.4.6.1.16.2 VLAN\_Aware Lookup Process

Condition and action
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and UVLAN_MEMBER_LIST less the host port and goto Egress process

if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and the UVLAN_MEMBER_LIST and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_NUMBER and goto Egress process
if (Unicast packet) # destination address not found then portmask is VLAN member LIST less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of CPSW3_CPSW_NU_ALE_ALE_UVLAN_URCAST and found destination address/VLAN portmask (PORT_MASK) and UVLAN_MEMBER_LIST and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_MASK and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of CPSW3_CPSW_NU_ALE_ALE_UVLAN_URCAST and UVLAN_MEMBER_LIST then goto Egress process
if (Broadcast packet) then use found UVLAN_MEMBER_LIST and goto Egress process

#### Note

The UVLAN\_MEMBER\_LIST, UVLAN\_UNREG\_MCAST\_FLOOD\_MASK, UVLAN\_REG\_MCAST\_FLOOD\_MASK and UVLAN\_FORCE\_UNTAGGED\_EGRESS are set in the [Section 12.2.1.4.6.1.16.1 Ingress Filtering Process](#), based on VLAN\_Unaware, Unknown\_VLAN rules and VLAN table entries.

#### 12.2.1.4.6.1.16.3 Egress Process

Condition and action
Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and ((not mcast destination address) and (SUPER))) then Clear host port from portmask
if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask
if ((ENABLE_RATE_LIMIT) and (BCAST_MCAST_CTL)) then if (not SUPER) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

#### 12.2.1.4.6.1.16.4 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

##### 12.2.1.4.6.1.16.4.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_LEARN)) then do not learn address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not learn address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not learn address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VLANID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VLANID))) then learn address without VLAN

##### 12.2.1.4.6.1.16.4.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_SA_UPDATE)) then do not update address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not update address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not update address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER)) then update address

#### 12.2.1.4.6.1.16.4.3 Touching Process

```
if ((source address found) and (ageable) and (not touched))
then set touched
```

#### 12.2.1.4.6.1.17 VLAN Aware Mode

The CPSW is in VLAN aware mode when the VLAN\_AWARE bit is set in the CPSW3\_CONTROL\_REG register.

In VLAN aware mode, transmitted packet data is changed depending on the packet type (PKT\_TYPE), packet priority (PKT\_PRI), and VLAN information.

The VLAN\_LTYPE\_SEL value is selected by the S\_CN\_SWITCH bit in the CPSW3\_CONTROL\_REG register and is either the VLAN\_LTYPE\_INNER (8100h default) or VLAN\_LTYPE\_OUTER (88A8h default) value.

#### 12.2.1.4.6.1.18 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the VLAN\_AWARE bit in the CPSW3\_CONTROL\_REG register is cleared to 0h. In VLAN unaware mode, transmit (egress) packets are not modified on egress.

#### 12.2.1.4.6.2 Packet Priority Handling

Packets are received on three ports, two Ethernet port and one CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN\_LTYPE\_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG or CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CONTROL\_REG, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG or CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CONTROL\_REG, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority.

The received packet priority is mapped through the receive ports associated packet-priority-to-header-packet-priority-mapping register (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG) to obtain the header packet priority. The header packet priority is the hardware switch priority. The header packet priority is also used as the actual transmit packet priority if the VLAN information is to be sent on egress.

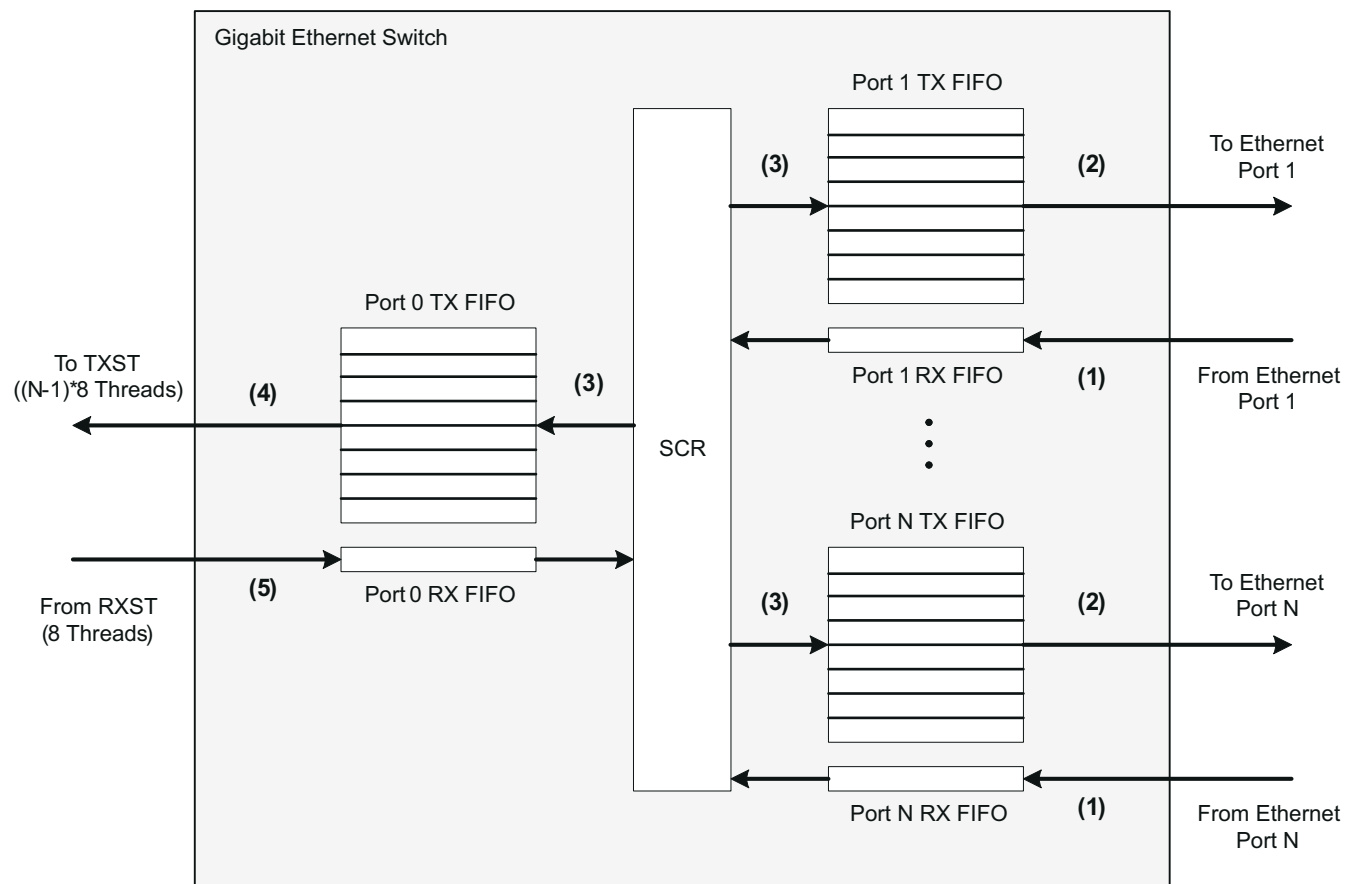

The header packet priority is mapped at each destination FIFO through the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TX\_PRI\_MAP\_REG register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

#### 12.2.1.4.6.2.1 Priority Mapping and Transmit VLAN Priority

There are three priorities that are used inside the Gigabit Ethernet Switch: **packet priority**, **header packet priority**, and **switch priority**. The **header packet priority** is used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The **switch priority** determines which of the 8 FIFO priority queues the packet uses during egress.

[Figure 12-96](#) below, as well as the corresponding explanation that follows, explains each of the priorities, how they are determined, and how they are used. A number in parentheses in the figure indicates a process

(Ethernet port ingress, host port egress, etc.). Each bullet in the text following the diagram explains one of the 5 processes pointed out in the figure.

**Figure 12-96. Gigabit Ethernet Switch Priority Mapping and Transmit VLAN Processing**

From [Figure 12-96](#) above:

- (1) is the ingress process that occurs at the external Ethernet ports
  - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the ingress port's priority. This **packet priority** is then mapped to a **header packet priority** using the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG register where N is the port where the packet entered the switch. This process is explained in further detail in [Section 12.2.1.4.6.2](#).
- (2) is the egress process that occurs at the external Ethernet ports
  - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1) or (5). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.1.4.6.4.1](#).
- (3) is the process by which it is decided which priority TX queue to place the packet on in the Port N TX FIFO during egress
  - Each Port's TX FIFO has 8 queues that each correspond to a priority that is used when determining which packet will egress from the switch next at that port. The **header packet priority** (Ethernet port ingress, process (1)) or the receive packet thread (host port 0 ingress, process (5)) gets mapped through the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG register (where N is the egress port number) to determine the **switch priority** of the packet. The **switch priority** determines which TX FIFO queue to place the packet in. The FIFO architecture is described in [Section 12.2.1.4.6.10.5](#). The header packet priority to switch priority mapping is discussed in [Section 12.2.1.4.6.2](#).
- (4) is the egress process that occurs at Host Port 0 toward the transmit streaming interface (TXST)
  - The TXST has 8 egress threads for each external Ethernet port (32 threads in a 5-port switch and 64 threads in a 9-port switch). The TX thread that is selected for a packet is determined by the Ethernet port of ingress and the **switch priority** of the packet that was determined in process (3).
  - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.1.4.6.4.1](#).
- (5) is the ingress process that occurs at Host Port 0
  - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the host port's priority. This packet priority is then mapped to a **header packet priority** using the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG register.
  - Host port 0 also has a received packet thread. The receive packet thread is based on either the packet's VLAN priority, IPv4 or IPv6 DSCP value, or the streaming interface (RXST) thread that the packet entered host port 0 on.

#### 12.2.1.4.6.3 CPPI Port Ingress

Packets received on the CPPI host port have a received packet priority (0 to 7 with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN\_LTYPE\_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG or CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CONTROL\_REG register, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG or CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CONTROL\_REG register, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority

The CPPI Port (port 0) also has a received packet thread. The received packet thread is determined exactly as the received packet priority except for untagged packets. For untagged packets, the received packet thread is the packet streaming interface thread that the packet was received on (instead of the port VLAN priority or DSCP priority). The received packet thread is the hardware switch priority. The received packet thread only determines which hardware switch priority the packet should be sent to, the egress VLAN rules are identical to packets that were received on Ethernet ports (as determined by the header packet priority).

For CPPI ingress packets, the destination port hardware switch priority is the below selected value remapped through CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG:

1. If the ingress packet is priority tagged or vlan tagged:
  - If RX\_REMAP\_VLAN in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_VLAN in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the packet priority value. Port transmit remapping (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TX\_PRI\_MAP\_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register:
  - If RX\_REMAP\_DSCP\_V4 bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_DSCP\_V4 bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPv4 packet). Port 1 transmit remapping (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TX\_PRI\_MAP\_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
3. Else if the ingress packet has the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in P0\_CONTROL\_REG register:
  - If RX\_REMAP\_DSCP\_V6 bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_DSCP\_V6 bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet). Port 1 transmit remapping (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TX\_PRI\_MAP\_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI receive thread number.

#### 12.2.1.4.6.4 Packet CRC Handling

The P0\_TX\_CRC\_REMOVE bit in the CPSW3\_CONTROL\_REG register determines if host port egress packets have CRC included or not. If P0\_TX\_CRC\_REMOVE is set to 1h then all packets that are transmitted from port 0 do not contain CRC. If P0\_TX\_CRC\_REMOVE bit is cleared to 0h then all packets that are transmitted from port 0 contain CRC. The CRC type, if present, is determined by the CRC\_TYPE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register. If the CRC\_TYPE bit is cleared to 0h then the CRC present in each packet after host port egress is Ethernet CRC. If the CRC\_TYPE bit is set to 1h then the CRC present in each packet after host port egress is Castagnoli CRC.

#### Note

The CRC type present in the packet after host port egress is determined solely by the CRC\_TYPE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register regardless of the CRC type present in the packet during Ethernet port ingress.

#### 12.2.1.4.6.4.1 Transmit VLAN Processing

Transmit packets are NOT modified during switch egress when the VLAN\_AWARE bit in the CPSW3\_CONTROL\_REG register is cleared to 0h. This means that the switch is not in VLAN-aware mode.

The next three sections cover transmit processing when the switch is in VLAN-aware mode for different packet types. The Gigabit Ethernet switch is in VLAN-aware mode when the VLAN\_AWARE bit is set in the CPSW3\_CONTROL\_REG register. While in VLAN-aware mode, VLAN is added, removed, or replaced according to the type of packet as well as the CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header as explained below.

##### 12.2.1.4.6.4.1.1 Untagged Packets (No VLAN or Priority Tag Header)

Untagged packets are all packets that are not a VLAN packet or a priority tagged packet. According to the CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header the packet may exit the switch with a VLAN tag inserted or the packet may leave the switch unchanged. The two cases are discussed below.

- Insert VLAN Case:

Untagged input packets have the header packet VLAN inserted when the CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the transmit packet header is de-asserted. For untagged packets, the VLAN EtherType = 0x8100 is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the header packet priority along with the PORT\_CFI and PORT\_VID values from the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_PORT\_VLAN\_REG register (where N is the port that the untagged packet entered the switch) through. The packet length/type field is output four bytes later than it is input and is not removed or replaced. If the CRC is present in the packet data (PASS\_CRC is asserted), then the packet CRC is replaced with a hardware generated CRC.

- No Change Case:

Untagged input packets are output unchanged when the CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS transmit packet header bit is asserted.

##### 12.2.1.4.6.4.1.2 Priority Tagged Packets (VLAN VID == 0 && EN\_VID0\_MODE == 0h)

Priority tagged packets are packets that contain a VLAN header with VID = 0. According to the CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header, priority tagged packets may exit the switch with their VLAN ID and priority replaced or they may have their priority tag completely removed. The two cases are discussed below.

#### Note

In order for a priority tagged packet to fall into this category the ENABLE\_VID0\_MODE bit in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register must also be set to 0h. If the ENABLE\_VID0\_MODE bit in the CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL register is set to 1h, then packets with a VLAN VID of 0 will fall into the VLAN Tagged Packets category in [Section 12.2.1.4.6.4.1.3](#) below.

- Replace Priority and VLAN ID Case:

Priority tagged input packets have the packet VLAN ID and the packet priority replaced with the header packet VLAN ID and the header packet priority when the transmit packet header CPSW\_FORCE\_UNTAGGED\_EGRESS\_REG[1-0] MASK bit is de-asserted. The header packet VLAN ID comes from the PORT\_VID bits in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_PORT\_VLAN\_REG register (where N is the port where the packet entered the switch). The header packet priority is based on the packet priority to header packet

priority mapping in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG register (where N is the port where the packet entered the switch).

- Remove VLAN Header Case:

Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS\_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority-tagged packets use all four input CRC bytes as pad, input 65-byte priority-tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS\_CRC input bit is not asserted - input 64-67 byte (on the wire) priority-tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

#### 12.2.1.4.6.4.1.3 VLAN Tagged Packets (VLAN VID != 0 || (EN\_VID0\_MODE == 1h && VLAN VID == 0))

VLAN tagged packets are packets that contain a VLAN header specifying the VLAN the packet belongs to (VID), the packet priority (PRI), and the drop eligibility indicator (CFI). According to the CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header, VLAN tagged packets may exit the switch with their VLAN priority replaced or they may have their VLAN header completely removed. The two cases are discussed below.

- Replace Priority Case:

VLAN tagged input packets are output with the packet priority replaced with the header packet priority when the transmit packet header CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is deasserted. The header packet priority is based on the packet priority to header packet priority mapping in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_PRI\_MAP\_REG register (where N is the port where the packet entered the switch). If the CRC is present in the packet data (PASS\_CRC is asserted), then the packet CRC is replaced with a generated CRC.

- Remove VLAN Header Case:

VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW3\_CPSW\_NU\_ALE\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS\_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS\_CRC input bit is not asserted - input 64-67 byte (on the wire) priority tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

#### 12.2.1.4.6.4.2 Ethernet Port Ingress Packet CRC

All Ethernet ports check the ingress packet CRC in all modes/speeds. The receive port can check either Ethernet CRC or Castagnoli CRC as determined by the CRC\_TYPE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register.

#### 12.2.1.4.6.4.3 Ethernet Port Egress Packet CRC

Ethernet ports transmit each egress packet with the CRC selected by the CRC\_TYPE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register, regardless of the type of CRC that the packet had on ingress to the switch. At the egress port after passing through the switch, the packet CRC is checked for correctness and if the CRC is correct then the packet is output with the generated selected output CRC. If the packet CRC is incorrect, due either to a bit flip in a memory or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on

error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

#### **12.2.1.4.6.4.4 CPPI Port Ingress Packet CRC**

CPPI port ingress packets can be passed in with or without a CRC. The host port is Ethernet CRC only. CPPI ingress packets are not checked for CRC correctness on CPPI ingress, however they are checked for correctness on Ethernet egress and are output with a CRC error if they came in with a CRC error. If a CPPI ingress packet does not have the INFO0 PASSED\_CRC bit set then a CRC will be generated for the packet on CPPI ingress. If the PASSED\_CRC bit is set then the packet is received and forwarded unchanged. The CRC type is input in the INFO0 word CRC\_TYPE bit and must be Ethernet CRC.

#### **12.2.1.4.6.4.5 CPPI Port Egress Packet CRC**

The P0\_TX\_CRC\_REMOVE bit in the CPSW3\_CONTROL\_REG register determines if CPPI egress packet have an Ethernet CRC included or not.

#### **12.2.1.4.6.5 FIFO Memory Control**

Each of the two CPSW\_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX\_MAX\_BKLS field in the FIFOs associated CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAX\_BKLS\_REG register determines the maximum number of 1k FIFO memory blocks to be allocated to the eight logical transmit queues (transmit total). The RX\_MAX\_BKLS field in the FIFO's associated CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAX\_BKLS\_REG register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX\_MAX\_BKLS value plus the RX\_MAX\_BKLS value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports is Port1.

Each transmit FIFO contains a configurable number of blocks (20 max) that are either 1k or 4k byte blocks that can be allocated to any priority.

#### **12.2.1.4.6.6 FIFO Transmit Queue Control**

There are eight transmit queues in the Ethernet port transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues).

##### **12.2.1.4.6.6.1 CPPI Port Receive Rate Limiting**

Port 0 receive operations can be configured to rate limit the host ingress data for each receive thread (priority). CPPI Receive has 8 threads for QOS. There is a committed information rate (CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_CIR\_REG\_y, where y = 0 to 7) and an excess information rate for each thread (CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_EIR\_REG\_y, where y = 0 to 7). Rate limiting is enabled for a thread when the committed information rate for the thread is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. No bulk thread will be enabled to send unless there are CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_PRI\_CTL\_REG[15-12] TX\_HOST\_BKLS\_REM number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The "blocks remaining check" ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then threads 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured

to be rate-limited, the priority type must be fixed for receive. Round-robin priority type is not allowed when rate-limiting is configured for any thread. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to receive is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

$$\text{Priority Transfer rate [Mbit/s]} = (((\text{Frequency in MHz}) * \text{CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_CIR\_REG\_y} / 32768) + (((\text{Frequency in MHz}) * \text{CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_EIR\_REG\_y} / 32768)))$$

Where the *frequency* is the CPPI\_ICLK frequency (in MHz) and priority 0 to 7.

For example, 10Mbps on priority 7 would give the below:

10Mbps = ~ ((350 \* 936) / 32768), at 350Mhz and  
CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_CIR\_REG\_y[27-0] PRI\_CIR value = 936 (no excess information rate)

#### 12.2.1.4.6.6.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_CIR\_REG\_y, where y = 0 to 7) and an excess information rate for each priority (CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_EIR\_REG\_y, where y = 0 to 7). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

$$\text{Priority Transfer rate [Mbit/s]} = (((\text{Frequency in MHz}) * \text{CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_CIR\_REG\_y} / 32768) + (((\text{Frequency in MHz}) * \text{CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_PRI\_EIR\_REG\_y} / 32768)))$$

Where the *frequency* is the CPPI\_ICLK frequency (in MHz) and priority 0 to 7.

#### 12.2.1.4.6.7 Interspersed Express Traffic (IET – P802.3br/D2.0)

When IET is enabled through CPSW3\_CONTROL\_REG[17] IET\_ENABLE = 1h and configured, IET allows preemptable traffic on selected transmit priorities to be preempted by express traffic on selected express priorities. Received traffic is separated onto express and preempt receive queues. When IET is disabled (IET\_ENABLE = 0h), all Ethernet traffic is express traffic and switch operation is as if IET does not exist. Traffic is only intended to be moved to the preempt queue after preemption is verified and enabled.

##### 12.2.1.4.6.7.1 IET Configuration

- Using the preempt receive queue requires more blocks to be allocated to the ports receive FIFO. Write a value of decimal 7 to the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAX\_BLKs\_REG[7-0] RX\_MAX\_BLKs bit field, and a value of decimal 13 to the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAX\_BLKs\_REG [15-8] TX\_MAX\_BLKs register for every port to be enabled for IET.
- Write the [23-0]MAC\_VERIFY\_CNT bit field in the Ethernet port CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_VERIFY\_REG register to set the verify/response timeout count. The default is 10ms for Gigabit mode. For other time values or link speeds the verify

count should be updated. If CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG[2] MAC\_DISABLEVERIFY bit is to be set (this is forced mode) then this step is unneeded.

3. The receive FIFO block allocation is insufficient if CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_RX\_BOTTOM\_OF\_FIFO\_DROP[31-0] COUNT is nonzero, indicating that receive packets are being dropped due to FIFO block allocation.
4. Write the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG register in the Ethernet port as below:
  - Set the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CONTROL\_REG[16] IET\_PORT\_EN bit. The port will not actually be enabled until bit IET\_ENABLE is set in the CSL\_CPSW3\_CONTROL\_REG.
  - The CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG[0] MAC\_PENABLE bit can be set as desired. No effect will occur until IET\_ENABLE is set. This bit enables preemptable packets to be preempted by express traffic but does not preclude packets from being sent to the preempt queue.
  - If verify/response is desired then CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG[3] MAC\_LINKFAIL should be cleared by software to enable verify and response packets. Otherwise, MAC\_DISABLEVERIFY bit should be set for forced mode. Verification and response will occur immediately after clearing this bit.
  - Configure the remaining CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG register bits as desired.
5. Set the IET\_ENABLE bit in the CSL\_CPSW3\_CONTROL\_REG register to enable IET operations.
6. After preemption has been verified, the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG[23-16] MAC\_PREMPT field is written to configure the FIFO priorities to be sent to the preempt queue (the other priorities with cleared bits go to the express queue). The hardware switch for each queue from express to preempt happens only when there are no packets queued on the priority.

#### 12.2.1.4.6.8 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)

##### 12.2.1.4.6.8.1 Enhanced Scheduled Traffic Overview

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 MSB's) and an 8-bit priority fetch allow (8 LSB's) that will be applied for the fetch count time in wireside clocks.
- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and preempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (zero allow).
- EST can be used with or without preemption. The CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG[23-16] MAC\_PREMPT value determines whether the priority is enabled on the express or preempt queue. Whether a priority is on the express or preempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the preempt queue unless preemption is configured, enabled, and verified allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

##### 12.2.1.4.6.8.2 Enhanced Scheduled Traffic Fetch RAM

- The EST fetch RAM is read/writable in the CPSW configuration address space.
- The Ethernet transmit port has 128 locations in the global EST fetch RAM.
  - Ethernet port 1 has EST fetch RAM addresses 0x000-0x07F.
- **One buffer operation:** When CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF is set to 1h, the 128 port locations operate as one buffer. The EST\_BUFACT bit in

CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_FIFO\_STATUS\_REG register is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.

- **Two buffer operation:** When CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF is cleared there are two 64-location buffers with CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[1] EST\_BUFSEL selecting the buffer to be used. When the buffer is switched by changing the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[1] EST\_BUFSEL value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the EST\_BUFACT bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_FIFO\_STATUS\_REG. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port address zero is then read again at the beginning of the next cycle repeating the time interval packet operations.

#### 12.2.1.4.6.8.3 Enhanced Scheduled Traffic Time Interval

- Each Ethernet port has an Enhanced Scheduled Traffic Function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS\_RFT\_CLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.
- The first fetch allowed value is at the port base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock cycle delay allows the first fetch value time to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF = 0h, and 128 maximum fetch values when CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF = 1h.
- The next cycle start then causes the fetch to once again start at the port address zero.

#### 12.2.1.4.6.8.4 Enhanced Scheduled Traffic Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in Gigabit mode (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[7] GIG = 1h) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. The actual packet transmission on the wire may carry over into the next fetch count and is the reason for the wire clear time in the fetch zero allow.
- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks.
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is

enabled in the next fetch but disabled in the current zero allow fetch. The fetch allow previous to a zero allow should have only preempt priorities enabled or only express priorities enabled but not both.

- The number of clocks required to clear the wire varies depending Ethernet wire speed and on whether express or preempt priorities were allowed in the previous fetch command.

#### 12.2.1.4.6.8.5 Enhanced Scheduled Traffic Packet Fill

Packet fill can (should) be configured and enabled to occur in the fetch count time associated with a fetched zero allow that precedes a timed express packet. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch. Incorrect configuration might push out in time any express timed packet which indicates that the fill margin needs to be increased.

Fill Configuration:

- The **pn\_est\_fill\_margin** value in **Enet\_Pn\_EST\_Control** should be written with a 0x100 value.
- The **pn\_est\_preempt\_comp** value in **Enet\_Pn\_EST\_Control** should be written with a 0x12 value (if IET is to be configured and enabled). This value times eight is the number of wireside clocks required to clear preempt packets off the wire at the end of a zero allow.
- The **pn\_est\_fill\_en** bit in **Enet\_Pn\_EST\_Control** should be set.

#### 12.2.1.4.6.8.6 Enhanced Scheduled Traffic Time Stamp

The EST can be configured to generate CPTS timestamp events for selected express traffic. The EST timestamp events use the CPTS host event type (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG[23-20] EVENT\_TYPE = 7 decimal). The EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.

- EST Events (host events) contain the below information:
  - Time Stamp of the selected express packet.
  - The event CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG[28-24] PORT\_NUMBER indicates the transmit port number.
  - The event CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG[23-20] EVENT\_TYPE is decimal 7 (host event).
  - The event CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG[23-20] MESSAGE\_TYPE indicates the packet transmit hardware switch priority.
  - The event CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG[15-0] SEQUENCE\_ID upper nibble indicates the packet receive port number.
  - The event CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG[15-0] SEQUENCE\_ID lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence ID rolls over to zero after 0xFF (8-bits).
  - The event domain is the value from the CPSW3\_CPSW\_NU\_EST\_TS\_DOMAIN\_REG[7-0] EST\_TS\_DOMAIN register.
- When CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[2] EST\_TS\_EN is set, timestamp events will be generated on selected express traffic.
- When CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[3] EST\_TS\_FIRST is also set, events will be generated only on the first express packet in each time interval. If CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is also set then the event will only be on the first CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[7-5] EST\_TS\_PRI express packet in the time interval. If CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is clear then the event will be generated on the first express packet in the time interval on any priority.
- When CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[3] EST\_TS\_FIRST is clear, events will be generated on every express packet. If CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is set then the event will be generated on every

CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[7-5] EST\_TS\_PRI express packet. If CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is clear then event will be generated on every express packet on any priority.

#### 12.2.1.4.6.8.7 Enhanced Scheduled Traffic Packets Per Priority

The number of packets allowed in a transmit FIFO priority can be selected by writing a non-zero value to CPSW\_P0\_RX\_PKTS\_PRI\_REG register (packet priority 0 to 7). Then port 0 receive gap should then be enabled by setting the corresponding priority through CPSW\_P0\_RX\_GAP\_REG[7-0] RX\_GAP\_EN bit field. The receive gap allows a packet to land in the transmit FIFO before another packet is allowed in which guarantees that only the selected number (max) of packets is allowed in on the specified priority. If the receive gap is not enabled, then there might be one or two more packets allowed in on the priority/thread than the packets per priority value has selected (through CPSW\_P0\_RX\_PKTS\_PRI\_REG register).

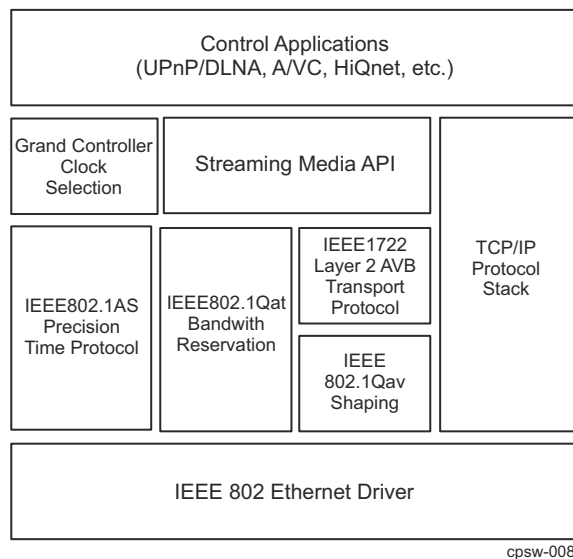

#### 12.2.1.4.6.9 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*". "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

**Figure 12-97. The Network Static with AVB**

The following sections describe the media transport protocols that work within the AVB framework.

#### **12.2.1.4.6.9.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))**

The protocol defined by 802.1AS automatically selects a device to be the controller clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

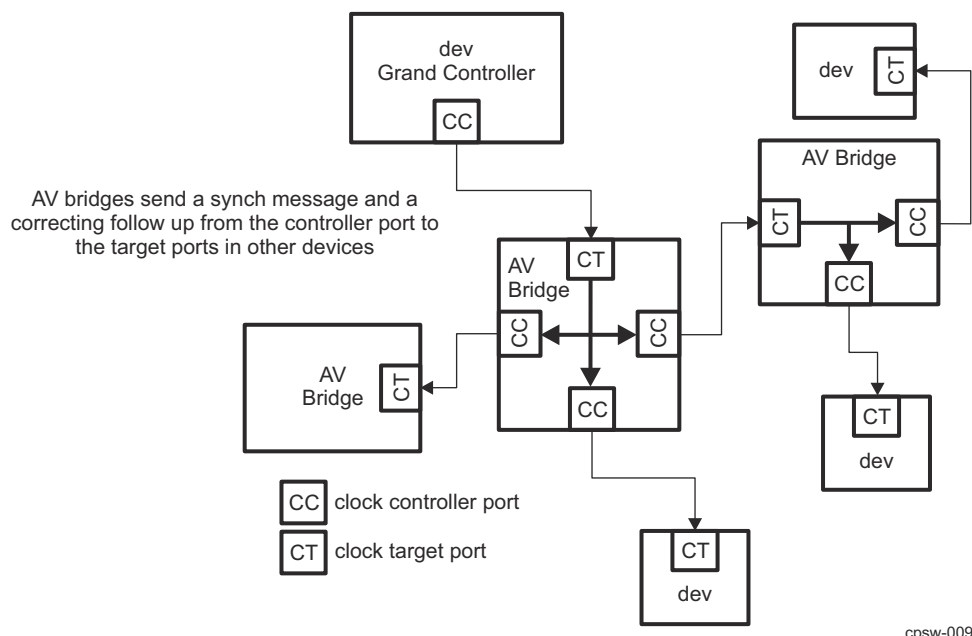

#### **Note**

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002, A PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock controller selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2-in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock controller, the Best Controller Clock Algorithm (BCCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BCCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandcontroller. Once a Grandcontroller has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Target nodes compare the value of their RTC against the PTP Grandcontroller and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW\_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1- $\mu$ s accuracy over seven network hops.

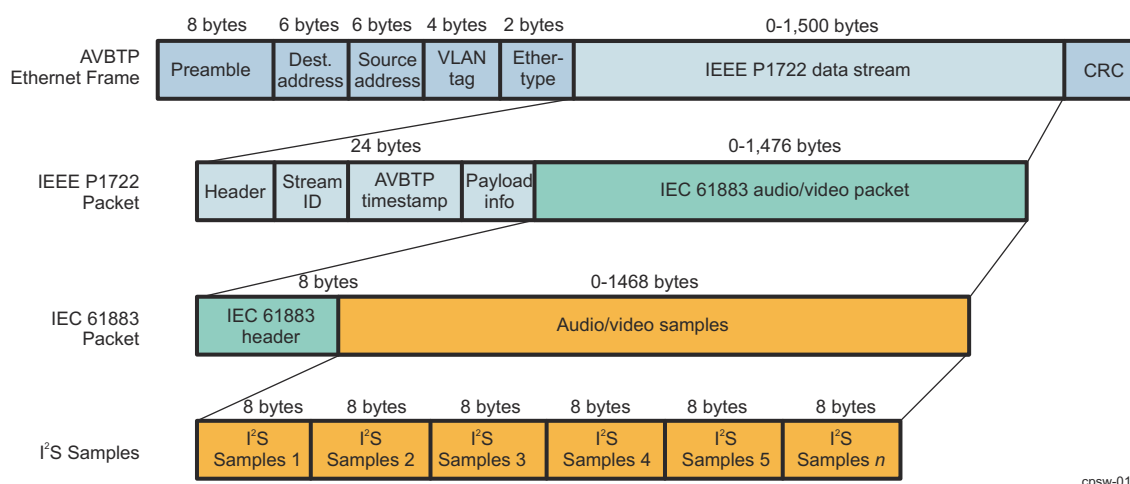

**Figure 12-98. AVB Network & PTP Clock Entities**

The media transport protocols that work within the AVB framework are:

#### 12.2.1.4.6.9.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 12-99 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

#### IEEE 1722 Packet Construction

**Figure 12-99. IEEE 1722 Packets**

1722 or AVBTP Presentation Time and Synchronization:

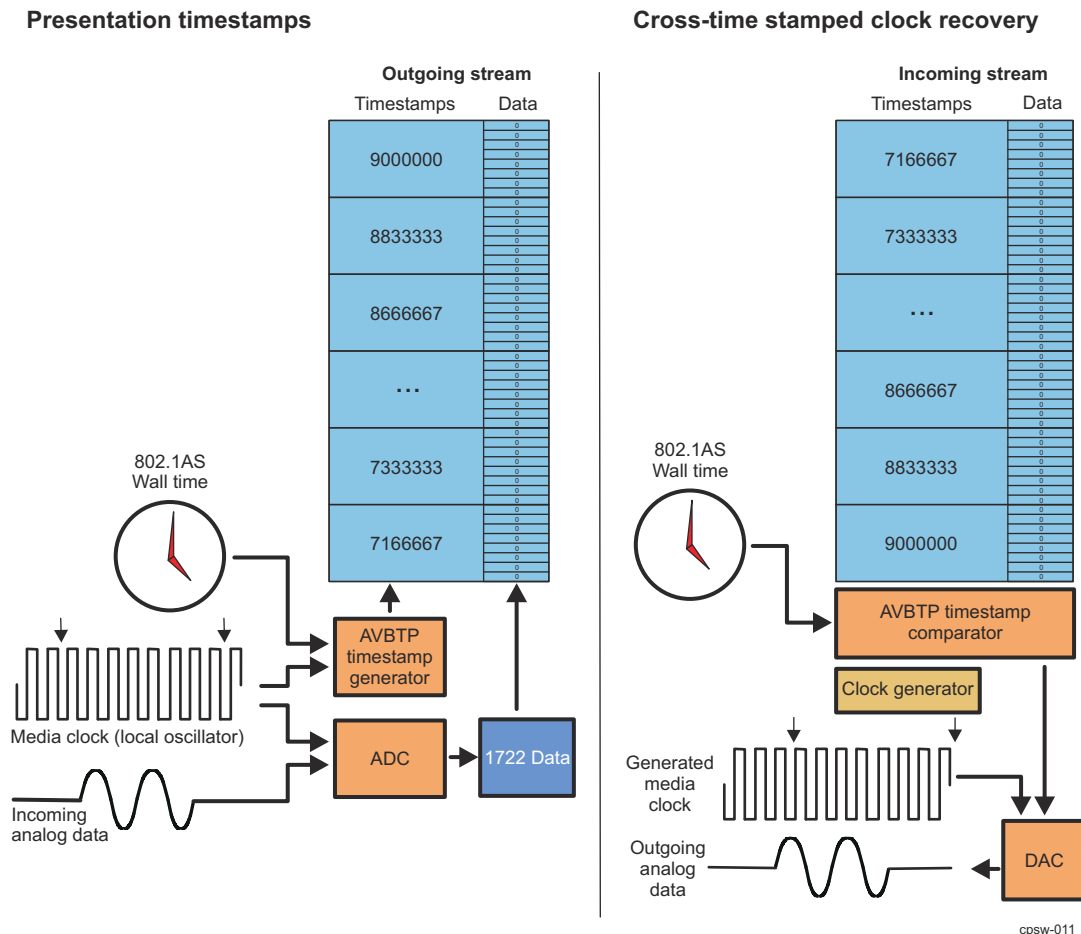

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for

synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

#### 12.2.1.4.6.9.1.1 Cross-timestamping and Presentation Timestamps

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandcontroller. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. [Figure 12-100](#) illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

**Figure 12-100. Cross Time Stamping and Presentation Timestamps**

#### 12.2.1.4.6.9.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

#### 12.2.1.4.6.9.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress

metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing
  - Transmit rate control.

### End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

### Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 12-101](#).

### Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

cpsw-012

**Figure 12-101. AV Stream Queuing/Policing**

#### 12.2.1.4.6.9.2.1 Configuring the Device for 802.1Qav Operation

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW\_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

**Table 12-123. Example of TX Configuration**

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

**Table 12-124. Example of RX Configuration**

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

#### 12.2.1.4.6.10 Ethernet MAC Sliver

The Ethernet port peripheral is compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

## Features:

- Synchronous 10/100/1000 Mbit operation
- RMII/RGMII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

**12.2.1.4.6.10.1 Ethernet MAC Sliver Overview****12.2.1.4.6.10.1.1 CRC Insertion**

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS\_CRC bit is 0h. For the Ethernet port generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS\_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS\_CRC bit is set.

**12.2.1.4.6.10.1.2 MTXER**

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

**12.2.1.4.6.10.1.3 Adaptive Performance Optimization (APO)**

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX\_PACE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

**12.2.1.4.6.10.1.4 Inter-Packet-Gap Enforcement**

The measurement reference for the IPG of 96-bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCERS is de-asserted within approximately 48-bit times of MTXEN being de-asserted, then 96-bit times is measured from MTXEN. If the frame suffered a collision, or if MCERS is not de-asserted until more than approximately 48-bit times after MTXEN is de-asserted, then 96-bit times (approximately, but not less) is measured from MCERS.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the [10] TX\_SHORT\_GAP\_ENABLE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the

gap is shortened, and so on. The CPSW3\_CPSW\_NU\_GAP\_THRESH\_REG register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the GAP\_THRESH value then short gap is triggered.

#### **12.2.1.4.6.10.1.5 Back Off**

The Gigabit Ethernet Mac Sliver implements the 802.3 binary exponential back-off algorithm.

#### **12.2.1.4.6.10.1.6 Programmable Transmit Inter-Packet Gap**

The transmit inter-packet gap (IPG) is programmable through the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

#### **12.2.1.4.6.10.1.7 Speed, Duplex and Pause Frame Support Negotiation**

The Ethernet port can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

#### **12.2.1.4.6.10.2 RMII Interface**

The CPRMII peripheral is compliant to the RMII specification document.

##### **12.2.1.4.6.10.2.1 Features**

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

##### **12.2.1.4.6.10.2.2 RMII Receive (RX)**

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII\_RXER on any di-bit in the received packet will cause an MII\_RXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII\_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII\_CRS\_DV toggle will issue an MII\_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII\_CRS\_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

##### **12.2.1.4.6.10.2.3 RMII Transmit (TX)**

The CPRMII transmit (TX) interface converts the CPGMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The CPGMAC does not source the transmit error (MII\_TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII\_TXD[1:0] for each clock that RMII\_TXEN is de-asserted.

#### **12.2.1.4.6.10.3 RGMII Interface**

The CPRGMII peripheral is compliant to the RGMII specification document.

### 12.2.1.4.6.10.3.1 Features

- Supports 1000/100/10 Mbps speed
- Full and Half Duplex support (CPGMAC supports only Full duplex in Gigabit mode).
- MII mode support
- Energy Efficient Ethernet Support

### 12.2.1.4.6.10.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

### 12.2.1.4.6.10.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII\_RX\_INBAND input is asserted. RGMII\_RX\_INPUT is asserted by configuring the CTL\_EN bit to 1h of the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX\_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 12-125](#).

**Table 12-125. In-Band Data**

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0h: half-duplex	0h: 10-Mbps mode	2.5 MHz	0h: Link is down
1h: full-duplex	1h: 100-Mbps mode	25 MHz	1h: Link is up
	2h: 1000-Mbps mode	125 MHz	
	3h: Reserved	Reserved	

### 12.2.1.4.6.10.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII\_RX\_INBAND input is deasserted by setting to 0h bit CTL\_EN of the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register. In the forced mode of operation, the in-band data is ignored if present.

The link status is forced high, and the duplexity and speed are determined from the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[0] FULLDUPLEX and CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[7] GIG bits. If bit [7] GIG = 1h, then CPRGMII is operating in Gigabit mode. If bit [7] GIG is cleared (0h), then CPRGMII is operating in 100 Mbps mode.

### 12.2.1.4.6.10.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

In 10/100 Mbps mode, the TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 Mbps mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII\_LINK. Packet transmission will begin on the first TX\_CTL rising edge after the 4096 transmit clock count has expired.

### 12.2.1.4.6.10.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_RX\_MAXLEN\_REG[13:0] RX\_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_RX\_MAXLEN\_REG/CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_MAXLEN\_REG register. The register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames. If RX\_CSF\_EN bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG is set to 1h, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If RX\_CSF\_EN and RX\_CEF\_EN in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain RX\_MAXLEN number of bytes transferred to memory (if CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[22]RX\_CEF\_EN = 1h). An example with RX\_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

#### 12.2.1.4.6.10.5 Receive FIFO Architecture

This section describes the architecture of the Ethernet port's receive FIFOs. Internal to the Gigabit Ethernet switch, all Ethernet ports have an identical associated packet FIFO. Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each transmit FIFO memory contains 81,920 bytes total organized as 2560 by 256-bit words. Each FIFO also contains a single memory for the receive queue. Each receive FIFO memory contains a total of 32768 bytes total organized as 1024 by 256-bit words.

#### 12.2.1.4.6.11 Embedded Memories

**Table 12-126. Embedded Memories**

Memory Type Description	Number of Instances	
Single-port 3072-word × 64 RAM	1	(Combined FIFO RAM)
Single-port 128-word × 28-bit RAM	1	1 (EST)

#### 12.2.1.4.6.12 Memory Error Detection and Correction

The CPSW\_3G error detection and correction logic uses the ECC Aggregator Module.

The CPSW3\_ECC\_ECC\_VECTOR register is used to select which ECC RAM's status and control registers are currently being read or written as shown in [Table 12-127](#). The CPSW FIFO RAMs implement ECC only on packet headers. The packet data is protected by Ethernet CRC. The ALE and EST RAMs have complete ECC as normal.

**Table 12-127. ECC RAM to CPSW RAM Mapping**

ECC RAM Number	CPSW RAM
0	ALE RAM
1	Port 0 FIFO RAM

##### 12.2.1.4.6.12.1 Packet Header ECC

Only packet headers bits are protected by ECC in the FIFO RAMs. The ECC\_ERR\_CTRL1[31-0] ECC\_ROW bit is used to activate a row address where force single-bit error or force double-bit error needs to be applied. ECC\_ERR\_CTRL2 [15-0] ECC\_BIT1 is implemented to determine which bit of the header is flipped for an SEC error when the ECC\_CRC\_MODE bit is cleared in the CPSW3\_CONTROL\_REG register. The ECC status registers return the RAM row address where the single or double-bit error has occurred (ECC\_ERR\_STAT2[31-0] ECC\_ROW) along with the bit position in the RAM data that is in error (ECC\_ERR\_STAT1[31-16] ECC\_BIT1 value). Forcing double-bit errors in testing can cause indeterminate operation if multiple used packet header bits are flipped given that only single-bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the CPSW and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when ECC\_CRC\_MODE is set to 1h. Either the RX\_ECC\_ERR\_EN (enable receive ECC error operations) or the TX\_ECC\_ERR\_EN (enable transmit ECC error operations) bits must be set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register to test ECC header errors.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on bit 0, it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse interrupt (ECC\_PULSE\_INTR) as does an ALE RAM ECC error.

##### 12.2.1.4.6.12.2 Packet Protect CRC

Each packet received without error is passed through the CPSW\_3G memories with a generated Ethernet protect CRC. The protect CRC is checked on egress for correctness and removed. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on host egress then the TXST\_DROP signal will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the ECC\_PULSE\_INTR signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on STAT\_PEND\_INTR if any CRC memory protect error occurs (and the statistics for that port are enabled). When the ECC\_CRC\_MODE bit in the CSL\_CPSW3\_CONTROL\_REG register is set, the ECC\_ERR\_CTRL2 [15-0] ECC\_BIT1 bit field will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when ECC\_CRC\_MODE is set. Either the RX\_ECC\_ERR\_EN or the TX\_ECC\_ERR\_EN bits must be set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register to test packet CRC errors.

##### 12.2.1.4.6.12.3 Aggregator RAM Control

The ECC logic for each FIFO RAM (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the RAM in the upper 48 unused bits in the header word.

The header data bits and ECC code bits are shown in [Table 12-128](#). The [15:0] ECC\_BIT1 value returned on error is a 16-bit value that is the concatenation of 5 bits of zero, 3 bits of the encoder/decoder number (0 to 7), 3 bits of zero, and 5 bits of index into the indicated 26-bit encoder/decoder.

For example, an ECC\_BIT1 value of 0x0308 is bit 8 of encoder/decoder 3, which is header bit 86 (that is,  $(26 \times 3) + 8$ ).

**Table 12-128. ECC Submodule Header Data Bit to Encoder/Decoder Mapping**

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:52	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 ECC
219:214	Encoder/Decoder 1 ECC
225:220	Encoder/Decoder 2 ECC
231:226	Encoder/Decoder 3 ECC
237:232	Encoder/Decoder 4 ECC
243:238	Encoder/Decoder 5 ECC
249:244	Encoder/Decoder 6 ECC
255:250	Encoder/Decoder 7 ECC

#### 12.2.1.4.6.13 Ethernet Port Flow Control

The Ethernet port have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The Ethernet port have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an Ethernet port can be sent to the CPPI port. The destination port can trigger the receive Ethernet port flow control. An Ethernet destination port triggers another Ethernet receive flow control when the destination port is full.

When a packet is received on an Ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the Ethernet port will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX\_BLK\_CNT = 0h). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX\_FLOW\_EN bit in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG be set to 1h. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit.

### 12.2.1.4.6.13.1 Ethernet Receive Flow Control

For every Ethernet port to be configured for full-duplex receive flow control, write a value of decimal 7 to the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAX\_BLKs\_REG[7-0] RX\_MAX\_BLKs bit field, and a value of decimal 13 to the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAX\_BLKs\_REG[15-8] TX\_MAX\_BLKs register. This re-allocation allows for flow control runout on the receive FIFO at the expense of FIFO memory on the Ethernet transmit side. 10/100Mbps half-duplex collision based receive flow control does not need this re-allocation. Receive flow control is enabled by the RX\_FLOW\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register.

#### 12.2.1.4.6.13.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

#### 12.2.1.4.6.13.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full at which time the receive FIFO will overrun and CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_RX\_BOTTOM\_OF\_FIFO\_DROP[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL\_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[3] RX\_FLOW\_EN is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to 0h and a 0 count pause frame will be sent.

#### 12.2.1.4.6.13.2 Flow Control Trigger

Receive flow control is triggered (when enabled), when the number of words in the receive FIFO is greater than or equal to the value written in the CPSW\_PN\_RX\_FLOW\_THRESH\_REG[8-0] COUNT bit field. The flow control packet runout is then contained in the remainder of the receive FIFO.

#### 12.2.1.4.6.13.3 Ethernet Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Ethernet port from transmitting any further frames. Incoming pause frames are only acted upon when the [0] FULLDUPLEX and [4] TX\_FLOW\_EN bits in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the [24] RX\_CMF\_EN (RX Copy MAC Control Frames Enable) bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register is set. The [4] TX\_FLOW\_EN and [0] FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- [4] TX\_FLOW\_EN is set in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register, and
- the RX maximum frame length is 64 bytes inclusive (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_MAXLEN\_REG[13-0] RX\_MAXLEN), and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If [4] TX\_FLOW\_EN in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01, or the Ethernet port SL\_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_TX\_PAUSETIMER\_REG[15-0] TX\_PAUSETIMER. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 Bytes. The standard allows pause frames longer than 64 Bytes to be discarded or interpreted as valid pause frames. The Ethernet port will recognize any pause frame between 64 Bytes and CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_MAXLEN\_REG[13-0] RX\_MAXLEN bytes in length.

#### 12.2.1.4.6.14 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the LPSC to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the CPSW3\_CPSW\_NU\_EEE\_PRESCALE\_REG register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IDLE2LPI\_REG[23-0] COUNT) are written with the desired values
3. The port LPI to Wake count values (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_LPI2WAKE\_REG[23-0] COUNT) are written with the desired values
4. The [0] EEE\_EN bit is set in the switch CSL\_CPSW3\_CPSW\_NU\_CONTROL\_REG register

EEE operation can begin after configuration. The host allows (through LPSC) the CPSW to enter a low power state by asserting the EEE\_CLKSTOP\_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert EEE\_CLKSTOP\_REQ to the CPSW.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IDLE2LPI\_REG value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPPI (port 0) LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive have both been idle for the Idle to LPI time (CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_IDLE2LPI\_REG). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

#### Note

External PHY signaling has the following conditions:

- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX\_CTL at the rising and the falling TXC edges, respectively. RXDV and RXER are the sampled values of RX\_CTL at the rising and the falling RXC clock edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the EEE\_CLKSTOP\_ACK signal is asserted, and the LPSC is allowed to stop the module clock. When EEE\_CLKSTOP\_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform target read/write operations to the CPSW memory address space, and then turn off the clock again while EEE\_CLKSTOP\_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting EEE\_CLKSTOP\_REQ. There must be at least one rising edge of the clock before EEE\_CLKSTOP\_REQ is de-asserted. The module EEE\_CLKSTOP\_ACK output signal will be deasserted on the

clock after the de-assertion of `EEE_CLKSTOP_REQ`. The host may queue CPPI receive packets at any time without regard to the CPSW module LPI state. The Host must deassert `EEE_CLKSTOP_REQ` on wakeup for a minimum of two clock periods. If `EEE_CLKSTOP_REQ` is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet port to awaken.

The external Ethernet PHY's can also wakeup the LPSC by removing the Ethernet receive LPI indication. If the CPSW module is in Idle state with `EEE_CLKSTOP_ACK` asserted and the receive LPI indication is removed, the `EEE_CLKSTOP_WAKEUP` signal will be asynchronously asserted. On wakeup, the LPSC restarts the clock and de-assert the `EEE_CLKSTOP_REQ` signal. The `EEE_CLKSTOP_WAKEUP` signal will be synchronously deasserted with `EEE_CLKSTOP_ACK`. Upon the deassertion of `EEE_CLKSTOP_REQ`, the Ethernet ports will count the `CPSW3_CPSW_NU_CPSW_NU_ETH_MAC_i_PN_LPI2WAKE_REG` time for each port at which time the port is available for transmit.

#### 12.2.1.4.6.15 Ethernet Switch Latency

When CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

The store and forward latency is shown in [Table 12-129](#):

**Table 12-129. Switch Latency**

Mode	Latency
Gig (1000)	880 ns
100	1.3 $\mu$ s
10	6.5 $\mu$ s

#### 12.2.1.4.6.16 MAC Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW operation to be completely or partially suspended. Each Ethernet port has associated emulation control registers (`CPSW3_CPSW_NU_EM_CONTROL_REG` and `CPSW3_CPSW_NU_CPSW_NU_ETH_MAC_i_PN_MAC_EMCONTROL_REG`). The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

#### Ethernet port Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the `CPSW3_CPSW_NU_CPSW_NU_ETH_MAC_i_PN_MAC_EMCONTROL_REG` register) allow Ethernet port operation to be suspended. When the emulation suspend state is entered, the Ethernet port will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the Ethernet port after the suspend state is entered are ignored.

[Table 12-130](#) shows the operations of the emulation control input and register bits.

**Table 12-130. Emulation Control Input**

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### 12.2.1.4.6.17 MAC Command IDLE

The CMD\_IDLE bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register allows MAC operation to be suspended. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

#### 12.2.1.4.6.18 CPSW Network Statistics

The CPSW has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of CPSW0\_RST. When one or more port enable (Pn\_STAT\_EN) bits in the CPSW3\_CPSW\_NU\_STAT\_PORT\_EN\_REG register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STAT\_PEND0) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

[Table 12-131](#) and [Table 12-132](#) summarize network statistics.

##### 12.2.1.4.6.18.1 Rx-only Statistics Descriptions

##### 12.2.1.4.6.18.1.1 Good Rx Frames (Offset = 3A000h)

###### All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

##### 12.2.1.4.6.18.1.2 Broadcast Rx Frames (Offset = 3A004h)

###### All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for address FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

##### 12.2.1.4.6.18.1.3 Multicast Rx Frames (Offset = 3A008h)

###### All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.1.4.6.18.1.4 Pause Rx Frames (Offset = 3A00Ch)**

##### **Ethernet port N where N = 1 to 2**

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (TX\_FLOW\_EN = 1h).

The port could have been in either half or full-duplex mode.

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.1.4.6.18.1.5 Rx CRC Errors (Offset = 3A010h)**

##### **All ports**

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had no code/align error
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles, and
- Failing the Frame Check Sequence test.

#### **12.2.1.4.6.18.1.6 Rx Align/Code Errors (Offset = 3A014h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had either an alignment error, or a code error.

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles

- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

---

**Note**

RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

---

**12.2.1.4.6.18.1.7 Oversize Rx Frames (Offset = 3A018h)****All ports**

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX\_MAXLEN in bytes
- Had no CRC error, alignment error, or code error.

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

**12.2.1.4.6.18.1.8 Rx Jabbers (Offset = 3A01Ch)****All ports**

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX\_MAXLEN in bytes
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

**12.2.1.4.6.18.1.9 Undersize (Short) Rx Frames (Offset = 3A020h)****All ports**

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes
- Had no CRC error, alignment error, or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

**12.2.1.4.6.18.1.10 Rx Fragments (Offset = 3A024h)****Ethernet port N where N = 1 to 2**

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long

- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half-duplex, collision-based flow control

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.1.4.6.18.1.11 RX IPG Error (Offset = 3A05Ch)**

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

#### **12.2.1.4.6.18.1.12 ALE Drop (Offset = 3A028h)**

##### **All ports**

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the PORT\_MASK was zero).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was not equal to the source address
- the packet was not destined for the port it was receive on
- had a zero PORT\_MASK

#### **12.2.1.4.6.18.1.13 ALE Overrun Drop (Offset = 3A02Ch)**

##### **All ports (non cut-thru mode)**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with RX\_CSF\_EN at a rate that exceeded the maximum lookup rate.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- The port has no receive priorities enabled for cut-thru, and
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

##### **Ethernet Ports (cut-thru mode)**

The total number of received frames on a port that were dropped due to packet errors. This statistic does not count error frames that are sent to the host with a set CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[22] RX\_CEF\_EN or CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG[24] RX\_CMF\_EN.

- was any data or MAC control frame, and
- the port has at least one receive priority enabled for cut thru, and
- the received packet was long, mac\_control, code, align, crc error, and
- was dropped on receive (not transferred to the host due to error enable bits).

#### **12.2.1.4.6.18.1.14 Rx Octets (Offset = 3A030h)**

##### **All ports**

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode

- Of length 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.1.4.6.18.1.15 Rx Bottom of FIFO Drop (Offset = 3A084h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames received on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI receive port) should not drop packets on receive because port 0 receive flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. An overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- Was dropped on port 0 due to a lack of memory space in the receive FIFO.

---

#### **Note**

This statistic should be zero if proper flow control is being followed.

---

##### **Host port 0**

This statistic also counts frames dropped on port 0 that were 17 to 63 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet was dropped. No other statistics are counted for frames shorter than 33 bytes.

#### **12.2.1.4.6.18.1.16 Portmask Drop (Offset = 3A088h)**

##### **All ports**

The total number of frames received on a port that were dropped by the ALE (the ALE did not forward the packet to any port). Port mask drop frame is defined to be:

- Any data or MAC control frame
- Any length greater than 32 bytes
- Was dropped by the ALE due to PORT\_MASK=0 (was not sent to any destination port)
- Was not a long or error packet with the port in cut-thru mode
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

---

#### **Note**

This statistic does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero PORT\_MASK.

---

#### **12.2.1.4.6.18.1.17 Rx Top of FIFO Drop (Offset = 3A08Ch)**

##### **All ports**

The total number of frames received on a port that had a start-of-frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode

- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error or code error
- had a SOF of frame overrun on another port egress.

#### **12.2.1.4.6.18.1.18 ALE Rate Limit Drop (Offset = 3A090h)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were reduced due to rate limiting).

#### **12.2.1.4.6.18.1.19 ALE VLAN Ingress Check Drop (Offset = 3A094h)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to VLAN ingress check failure.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the VLAN ID ingress check failed (the receive port was not in the group)
- The address lookup did not return a match with the SUPER bit set.

#### **12.2.1.4.6.18.1.19.1 ALE DA=SA Drop (Offset = 3A098h)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to destination address equal to source address.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was equal to the source address
- the source address was not an entry in the table.

#### **12.2.1.4.6.18.1.19.2 Block Address Drop (Offset = 3A09Ch)**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source or destination address matched a table entry with the block bit set.

#### **12.2.1.4.6.18.1.19.3 ALE Secure Drop (Offset = 3A0A0h)**

The total number of frames received on a port that were dropped (zero port\_mask) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source address is an entry in the table with the SECURE bit set and a port number for a different receive port.

#### **12.2.1.4.6.18.1.19.4 ALE Authentication Drop (Offset = 3A0A4h)**

The total number of frames received on a port that were dropped (zero port\_mask) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- CPSW3\_CPSW\_NU\_ALE\_ALE\_CONTROL[1] ENABLE\_AUTH\_MODE is set to 1h, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the SUPER bit set.

#### **12.2.1.4.6.18.1.19.5 ALE Unknown Unicast (Offset = 3A0A8h)**

##### **All ports**

The total number of frames received on a port that had a unicast destination address with an unknown source address.

- was any data frame with a unicast destination address
- the source address was not a table entry
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

Note: The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

#### **12.2.1.4.6.18.1.19.6 ALE Unknown Unicast Bytecount (Offset = 3A0ACh)**

The total number of bytes received on a port that had a unicast destination address with an unknown source address.

#### **12.2.1.4.6.18.1.19.7 ALE Unknown Multicast (Offset = 3A0B0h)**

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

#### **12.2.1.4.6.18.1.19.8 ALE Unknown Multicast Bytecount (Offset = 3A0B4h)**

The total number of bytes received on a port that had a multicast destination address with an unknown source address.

#### **12.2.1.4.6.18.1.19.9 ALE Unknown Broadcast (Offset = 3A0B8h)**

The total number of frames received on a port that had a broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and

- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

#### **12.2.1.4.6.18.1.19.10 ALE Unknown Broadcast Bytecount (Offset = 3A0BCh)**

The total number of bytes received on a port that had a broadcast destination address with an unknown source address.

#### **12.2.1.4.6.18.1.19.11 ALE Policer/Classifier Match (Offset = 3A0C0h)**

### **All ports**

The total number of frames received on a port that matched a policer. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.1.4.6.18.2 ALE Policer Match Red (Offset = 3A0C4h)**

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.1.4.6.18.3 ALE Policer Match Yellow (Offset = 3A0C8h)**

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.1.4.6.18.4 IET Receive Assembly Error (Offset = 3A140h)**

The total number of preemptable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine)

#### **12.2.1.4.6.18.5 IET Receive Assembly OK (Offset = 3A144h)**

The total number of correctly received and re-assembled preemptable frames.

- any preemptable frame received
- was any size, and
- was correctly received and re-assembled without error

#### **12.2.1.4.6.18.6 IET Receive SMD Error (Offset = 3A148h)**

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and

- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note: If IET\_ENABLE is not set, this statistic counts any received frame with any non express SMD.

#### **12.2.1.4.6.18.7 IET Receive Merge Fragment Count (Offset = 3A14Ch)**

The total number of received non-initial fragments that did not have an assembly error. The IET stat CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_RXFRAGMENTS\_k is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error

#### **12.2.1.4.6.18.8 Rx Cut Thru with No Delay**

The total number of frames received on the port and subsequently sent cut-thru to all internal destination port FIFOs with no delay. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size greater than or equal to 128 bytes, and
- was sent cut-thru by the receive port to all destination ports without delay.

#### **12.2.1.4.6.18.9 Rx Cut Thru with Delay**

The total number of frames received on the port and subsequently sent cut-thru to all destination ports with some amount of delay. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size greater than or equal to 128 bytes, and
- was sent cut-thru by the receive port to all destination ports with some amount of delay.

#### **12.2.1.4.6.18.10 Rx Cut Thru Store-and-Forward**

The total number of frames received on the port were attempted to be sent cut-thru to all destination ports but were held off due to configuration or traffic conditions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size greater than or equal to 128 bytes, and
- was attempted to be sent cut-thru by the receive port to all destination ports but was sent store-and-forward.

#### **12.2.1.4.6.18.11 Tx-only Statistics Descriptions**

The maximum and minimum transmit frame size is software controllable.

##### **12.2.1.4.6.18.11.1 Good Tx Frames (Offset = 3A034h)**

#### **All ports**

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **Note**

A nonzero CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_TXDEFERREDFRAMES\_k value should be subtracted from this value to obtain the actual good frames value (the good frames statistic also increments on a transmitted CRC error).

##### **12.2.1.4.6.18.11.2 Broadcast Tx Frames (Offset = 3A038h)**

#### **All ports**

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **12.2.1.4.6.18.11.3 Multicast Tx Frames (Offset = 3A03Ch)**

##### **All ports**

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **12.2.1.4.6.18.11.4 Pause Tx Frames (Offset = 3A040h)**

##### **Ethernet port N where N = 1 to 2**

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex, carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64-byte multicast frames so will appear in the *Tx Multicast Frames* and *64octet Frames* statistics.

#### **12.2.1.4.6.18.11.5 Deferred Tx Frames (Offset = 3A044h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.11.6 Collisions (Offset = 3A048h)**

##### **Ethernet port N where N = 1 to 2**

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
  - Was destined for any unicast, broadcast or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

#### **12.2.1.4.6.18.11.7 Single Collision Tx Frames (Offset = 3A04Ch)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.11.8 Multiple Collision Tx Frames (Offset = 3A050h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.11.9 Excessive Collisions (Offset = 3A054h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.11.10 Late Collisions (Offset = 3A058h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The *Late Collisions* statistic dominates over the single-, multiple-, and excessive- collision statistics. If a late collision occurs, the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.11.11 Carrier Sense Errors (Offset = 3A060h)**

##### **Ethernet port N where N = 1 to 2**

The total number of frames on the port that experienced carrier loss. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

#### 12.2.1.4.6.18.11.12 Tx Octets (Offset = 3A064h)

##### All ports

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

#### 12.2.1.4.6.18.11.13 Transmit Priority 0-7 (Offset = 3A180h to 3A1A8h)

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- Any frame transmitted from priority 0-7, and
- Was less than or equal to CPSW3\_CPSW\_NU\_TX\_PRI0\_MAXLEN\_REG to CPSW3\_CPSW\_NU\_TX\_PRI7\_MAXLEN\_REG
- Collision retries are not counted in this statistic.
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note: The Transmit Priority 0-7 Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

#### 12.2.1.4.6.18.11.14 Transmit Priority 0-7 Drop (Offset = 3A1C0h to 3A1E8)

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to CPSW3\_CPSW\_NU\_TX\_PRI0\_MAXLEN\_REG to CPSW3\_CPSW\_NU\_TX\_PRI7\_MAXLEN\_REG.

- Any frame destined to be transmitted from priority 0-7, and
- Was any size, and
- Was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than CPSW3\_CPSW\_NU\_TX\_PRI0\_MAXLEN\_REG to CPSW3\_CPSW\_NU\_TX\_PRI7\_MAXLEN\_REG.

Note: The Transmit Priority 0-7 Drop Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

#### 12.2.1.4.6.18.11.15 Tx Memory Protect Errors (Offset = 3A17Ch)

##### All ports

The total number of transmit frames on the port that had a memory protect CRC error on egress:

- Any frame destined to be transmitted,
- Was any size
- Had a memory protect CRC error on egress.

##### Note

1. Frames to the host with memory protect errors are dropped via TXST\_DROP. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.
2. This statistic is 8-bits wide only and will not rollover but will limit at 0xFF.
3. A non-zero value in this statistic will issue a STAT\_PEND0 interrupt for the associated port.

#### 12.2.1.4.6.18.11.16 IET Transmit Merge Hold Count (Offset = 3A150h)

The total number of preemptable frames that were preempted and reassembled by the assertion of MAC\_HOLD in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_IET\_CONTROL\_REG register or were preempted by Enhanced Scheduled Traffic (EST). The IET statistic can be derived and maintained by software.

- Any frame destined to be transmitted on the preemptable port, and

- was any size, and
- was preempted by the assertion of MAC\_HOLD.
- was preempted by Enhanced Scheduled Traffic (EST).

#### **12.2.1.4.6.18.11.17 IET Transmit Merge Fragment Count (Offset = 3A14Ch)**

The total number of non-initial preemptable transmit fragments on preemptable transmit.

- Any frame destined to be transmitted on the preemptable port, and
- Was any size, and
- was a non-initial fragment.

#### **12.2.1.4.6.18.11.18 Tx CRC Errors**

The total number of frames transmitted on the port with a CRC error. Such a frame:

- was any data frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- was sent cut-thru by the receive port and was received with a CRC error, or
- was a transmitted frame that also had a memory protect error (counted also in CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_TX\_MEMORY\_PROTECT\_ERROR\_k).

---

#### **Note**

For port0 this statistics location (CPSW\_STAT0\_TXDROP) counts the number of drops to the host due to a memory protect error, or due to a cut-thru packet having an error on reception but was forwarded with the error. The Ethernet port receive error could be long, CRC, jabber, or code. For Ethernet ports, the receive error could be the same but the packet is transmitted with at least one byte of the actual outgoing packet CRC inverted to indicate the error.

---

---

#### **Note**

A nonzero CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_TXDEFERREDFRAMES\_k value should be subtracted from the CPSW3\_CPSW\_NU\_CPSW\_NU\_STAT\_TXGOODFRAMES\_k value to obtain the actual good frames value (the good frames statistic also increments on a transmitted CRC error).

---

#### **12.2.1.4.6.18.11.19 Tx Cut Thru**

The total number of cut-thru frames transmitted on the port with or without delay. Such a frame:

- was any data frame destined for any unicast, broadcast or multicast address, and
- was any size greater than or equal to 128 bytes, and
- was sent cut-thru by the receive port.
- was transmitted cut-thru with or without delay.

#### **12.2.1.4.6.18.11.20 Tx Cut Thru Store-and-Forward**

The total number of cut-thru frames transmitted store and forward. Such a frame:

- was any data frame destined for any unicast, broadcast or multicast address, and
- was any size greater than or equal to 128 bytes, and
- was sent cut-thru by the receive port.
- was transmitted store-and-forward due to traffic congestion.

#### **12.2.1.4.6.18.12 Rx- and Tx (Shared) Statistics Descriptions**

##### **12.2.1.4.6.18.12.1 Rx + Tx 64 Octet Frames (Offset = 3A068h)**

#### **All ports**

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error

- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.12.2 Rx + Tx 65–127 Octet Frames (Offset = 3A06Ch)**

##### **All ports**

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.12.3 Rx + Tx 128–255 Octet Frames (Offset = 3A070h)**

##### **All ports**

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.12.4 Rx + Tx 256–511 Octet Frames (Offset = 3A074h)**

##### **All ports**

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.12.5 Rx + Tx 512–1023 Octet Frames (Offset = 3A078h)**

##### **All ports**

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.12.6 Rx + Tx 1024\_Up Octet Frames (Offset = 3A07Ch)**

##### **All ports**

The total number of frames of size 1024 to RX\_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to RX\_MAXLEN bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### 12.2.1.4.6.18.12.7 Net Octets (Offset = 3A080h)

#### All ports

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (that is, multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

#### 12.2.1.4.6.18.13

**Table 12-131. Rx Statistics Summary**

Rx Statistic	Fra me/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data <sup>(5)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024- rx_max len	>rx_max len	Flow Coll. (8)	CRC Error	Align/ Code	Overrun	Add r. Disc.

Rx Overruns <sup>(9)</sup>	F	Rx	(y	y	y	y	y	(y	y	y	y	y	y	y	y	-	-	-	y	n
64octet Frames	F	Rx+ Tx <sup>(3)</sup>	(y	y	y	y	y	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	Rx+ Tx	(y	y	y	y	y	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	Rx+ Tx	(y	y	y	y	y	n	n	n	y	n	n	n	n	-	-	-	-	n

**Table 12-131. Rx Statistics Summary (continued)**

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data <sup>(5)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. <sup>(8)</sup>	CRC Error	Align/ Code	Overrun	Add. r. Disc.
			Pause frame	Non-pause <sup>(4)</sup>	Multicast	Broadcast	Unicast													
256-511octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	-	-	-	-	n	
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	Rx+ Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	y)	-	-	-	-

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx\_overruns stat is for RX\_MOF\_OVERRUNS and RX\_SOF\_OVERRUNS added together.

**Table 12-132. Tx Statistics Summary**

Tx Statistic <sup>(9)</sup>	Frame Type							Frame Size (bytes)							Event										
	Fra me/ Oct	Tx/ Rx +Tx	MAC control (4)		Data			64	65- 127	128- 255	256- 511	512- 1023	1024- 1535	>1535	CRC Error	Collision Type					No Carrier	Queue	Deferred	Under run	
			Pause- MAC	Any- CPU	Multi- cast	Broad- cast	Uni- cast																		
																Flow <sup>(8)</sup>	1	2-15	16	Late

Net Octets	O	Rx+ Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	<sup>(7)</sup> \$	\$	\$	\$	\$	-	-	-	

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
- (5) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 12-131](#).)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

#### 12.2.1.4.7 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

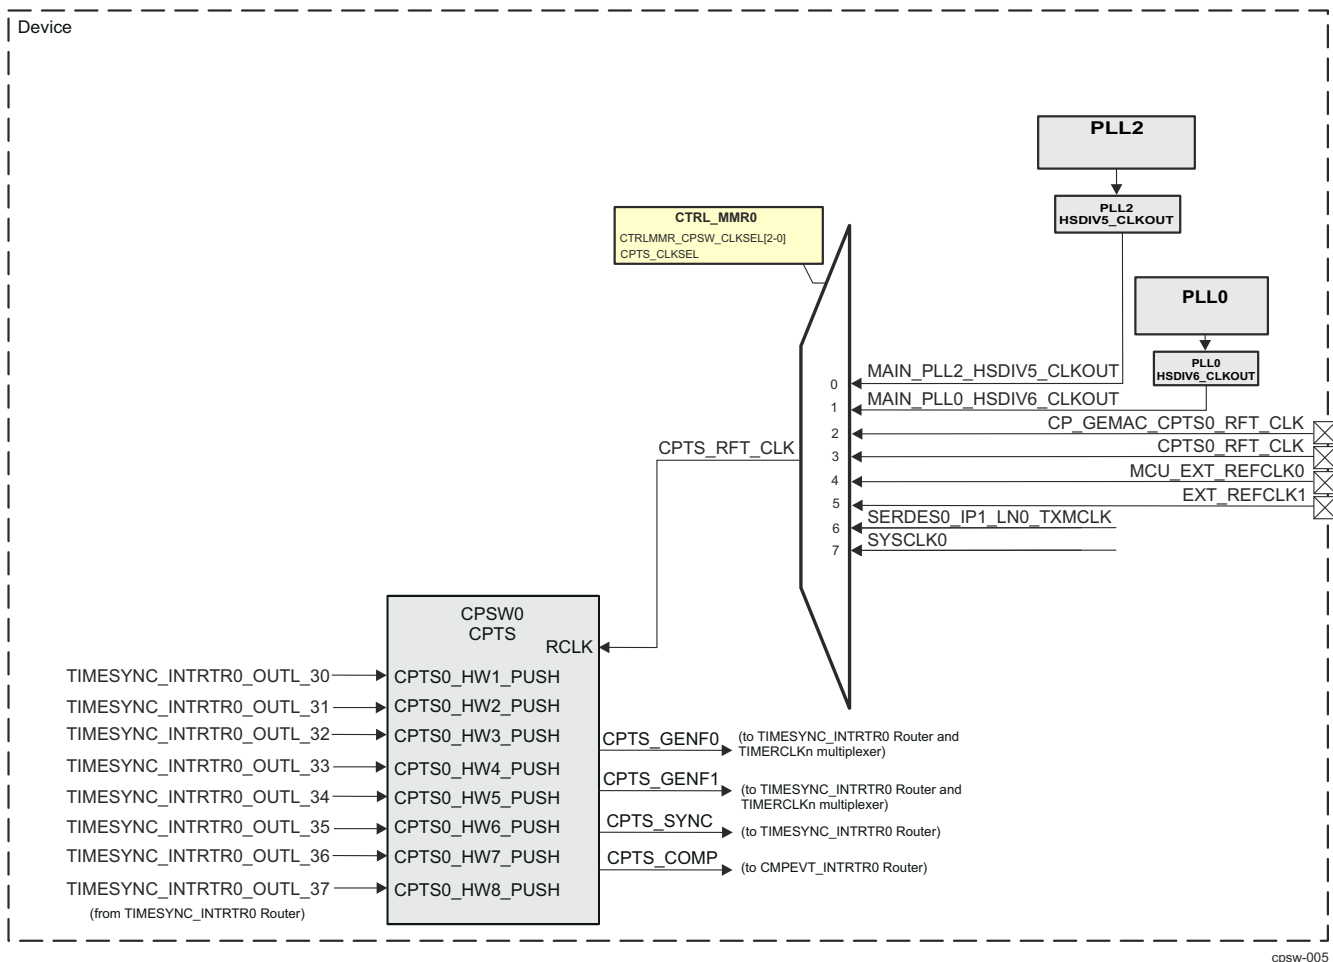

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling

- Supports up to 8 hardware timestamp push inputs
- Supports timestamp counter compare output (CPTS\_COMP)
- Supports timestamp counter bit output (CPTS\_SYNC)
- Supports a configurable number of timestamp Generator bit outputs (CPTS\_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (CPTS\_ESTFn).
- 32-bit and 64-bit timestamp modes with PPM and nudge adjustment.

#### 12.2.1.4.7.1 CPSW0 CPTS Integration

This section describes CPTS module integration in the CPSW0 module, including information about clocks, resets, and hardware requests.

Figure 12-102 shows CPTS integration in the device CPSW0 module.

**Figure 12-102. CPSW0 CPTS Integration**

CPTS IEEE 1588 clock (RCLK) is selected through the CTRLMMR\_CPTS\_CLKSEL register.

#### Note

For more information about CPTS clocks and resets, see *CPWS0 Clocks* in *CPSW0 Integration*.

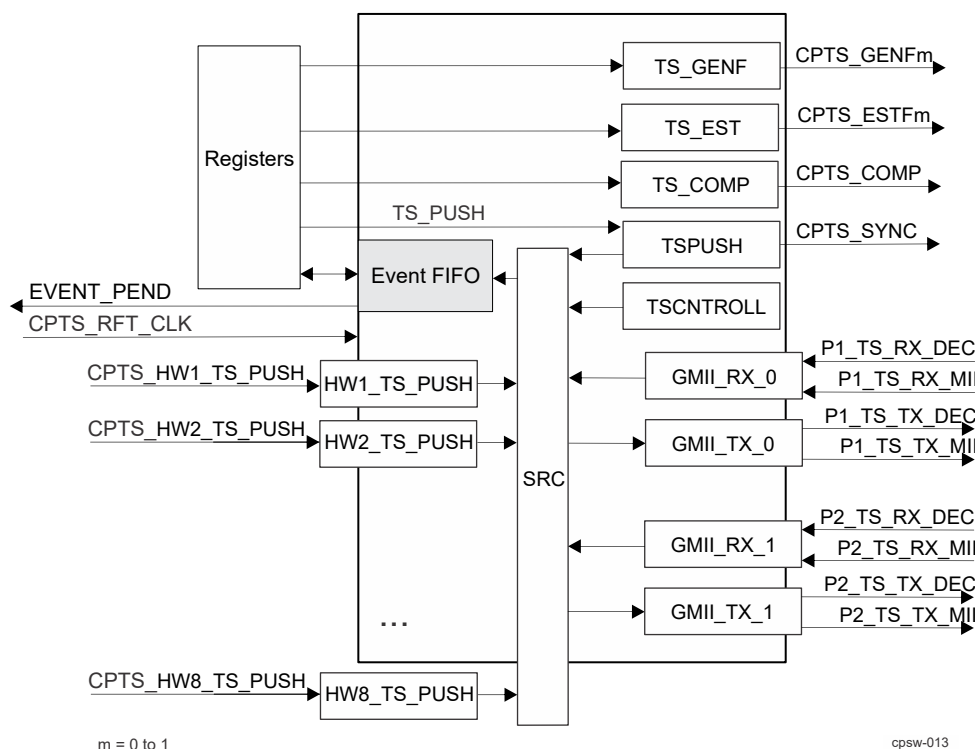

#### 12.2.1.4.7.2 CPTS Architecture

Figure 12-103 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on external port of the CPSW are recorded. At the same time,

each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWN\_TS\_PUSH) and software (TS\_PUSH) can be used to read the current time stamp value through the Event FIFO. The reference clock used for the time stamp (CPTS\_RFT\_CLK) can be derived from several sources.

**Figure 12-103. CPTS Block Diagram**

### Note

See [Section 12.2.1.4.7.1](#), *CPSW0 CPTS Integration* for CPTS integration in the device CPSW0 module.

#### 12.2.1.4.7.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the CPTS\_CLKSEL value in the CTRLMMR\_CPTS\_CLKSEL register with the desired reference clock selection. This value is allowed to be written only when the CPTS\_EN bit in the CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG register is cleared to zero.
3. Set the CPTS\_EN bit in the CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG register.
4. If using interrupts and not polling, enable the interrupt by setting the TS\_PEND\_EN bit in the CPSW3\_CPSW\_NU\_CPTS\_INT\_ENABLE\_REG register.

#### 12.2.1.4.7.4 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN bit is set to 1h. When CPTS\_EN bit is cleared to 0h, the time stamp value is reset to 0h.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPSW3\_CPSW\_NU\_CPTS\_TS\_LOAD\_VAL\_REG / CPSW3\_CPSW\_NU\_CPTS\_TS\_LOAD\_HIGH\_VAL\_REG and CPSW3\_CPSW\_NU\_CPTS\_TS\_LOAD\_EN\_REG registers).

#### 12.2.1.4.7.5 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN bit is set to 1h. When CPTS\_EN bit is cleared to 0h, the time stamp value is reset to 0h.

64-bit mode is selected when CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[5] MODE bit set to 1h.

For test purposes, the time stamp value can be written via the time stamp load function (CPSW3\_CPSW\_NU\_CPTS\_TS\_LOAD\_EN\_REG, CPSW3\_CPSW\_NU\_CPTS\_TS\_LOAD\_VAL\_REG, and CPSW3\_CPSW\_NU\_CPTS\_TS\_LOAD\_HIGH\_VAL\_REG registers). The CPSW3\_CPSW\_NU\_CPTS\_TS\_ADD\_VAL\_REG feature is included to allow 1ns timestamp operations with an CPTS\_RFT\_CLK rate less than 1Ghz. [Table 12-133](#) shows the CPTS\_RFT\_CLK and CPSW3\_CPSW\_NU\_CPTS\_TS\_ADD\_VAL\_REG values for 1ns operations.

**Table 12-133. ADD\_VAL feature**

CPTS_RFT_CLK (MHz)	CPSW3_CPSW_NU_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL
1 GHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

#### 12.2.1.4.7.6 64-Bit Timestamp Nudge

The 64-bit TIME\_STAMP value can be adjusted by writing the CPSW3\_CPSW\_NU\_CPTS\_TS\_NUDGE\_VAL\_REG[7-0] TS\_NUDGE\_VAL bit field value which is a two's complement value. A value of FFh will subtract 1 clock cycle from the next incremented 64-bit time stamp value (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG[31-0] TIME\_STAMP and CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG[31-0] TIME\_STAMP value). A nudge value of 1h will add 1 clock cycle to the next incremented TIME\_STAMP[63-0] value. For example, if the current TIME\_STAMP value is F06h, and CPSW3\_CPSW\_NU\_CPTS\_TS\_ADD\_VAL\_REG[2-0] ADD\_VAL = 3h, the next incremented timestamp value would be F0Ah without a nudge and F0Ah +/- [7-0] TS\_NUDGE\_VAL with a nudge. The [7-0] TS\_NUDGE\_VAL value is cleared to zero when the nudge has occurred.

#### 12.2.1.4.7.7 64-bit Timestamp PPM

The 64-bit TIME\_STAMP can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the CPSW3\_CPSW\_NU\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL (Time stamp PPM Low value) and CPSW3\_CPSW\_NU\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL (Time stamp PPM High value) enables PPM operations. The adjustment is up or down depending on the [7] TS\_PPM\_DIR bit in the CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG register. The TIME\_STAMP value is increased by the PPM value when [7] TS\_PPM\_DIR bit is cleared. The TIME\_STAMP value is decreased by the PPM value when [7] TS\_PPM\_DIR bit is set.

**Parts Per Million example:**

To adjust for 100 parts per million the configured value for TS\_PPM[41-0] (through CPSW3\_CPSW\_NU\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL and CPSW3\_CPSW\_NU\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL) is:  
 $1,000,000/100 = 10,000(\text{decimal})$

#### Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS\_RFT\_CLK the configured value for TS\_PPM[41-0] (through CPSW3\_CPSW\_NU\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL and CPSW3\_CPSW\_NU\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL) is:  
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds}/\text{hour}) = 34630\text{B8A000} (\text{hex})$

#### 12.2.1.4.7.8 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 32 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### 12.2.1.4.7.9 Timestamp Compare Output

CPTS features one Time Stamp Compare (CPTS\_COMP) output. The CPTS\_COMP function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. CPTS\_COMP is not compatible with timestamp PPM or a non-zero CPSW3\_CPSW\_NU\_CPTS\_TS\_ADD\_VAL\_REG[2-0] ADD\_VAL value.

##### 12.2.1.4.7.9.1 Non-Toggle Mode: 32-bit

The CPTS\_COMP output is asserted for CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH periods when the CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG[31-0] TIME\_STAMP value (lower 32-bits) compares with the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_VAL and the length value is non-zero. The CPTS\_COMP rising edge occurs three CPTS\_RFT\_CLK clock periods after the values compare. A timestamp compare event is pushed into the event FIFO when CPTS\_COMP is asserted. The polarity of the CPTS\_COMP output is determined by the CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit. The output is asserted low when the polarity bit is 0h.

##### 12.2.1.4.7.9.2 Non-Toggle Mode: 64-bit

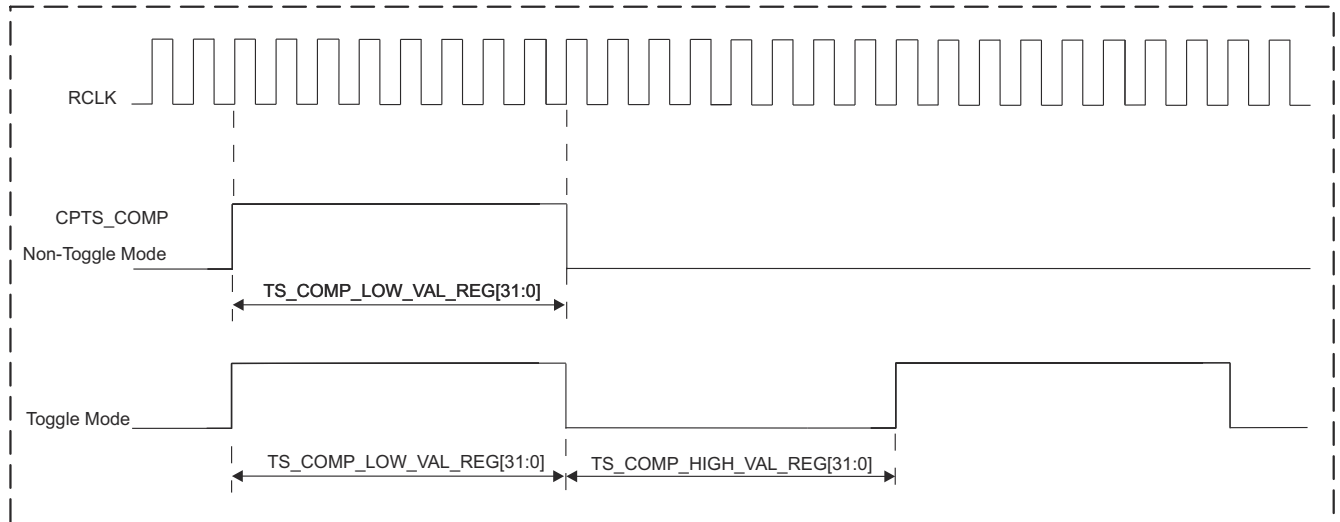

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIME\_STAMP are used (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG and CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG). In 32-bit mode only the lower 32-bits (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG) are used.

##### 12.2.1.4.7.9.3 Toggle Mode: 32-bit

The CPTS\_COMP output is asserted (CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH) for CPTS\_RFT\_CLK clock periods when the TIME\_STAMP[31:0] value compares with the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG and the length value is non-zero. The CPTS\_COMP toggles thereafter on CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_LENGTH for CPTS\_RFT\_CLK periods. The length high or low can be adjusted by writing the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE bit field value which is a two's complement value. A value of FFh will subtract one CPTS\_RFT\_CLK period from the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_LENGTH value. A value of 0x01h will add one CPTS\_RFT\_CLK period to the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH value. Only a single high or low time is adjusted (nudged) and the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred. The CPTS\_COMP output is asserted low when the CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit is 0h. No compare events and no CPTS\_EVT interrupts are generated in toggle mode. The CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[6] TS\_COMP\_TOG bit must be set for toggle mode (value 1h). Note this bit must be set before writing a non-zero value to CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG register.

#### 12.2.1.4.7.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **TIME\_STAMP** are used (**CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG** and **CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG**). In 32-bit mode only the lower 32-bits (**CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG**) are used.

cpsw-0013a

**Figure 12-104. CPTS\_COMP Output in Toggle and Non-Toggle Mode**

#### 12.2.1.4.7.10 Timestamp Sync Output

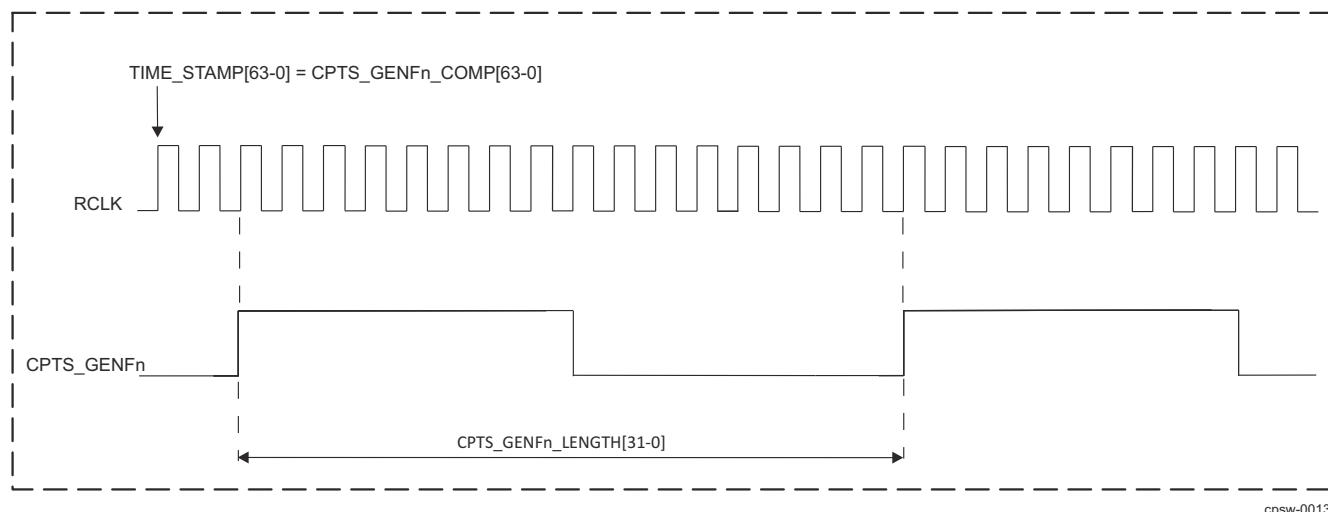

The **CPTS\_SYNC** output is a selected bit of the [31:0]**TIME\_STAMP** counter value. One of bits 17-31 can be selected in **CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[31:28]** **TS\_SYNC\_SEL**. The **CPTS\_SYNC** output is disabled when **CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[31:28]** **TS\_SYNC\_SEL** is zero.

If the selected counter bit is 1 at the time when **TS\_SYNC\_SEL** value is written then a rising edge will not occur on the **CPTS\_SYNC** output. A rising edge will occur on the **CPTS\_SYNC** output upon the next transition to 1 of the selected counter bit. The **TS\_SYNC\_SEL** value must be written to zero before changing to a different non-zero value. No events are generated due to the **CPTS\_SYNC** operation. The **CPTS\_SYNC** output is two **CPTS\_RFT\_CLK** periods after the actual count value.

#### 12.2.1.4.7.11 Timestamp GENFn Output

The **CPTS\_GENFn** outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The **CPTS\_GENFn** output cycle is **CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_LENGTH\_REG\_L[31:0]** **CPTS\_RFT\_CLK** periods (which is different than **CPTS\_COMP** operation). [Figure 12-105](#) represents the **CPTS\_GENFn** output signal.

The **CPTS\_GENFn** output cycle is **CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_LENGTH\_REG\_L[31:0]** **CPTS\_RFT\_CLK** periods beginning when the 64-bit **TIME\_STAMP** value compares with the 64-bit **GENFn\_COMP** value (**CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_COMP\_LOW\_REG\_L** and **CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_COMP\_HIGH\_REG\_L** registers) and the length value is non-zero. The **CPTS\_GENFn** output cycle repeats thereafter every **CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_LENGTH\_REG\_L[31:0]** **CPTS\_RFT\_CLK** periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the **CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG[2]** **TS\_COMP\_POLARITY** bit is low. No compare events and no **CPTS\_EVNT** interrupts are generated.

cpsw-0013b

**Figure 12-105. CPTS\_GENFn Output Signal Diagram**

#### 12.2.1.4.7.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_NUDGE\_REG[7:0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS\_RFT\_CLK from the CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_LENGTH\_REG\_L[31:0] value. A value of 1h will add 1 CPTS\_RFT\_CLK to the CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_LENGTH\_REG\_L[31:0] value. The CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_NUDGE\_REG[7:0] NUDGE value is cleared to zero when the nudge has occurred.

#### 12.2.1.4.7.11.2 GENFn PPM

The CPTS\_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_PPM\_LOW\_REG\_L/ CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_PPM\_HIGH\_REG\_L enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS\_RFT\_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_CONTROL\_REG[0] PPM\_DIR bit. When PPM\_DIR bit is set a single CPTS\_RFT\_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM\_DIR bit is cleared a single CPTS\_RFT\_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

#### Parts Per Million example:

To adjust for 100 parts per million the configured value for GENF\_PPM[41:0] (through CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_PPM\_LOW\_REG\_L and CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_PPM\_HIGH\_REG\_L) is:  
 $1,000,000/100 = 10,000$ (decimal)

#### Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS\_RFT\_CLK the configured value for GENF\_PPM[41:0] (through CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_PPM\_LOW\_REG\_L and CPSW3\_CPSW\_NU\_CPTS\_TS\_GENF\_PPM\_HIGH\_REG\_L) is:  
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600\text{ seconds/hour}) = 34630\text{B8A000}$  (hex)

#### 12.2.1.4.7.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

#### 12.2.1.4.7.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG through CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event
- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

##### 12.2.1.4.7.13.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the [0]TS\_PUSH bit of the CPSW3\_CPSW\_NU\_CPTS\_TS\_PUSH\_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG register) of the timestamp are zero in 32-bit mode.

##### 12.2.1.4.7.13.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

##### 12.2.1.4.7.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG[31:0] TIME\_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 12-106](#) shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

**Figure 12-106. Event FIFO Misalignment Condition**

#### 12.2.1.4.7.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs ( CPTS\_HW[1:4]\_TS\_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPTS Integration*. The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS\_RFT\_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW3\_CPSW\_NU\_CPTS\_CONTROL\_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 12.2.1.4.7.13.5 Ethernet Port Events

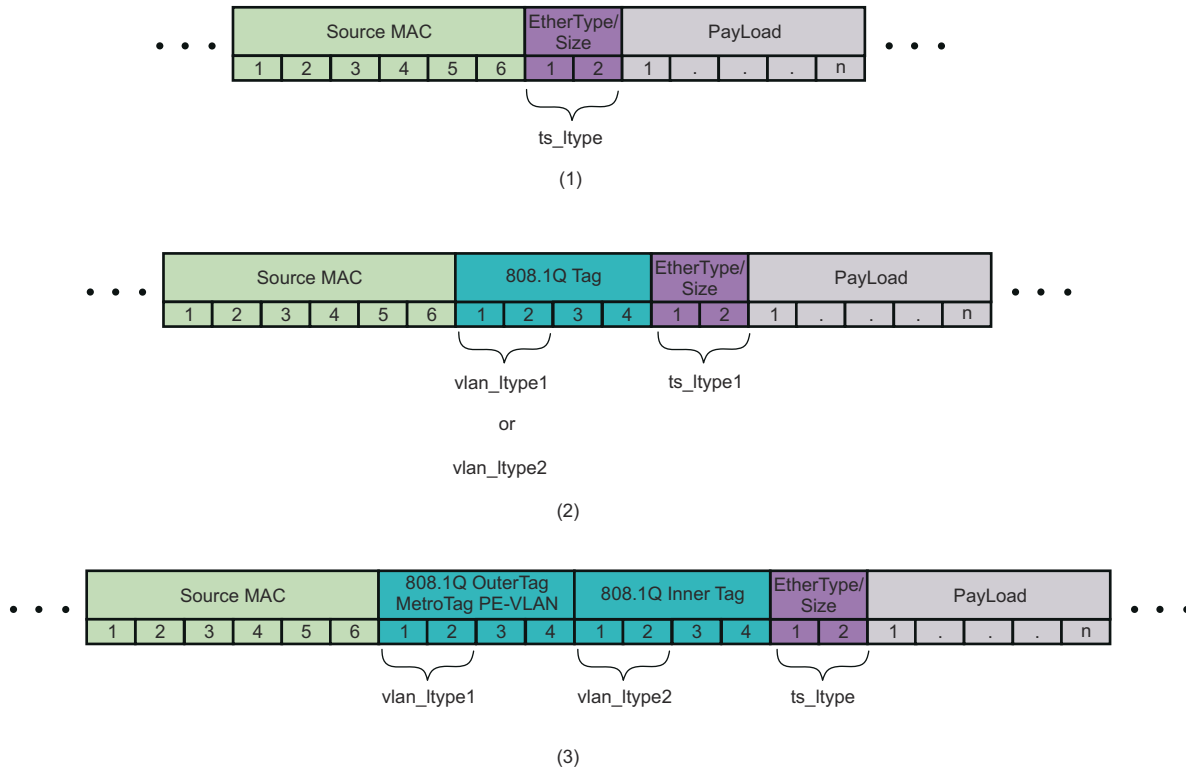

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the Payload field, as shown in [Figure 12-107](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS\_LTYPE1 field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG or the TS\_LTYPE2 field in CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 12-107](#). To indicate to the CPTS hardware that a

virtual LAN is in use, the TS\_TX\_VLAN\_LTYPE1\_EN (or TS\_TX\_VLAN\_LTYPE2\_EN) enable bit must be set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS\_VLAN\_LTYPE1 (or TS\_VLAN\_LTYPE2 depending on which enable bit was set) field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 12-107. In this case, both TS\_VLAN\_LTYPE1 and TS\_VLAN\_LTYPE2 must be enabled. The outer tag must match the value of the TS\_VLAN\_LTYPE1 field, and the inner tag must match the value of the TS\_VLAN\_LTYPE2 field.

**Figure 12-107. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)**

#### 12.2.1.4.7.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS\_RFT\_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

#### Annex D (IPv4)

1. Receive annex D time sync is enabled (TS\_RX\_ANNEX\_D\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x0800
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

#### Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 22 contains any value if CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h and Bytes 30 through 33 contain:
  - a. Decimal 224.0.1.129 and the TS\_129 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 224.0.1.130 and the TS\_130 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - c. Decimal 224.0.1.131 and the TS\_131 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - d. Decimal 224.0.1.132 and the TS\_132 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - e. Decimal 224.0.0.107 and the TS\_107 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set

-OR-

The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set and Bytes 30 through 33 contain any values.

8. Bytes 36 and 37 contain:
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set -OR-

- b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
11. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

### Annex E (IPv6)

1. Receive annex E time sync is enabled (TS\_RX\_ANNEX\_E\_EN bit is set in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x86dd.
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 21 contains any value if TS\_TTL\_NONZERO is set to 1h. Byte 21 is the TTL/HOP field.
6. The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0 and Bytes 38 through 53 contain:
  - a. FF0M:0:0:0:0:0:0:0181 and the TS\_129 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. FF0M:0:0:0:0:0:0:0182 and the TS\_130 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - c. FF0M:0:0:0:0:0:0:0183 and the TS\_131 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - d. FF0M:0:0:0:0:0:0:0184 and the TS\_132 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - e. FF0M:0:0:0:0:0:0:006B and the TS\_107 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set

### Note

All values above are 16-bit hex numbers where M is enabled in the TS\_MCAST\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL2\_REG register.

-OR-

The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set to 1h and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL2\_REG register is set, or
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL2\_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL2\_REG register.
10. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

### **Annex F (IEEE 802.3)**

1. Receive Annex F time sync is enabled (TS\_RX\_ANNEX\_F\_EN is set in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true:
  - a. The first packet LTYPE matches TS\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG/CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
  - b. The first packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG register
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
  - e. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG register.
  - f. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
  - g. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG

register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches TS\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG register.

- h. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register

3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
5. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

#### 12.2.1.4.7.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

#### Annex D (IPv4)

1. Transmit time sync is enabled (TS\_TX\_ANNEX\_D\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x0800
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the

CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x0800

3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

#### Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 22 contains any value if TS\_TTL\_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h and Bytes 30 through 33 contain:
  - a. Decimal 224.0.1.129 and the TS\_129 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 224.0.1.130 and the TS\_130 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - c. Decimal 224.0.1.131 and the TS\_131 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - d. Decimal 224.0.1.132 and the TS\_132 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - e. Decimal 224.0.0.107 and the TS\_107 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - f. The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
11. The packet was sent by host port 0.

#### Annex E (IPv6)

1. Transmit annex E time sync is enabled (TS\_TX\_ANNEX\_E\_EN bit is set in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x86dd.
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the

- CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd
- d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x86dd
  3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
  4. Byte 20 contains 0x11 (UDP Fixed Next Header).
  5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 21 contains any value if TS\_TTL\_NONZERO is set to 1h. Byte 21 is the TTL/HOP field..
  6. The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0 and Bytes 38 through 53 contain:
    - a. FF0M:0:0:0:0:0:0:0181 and the TS\_129 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
    - b. FF0M:0:0:0:0:0:0:0182 and the TS\_130 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
    - c. FF0M:0:0:0:0:0:0:0183 and the TS\_131 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
    - d. FF0M:0:0:0:0:0:0:0184 and the TS\_132 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
    - e. FF0M:0:0:0:0:0:0:006B and the TS\_107 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set

#### Note

All values above are 16-bit hex numbers where M is enabled in the TS\_MCAST\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL2\_REG register.

-OR-

The TS\_UNI\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set to 1h and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
10. The packet was sent by host port 0.

#### Annex F (IEEE 802.3)

1. Transmit time sync is enabled (TS\_TX\_ANNEX\_F\_EN is set in the switch CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true:
  - a. The first packet LTYPE matches TS\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.

- b. The first packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register.
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_SEQ\_LTYPE\_REG register.
  - e. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register.
  - f. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
  - g. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register.
  - h. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches TS\_LTYPE2 in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
3. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_TS\_CTL\_REG register.
  4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS\_RFT\_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

#### 12.2.1.4.7.13.5.3 Time Sync Message Types

**Table 12-134. Values of Message Type Field**

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW3\_CPSW\_NU\_CPTS\_EVENT\_1\_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG (and CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG) register contains the time stamp value when the packet arrived at the corresponding port.

#### 12.2.1.4.7.14 Timestamp Compare Event

##### Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

##### 12.2.1.4.7.14.1 32-Bit Mode

The CPTS\_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG) compares with the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG register and the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG register is written and should be zero when the comparison value is written.

##### 12.2.1.4.7.14.2 64-Bit Mode

The CPTS\_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG and CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG) compares with the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG and CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_HIGH\_VAL\_REG registers and the

CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPSW3\_CPSW\_NU\_CPTS\_TS\_COMP\_VAL\_REG register is written and should be zero when the comparison value is written.

#### 12.2.1.4.7.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP\_EN bit and sends the DOMAIN, MESSAGE\_TYPE, and SEQUENCE\_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW\_3G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

#### 12.2.1.4.7.16 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPSW3\_CPSW\_NU\_CPTS\_INT\_ENABLE\_REG register.
2. Upon interrupt, read the CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG through CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG registers values.
3. Set the CPSW3\_CPSW\_NU\_CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1h to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPSW3\_CPSW\_NU\_CPTS\_INT\_ENABLE\_REG
2. Upon interrupt, enter the CPTS service routine.
3. Read the CPSW3\_CPSW\_NU\_CPTS\_EVENT\_0\_REG through CPSW3\_CPSW\_NU\_CPTS\_EVENT\_3\_REG registers values.
4. Set the CPSW3\_CPSW\_NU\_CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1h to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four CPTS\_RFT\_CLK periods plus four CPPI\_ICLK periods.
6. Read the TS\_PEND\_RAW bit in the CPSW3\_CPSW\_NU\_CPTS\_INTSTAT\_RAW\_REG register to determine if another valid event is in the event FIFO. If bit TS\_PEND\_RAW is asserted, go to step 3. If bit TS\_PEND\_RAW is not asserted proceed with step 7.
7. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS\_PEND\_RAW bit of the CPSW3\_CPSW\_NU\_CPTS\_INTSTAT\_RAW\_REG register to determine if a valid event is on the event FIFO.

#### 12.2.1.4.8 CPPI Streaming Packet Interface

The receive streaming interface on port 0 of the CPSW is responsible for receiving packet for Ethernet egress data from the packet streaming switch in the . The CPPI receive port is equivalent to an Ethernet port with the difference being that the data is provided to the CPSW in the 128-bit streaming interface data format instead RGMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW.

The tables below show the information that may be passed along with which descriptor information word to put it in.

#### 12.2.1.4.8.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW\_3G Egress)

The CPSW\_3G has a single transmit packet streaming interface. All Ethernet packet data destined for the host (Port 0) is transferred on the transmit packet streaming interface. The transmit packet streaming interface is equivalent to an Ethernet MAC output with the difference being that 128-bit streaming interface data is output. Egress packet data is packed on the 128-bit data bus with all words having 16-bytes except possibly the last packet data word which is the word previous to the EOP word. INFO Word 0–3 is transferred on SOP. The EOP word contains the packet status 0–3 (data type 24) which includes the timestamp and checksum data. Packets are not dropped on the transmit streaming interface due to pushback, but packets may be dropped in the associated priority FIFO.

INFO Word 0–3 and Status Data Word 0–3 (on EOP) are the only non-payload data word types that are transferred. Long packets are truncated at the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_MAXLEN\_REG\_k[13:0] RX\_MAXLEN byte value of the ingress port (only the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_RX\_MAXLEN\_REG\_k number of bytes are kept if long packets are transferred due to CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG\_k register copy error frames set - RX\_CEF\_EN). MAC control frames are only transferred if the receiving Ethernet port has the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG\_k[24] RX\_CMF\_EN bit set.

The error encoding on the TXST\_PKT\_ERR[3:0] output is shown in [Table 12-135](#):

**Table 12-135. Error Encoding on the TXST\_PKT\_ERR[3:0] Output**

TXST_PKT_ERR[3:0]	Description
0000	No Error
0001	CRC Error
0010	Code or alignment error
0011	Short (no code/align/crc error)
0100	FragCRC (short with crc error)
0101	Frag Code/Align (short with code/align error)
0110	Long
0111	Jabber CRC (long with crc error)
1000	Jabber Code/Align (long with code/align error)
1001	Mac ontl packet (CPSW3_CPSW_NU_CPSW_NU_ETH_MAC_i_PN_MAC_CONTROL_REG_k[24] RX_CMF_EN set on ingress Ethernet port)
1010	Mac control CRC
1011	Mac control Code/Align
1100	Mac control short/frag (short MAC control frame with CRC/Code/Align)
1101	Mac control long/jabber (long MAC control frame with CRC/Code/Align)
1110	Reserved
1111	Reserved

The CPPI Port 0 transmit packet streaming interface has a single output thread. If a packet transmission has begun then the entire packet will be transmitted before the next packet is sent (packet data from multiple packets are not interleaved on the transmit streaming interface). The default egress flow is the port number minus 1, concatenated with the 3-bit Port 0 transmit FIFO hardware switch priority. For example, a packet that was received on port 4 with a Port 0 transmit FIFO hardware switch priority of 5 would be sent on flow 29 (decimal) or flow 0b0011101 (binary). Priority remapping on ingress and Port 0 transmit egress effects the output flow.

INFO Words are a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 12-108. TX INFO Word 0 Format**

RESERVED								FLOW_ID							

Bit	Field	Description
31-27	PKT_TYPE	Always set to 0b00111. Host PD (Packet Descriptor) Word 2. Packet Type: bits[31-27].
26-24	RESERVED	Reserved.
23	PASS_CRC	This bit is cleared to zero (no CRC passed) when the P0_TX_CRC_REMOVE bit in the CPSW3_CONTROL_REG register is set (and the egress packet has no errors). When the remove bit is cleared to zero then this bit is cleared and no CRC is passed with the output packet. The packet length includes the CRC if it is present.
22	CRC_TYPE	The packet CRC type. The type of CRC passed is determined by CRC_TYPE field in the CPSW3_CPSW_NU_CPSW_NU_ETH_MAC_i_PN_MAC_CONTROL_REG_k register (not by the type of CRC the packet had on Ethernet port ingress). Host PD Word 1. Protocol Specific Flags: bits[27-24]. 0h: Ethernet CRC 1h: Castagnoli CRC
21-8	RESERVED	Reserved.
7-0	FLOW_ID	This is the packet output transmit streaming interface flow. The default flow ID can be overridden by ALE classification (Thread mapping). The switch default flow is the 3-bit “From Port” value concatenated with the 3-bit “Switch Priority” {From_Port[2:0], Switch_Priority[2:0]} as shown below: Host PD (Packet Descriptor) Word 1. Flow ID: bits[13-0]. 0h: The packet was received on Ethernet port 1 Switch Priority – The actual hardware switch priority that the packet was stored in on the CPPI transmit FIFO.

#### 12.2.1.4.8.2 Port 0 CPPI Receive Packet Streaming Interface (CPSW\_3G Ingress)

Info Word 0/1/2/3 (INFO1 and INFO3 are ignored) are transferred on SOP. If a timestamp word (Extended Packet Info Word 0/1/2/3) is to be transferred it must be after SOP and before any packet data is transferred. Any following non-data type words will be dropped. The EOP word must be payload data.

Input receive packets cannot be aborted by the host. The INFO Word bit descriptions and Extended Packet INFO Word bit descriptions are shown below. The PASS\_CRC bit indicates that the CRC is passed with the packet data. Packets that have a passed CRC that is an error CRC will be output on the Ethernet port with at least one CRC byte inverted to indicate the error if P0\_RX\_PASS\_CRC\_ERR bit is set, otherwise they are dropped. The packet is a directed packet when any of the TO\_PORT bits are nonzero. A packet may be directed only to a single port. The packet will be sent to the port number indicated. For directed packets the lookup process is skipped to determine the destination. However, in vlan aware mode (when VLAN\_AWARE bit in the CPSW3\_CONTROL\_REG register is set to 1h) the lookup is performed to determine untagged egress. Packets longer than the value in CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_RX\_MAXLEN\_REG[13:0] RX\_MAXLEN bit field are dropped. Packets shorter than 60-Bytes are padded to 64-Bytes (after adding pad and CRC) if P0\_RX\_PAD bit in the CPSW3\_CONTROL\_REG register is set and if PASS\_CRC is clear, otherwise they are dropped. This means that packets shorter than 64-Bytes are dropped if the PASS\_CRC info bit is set regardless of P0\_RX\_PAD bit (packets are padded only if they are short and do not have CRC).

A RX INFO word is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

#### Note

RX Control Data Words [0..2] are mapped to Host Packet Descriptor Protocol Specific Words if (TCHAN[a]\_TCFG.tx\_filt\_pswords = 0) and (Host PD Word 1.Protocol Specific Region Location.bit[28] = 0h) and (Host PD Word 1.Protocol Specific Valid Word Count.bits[22-27] = 4h)

**Figure 12-116. RX INFO Word 0 Format**

Bit	Field	Description
31-24	CHECKSUM_RESULT	This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is Byte 1 (not byte zero).
23-16	CHECKSUM_START_BYTE	This is the packet byte number to start the checksum calculation on. The first packet byte is Byte 1.
15	CHECKSUM_INV	When set, a zero checksum value will be inverted and sent as FFFFh.
14	RESERVED	Reserved.
13-0	CHECKSUM_BYTECOUNT	This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

Other INFO words are not taken into account.

### 12.2.1.4.8.3 Cut-Thru

An Ethernet port received packet can be sent cut-thru to all destination ports when the following is true:

- The CPSW3\_CONTROL\_REG[19] CUT\_THRU\_ENABLE bit is set, and
- The receive port is full duplex, and
- The Ethernet receive port speed is non-zero, and
- The packet was received on an express priority, and
- The Ethernet receive port has the remapped received packet priority enabled via the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CUT\_THRU\_REG[15-8] RX\_PRI\_CUT\_THRU\_EN field, and
- All Ethernet destination ports have the remapped packet priority enabled via the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_CUT\_THRU\_REG[7-0] TX\_PRI\_CUT\_THRU\_EN field, and
- All Ethernet destination ports are full duplex, and
- All Ethernet destination ports are express priorities, and
- All Ethernet destination ports have a non-zero CPSW\_PN\_SPEED\_REG\_k[3-0] SPEED, and
- All Ethernet destination ports are equal to or slower in speed than the Ethernet receive port, and
- The host port is not in the destination port list unless the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG[19] CUT\_MODE\_ETH bit is set.

Whether or not a packet actually egresses cut-thru (with or without delay) on an Ethernet destination port depends on traffic congestion on that port. Cut-thru is compatible with Interspersed Express Traffic (IET) and Enhanced Scheduled Traffic (EST).

#### 12.2.1.4.8.3.1 Host Port Cut-Thru Operations

Packets received (CPSW ingress) on the host port are sent store-and-forward to all Ethernet destination ports. Setting the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG[19] CUT\_MODE\_ETH bit enables Ethernet received packets to be sent cut-thru to a destination port mask that includes the host port. The packet can egress cut-thru on Ethernet ports, but the packet will not actually egress cut-thru on the host port. Setting CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG[19] CUT\_MODE\_ETH can cause head of line blocking on the host priority if multiple Ethernet ports are sending to the same host port priority. The head of line blocking issue is worsened if there are differing Ethernet port speeds. Clearing the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG[19] CUT\_MODE\_ETH bit causes packets with the host port in the destination mask to egress store-and-forward on all egress ports.

#### 12.2.1.4.8.3.2 Cut-Thru Error Packets

Any received packets with errors sent cut-thru from an Ethernet receive port to any Ethernet transmit port(s) will egress with at least one byte of the generated outgoing packet CRC inverted to indicate the error. This is due to the fact that cut-thru operations begin before the end of packet when the receive port determines that the packet had an error (long/code/align/CRC).

Any packet also sent cut-thru with the host included in the destination port mask will be dropped to the host (TXST\_PKT\_DROP) with the packet error indicated on TXST\_PKT\_ERR[3:0].

Any long/Jabber/Code/Align/CRC errored Ethernet received packet that is not actually sent cut-thru by the receive port will be dropped unless CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG\_k[22] RX\_CEF\_EN is set (which if set will cause the packet to be sent to the host port with the error indicated on TXST\_PKT\_ERR[3:0]). If a long/Jabber/Code/Align/CRC errored Ethernet received packet is sent cut-thru by the received port then a set CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG\_k[22] RX\_CEF\_EN will not cause the errored packet to be sent to the host port since the packet has already been transferred to the destination ports.

The following cut-thru notes are valid:

- Any Ethernet received packet and that is sent cut-thru to any destination port will not be dropped at any destination port due to priority maximum lengths (CPSW3\_CPSW\_NU\_TX\_PRIx\_MAXLEN\_REG).
- Any Ethernet received packet that is decoded as a timesync packet will be sent store-and-forward to all destination ports.
- Cut-Thru is full duplex only.
- Cut-Thru is not compatible with any form of flow control.
- Cut-Thru should not be enabled for any receive port that is in ALE bypass mode.

#### 12.2.1.4.8.4 Port Speed

Cut-thru operations require that the Ethernet port speeds be known. Port speed can be set manually by software or be automatically determined by the hardware. A zero port speed causes the port to be disabled for cut-thru operations, but does not disable the port. The port speed values are as follows:

- 0000 – Port speed operations disabled (not a port disable)
- 0001 – 10Mbps
- 0010 – 100Mbps
- 0011 – 1G
- 0100 – 2.5G
- 0101 – 5G
- 0110 – 10G
- 0111 through 1111 Reserved

When the CPSW\_PN\_SPEED\_REG\_k[8] AUTO\_SPEED\_EN bit is cleared, the port speed is written by software. When the CPSW\_PN\_SPEED\_REG\_k[8] AUTO\_SPEED\_EN bit is set, the port speed is automatically detected by the hardware.

#### 12.2.1.4.8.5 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP (User Datagram Protocol) and TCP (Transmission Control Protocol) over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the S\_CN\_SWITCH bit in the CPSW3\_CONTROL\_REG register must be set for the Outer VLAN L type to be supported.

##### 12.2.1.4.8.5.1 CPPI Transmit Checksum Offload

IPV4 and IPV6 UDP and TCP packets that are received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLAN's. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host.

##### 12.2.1.4.8.5.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

##### 12.2.1.4.8.5.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).
- Byte 24 = 0x06 for TCP protocol.

##### 12.2.1.4.8.5.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.

- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

#### **12.2.1.4.8.5.1.4 IPV6 TCP**

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

#### **12.2.1.4.8.6 CPPI Receive Checksum Offload**

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The RX\_CHECKSUM\_EN bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_CPPI\_P0\_CONTROL\_REG register must be set for receive checksum operation to be enabled. When bit RX\_CHECKSUM\_EN is enabled, Control Data Word 2 input on CPPI receive PSI interface determines how the checksum is calculated. The CHECKSUM\_RESULT field in Control Data Word 2 determines where the checksum is inserted. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

#### **12.2.1.4.8.7 Egress Packet Operations**

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations (CPSW3\_CPSW\_NU\_ALE\_EGRESSOP). IntraVLAN processing either adds, removes, or replaces VLAN information or does nothing. InterVLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, the packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

#### 12.2.1.4.9 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

##### 12.2.1.4.9.1 MDIO Frame Formats

[Table 12-136](#) shows the address, [Table 12-137](#) shows the read format and [Table 12-138](#) shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

**Table 12-136. MDIO Clause 45 Address Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

**Table 12-137. MDIO Clause 45 Read Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

**Table 12-138. MDIO Clause 45 Write Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction. The MDIO CPSW3\_MDIO\_USER\_ADDR0\_REG register must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

#### Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

#### Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 00 pattern.

#### Operation Code

The operation code for an address transaction is 00. The operation code for a read is 11, while the operation code for a write is a 01.

#### PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

#### MMD Number

The MMD number is the 5 bits allowing 32 unique values. The first bit transmitted is the MSB.

#### Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall

drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

### Address

The address field is 16 bits on address operations. The first bit transmitted is the MSB of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the MDIO CPSW3\_MDIO\_USER\_ADDR0\_REG/ CPSW3\_MDIO\_USER\_ADDR1\_REG register values as the 16-bit address.

### Data

The Data field is 16 bits on read and write operations. The first bit transmitted and received is the MSB of the data word.

#### 12.2.1.4.9.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the CPSW3\_MDIO\_CONTROL\_REG register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO CPSW3\_MDIO\_LINK\_REG register. Individual PHY's can be enabled or disabled for polling the associated bit in the CPSW3\_MDIO\_POLL\_EN\_REG register. The CPSW3\_MDIO\_LINK\_REG and CPSW3\_MDIO\_ALIVE\_REG register bit values are updated on the poll of each PHY. The LINKSEL bit in the CPSW3\_MDIO\_USER\_GROUP\_USER\_PHY\_SEL\_REG\_k register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO CPSW3\_MDIO\_LINK\_INT\_RAW\_REG register and the MDIO CPSW3\_MDIO\_LINK\_INT\_MASKED\_REG register, if enabled by the LINKINT\_ENABLE bit in the CPSW3\_MDIO\_USER\_GROUP\_USER\_PHY\_SEL\_REG\_k register.

The MDIO CPSW3\_MDIO\_ALIVE\_REG register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO CPSW3\_MDIO\_ALIVE\_REG register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW field in the CPSW3\_MDIO\_USER\_INT\_RAW\_REG register corresponding to the CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register being used. The corresponding bit in the CPSW3\_MDIO\_USER\_INT\_MASKED\_REG register may also be set depending on the mask setting in the MDIO CPSW3\_MDIO\_USER\_INT\_MASK\_SET\_REG and CPSW3\_MDIO\_USER\_INT\_MASK\_CLEAR\_REG registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k registers. The host should check the status of the GO bit in the MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG register in the corresponding MAC.

#### 12.2.1.5 CPSW0 Programming Guide

##### 12.2.1.5.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, SGMII, or RGMII ) Mode. See the CTRLMMR\_ENET1\_CTRL and CTRLMMR\_ENET2\_CTRL[2-0] PORT\_MODE\_SEL fields.

2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*
4. Ensure that at least 2000 CPPI\_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW3\_CONTROL\_REG register
6. Configure the Ethernet Port Source Address registers (CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_SA\_L\_REG\_k and CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_SA\_H\_REG\_k)
7. Configure the CPSW statistic port enable register CPSW3\_CPSW\_NU\_STAT\_PORT\_EN\_REG
8. Configure the ALE ([Section 12.2.1.4.6.1, Address Lookup Engine](#))
9. Configure the MDIO ([Section 12.2.1.5.3.1, Initializing the MDIO Module](#))
10. Configure Ethernet port, as per the desired mode of operations

### 12.2.1.5.2 CPSW Reset

To reset the Ethernet port, the host must perform the following:

1. Set CMD\_IDLE bit to 1h in the Ethernet port control register: CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_CONTROL\_REG.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status register: CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_STATUS\_REG.
3. Set SOFT\_RESET bit to 1h in the Ethernet port software reset register: CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_SOFT\_RESET\_REG.
4. Wait for SOFT\_RESET bit in the CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_SOFT\_RESET\_REG registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.
6. Re-configure registers reset to default value by CPSW3\_CPSW\_NU\_CPSW\_NU\_ETH\_MAC\_i\_PN\_MAC\_SOFT\_RESET\_REG.

### 12.2.1.5.3 MDIO Software Interface

#### 12.2.1.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW3\_MDIO\_CONTROL\_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW3\_MDIO\_CONTROL\_REG.
3. The MDIO PHY alive status register (MDIO CPSW3\_MDIO\_ALIVE\_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW3\_MDIO\_LINK\_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW3\_MDIO\_USER\_GROUP\_USER\_PHY\_SEL\_REG\_k, where k = 0 or 1), and set the LINKINT\_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW3\_MDIO\_USER\_GROUP\_USER\_PHY\_SEL\_REG\_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW3\_MDIO\_USER\_INT\_MASK\_SET\_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW3\_MDIO\_USER\_INT\_MASK\_SET\_REG) to use the MDIO user access register (MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k, where k = 0 or 1).

#### 12.2.1.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW3\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW3\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW3\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

#### 12.2.1.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k, where k = 0 or 1) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in the CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW3\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW3\_MDIO\_USER\_GROUP\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW3\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW3\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

## **12.2.2 Peripheral Component Interconnect Express (PCIe) Subsystem**

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) subsystem.

<b>12.2.2.1 PCIe Subsystem Overview.....</b>	<b>1611</b>
<b>12.2.2.2 PCIe Subsystem Environment.....</b>	<b>1613</b>
<b>12.2.2.3 PCIe Subsystem Functional Description.....</b>	<b>1615</b>

### 12.2.2.1 PCIe Subsystem Overview

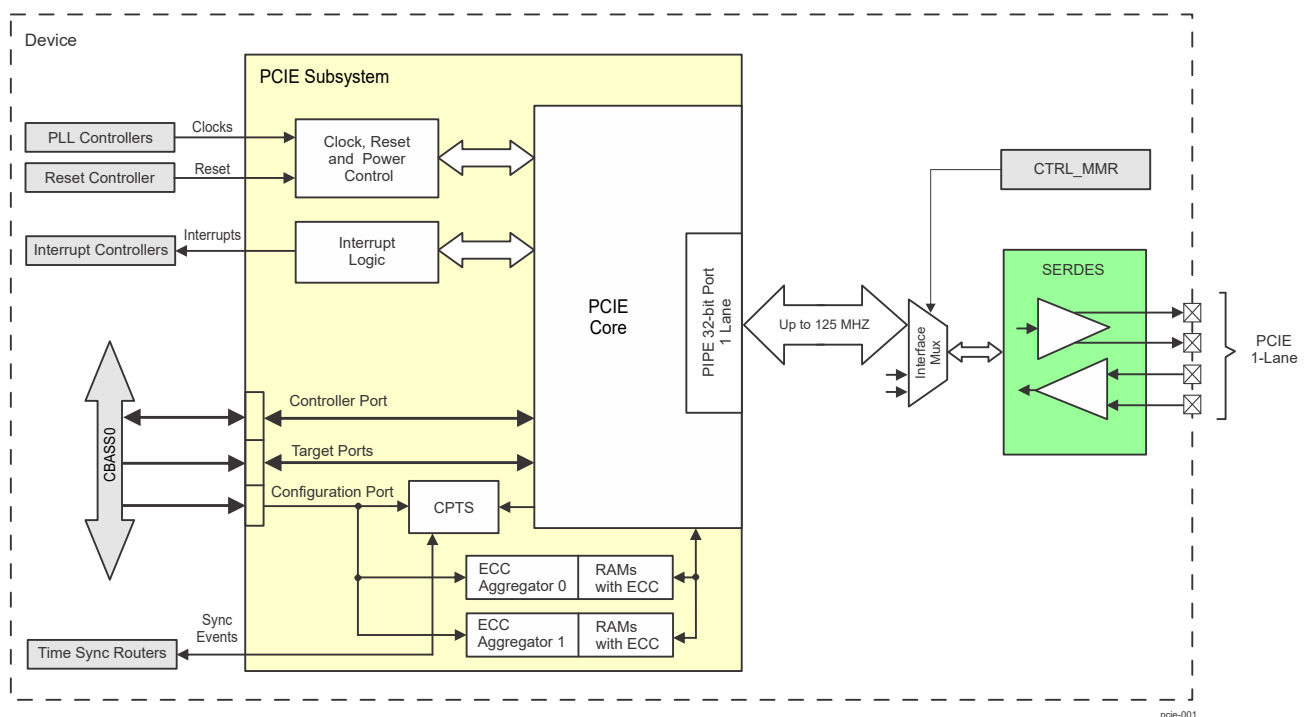

The Peripheral Component Interconnect Express (PCIe) subsystem is built around a single-lane dual-mode PCIe controller that provides low pin-count, high reliability, and high-speed data transfers at rates of up to 5.0 Gbps per lane for serial links on backplanes and printed wiring boards.

The device includes one instantiation the of PCIe subsystem - PCIE0. Table 12-139 shows the PCIe subsystem allocation across device domains.

**Table 12-139. PCIe Subsystem Allocation Across Device Domains**

Module Instance	Domain	
	MCU	MAIN
PCIE0	-	✓

Figure 12-120 provides PCIe subsystem overview.

**Figure 12-120. PCIe Subsystem Overview**

#### 12.2.2.1.1 PCIe Subsystem Features

Each PCIe subsystem supports the following main features:

- Compliance to PCIe® Base Specification, Revision 4.0 (Version 0.7)
- 1-lane configuration with up to 8.0 Gbps/lane (Gen3).
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- 62.5/125 MHz operation on PIPE interface for Gen1/Gen2, respectively
- Constant 32-bit PIPE width for Gen1/2 modes
- Dual mode of operation: Root Complex (RC) or End Point (EP)
- Maximum payload size of 128 bytes
- Maximum remote read request size of 4K bytes
- Maximum Number of non-posted outstanding transactions: 8
- Single Physical Function in End Point (EP) mode
- Four virtual channels (VC)

- Four traffic classes (TC)
- PCI Power Management states:
  - L1 Power Management sub-state support
  - Device Power Management states D0, D1, D3Hot
- Resizable BAR capability
- Functional Level Reset (FLR) support
- Separate Reference Clock with Independent Spread (SRIS) support
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision Time Measurement (PTM) for both RC and EP modes in combination with internal Common Platform Time Sync (CPTS) module
- PCIe compliant PHY (PIPE 4.0) interface for connection to a SERDES-based PHY

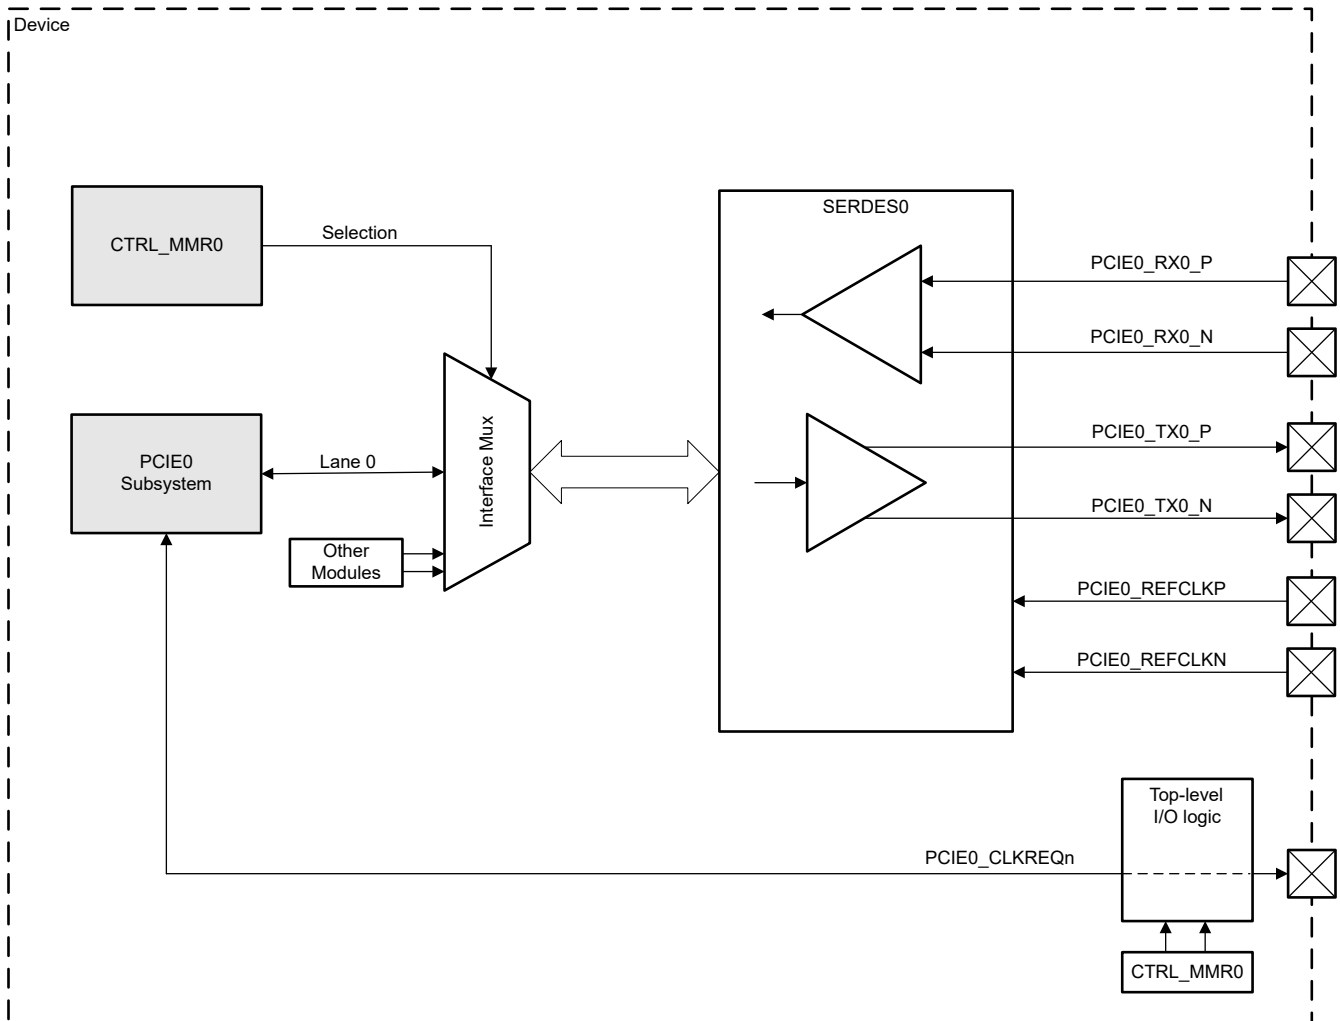

#### **12.2.2.1.2 PCIe Subsystem Not Supported Features**

The PCIe subsystem does not support the following features:

- PCIe beacon for in-band wake
- Vendor Messaging
- I/O access in inbound direction in RC or EP mode
- Addressing modes other than incremental for burst transactions. As a result, the PCIe addresses cannot be in cacheable memory space.
- Single-root I/O virtualization (SR-IOV)
- Address Translation Services (ATS) capability to support virtualization in RC mode
- L2 power state
- PCI Device Power Management state D3Cold
- Hot-plug
- 48-bit address on VBUSM controller and target interfaces. Only 36-bit address is supported for these interfaces.
- Parity checking on VBUSM and VBUSP interfaces

### 12.2.2.2 PCIe Subsystem Environment

This section describes the PCIe subsystem and related application fields from an external system environment point of view.

**Figure 12-121. PCIe Subsystem Environment**

Table 12-140 describes the SERDES signal names at device level related to PCIe subsystem and specifies their functions. For more information on the SERDES operation and interface signals, refer to Section 12.2.3, *Serializer/Deserializer (SerDes)*.

**Table 12-140. PCIe Subsystem I/O Signals**

Device Level Signal	I/O <sup>(1)</sup>	Description
<b>PCIE1 Subsystem</b>		
PCIE0_RX0_N	I	PCIe Lane 0 Receive Differential Data (-)
PCIE0_RX0_P	I	PCIe Lane 0 Receive Differential Data (+)
PCIE0_TX0_N	O	PCIe Lane 0 Transmit Differential Data (-)
PCIE0_TX0_P	O	PCIe Lane 0 Transmit Differential Data (+)
PCIE0_REFCLKP	I	PCIe Differential Reference Clock (+)
PCIE_REFCLKN	I	PCIe Differential Reference Clock (-)
PCIE0_CLKREQn	I/O <sup>(2)</sup>	PCIe sideband signal for negotiation of L1 Substate entry/exit. The CLKREQn pin operates as an active low open-drain bi directional reference clock request pin. 1 = no request for clock; 0 = request for clock

(1) I = Input; O = Output.

(2) 3.3-V LVCMOS input/open-drain output

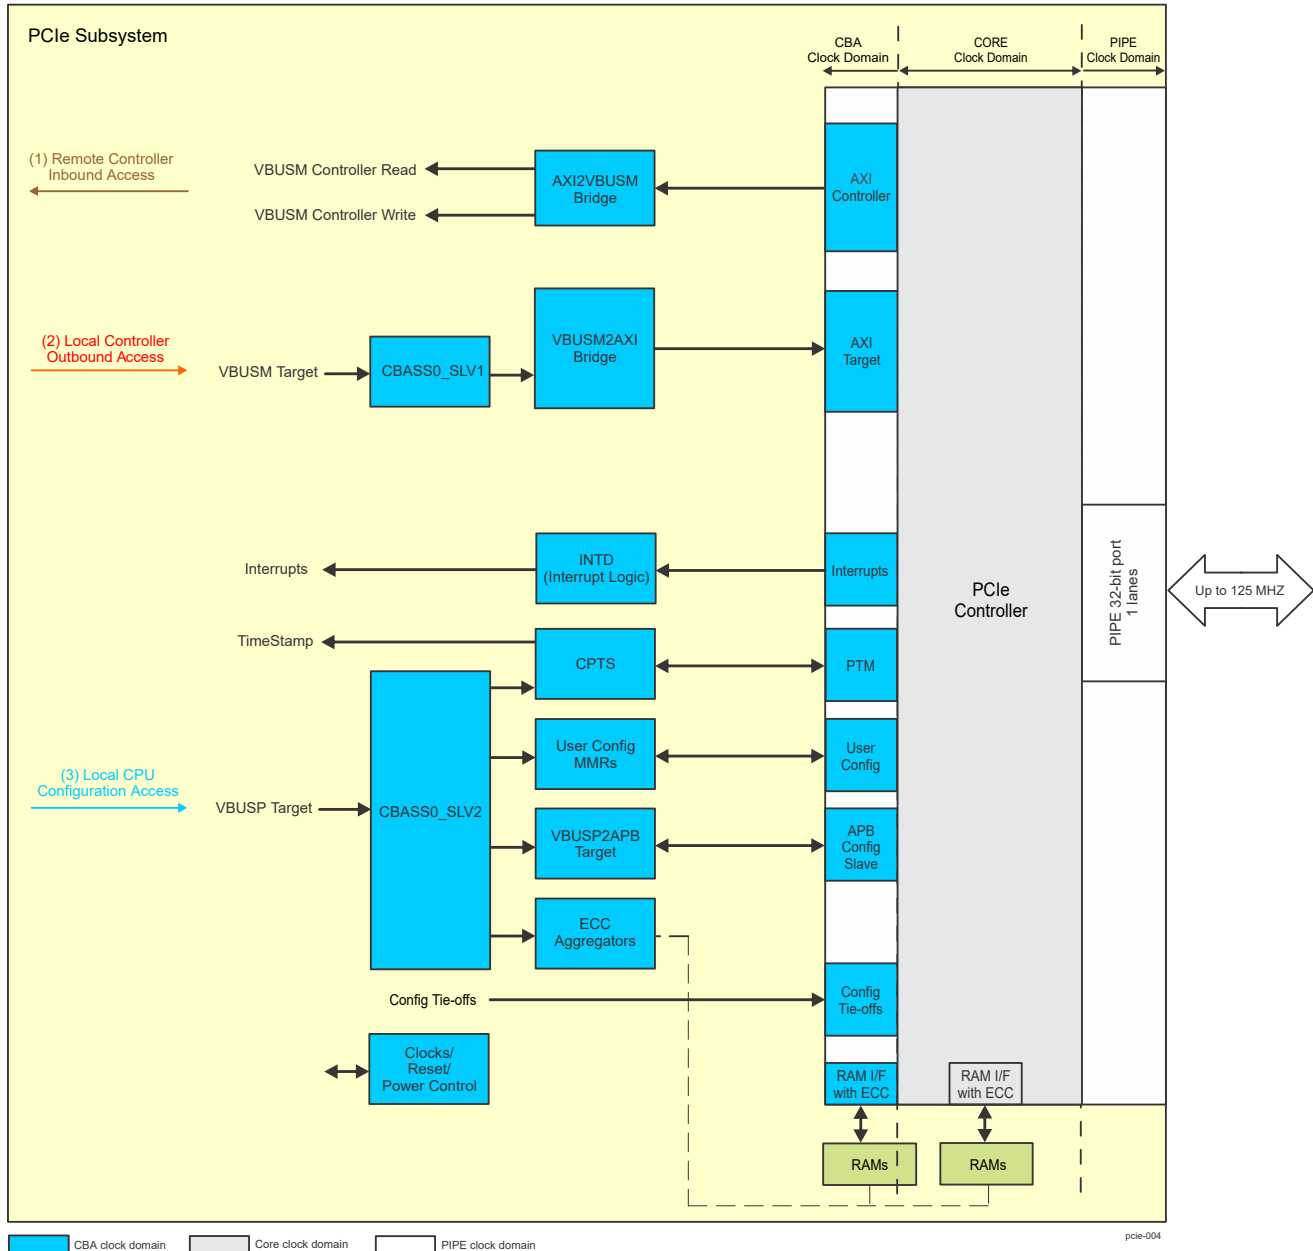

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.2.2.3 PCIe Subsystem Functional Description

#### 12.2.2.3.1 PCIe Subsystem Block Diagram

The block diagram of PCIe subsystem is shown in Figure 12-122. The subsystem is comprised of these major components – the PCIe Core with AXI interfaces, bridges to connect to the system CBASS0 interconnect controller and target interfaces, bridges to connect the system CBASS0 configuration interfaces, additional logic to implement the Precision Time Measurement (PTM), user configuration and interrupt, and RAM to support the controller FIFOs.

**Figure 12-122. PCIe Subsystem Block Diagram**

Figure 12-122 also shows some example data flows in the PCIe subsystem, such as:

1. A remote controller issues a read or write access over PCIe to the local device. This will create a command to be issued on the PCIe VBUSM controller read or write interface.

2. A controller in the local device issues a read or write access over PCIe to the remote device. This will create a command to be issued on the PCIe VBUSM target read or write interface.
3. A controller in the local device wants to access the local PCIe configuration registers, the ECC aggregator registers, or the CPTS registers. This will create a transaction over the PCIe VBUSP target interface.

#### 12.2.2.3.1.1 PCIe PHY Interface

The PCIe subsystem incorporates a 1-lane PCIe compliant PHY (PIPE) interface to connect to a SERDES-based PHY. The PCIe PHY module consist of a SERDES module and a PCIe PCS (Physical Coding Sub-block) module. The SERDES module converts parallel data into PCIe serial signals and the PCIe PCS module provides an industry standard PIPE Interface to PCIe MAC. The frequency of the PIPE interface can be 62.5MHz or 125MHz depending on whether the system is operating in Gen1 or Gen2 mode. The width of the PIPE interface remains constant at 32-bits for all modes of operation. For more information on the SERDES module, see [Section 12.2.3, Serializer/Deserializer \(SerDes\)](#).

#### 12.2.2.3.1.1.1 PCIe Core Module

The PCIe Core module supports dual mode of operation - it can be configured as an End Point (EP) and also as a Root Complex (RC). The operational mode is selected with the CTRLMMR\_PCIE0\_CTRL[7] MODE\_SEL register bit within the device Control Module (CTRL\_MMR). It is expected that the MODE\_SEL bit is programmed during initial power up based on settings in the SoC boot configuration or a non-volatile storage such as eFuse or Flash memory.

It is not expected that the MODE\_SEL setting would have to change during a full power cycle of the device. It is more likely that the operational mode of a SoC will stay as EP or RC for a particular end product's life cycle. It is not expected to switch back and forth during operation without a reset cycle.

The PCIe core module supports four virtual channels (VC) and four transfer classes (TC). The VCs can be used to implement Quality-of-Service (QoS) mechanism by enabling priority or round-robin arbitration. Typically, the highest numbered enabled VC is assigned the highest priority.

There is one initiator port and one target port in the PCIe core. All ingress data traffic regardless of the VC assigned will be delivered on the initiator port. Similarly, all egress data that is presented on target port of the PCIe core will be assigned VCs through the outbound address translation registers.

#### 12.2.2.3.1.2 Custom Logic

The PCIe subsystem includes custom logic to implement Precision Time Management (PTM), interrupts and user configuration registers.

#### 12.2.2.3.2 PCIe Subsystem Reset Schemes

This section describes the reset schemes supported by PCIe Base Specification and the way these resets are supported by the PCIe Subsystem. PCIe Base Specification specifies two mechanisms for performing reset – Conventional Reset mechanism and Functional Level Reset mechanism.

##### 12.2.2.3.2.1 PCIe Conventional Reset

There are three distinct types of Conventional Reset and each of these causes the hardware state machines, hardware logic, port states and configuration registers to be initialized to their default values.

1. Cold Reset – The reset occurring at power-up of the device is referred to as Cold Reset. Cold Reset is triggered by the PERSTn signal being asserted. PERSTn signal is an auxiliary signal in PCIe Specification and can be used at power on reset for the device that has PCIe as its primary bus interface to rest of the system. The device is allowed to generate its own power-on reset as long as the PCIe requirements for PERSTn are met. See PCIe Base Specifications for details.
2. Warm Reset – A reset can be triggered by the hardware without the removal of power from the device. This reset is referred to as Warm Reset. The hardware implementation is not specified by the PCIe Specification.
3. Hot Reset – The PCIe Specifications provides an in-band mechanism to propagate a Conventional Reset across a Link. This reset, called the Hot Reset, propagates via the transmission of TS1 Ordered Sets. In general, Hot Reset is software controlled procedure and can only be issued by Root Complex in a PCIe

network as the propagation is downstream only. PCIe subsystem translates the received in-band hot reset into an interrupt that can then be used by software to reset the PCIe subsystem.

After a conventional reset, the software must wait at least 100 ms before attempting any PCIe transaction on the device that has been reset. If the downstream device does not respond to transaction packets, it must not give up until 1 second plus an additional 50% (0.5 second) time is lapsed.

#### **12.2.2.3.2.2 PCIe Function Level Reset**

The Function Level Reset (FLR) is an optional in-band reset mechanism that is used to reset one particular function in a PCIe device. The PCIe core will initiate the appropriate function level reset process when it receives the FLR message. The PCIe subsystem will raise an interrupt to the SoC, based on the FLR\_IN\_PROGRESS[0] status output from the PCIe core. Software can update the PCIE\_USER\_FLR\_DONE[5-0] FLR\_DONE register bits to signal to the PCIe core that the application layer FLR processing is complete.

#### **12.2.2.3.2.3 PCIe Reset Isolation**

It can be important to isolate reset of PCIe subsystem from reset of the rest of the device. The procedure to implement this depends upon what functionality the PCIe subsystem is providing – Root Complex or End Point.

##### **12.2.2.3.2.3.1 Root Complex Reset with Device Not Reset**

When PCIe subsystem is operating as a Root Complex, it is the controller controller on the PCIe subsystem. When PCIe subsystem is to be reset in this operating mode, the link to the downstream device will get disconnected. To accomplish this reset, the PCIe subsystem RC should issue a hot reset to End Point or Switch downstream. It should also stop any ongoing transactions. Then, a PCIe subsystem reset can be issued. The sequence of events is outlined below:

1. Stop transactions at system and application level. This is recommended for graceful suspension of activity at system level. It is not required by PCIe subsystem though. Not choosing to gracefully stop transaction would cause some of the outstanding transactions to complete in error and it may be harmful from software stability standpoint.
2. Disable “Bus Controller Enable” for End Points (see [Section 12.2.2.3.6.2, PCIe Transaction Limitations](#)). Note that a hand shake with EP Software may be required as not all End Point application software will automatically become aware of this disable action from RC.
3. Optionally, issue Hot Reset to End Point devices via PCIE\_USER\_RSTCMD[0] INIT\_HOT\_RESET bit . Note that the link will be getting disconnected. So, a reset may be happening regardless of the Hot Reset command from RC. It depends on the architecture of the other (external) device. In devices with PCIe subsystem, link disconnection automatically results in a reset request interrupt. A PCIe subsystem reset is required to get the memory buffers out of internal flush modes.
4. Initiate Clock Stop sequence and wait for Acknowledgement. For more information, see [Section 12.2.2.3.3.1, CBA Power Management](#).
5. Issue reset to PCIe subsystem (local reset).
6. Reinitialize PCIe subsystem and downstream devices. PCIe bus enumeration must be performed again.

Note that it is possible for Root Complex to occasionally see the downstream device going down for some reason and disconnecting. Such events typically occur due to an internal error condition in the End Point. When such an event occurs, the sequence of events for the Root Complex will be as follows:

1. The PCIe subsystem in RC mode will issue the “Reset Request” interrupt when it detects link getting disconnected unexpectedly.
2. The PCIe subsystem will flush all controller transactions and any completion data from pending transactions. It will also start completing target transactions with error completions.
3. After servicing the interrupt and disabling further interrupts, the system software must reset PCIe subsystem Root Complex (see steps #4 and later specified previously in this section).

##### **12.2.2.3.2.3.2 Device Reset with Root Complex Not Reset**

As a Root Complex, PCIe core is the controller of PCIe subsystem. If the device hardware and the software is reset and re-initialized, the system does not get additional benefit of keeping the PCIe subsystem alive as all context information is lost. So, this mode is not supported.

#### **12.2.2.3.2.3.3 End Point Device Reset with Root Complex Not Reset**

It may be desirable to isolate the reset only to PCIe subsystem when it is operating as an End Point. Such resets may be implemented when a Hot Reset command is received from upstream device (Root Complex or Switch). The sequence to be followed is as outlined below.

1. Hot Reset is received. The “Request Reset” interrupt is triggered.
2. The PCIe subsystem will automatically enter Flush Mode. The PCIe Link Training and Status State Machine (LTSSM) will be disabled automatically.
3. PCIe subsystem will complete all controller transactions and any completion data from pending transactions will be accepted and discarded. It will also start issuing error response for new target transactions.
4. Upon receipt of the reset interrupt from PCIe subsystem, the system software must immediately start preparing for shut down of PCIe subsystem. The DMA or software process accessing PCIe subsystem should gracefully suspend operations. Otherwise, step #3 may continue for unduly long time and Root Complex may assume that the EP is non-responsive to its link re-training attempts.
5. Read the Reset Command register (PCIE\_USER\_RSTCMD) to check if the bridge activity flush bit is zero. This indicates that it is safe to issue warm reset to PCIe subsystem.
6. Initiate Clock Stop sequence. This will ensure no outstanding transactions exist.
7. Issue a PCIe subsystem Reset.
8. Resume initialization sequence.

#### **12.2.2.3.2.3.4 Device Reset with End Point Device Not Reset**

As an End Point, the PCIe subsystem does not need to stay operational when the device reset is happening. Upon detecting the link disconnection, the upstream port will re-train the link when Root Port issues a link retrain command to itself or to a switch port next to the EP.

If it is required that the PCIe subsystem be operational (without any transactions though), the End Point must negotiate with the other devices (primarily Root Port) to stop activity. Otherwise, if the End Point goes into force idle/standby or clock stop modes without properly managing the process, there will be timeouts or errors on incoming read transactions and writes will be completely lost. In such situation, the Root Port will encounter excessive errors and may issue a hot reset to the End Point anyway.

#### **12.2.2.3.2.4 PCIe Reset Limitations**

Once a reset situation occurs, the PCIe subsystem prepares for reset assertion from the device level reset controller. In this mode, all outbound write transactions are discarded and all outbound reads are returned with error. Similarly, all inbound reads/writes are discarded and any pending reads are completed but data is discarded. Additionally, any register reads on local or remote registers regions are returned in error even though data may be correct. Register writes on local registers are executed correctly.

Whenever the reset interrupt is asserted by PCIe subsystem, the host controller should clear the interrupt, perform a clock stop request/ack sequence and issue a local reset to PCIe subsystem.

#### **12.2.2.3.2.5 PCIe Reset Requirements**

Whenever link goes from connected to disconnected state, the PCIe subsystem requires re-initialization based on the events occurring in PCIe core. A request for reset is typically going to be issued and will manifest as a reset request interrupt. Since loopback requires transitions through link connect and disconnect, it will generate reset request interrupts. Typically, issuing the warm reset (module reset for CBA) would be sufficient.

#### **12.2.2.3.3 PCIe Subsystem Power Management**

PCIe has multiple power management protocols. Some of them are invoked by the hardware, such as Active State Power Management (ASPM), while others are activated at higher levels via software.

The PCIe core supports D0, D1 and D3-Hot power states.

Link power states L0, L0s, L1, L1s are supported.

L0s entry and exit is managed by the PCIe core if ASPM L0s is enabled.

L1 entry and exit is also managed by the PCIe core if ASPM L1 is enabled. Software can force the exit from L1 by writing to the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 bit in the PCIe subsystem. Entry into L1 can also be blocked by setting the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 bit.

L1s support requires that the CLKREQ pin be connected to the remote peer. L1s power state is entered when the link is in L1 and CLKREQ pin is de-asserted. Software can force the exit from L1s by writing to either the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 or PCIE\_USER\_PMCMD[1] CLIENT\_REQ\_EXIT\_L1\_SUBSTATE bits in the PCIe subsystem.

#### 12.2.2.3.3.1 CBA Power Management

The power management for PCIe subsystem with CBA interface is primarily accomplished through the clock stop protocol. Any time the clock stop protocol is initiated, the PCIe subsystem will acknowledge after making sure that there are no outstanding transactions. If there are any pending transactions in the subsystem, then the clock stop acknowledgement procedure cannot be completed. Therefore, it is necessary that the system software first suspend activity on the serial link as well as on the CBA interface. To do so, it is expected that the devices communicating with the device on which clock stop procedure is to be performed agree to stop transactions targeted to the device in question. Similarly, it is required that the outgoing transactions also be stopped to successfully complete the clock stop sequence. The PCIe subsystem will guarantee that in the event there are pending transactions that are still in process of draining will prevent the clock-stop acknowledgement to be issued to CBA subsystem power management logic.

#### Note

The PCIe subsystem does not have ability to terminate the clock stop state. Therefore, any wakeup sequence can only be initiated through other means such as software driven timers or software detected events occurring outside of PCIe subsystem.

#### 12.2.2.3.4 PCIe Subsystem Interrupts

The PCIe subsystem provides a mix of interrupts from the PCIe controller interrupt, CPTS interrupts, and interrupts generated in the subsystem using the internal Interrupt Distributor (CP\_INTD) module.

The CP\_INTD module is used to generate and aggregate interrupts from various status signals of the PCIe core. Interrupts from the PCIe core and CPTS module are ported out directly to the PCIe subsystem boundary without any aggregation. [Table 12-141](#) shows the details on the PCIe subsystem interrupt outputs.

**Table 12-141. PCIe Subsystem Interrupt Events**

Interrupt Name	Clock Dependency	Description
PCIE_LEGACY_PULSE	CBA_CLK	PCIe legacy interrupt. INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT status outputs from the PCIe core are aggregated. Note: Valid in RC mode only.
PCIE_ERROR_PULSE	CBA_CLK	PCIe error interrupt. FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT status outputs from the PCIe core are aggregated. Note: Valid in both RC and EP modes.
PCIE_FLR_PULSE	CBA_CLK	PCIe Function Level interrupt. FLR_IN_PROGRESS[0] status outputs from the PCIe core is used to generate this interrupt. Note: Valid in EP mode only.
PCIE_DOWNSTREAM_PULSE	CBA_CLK	PCIe downstream interrupt. <ul style="list-style-type: none"> <li>F0_VSEC_INTERRUPT_OUT,</li> </ul> status output from the PCIe controller is used to generate this interrupt. Note: Valid in EP mode only
PCIE_HOT_RESET_PULSE	CBA_CLK	PCIe hot reset interrupt. HOT_RESET_OUT status output from the PCIe controller is aggregated. Note: Valid in EP mode only.
PCIE_LINK_STATE_PULSE	CBA_CLK	PCIe link state interrupt. LINK_DOWN_RESET_OUT status from the PCIe core is used to generate this interrupt. Note: Valid in both RC and EP modes.

**Table 12-141. PCIe Subsystem Interrupt Events (continued)**

Interrupt Name	Clock Dependency	Description
PCIE_PWR_STATE_PULSE	CBA_CLK	PCIe power state interrupt. POWER_STATE_CHANGE and DPA_INTERRUPT[0] status output from the PCIe core are used to generate this interrupt. Note: Valid in both EP and RC modes.
PCIE_DPA_PULSE	CBA_CLK	PCIe dynamic power allocation interrupt. DPA_INTERRUPT[0] status output from the PCIe core is used to generate this interrupt. Note: Valid in both EP and RC modes.
PCIE_LOCAL_LEVEL	CBA_CLK	PCIe local interrupt. The LOCAL_INTERRUPT from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RC and EP modes.
PCIE_PHY_LEVEL	CBA_CLK	PCIe PHY interrupt. The PHY_INTERRUPT_OUT from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RC and EP modes.
PCIE_PTM_VALID_PULSE	CBA_CLK	PCIe PTM valid interrupt. PTM_LOCAL_TIMER_OUT_VALID status output from the PCIe controller is used to generate this interrupt. Note: Valid only in EP mode.
PCIE_ECC0_UNCORR_PULSE	CBA_CLK	PCIe ECC Aggregator0 uncorrected pulse interrupt.
PCIE_ECC0_UNCORR_LEVEL	CBA_CLK	PCIe ECC Aggregator0 uncorrected level interrupt.
PCIE_ECC0_CORR_PULSE	CBA_CLK	PCIe ECC Aggregator0 corrected pulse interrupt.
PCIE_ECC0_CORR_LEVEL	CBA_CLK	PCIe ECC Aggregator0 corrected level interrupt.
PCIE_ECC1_UNCORR_PULSE	LANE0_TXMCLK	PCIe ECC Aggregator1 uncorrected pulse interrupt.
PCIE_ECC1_UNCORR_LEVEL	LANE0_TXMCLK	PCIe ECC Aggregator1 uncorrected level interrupt.
PCIE_CPTS_PEND_INTR	CBA_CLK	PCIe CPTS level interrupt.

#### 12.2.2.3.4.1 Interrupts Aggregation

The PCIe subsystem includes the CP\_INTD module to aggregate some of the PCIe controller signals into the subsystem interrupts indicated in [Table 12-141](#). The interrupt aggregator takes both level and pulse signals from the PCIe core and produces the aggregated pulse interrupt outputs.

The aggregator also supports the End of Interrupt (EOI) feature. EOI can be used to re-trigger a pulse interrupt output, if a PCIe controller level signal is still asserted at the end of interrupt processing. The re-triggering of the the pulse interrupt can be achieved by writing the specified EOI vector value to the PCIE\_USER\_EOI\_VECTOR register.

**Table 12-142. PCIe Controller Interrupts Aggregation - 1**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_0 PCIE_INTD_ENABLE_CLR_REG_SYS_0 PCIE_INTD_STATUS_REG_SYS_0 PCIE_INTD_STATUS_CLR_REG_SYS_0 <sup>(1)</sup>				
PCIE_DOWNSTREAM_PULSE	0	pcie_downstream_0	0	down_pf0_intr_out	Downstream PF0 interrupt (EP mode only)
-	31-1	Reserved	-	-	-

(1) Register is not used since all PCIe controller signals being aggregated are of type 'level'.

**Table 12-143. PCIe Controller Interrupts Aggregation - 2**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_1 PCIE_INTD_ENABLE_CLR_REG_SYS_1 PCIE_INTD_STATUS_REG_SYS_1 PCIE_INTD_STATUS_CLR_REG_SYS_1				
PCIE_FLR_PULSE	0	pcie_flr_0	1	flr_in_progress	PF0 function-level reset (EP mode only)
-	21-1	Reserved	-	-	-
PCIE_LEGACY_PULSE	22	pcie_legacy_0	2	inta_out	Legacy interrupt A (RC mode only)
	23	pcie_legacy_1		intb_out	Legacy interrupt B (RC mode only)
	24	pcie_legacy_2		intc_out	Legacy interrupt C (RC mode only)
	25	pcie_legacy_3		intd_out	Legacy interrupt D (RC mode only)
PCIE_PWR_STATE_PULSE	26	pcie_pwr_state	3	power_state_change_intr	Power state change to D1 or D3
-	31-27	Reserved	-	-	-

**Table 12-144. PCIe Controller Interrupts Aggregation - 3**

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_2 PCIE_INTD_ENABLE_CLR_REG_SYS_2 PCIE_INTD_STATUS_REG_SYS_2 PCIE_INTD_STATUS_CLR_REG_SYS_2				
PCIE_DPA_PULSE	0	pcie_dpa	N/A <sup>(1)</sup>	dpa_intr	PF0 DPA power state change (EP mode only)
-	5-1	Reserved	-	-	-
PCIE_ERROR_PULSE	6	pcie_error_0	N/A <sup>(1)</sup>	correctable_error	Correctable error
	7	pcie_error_1		non_fatal_error	Non-Fatal error
	8	pcie_error_2		fatal_error	Fatal error
PCIE_HOT_RESET_PULSE	9	pcie_hot_reset	N/A <sup>(1)</sup>	c_hot_reset_out_sync	Hot reset (EP mode only)
PCIE_LINK_STATE_PULSE	10	pcie_link_state	N/A <sup>(1)</sup>	link_down_reset_out	Link down reset
PCIE_PTM_VALID_PULSE	11	pcie_ptm	N/A <sup>(1)</sup>	ptm_local_timer_out_valid_sync	PTM local timer valid (EP mode only)
-	31-12	Reserved	-	-	-

(1) EOI is not used since the input signal is of type 'pulse'.

#### 12.2.2.3.4.2 Interrupt Generation in EP Mode

When PCIe subsystem is operating as an End Point (EP), either the legacy interrupts, MSI or MSI-X interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RC device). As per PCIe Specifications, each PCIe function may generate only one of the Legacy or MSI interrupt types as decided during configuration period.

##### 12.2.2.3.4.2.1 Legacy Interrupt Generation in EP Mode

The End Point (EP) can trigger generation of a PCI Legacy Interrupt at the Root Complex via an in-band Assert\_INTx / Deassert\_INTx messages (where x = A, B, C, or D). Software can write to the PCIE\_USER\_LEGACY\_INTR\_SET register to trigger the required INTx (where x = A, B, C, or D) assert and de-assert message from the PCIe core. Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

#### Note

The interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

##### 12.2.2.3.4.2.2 MSI and MSI-X Interrupt Generation

In the case of MSI interrupts signaling, the interrupt conditions are communicated from the EP to the RC via messages. Thus, upon the occurrence of an interrupt condition, a message is sent by the EP with information that identifies the origin of the interrupt. Each message is in the form of a memory write request, containing an address and a data value to be written. Each PCI function supported by a device can be assigned a separate memory address, thus providing separate virtual channels for signaling interrupts generated by each function. In addition, the MSI mechanism allows a maximum of 32 distinct data patterns in the messages generated by each PCI function, and each pattern can be assigned to an interrupt condition within the function.

In the case of MSI-X interrupts signaling, the operation is similar to the MSI mode, except that the mechanism allows a much larger number of distinct interrupt conditions as many as 2048 per function to be communicated, and enables a distinct address to be defined for each of these conditions. This mechanism requires two tables to be stored in the EP memory. The MSI-X table contains the address/data patterns to be used for each interrupt condition (as many as 2048 per function) as well as individual enable/mask bits, and the Pending Bit Array (PBA) stores the status of each interrupt condition. Interrupt conditions are communicated from the EP to the RC via messages (write requests), as in the case of the MSI mode.

##### 12.2.2.3.4.3 Interrupt Reception in EP Mode

The PCIe specification does not have provision for End Points to receive legacy interrupts. As a result, only events other than these are used to map to interrupts.

##### 12.2.2.3.4.3.1 PCIe Core Downstream Interrupts

The Vendor Specific Capability signal of the PCIe core, F0\_VSEC\_INTERRUPT\_OUT, is used to generate interrupts to the EP from the RP. The F0\_VSEC\_INTERRUPT\_OUT represents the interrupt for the EP Physical Function 0. This signal is used to generate the PCIE\_DOWNSTREAM\_PULSE interrupt to the local host.

The RP can write to the Vendor Specific Control registers (PCIE\_CORE\_PFn\_I\_VENDOR\_SPECIFIC\_CONTROL\_REG) to assert this signal at the EP and this will trigger the PCIE\_DOWNSTREAM\_PULSE interrupt to the EP host.

##### 12.2.2.3.4.3.2 PCIe Core Function Level Reset Interrupts

The PCIE\_FLR\_PULSE interrupt is asserted to indicate to the host that the PCIe controller has received a function-level reset request from the remote side. The PCIE\_FLR\_PULSE interrupt is an aggregation of the

FLR\_IN\_PROGRESS[0] signal from the PCIe core. The FLR\_IN\_PROGRESS[0] represents Physical Function 0.

Upon assertion of the function level reset interrupt, software will need to write to the PCIE\_USER\_FLR\_DONE[5-0] FLR\_DONE bit field within 100ms to acknowledge to the PCIe core that all the application level processing related to the function level reset is complete.

#### **12.2.2.3.4.3.3 PCIe Core Power Management Event Interrupts**

The PCIE\_PWR\_STATE\_PULSE interrupt is generated to let the software know of the power management events. The PCIE\_PWR\_STATE\_PULSE interrupt is generated by the POWER\_STATE\_CHANGE\_INTERRUPT output of the PCIe core. This interrupt is asserted when the power state of a physical is being changed to D1 or D3 state by writing into their Power Management Control register (PCIE\_CORE\_PFn\_I\_PWR\_MGMT\_CTRL\_STAT\_REP).

Software can check the PCIE\_USER\_LINKSTATUS[23-16] POWER\_STATE\_CHANGE\_FUNCTION\_NUM register field to determine the physical function for which power state change occurred. The PCIE\_USER\_PMCMD[2] POWER\_STATE\_CHANGE\_ACK register bit can be used to acknowledge the POWER\_STATE\_CHANGE\_INTERRUPT.

The PCIE\_DPA\_PULSE interrupt is generated by aggregating the PCIe controller DPA\_INTR0 interrupt status output. This interrupt is asserted in EP mode when there is a configuration write to the dynamic power allocation control register (PCIE\_CORE\_PFn\_I\_DPA\_CTRL\_STATUS\_REG) to modify the DPA power state of the device. The DPA\_INTR0 is asserted for such an event for PF0.

#### **12.2.2.3.4.3.4 PCIe Core Hot Reset Request Interrupt**

When the link is down, the Root Complex may request reset of the End Point. This request is terminated as a PCIE\_HOT\_RESET\_PULSE interrupt to the End Point host software. All outstanding transactions are completed in error on target port and further transactions are not generated on the controller port. Once the transactions are completely stopped, the software should issue a local reset to PCIe subsystem. The re-initialization process may then be started.

The PCIE\_HOT\_RESET\_PULSE interrupt is generated from the HOT\_RESET\_OUT output of the PCIe core.

#### **12.2.2.3.4.3.5 PTM Valid Interrupt**

In EP mode, the PCIe subsystem will generate the PCIE\_PTM\_VALID\_PULSE interrupt to the local CPU after a PTM dialog between the PTM requester (EP) and the PTM responder (RP). The PTM valid interrupt indicates to the CPU in the EP that the local timers have been updated with the timestamp data obtained from the RP. The CPU can read the timer registers inside the EP to determine the current timebase.

The PCIE\_PTM\_VALID\_PULSE interrupt is generated from the PTM\_LOCAL\_TIMER\_OUT\_VALID signal from the PCIe core.

#### **12.2.2.3.4.4 Interrupt Generation in RC Mode**

As per PCIe Base Specifications, Root Complex ports only receive interrupts. There is no mechanism to generate interrupts from RC port to EP mode as per PCIe specification.

However, PCIe subsystem does support generation of interrupts from RC to EP. The downstream interrupts described in [Section 12.2.2.3.4.3.1, PCIe Core Downstream Interrupts](#) provides a mechanism for the RC to generate software triggered interrupts to the EP.

#### **12.2.2.3.4.5 Interrupt Reception in RC Mode**

##### **12.2.2.3.4.5.1 PCIe Legacy Interrupt Reception in RC Mode**

The RC can receive any of the four legacy INTx interrupts from the EP. These will trigger the PCIE\_LEGACY\_PULSE interrupt to the host CPU.

The PCIE\_LEGACY\_PULSE interrupt is an aggregation INTA\_OUT, INTB\_OUT, INTC\_OUT and INTD\_OUT signals from the PCIe core.

#### **12.2.2.3.4.5.2 MSI/MSI-X Interrupt Reception in RC Mode**

The PCIe core decodes all MSI and MSI-X messages received from the link and forwards them as a 32-bit write transaction on the AXI controller interface.

The destination address for MSI/MSI-X write transactions should be the ARM GIC. The GIC will process the write transaction and create an interrupt to the ARM Ax CPU core in the device.

#### **12.2.2.3.4.5.3 Advanced Error Reporting Interrupt**

If enabled by software at the time of enumeration, PCIe subsystem will generate this interrupt to indicate occurrence of errors of various levels of severity. The software can choose not to enable Advanced Error Reporting but if it enables, it must process the interrupt as per PCIe Specifications.

The advanced error reporting interrupt is signaled by the PCIE\_ERROR\_PULSE interrupt. The PCIE\_ERROR\_PULSE is an aggregation of the FATAL\_ERROR\_OUT, NON\_FATAL\_ERROR\_OUT and CORRECTABLE\_ERROR\_OUT from the PCIe core.

#### **12.2.2.3.4.6 Common Interrupt Reception in RC and EP Modes**

These interrupts are common to both RC and EP modes of operation.

##### **12.2.2.3.4.6.1 PCIe Local Interrupt**

The LOCAL\_INTERRUPT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

##### **12.2.2.3.4.6.2 PHY Interrupt**

The PHY\_INTERRUPT\_OUT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

##### **12.2.2.3.4.6.3 Link down Interrupt**

If the PHY link is disconnected, the PCIE\_LINK\_STATE\_PULSE interrupt will be generated. The expected course of action is to reset the entire PCIe subsystem and restart. All application states must also be initialized so that the operations can resume following the reset and renegotiation of the link.

The PCIE\_LINK\_STATE\_PULSE interrupt is generated from the LINK\_DOWN\_RESET\_OUT output of the PCIe core.

##### **12.2.2.3.4.6.4 Transaction Error Interrupts**

If there is a timeout on PCIe or an abort, PCIE\_PHY\_LOCAL\_LEVEL interrupt will be issued. The PCIE\_PHY\_LOCAL\_LEVEL interrupt is generated by the aggregation of the LOCAL\_INTERRUPT and PHY\_INTERRUPT\_OUT signals from the PCIe core. For more details, see the PCIe specification.

##### **12.2.2.3.4.6.5 Power Management Event Interrupt**

This PCIE\_PWR\_STATE\_PULSE interrupt is generated to let the software know of the power management events. The PCIE\_PWR\_STATE\_PULSE interrupt is generated by aggregating the POWER\_STATE\_CHANGE\_INTERRUPT and DPA\_INTERRUPT outputs of the PCIe core.

In EP mode, software can check the PCIE\_USER\_LINKSTATUS[23-16] POWER\_STATE\_CHANGE\_FUNCTION\_NUM bit field to determine the physical function for which power state change occurred.

The PCIE\_USER\_PMCMD[2] POWER\_STATE\_CHANGE\_ACK bit can be used to acknowledge the POWER\_STATE\_CHANGE\_INTERRUPT.

##### **12.2.2.3.4.7 ECC Aggregator Interrupts**

The PCIE\_ECC0\_UNCORR\_PULSE/PCIE\_ECC0\_UNCORR\_LEVEL and PCIE\_ECC0\_CORR\_PULSE/PCIE\_ECC0\_CORR\_LEVEL interrupts are asserted by the CBA clock domain ECC Aggregator. The PCIE\_ECC1\_UNCORR\_PULSE/PCIE\_ECC1\_UNCORR\_LEVEL interrupts are asserted by the Core clock domain ECC Aggregator. The Core clock domain ECC Aggregator correctable interrupts are not exported since

this aggregator is only connected to the error injection logic and the correctable interrupts for this module will never fire.

#### **12.2.2.3.4.8 CPTS Interrupt**

The PCIe CPTS\_PEND\_INT interrupt is asserted by the CPTS module in the PCIe subsystem to signal a TimeStamp event.

#### **12.2.2.3.5 PCIe Subsystem DMA Support**

The PCIe Subsystem has different requirements based upon whether it is operated in Root Complex (RC) or End Point (EP) mode. The PCIe subsystem does not have DMA capabilities built into it. It has internal target and controller ports connected to the device-level interconnect.

An external DMA engine can make burst data read/writes on the target port and the controller port on PCIe subsystem can initiate reads/writes to memory on behalf of a remote PCIe device.

The PCIe subsystem does not specify the DMA protocol that is used for data transfers. The software implementations on the two ends of the PCIe link implement a data transfer protocol that is compatible with each other.

As a result, there will be several software drivers required – one driver that will manage the PCIe subsystem in RC mode and another set of drivers that will run on the RC side and will manage each of the End Points connected to the PCIe subsystem RC.

Similarly, when PCIe subsystem is operating as an End Point, there are two drivers – one to manage the PCIe subsystem from the device side and another driver that will run on the device operating as the Root Complex.

##### **12.2.2.3.5.1 PCIe DMA Support in RC Mode**

When operating in Root Complex mode, a DMA controller internal to the device (outside PCIe subsystem) can perform DMA to and from any remote device located on the PCIe subsystem. The memory address of such devices is available to the software via the PCIe bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCIe side.

##### **12.2.2.3.5.2 PCIe DMA Support in EP Mode**

When operating as a PCIe End Point, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe Root device. Any PCIe transactions destined for the device from the upstream ports will get transferred to the controller port on the PCIe subsystem. Similarly, any transactions originating from the software will be sent over to PCIe link.

In End Point mode, the PCIe subsystem provides address translation functionality. It is possible to map memory accesses originating on PCIe side to memory accesses with different address on the CBA bus side. These address ranges are configurable through application registers.

#### **12.2.2.3.6 PCIe Subsystem Transactions**

##### **12.2.2.3.6.1 PCIe Supported Transactions**

PCIe subsystem supports the following transactions:

1. Memory Read/Write in inbound/outbound direction in Root Complex (RC) and End Point (EP) modes.
2. I/O Read/Write in outbound direction in RC mode.
3. Configuration Read/Write in outbound direction in RC mode.
4. Configuration Read/Write in inbound direction in EP mode.
5. Message Transactions for interrupts and power management in RC and EP modes.

The following transactions are not supported:

1. Locked Read transactions and associated messages.
2. Inbound I/O Transaction Layer Packets (TLPs).

### 3. User defined messages.

#### **12.2.2.3.6.2 PCIe Transaction Limitations**

There are some limitations that must be adhered to while issuing transactions to PCIe subsystem internal bus interface.

- System Initialization

The PCIe subsystem operation is completely dependent upon the availability of the clock from the PLL that is inside the SERDES. All registers in the PCIe controller located in the core clock domain need the PLL to be in lock and properly configured. Register access transactions that are initiated before ensuring that the PLL is locked will result in a status error.

- Remote Configuration and I/O Requests

Since the remote configuration and I/O transaction windows are directly mapped to internal bus space, the software must care to not access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

- Byte Strobe Limitations

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater than 32-bit, the TLP (Transaction Layer Packets) size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

- Burst Type Limitations

The PCIe core and respectively the PCIe subsystem does not support 'fixed' or 'wrap' burst types on its Target or Controller port. Transactions that require any burst type other than incremental burst type will result in unspecified behavior, possibly bus lock up.

- Transaction Address Alignment

The PCIe subsystem imposes a limitation of a maximum of 128-byte outbound read/write command. However, if the starting address is not aligned to an 8-byte boundary, then the maximum transaction size is reduced to 120 bytes. This limitation is placed to avoid arithmetic overflow in computing transaction length from CBA to AXI. Unspecified behavior will occur, if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

- Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). The PCIe core will not interleave read responses, if the outbound read command/transaction size does not exceed the maximum transaction size configured in the PCIe core.

#### **12.2.2.3.7 PCIe Subsystem Address Translation**

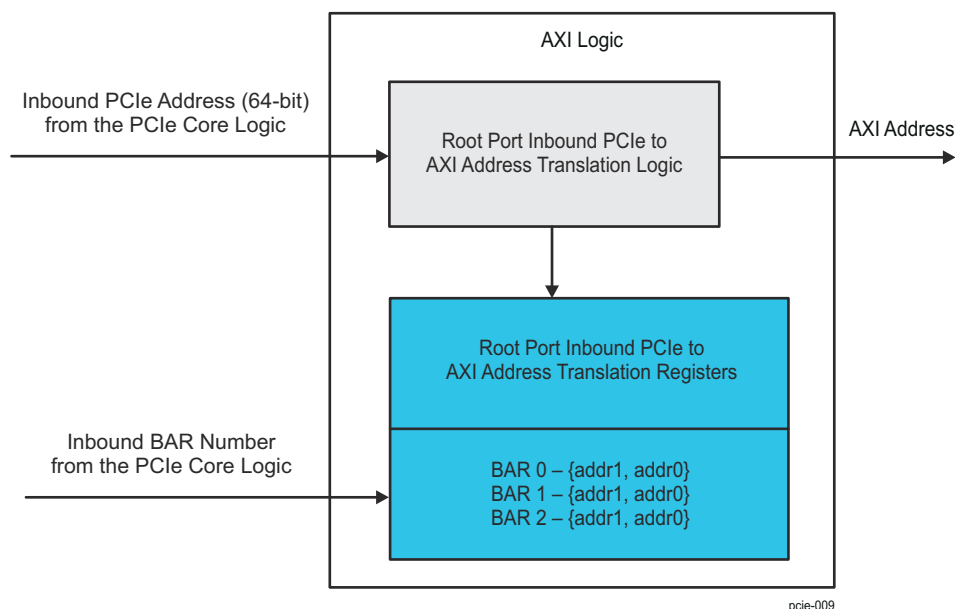

The PCIe subsystem uses the address translation registers in the PCIe core to translate outbound system addresses to PCIe space and inbound PCIe address to a valid system address.

##### **12.2.2.3.7.1 PCIe Inbound Address Translation**

###### **12.2.2.3.7.1.1 Root Complex Inbound PCIe to AXI Address Translation**

The Root Complex inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the BAR match of the incoming TLP. In Root Complex mode there are 2 bars, so BAR0 and BAR1 registers are implemented. There is a BAR7 register which is used as a no match BAR address translation register. In Root Complex mode there are 2 bars but a BAR value of 7 will be indicated by HAL2AXI when BAR matching is disabled.

Any address that does not match the Root Complex BARs will be sent out as a BAR7 TLP. Each BAR register is implemented as two 32-bit registers which are named `addr0` and `addr1`. The 'Root Complex Inbound PCIe to AXI Address Translation Logic' takes the upper bits from the 'Root Complex Inbound PCIe to AXI Address Translation Registers' and the lower bits are taken from the inbound PCIe address to form the AXI address. An `addr0 [5:0] + 1` number of lower bits are passed from the inbound PCIe address to AXI address. In other words, the number of bits taken from inbound PCIe address is given by the `addr0[5:0] + 1` value.

**Figure 12-123. PCIe Root Complex Inbound PCIe to AXI Address Translation**

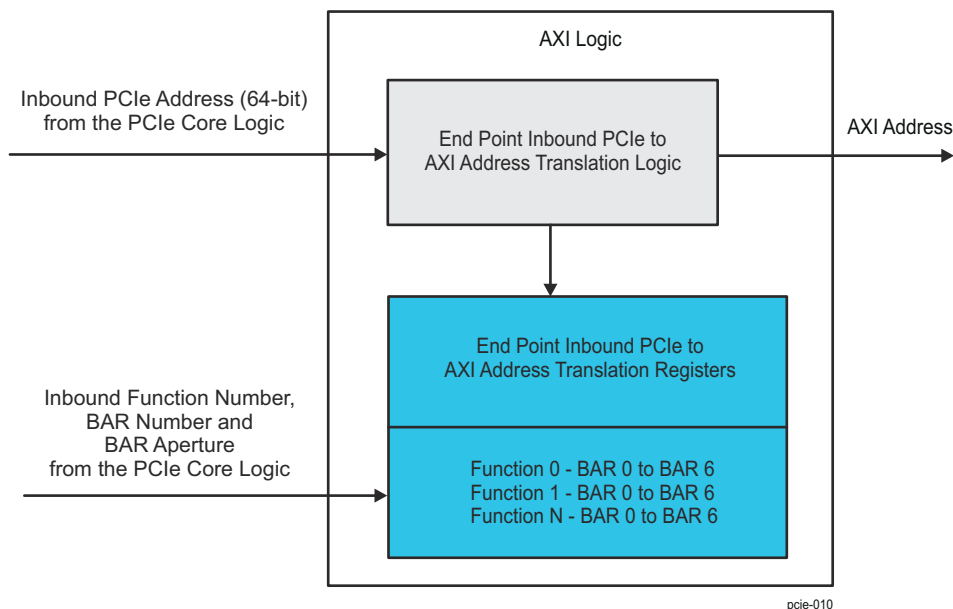

A set of registers corresponding to one Root Complex BAR is shown in [Table 12-145](#).

**Table 12-145. PCIe Root Complex Inbound PCIe to AXI Address Translation Registers for one BAR**

Register Name	Bits	Description	Default Value
<code>addr1</code>	31:0	Upper [63:32] bits of the AXI address.	32'd0
<code>addr0</code>	31:8	Lower [31:8] bits of the AXI address.	24'd0
	7:6	Reserved	2'd0
	5:0	Number of address bits passed through from PCIe to AXI. The PCIe controller passes the programmed value + 1 bits from PCIe to AXI. Minimum value to be programmed into this field is 7 as the lower 8 bits of the base address programmed in these registers (AXI) are replaced by zeros by the 'Root Complex Inbound PCIe to AXI Address Translation Logic'.	6'd0

#### 12.2.2.3.7.1.2 End Point Inbound PCIe to AXI Address Translation

The End Point Inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the function number and BAR match of the incoming TLP. In End Point mode there are 7 bars per function, so 7 sets of registers are implemented per function, each BAR having two 32-bit registers (`addr0` and `addr1`). The 'End Point Inbound PCIe to AXI Address Translation Logic' takes the upper bits from the 'End Point Inbound PCIe to AXI Address Translation Registers' and the lower bits are taken from the Inbound PCIe Address to form the AXI address. The number of bits to pass from Inbound PCIe Address to AXI is decided by the Inbound BAR aperture.

**Figure 12-124. PCIE End Point Inbound PCIe to AXI Address Translation**

A set of registers corresponding to one End Point BAR is shown in [Table 12-146](#).

**Table 12-146. PCIE End Point Inbound PCIe to AXI Address Translation Registers for one BAR**

Register Name	Bits	Description	Default Value
[PF]_ib_ep_[BAR]_addr1 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Upper [63:32] bits of the AXI address.	32'd0
[PF]_ib_ep_[BAR]_addr0 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Lower [31:0] bits of the AXI address.	32'd0

#### 12.2.2.3.7.2 PCIe Outbound Address Translation

The PCIe Subsystem allows mapping of PCIe addresses to/from the internal bus addresses of the device. This is accomplished by using internal address translation unit (iATU) in the PCIe core. For each outbound read/write request, the address translation module within PCIe subsystem can convert a VBUSM address to a PCIe address of memory Read/Write type.

If a transaction is large enough that it goes past the address translation region, unspecified behavior may occur. The address translation only works at the time a command is issued. So, a memory write, for example, will not automatically go to next translation region, if it starts in the previous one and is bigger than the remaining size in the starting translation region.

The “Dynamic Method: Sideband Descriptor Based” outbound address translation mechanism is used to bypass the outbound address translation unit under certain conditions. For more details on the bypass operation, see [Section 12.2.2.3.7.2.1, PCIe Outbound Address Translation Bypass](#).

##### 12.2.2.3.7.2.1 PCIe Outbound Address Translation Bypass

The PCIe subsystem supports bypassing the outbound address translation in the PCIe controller when the *casel* value on the VBUSM target interface is non-zero.

The device DMA has the ability to send transactions to alternate address maps which are external to the local device. This is achieved by using casel identifier in the DMA descriptors. There are three requirements that need to be met in the PCIe subsystem when using this mode in the DMA, namely:

- Block transactions based on initiator credentials to support FFI (Freedom from Interference)
- Bypass the Address Translation Unit (ATU) inside the PCIe controller since the transaction address is external to the local device
- Assign the correct Bus, Device, Function (BDF) and Traffic Class (TC) values to the transaction

To meet these requirements, the PCIe subsystem uses the *cvirtid* values on the VBUSM target interface to filter transactions based on initiator credentials. The VMAP block in the PCIe subsystem has a *virtid* match register (PCIE\_VMAP\_OB\_VIRTID\_MATCH) and a set of 32 registers that can be used to program the descriptor fields when the ATU logic in the PCIe controller is bypassed.

The PCIe subsystem will filter outbound VBUSM target transactions that have a non-zero casel value. If the *cvirtid*[11:5] attribute of the VBUSM target transaction matches the value programmed in the PCIE\_VMAP\_OB\_VIRTID\_MATCH register, the credentials of the transaction initiator are verified. The *cvirtid*[11:5] value should also be non-zero for a successful match.

When the credentials match, the ATU of the PCIe controller is bypassed. The *cvirtid*[4:0] is used to select one of the 32 PCIE\_VMAP\_DESC\_j descriptor registers. These registers can be programmed to assign the BDF and TC values to the outbound PCIe transaction. If the PCIE\_VMAP\_DESC\_j[16] BD\_EN0 register bit is set, then the bus, device and function numbers are all set from the external descriptor registers. If the BD\_EN bit is not set, then the bus and device numbers are assigned by the PCIe controller using the values captured during enumeration. If ARI mode is enabled (in the PCIE\_CORE\_PFn\_I\_SRIOV\_CTRL\_STATUS\_REG register), the function number uses the PCIE\_VMAP\_DESC\_j[7:0] DEV\_FUNC\_NUM register field. If ARI mode is not enabled, the device number uses PCIE\_VMAP\_DESC\_j[7:4] DEV\_FUNC\_NUM field and the function number uses the [3:0] DEV\_FUNC\_NUM field. The ARI mode is a PCIe controller hardware configuration option that is enabled for PCIe endpoints that support SR-IOV.

If the credentials of the initiator fail to match the programmed value in the PCIE\_VMAP\_OB\_VIRTID\_MATCH register, the VBUSM target transaction is then flushed by the bridge and is not submitted to the PCIe controller. The VBUSM2AXI2 bridge will return a protection error status for both read and write transactions. In addition, the write data is discarded and the correct number of read data phases with data value of zero are returned.

#### 12.2.2.3.8 PCIe Subsystem Quality-of-Service (QoS)

The Virtual Channel/Transfer Class (VC/TC) feature in the PCIe core, in conjunction with the device system CBASS Quality-of-Service (QoS) capabilities, provide a mechanism for supporting differentiated QoS within the PCIe subsystem. The policy for traffic differentiation is determined by the Transfer Class (TC) and Virtual Channel (VC) mapping and VC-based arbitration mechanism.

A Virtual Channel is established when one or more TCs are associated with a physical resource designated by a VC ID. Every Traffic Class that is supported on a given path within the subsystem must be mapped to one of the enabled Virtual Channels. Every Port must support the default TC0/VC0 pair – this is “hardwired.” Any additional TC mapping or additional VC resource enablement is optional. The number of VC resources provisioned within a component or enabled within a given subsystem may vary due to implementation and usage model requirements.

The PCIe core in the PCIe subsystem is configured to support four virtual channels (4VC/4TC). For both ingress and egress traffic, VC3, the highest numbered virtual channel, has the highest priority.

For ingress traffic, the TC information from each transaction on the AXI controller information is mapped to the CCHANID signal of the VBUSM controller interface. The system level interconnect can use the CCHANID along with the ORDERID for QoS purposes. Table 12-147 shows the TC mapping to the 12-bit CCHANID of each VBUSM controller interface.

**Table 12-147. PCIe Subsystem QoS Ingress CCHANID Mapping**

TC Value	CCHANID[11:0]
0	{9'd0, 3'b000}
1	{9'd0, 3'b001}
2	{9'd0, 3'b010}

**Table 12-147. PCIe Subsystem QoS Ingress CCHANID Mapping (continued)**

TC Value	CCHANID[11:0]
3	{9'd0, 3'b011}
4	{9'd0, 3'b110}
5	{9'd0, 3'b101}
6	{9'd0, 3'b110}
7	{9'd0, 3'b111}

For egress traffic requiring the highest priority it should be mapped to VC=3 in the PCIe controller. The VC mapping is done using the AXI outbound descriptor registers in the PCIe controller.

#### 12.2.2.3.9 PCIe Subsystem Precision Time Measurement (PTM)

The Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Controller Time: an independent time domain associated with a PTM Root.

The PTM defines the following components:

- PTM Requester - A Function capable of using PTM as a consumer associated with an Endpoint.
- PTM Responder - A Function capable of using PTM to supply PTM Controller Time associated with a RC.
- Time Source - A local clock associated with a PTM Responder.
- PTM Root – The source of PTM Controller Time for a PTM hierarchy. A PTM Root must also be a Time Source and is typically also a PTM Responder.

When using PTM between two components on a Link, the EP sends PTM requests to the RC on the same link. During each dialog, the RC populates the PTM Response message based on timestamps stored during previous PTM dialogs. Once each component has historical timestamps from the preceding dialog, the EP can combine its timestamps with those passed in the PTM Response message to calculate the PTM Controller Time.

The PCIe core implements all of the features required to handle the PTM conversation between the requestor and responder in hardware. In addition, an internal TimeStamp module (CPTS) is connected to the timestamp interface of the PCIe core so that events can be logged.

The Precision Time Measurement (PTM) support in the PCIe subsystem is handled by the combination of the PCIe core and the CPTS module.

The PCIe core controller handles the PCIe conversation to exchange timestamps between the RC and EP. It also includes logic to calculate the timestamp differences as specified in the PCIe standard.

A 64-bit timer that is the controller clock is included in the PCIe core. The PCIe controller can be programmed to initiate the PTM conversation automatically by setting the [0] PTMRQM bit in the PCIE\_CORE\_LM\_I\_PTM\_LOCAL\_CONTROL\_REG register.

In EP mode, there are two methods to register a CPTS HW1 push timestamp that is needed to transfer the PCIe PTM timebase to the local system time base.

1. The first method involves the PTM\_LOCAL\_TIMER\_OUT\_VALID and PTM\_EP\_TIMER. The PTM\_LOCAL\_TIMER\_OUT\_VALID output from the PCIe controller will be asserted when the PTM conversation is complete and the EP local timer has been updated. The adjusted value of the EP 64-bit timer is available in the PTM\_LOCAL\_TIMER\_OUT output of the controller. A second 64-bit free running timer, PTM\_EP\_TIMER, is used to shadow the value of the EP timebase. The PTM\_EP\_TIMER is loaded with the value of the PTM\_LOCAL\_TIMER\_OUT[63:0] when PTM\_LOCAL\_TIMER\_OUT\_VALID is high. When PTM\_LOCAL\_TIMER\_OUT\_VALID is low, PTM\_EP\_TIMER will be free running based on the same PCIE CORE\_CLK that drives the PTM\_LOCAL\_TIMER\_OUT. The increment value of PTM\_EP\_TIMER can be adjusted by writing to the PCIE\_USER\_PTM\_CFG[10-8] PTM\_EP\_TIMER\_ADJ register field. The increment value is one by default. The value of the PTM\_EP\_TIMER will not be updated to the RC timebase until the first PTM dialog has occurred. Software can set the PCIE\_USER\_PTM\_CFG[6-0] PTM\_CLK\_SEL register

2. The second method to register the CPTS HW1 push timestamp involves only the PTM\_LOCAL\_TIMER\_OUT\_VALID output from the PCIe controller. Software can set the PCIE\_USER\_PTM\_CFG[6-0] PTM\_CLK\_SEL register field value to 64 to select the PTM\_LOCAL\_TIMER\_OUT\_VALID as the source of the CPTS HW1 time stamp push event. This will create a CPTS HW1 timestamp when there is a PTM dialog between the PCIe End Point and Root Complex. The actual value of the EP PTM local timer can be read from the PCIE\_USER\_PTM\_TIMER\_LOW and PCIE\_USER\_PTM\_TIMER\_HIGH registers.

The reference clock (RCLK) for the CPTS can be controlled via the CTRLMMR\_PCIE0\_CLKSEL[2-0] CPTS\_CLKSEL register field in the device Control Module. This enables the SoC flexibility in choosing the CPTS reference clock input. In RC mode, the RCLK needs to be connected to the SERDES PIPE clock since the CPTS will be driving the PTM controller clock. For more information on the RCLK source clock selection, see *PCIe Subsystem Integration*.

[illegible]

pcje-006

The PCIe subsystem provides loopback support through PIPE interface (Link Layer).

#### **12.2.2.3.10.1 PCIe Loopback**

The procedure depends upon whether the device is operating in RC or EP Mode. In either case, the PCIe subsystem can be loopback initiator or loopback target as outlined in PCIe specifications. A loopback initiator is the component requesting loopback and transmitting the data. A loopback target is the component looping back the data.

##### **12.2.2.3.10.1.1 PCIe Loopback Initiator Mode**

The loopback path when PCIe subsystem is loopback initiator is:

PCIe subsystem (loopback initiator) -> PIPE (TX) -> PCIe Link -> Loopback -> PCIe Link -> PIPE (RX) -> PCIe subsystem

##### **12.2.2.3.10.1.2 PCIe Loopback Target Mode**

The loopback path when PCIe subsystem is loopback target is:

Remote device -> PCIe Link -> PIPE (RX) -> Loopback -> PIPE (TX) -> PCIe Link -> Remote device

If the PCIe subsystem is a loopback target, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback initiator and it will transition PCIe subsystem into loopback target state following which, the inbound transactions will be looped back to the test equipment.

#### **12.2.2.3.11 PCIe Subsystem Error Handling**

As an End Point, PCIe subsystem reports errors to root complex so that corrective action may be taken. These messages become error interrupts on the Root Complex side. In addition, the errors that are detected by the PCIe subsystem locally are also reported to software via interrupts.

Note that for several errors of the same type that are detected in close succession, the PCIe subsystem will not necessarily send as many error messages to Root Complex. It is guaranteed to send at least one such error message.

#### **12.2.2.3.12 PCIe Subsystem Internal Diagnostics Features**

##### **12.2.2.3.12.1 ECC Aggregators**

The PCIe subsystem instantiates two ECC Aggregators: AXI\_ECC\_AGGR and CORE\_ECC\_AGGR.

AXI\_ECC\_AGGR is connected to the RAMs in PCIe CBA Clock Domain and CORE\_ECC\_AGGR is connected to the RAMs in the PIPE Clock Domain.

The ECC Aggregator modules integrated within the PCIe subsystem provide a mechanism to control and monitor the ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions. Each ECC Aggregator module gathers level pending status from the ECC RAMs into two interrupts to system level. One interrupt is for correctable errors (SEC) and the other one for uncorrectable errors (DED). The ECC Aggregator supports software readable status of ECC single/double-bit errors and associated information such as RAM address and data bit(s) that are in error. Write back correction for async read RAMs is not supported.

For more information on the ECC Aggregator operation, see *ECC Aggregator*.

##### **12.2.2.3.12.2 RAM ECC Inversion**

The RAM ECC logic inside the PCIe controller can be tested using the ECC inversion logic.

### 12.2.3 Serializer/Deserializer (SerDes)

This section describes the Serializer/Deserializer (SerDes) in the device.

<b>12.2.3.1 SerDes Overview</b> .....	<a href="#">1635</a>
<b>12.2.3.2 SerDes Environment</b> .....	<a href="#">1638</a>
<b>12.2.3.3 SerDes Integration</b> .....	<a href="#">1639</a>
<b>12.2.3.4 SerDes Functional Description</b> .....	<a href="#">1642</a>

### 12.2.3.1 SerDes Overview

SerDes's goal is to convert device (SoC) parallel data into serialized data that can be output over a high-speed electrical interface. In the opposite direction, SerDes converts high-speed serial data into parallel data that can be processed by the device. To this end, the SerDes contains a variety of functional blocks to handle both the external analog interface as well as the internal digital logic.

Most important building blocks of SerDes are:

- Physical Media Attachment (PMA):
  - Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer, and Clock and Data Recovery (CDR) unit.
  - Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes, and muxes SerDes to peripherals.

Figure 12-126 shows SERDES0 highlights.

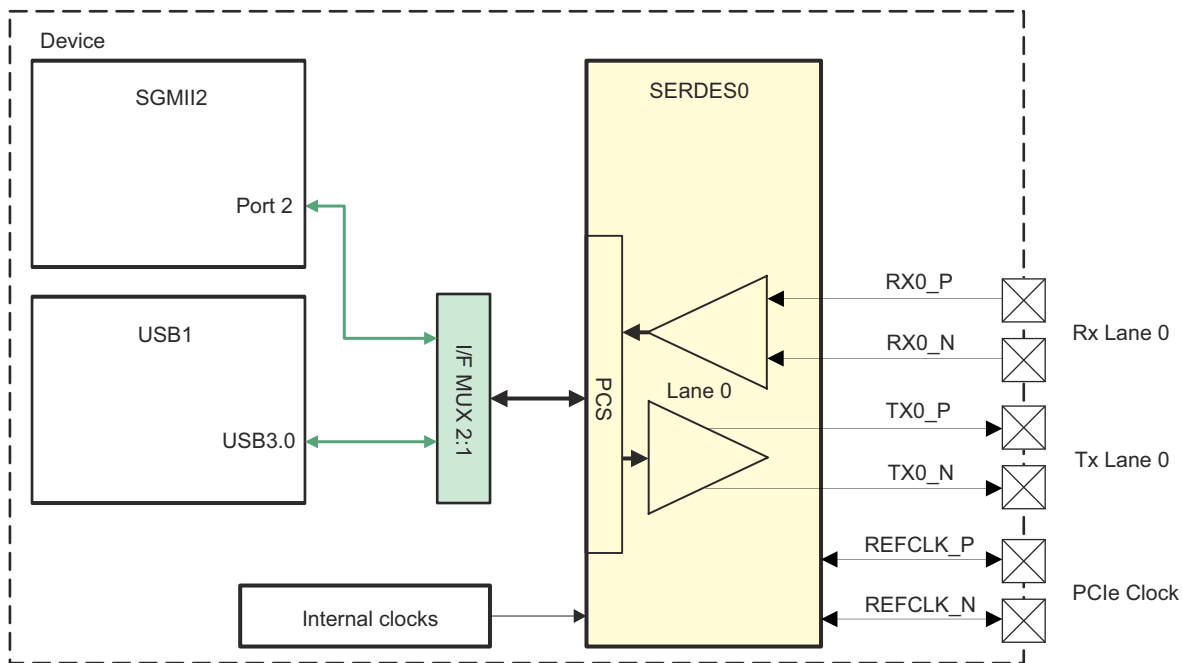

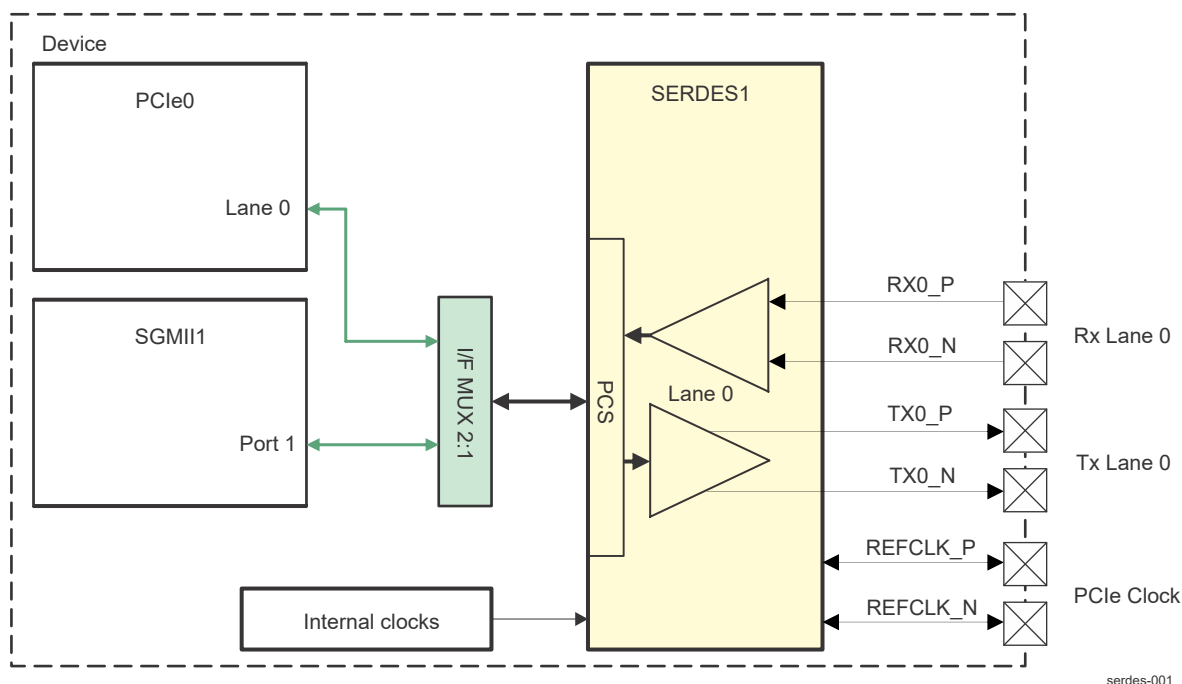

Figure 12-126. SERDES0 Overview

**Figure 12-127. SERDES1 Overview**

serdes-001

### 12.2.3.1.1 SerDes Features

The SERDES module features include:

- Single lane PHY containing:
  - Transmit and Receive I/Os
  - Serializer
  - Deserializer
  - Clock and data recovery (CDR) unit
- Common Module (CMN)
  - PLLs
  - Controller bias
  - Automatic calibration of pin termination resistors
  - Reference clock input buffers
  - Reset and startup management
- Physical Coding Sub-block (PCS)
  - USB3.1 Gen 1 (5 Gbps)
  - PCIe Gen 1 (2.5 Gbps), Gen 2 (5 Gbps), and PCIe Gen 3 (8 Gbps)
  - Symbol alignment
  - Selectable serial pin polarity reversal for both transmit and receive paths
  - Bit stream reordering
- Physical Media Attachment (PMA) layer
  - Transmit equalization
  - Receive equalization
  - Supports on-the-fly eye and bathtub curve diagramming with 8-bit voltage amplitude resolution and up to 1/64 UI time resolution
  - Data path BIST with programmable pattern generation and error detection
  - Serial bit stream and parallel word loopback for both line and parallel side
  - 8-bit ADC provides digitized ATB measurement results
  - Supports DC and AC JTAG (boundary scan) per IEEE 1149.6

The SERDES mux (WIZ) module supports the following features:

- Multiplexes device interfaces onto a single SERDES lane (Tx and Rx)
- Provides registers to implement SERDES control and status functions and alignment delays
- Clock generator block for providing MAC transmit clock
- Rx comma align block
  - Performs de-stuffing the Rx data stream in the event that the Rx rate is different from the Tx rate
  - Supports comma detection that is not sensitive to false commas using all 8b/10b character combinations

#### 12.2.3.1.2 Not Supported Features

All features described in this chapter are supported.

#### 12.2.3.1.3 Industry Standards Compatibility

All SerDes interfaces are configured as point-to-point connections. It is assumed that the connection is made between the SoC and another device that is compliant to the appropriate industry standard. The list of supported standards is given below.

This chapter deals with the physical layer and, therefore, it is the electrical specifications in these standards that are relevant. For more information regarding protocol compliance <sup>1</sup>, see the device-specific Datasheet.

- PCIe is electrically compliant with Base specification revision 4.0.
- USB is electrically compliant with USB 3.1.
- SGMII: Electrically compliant with IEEE 802.3 Clause 70-7

**Table 12-148. SerDes Supported Standards**

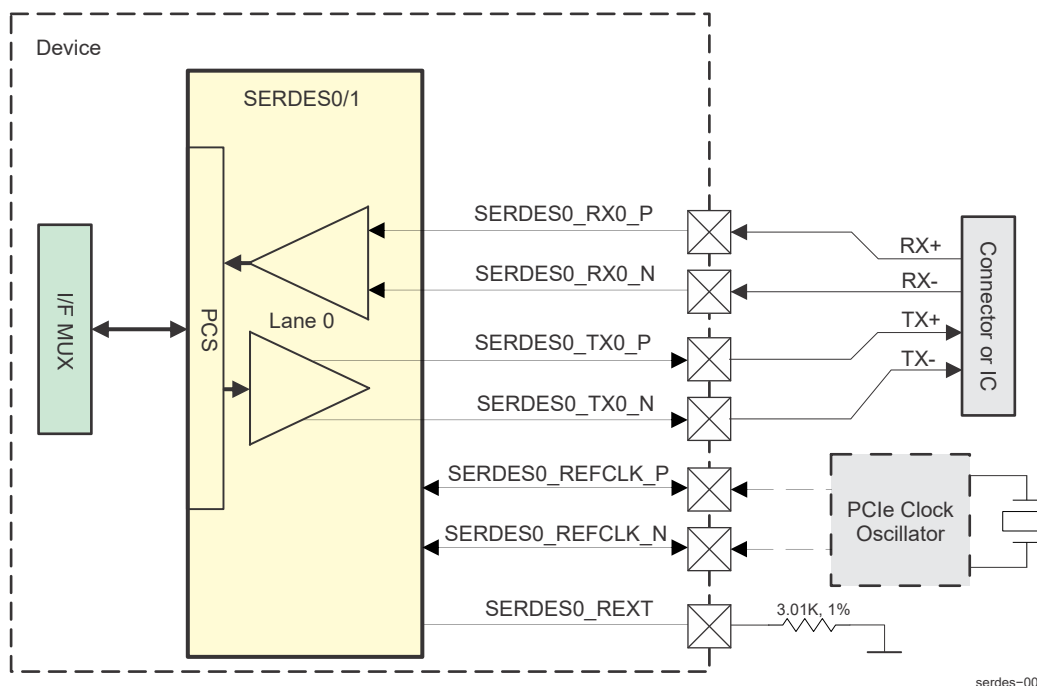

Standard	Bit Rate (Gbps)	Reference Clock Frequency (MHz)
PCI Express 4.0 Gen1	2.5	100
PCI Express 4.0 Gen2	5.0	100
PCI Express 4.0 Gen3	8.0	100
USB 3.1 Gen1 SuperSpeed	5.0	100
SGMII	1.0	100

<sup>1</sup> Electrical compatibility does not guarantee interoperability with devices

## 12.2.3.2 SerDes Environment

### 12.2.3.2.1 SerDes I/Os

Figure 12-128 shows the I/O interface signals of SERDES.

**Figure 12-128. SerDes Environment**

### Note

Although containing some of the basic external components, [Figure 12-128](#) must not be considered as an exhaustive guide for the PCB designer. TI provides additional documents for those who are willing to design PCBs and/or fine tune the SerDes.

[Table 12-149](#) describes the external signals of SERDES0 module.

**Table 12-149. SERDES0/1 Input/Output Description**

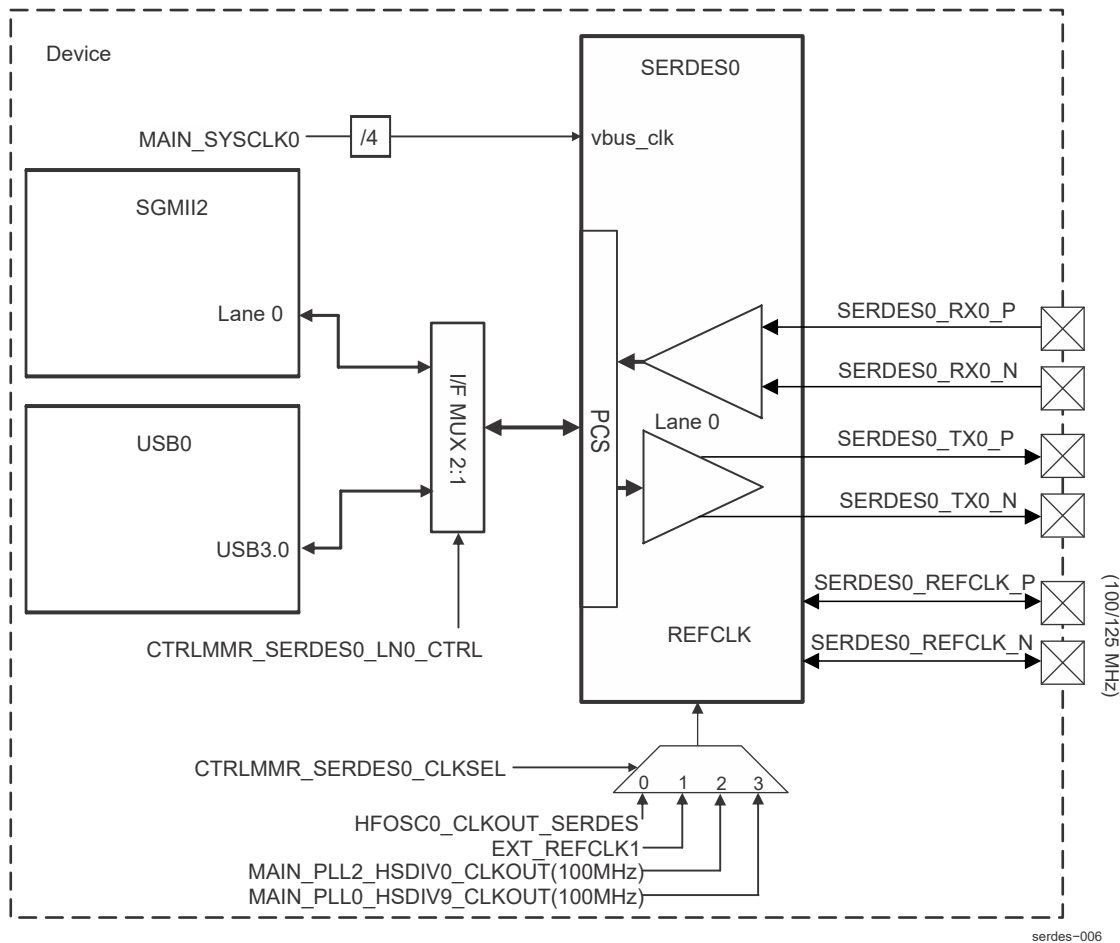

Device Pin <sup>(2)</sup>	Module Signal	I/O <sup>(1)</sup>	Description	Value at Reset
SERDES <sub>x</sub> _RX0_P	RX_P_LN0	I	SerDes differential data receive pins	HiZ
SERDES <sub>x</sub> _RX0_N	RX_M_LN0	I		HiZ
SERDES <sub>x</sub> _TX0_P	TX_P_LN0	O	SerDes differential data transmit pins	HiZ
SERDES <sub>x</sub> _TX0_N	TX_M_LN0	O		HiZ
SERDES <sub>x</sub> _REFCLK0P	CMN_REFCLK_P	I/O	SerDes external PCIe reference clock	HiZ
SERDES <sub>x</sub> _REFCLK0N	CMN_REFCLK_N	I/O		HiZ
SERDES <sub>x</sub> _REXT	CMN_REXT	A/I	PMA external calibration resistor. Requires a 3.01 kOhm ±1% accurate off-chip resistor connected from this pin to ground.	HiZ

(1) I = Input; O = Output; A = Analog

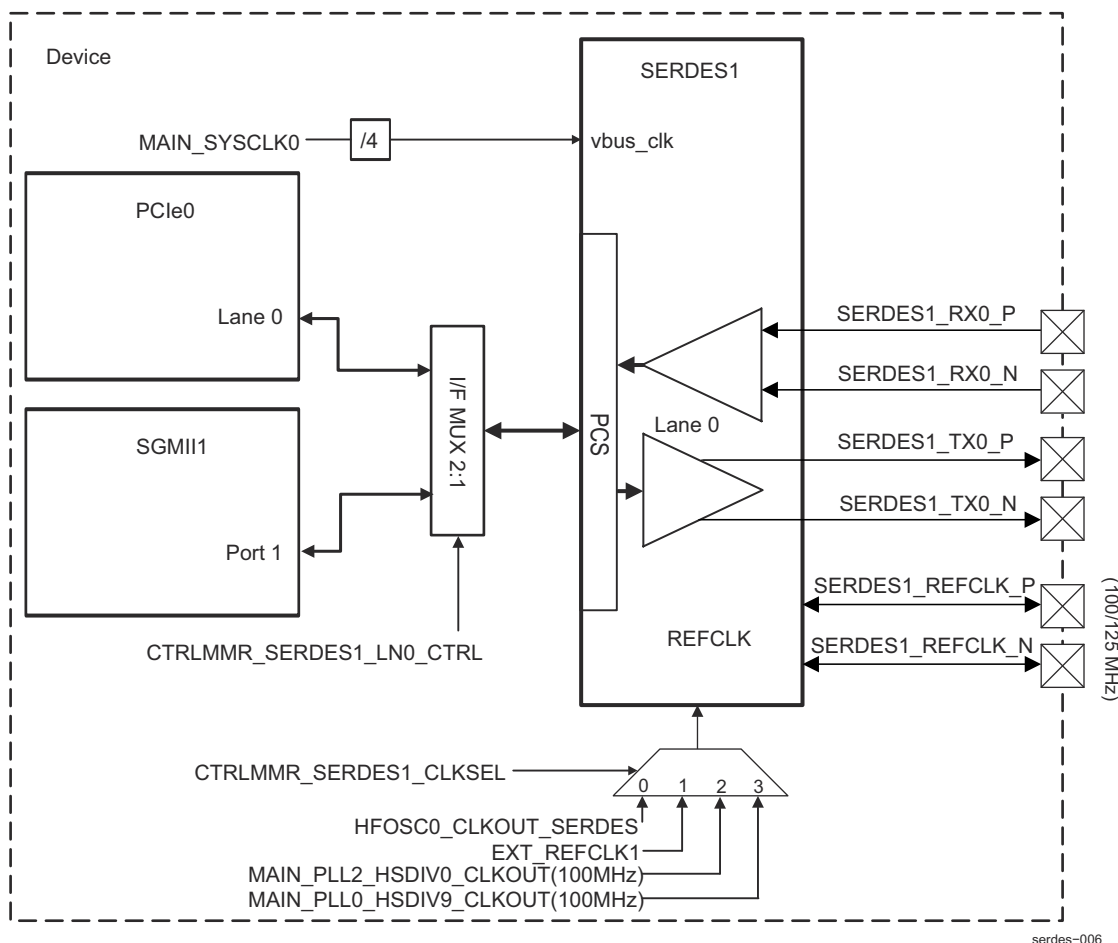

(2) x = 0 or 1

### 12.2.3.3 SerDes Integration

Figure 12-129 shows the integration of the SERDES0 module in the device.

**Figure 12-129. SERDES0 Integration**

**Figure 12-130. SERDES1 Integration**

The following table summarizes the integration of SerDes in device MAIN domain.

**Table 12-150. SerDes Clocks**

Module Instance	Module Clock Input	Source Clock Signal	Source	Description
SERDES0/1	SERDES0/1_ICLK	MAIN_SYCLK0/4	PLL_CTRL0	VBUS interface clock
	CMN_REFCLK_INT	HFOSC0_CLKOUT_SE	HFOSC0	Internal reference clock from device sources. Software selectable. See <a href="#">Section 12.2.3.3.1.2</a>
		EXT_REFCLK1	External REFCLK	
		MAIN_PLL2_HSDIV0_C	PLL2	
		MAIN_PLL0_HSDIV9_C	PLL9	

### 12.2.3.3.1 WIZ Settings

This section describes the quazi-static settings that software must perform after global resets. These settings are made via registers in the CTRL\_MMR0 module. For CTRL\_MMR0 description, please refer to *Control Module (CTRL\_MMR)*.

#### 12.2.3.3.1.1 Interface Selection

SerDeses provide PHY functions for the following high-speed interfaces:

- PCIe0 (one lane)
- USB1 SS
- SGMII ( 1G )

[Table 12-151](#) describes the interface combinations supported by SERDES0.

**Table 12-151. SERDES0 Supported Configurations**

Interface Alias	CTRLMMR_SERDES0_LN0_CTRL [1:0]	
	LANE_FUNC_SEL	Interface on Lane 0
IP1	0x0	USB1 SS
IP2	0x1	SGMII2

**Table 12-152. SERDES1 Supported Configurations**

Interface Alias	CTRLMMR_SERDES1_LN0_CTRL [1:0]	
	LANE_FUNC_SEL	Interface on Lane 0
IP1	0x0	PCIe0
IP2	0x1	SGMII1

#### 12.2.3.3.1.2 Internal Reference Clock Selection

[Table 12-153](#) describes the internal reference clock options for SERDES0.

**Table 12-153. SerDes Internal Reference Clock Selection**

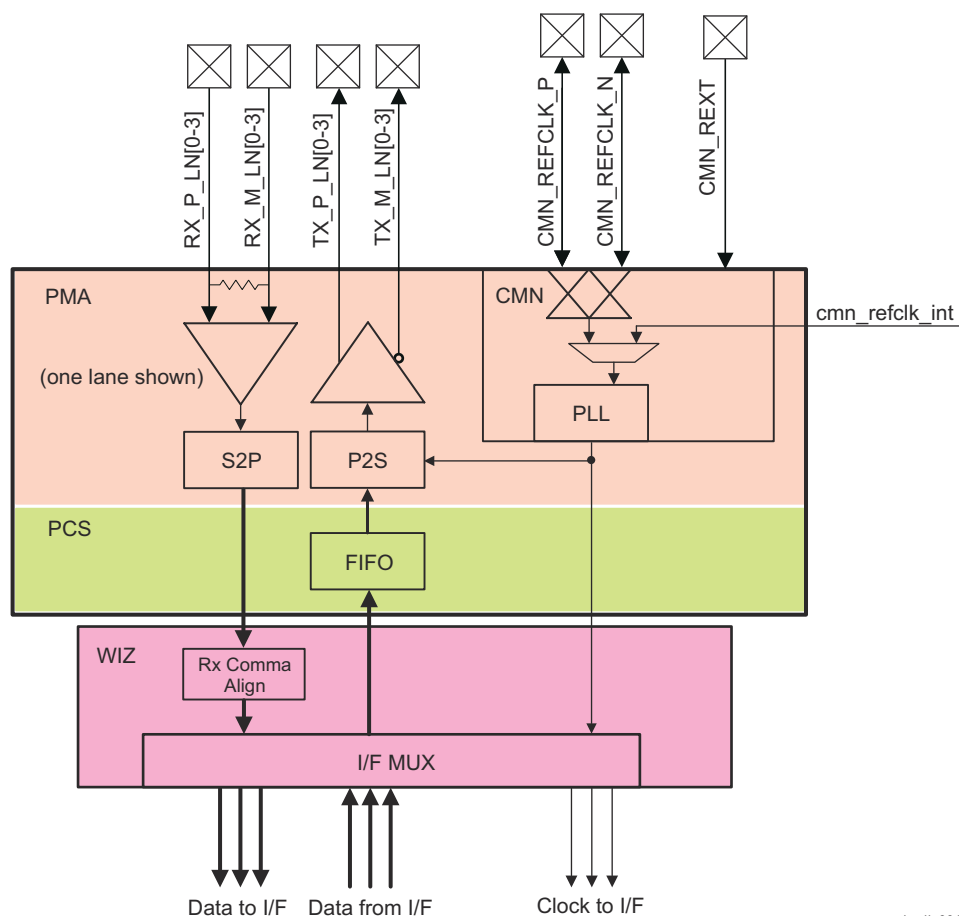

CTRLMMR_SERDES0/1_CLKSEL	
[1:0] CLK_SEL	Internal Clock to SERDES Core
0x0	HFOSC0_CLKOUT_SERDES
0x1	EXT_REFCLK1
0x2	MAIN_PLL2_HSDIV0_CLKOUT(100MHz)
0x3	MAIN_PLL0_HSDIV9_CLKOUT(100MHz)

### 12.2.3.4 SerDes Functional Description

#### 12.2.3.4.1 SerDes Block Diagram

Figure 12-131 is a top-level, non-exhaustive diagram of SerDes and WIZ wrapper. Note that only one (Tx + Rx) lane is shown.

serdes41-004

**Figure 12-131. SerDes and WIZ Block Diagram**

Building blocks of SerDes include:

- Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer (P2S/S2P), and Clock and Data Recovery (CDR) unit. Each SerDes contains one Tx and Rx lane.
- Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Lanes and CMN are parts of the Physical Media Attachment (PMA) layer.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes (register interface), and muxes SerDes to peripherals (USB, PCIe, and others).

## 12.2.4 Universal Serial Bus Subsystem (USBSS)

This section describes the Universal Serial Bus Subsystem (USBSS) in the device.

### 12.2.4.1 USB Overview

USB (Universal Serial Bus) provides a low-cost connectivity solution for numerous consumer portable devices by implementing a mechanism for data transfer between USB devices.

The device instantiates two independent instances of a third-party USB subsystem (USB2SS) operating at up to USB2.0 speeds (480Mb/s), either of which can be independently configured to act as a USB Host or a USB Device. SuperSpeed (5.0 Gb/s) operation is not supported in either operational mode.

#### 12.2.4.1.1 USB Features

The USB 2.0 subsystem supports the following USB Features:

- Operational modes:
  - Supports USB 2.0 Host mode at High-Speed (HS, 480 Mbps), Full-Speed (FS, 12 Mbps), and Low-Speed (LS, 1.5 Mbps)
  - Supports USB 2.0 Device mode at High-Speed (HS, 480 Mbps), and Full-Speed (FS, 12 Mbps). Low-Speed is not supported in Device mode.
  - Supports all modes of transfers - Control, Bulk, Interrupt, and Isochronous.
- A DRD (Dual-Role-Device - Host or Device) USB controller with the following features:
  - Compatible to the xHCI 1.0 specification in Host mode
  - Compatible with the USB 2.0 specification in Device mode
  - Supports 15 IN (Receive), 15 OUT (Transmit) endpoints (EPs), and one EP0 endpoint which is bidirectional
  - Internal DMA controller
  - Descriptor caching and data pre-fetching ensures high performance
  - Dynamic FIFO memory allocation for all endpoints
- Operation flexibility
  - Same programming model for HS, FS, and LS operation
  - Each controller instance can provide either USB Host or USB Device functionality

#### 12.2.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

### 12.2.4.2 USB Environment

#### 12.2.4.2.1 USB Pin List

The names of the pins used by the USB2SS with descriptions are shown in [Table 12-154](#) and [Table 12-155](#).

**Table 12-154. USB Signal Pins Description**

Pin Name	I/O <sup>(1)</sup>	Description
USBn_DP	I/O	USB 2.0 and 1.1 Specification-compliant signal pins. They are HS/FS/LS bidirectional differential data pins.
USBn_DM	I/O	

(1) I = Input, O = Output, A = Analog

**Table 12-155. USB Control, Configuration, and Monitor Signal Pins**

Pin Name	I/O <sup>(1)</sup>	Description
USBn_DRVVBUS	O	An active-high digital output signal for VBUS power supply. Used to enable an external charge pump to supply +5V power to the VBUS receptacle when operating in USB Host mode.
USBn_VBUS <sup>(2)</sup>	A/I	An analog input for monitoring the voltage on VBUS.

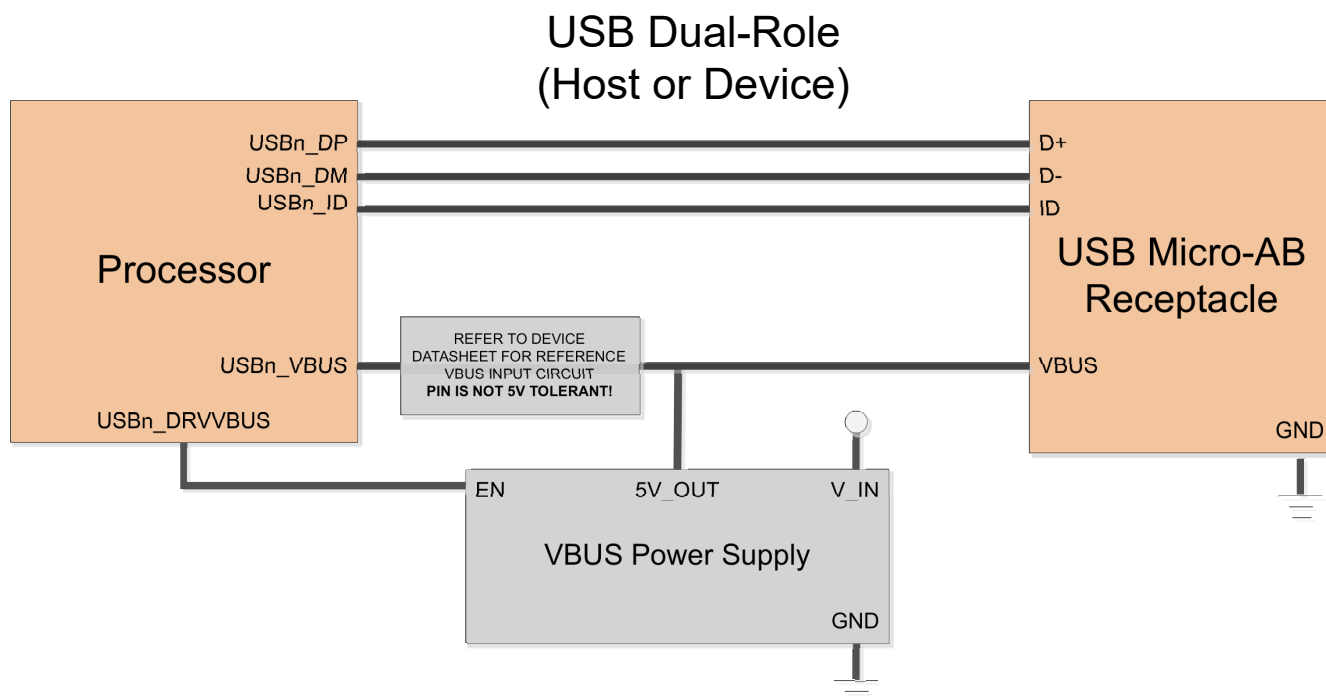

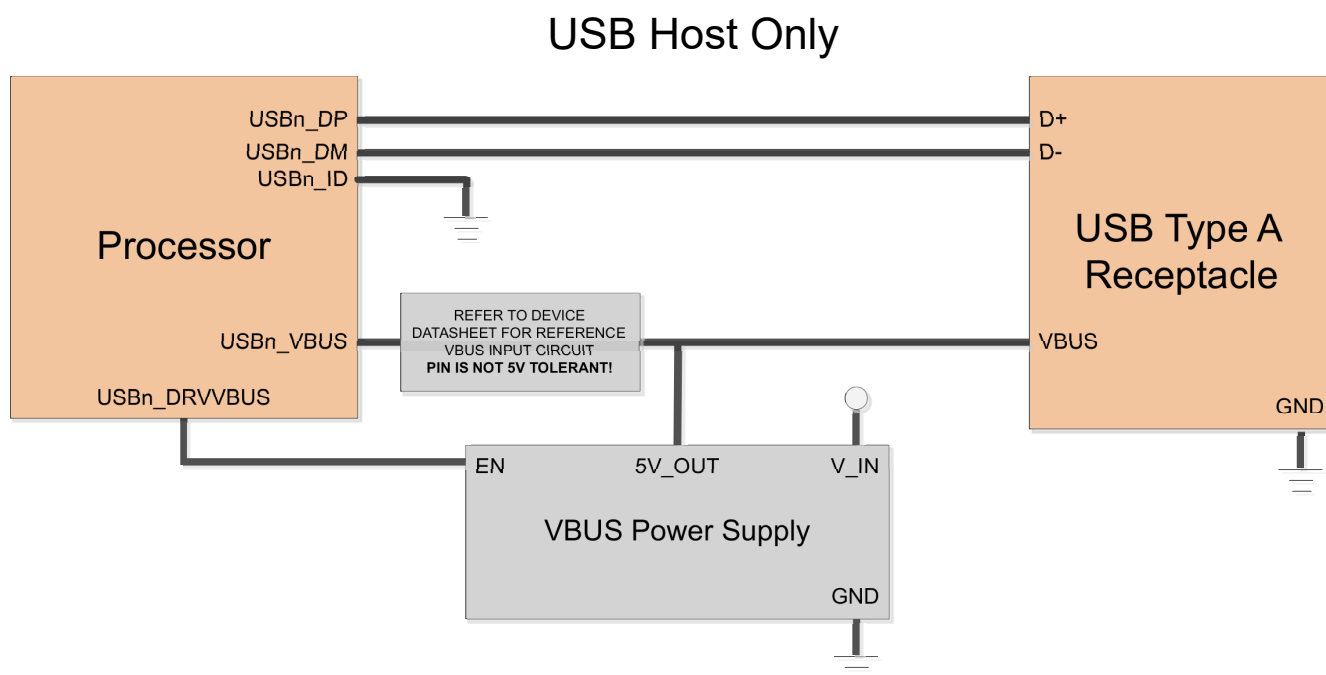

**Table 12-155. USB Control, Configuration, and Monitor Signal Pins (continued)**

Pin Name	I/O <sup>(1)</sup>	Description
USBn_ID	I	USB operational mode identifier. This functionality is supported via GPIO.

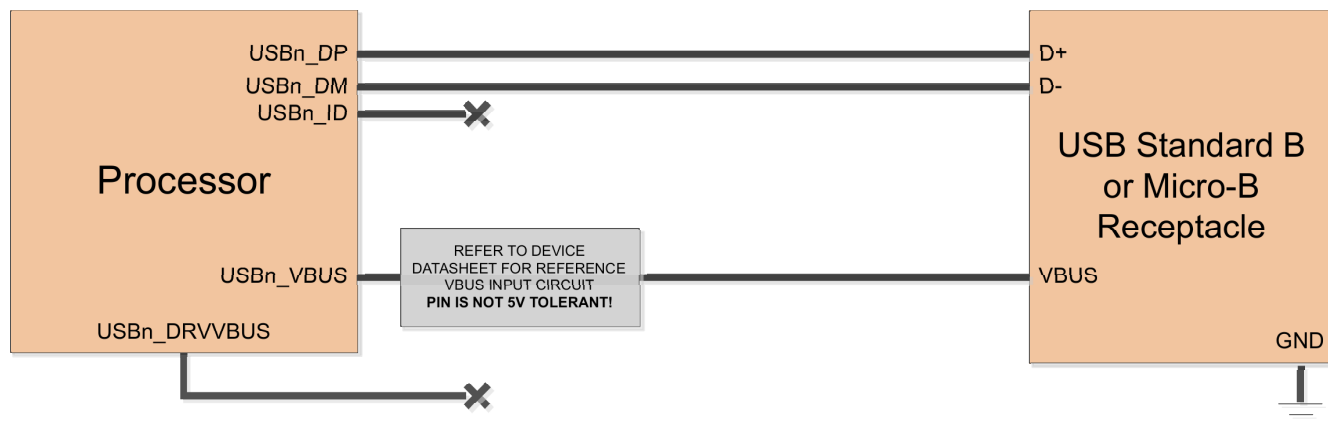

(1) I = Input, O = Output, A = Analog

(2) This pin is not 5V tolerant. Refer to the device-specific datasheet for implementation requirements.

#### 12.2.4.2.2 Typical Pin Connections of Device

**Figure 12-132. USB Dual-Role Connections**

**Figure 12-133. USB Host-Only Connections**

## USB Device Only

**Figure 12-134. USB Device-Only Connections**

### 12.2.4.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.2.4.4 Use Cases

This is a standard USB 2.0 module, and is optimized for following applications and systems:

- Portable electronic devices
- High-bandwidth applications

It supports all typical USB connections, and [Table 12-156](#) shows some examples.

**Table 12-156. Typical Use Cases In Terms of Connections**

Connectors (Receptacle)	Signals to Use	SS	HS/FS	LS (Host only)	Comments
USB 2.0 Micro-AB	DP, DM, VBUS, ID	N	Y	Y	Support Host or Device operation, depending on state of the ID pin.
USB 2.0 Type-A	DP, DM, VBUS	N	Y	Y	Support HS/FS/LS Host
USB 2.0 Type-B	DP, DM, VBUS	N	Y	Y	Only used for USB2.0 Device (no LS)

#### 12.2.4.4.1 USB Operational Mode Determination

USB[n]_ID Pin	USB[n]_VBUS Pin <sup>(1)</sup>	USB Role
FLOAT	FLOAT or GROUND	INDETERMINATE
GROUND	UNUSED	HOST
FLOAT	RAIL VOLTAGE	DEVICE

(1) PHY VBUS pin voltage is dependent on the divider circuit used on the board. Refer to the device datasheet for VBUS implementation requirements.

#### 12.2.4.4.2 VBUS Voltage Sourcing Control

When either of the USB controllers assumes the role of a host, the controller is required to supply 5V to an attached device through its VBUS line. In order to achieve this task, the USB controller requires the use of external power logic (or a charge pump) capable of sourcing 5V power. The USB\_DRVVBUS pin is used as a control signal to enable/disable this external power logic to either source or disable power on the VBUS line. The control on the USB\_DRVVBUS is handled by the controller based on host software programming. The control should be transparent to the user so long as the proper hardware connection and software initialization are in place. The USB controller drives the USB\_DRVVBUS signal high when it assumes the role of a host while the

controller is in session. When assuming the role of a device, the controller drives the USB\_DRVVBUS signal low disabling the external charge pump/power logic; hence, no power is driven on the VBUS line (in this case, power is expected to be provided by the external host).

Note that both USB controllers are self-powered and the device does not rely on the voltage on the VBUS line sourced by an external host for controller operation when assuming the role of a device. The voltage present on the VBUS line is used to identify the presence of a Host. The USB PHY continually monitors the voltage on the VBUS and reports the status to USB controller.

#### 12.2.4.4.3 VBUS Detection

VBUS detection is supported by the USB2SS via the USB\_VBUS pin, but **it is important that this pin not be connected directly to the connector 5V or any other 5V source**. Instead, an external circuit must be used to ensure that the recommended operating conditions of the pin are not exceeded. Refer to the device datasheet for requirements and example VBUS-sense circuitry.

The PHY includes session valid and VBUS valid comparators and provides corresponding status signals.

The Controller uses the session valid output from the PHY in device mode. One of the reasons is because the USB specification requires that the DP pull-up (implemented inside the PHY) must be enabled only after VBUS is turned on by host. This PHY output also in general indicates that a connection is active from host and it can also be used to detect disconnects.

The USB2SS wrapper also includes logic to detect a change on session valid and VBUS valid outputs from PHY.

#### 12.2.4.4.4 Pull-up/Pull-down Resistors

As the USB controllers are dual role controllers, capable of assuming a role of a host or device, the required pull-up/pull-down resistors cannot exist external to the device. These pull-up/pulldown resistors exist internal to the device, within the PHY to be more specific, and are enabled or disabled based on the role the controller assumes allowing for dynamic hardware configuration. When assuming the role of a host, the data lines are pulled low by the PHY enabling the internal 15K $\Omega$  resistors. When assuming the role of a device the required 1.5K $\Omega$  pull-up resistor on the D+ line is enabled automatically to signify the USB capability to the external host as a FS device (HS operation is negotiated during reset bus condition). Low-Speed Device functionality is not supported.

## 12.2.5 Universal Serial Bus Subsystem (USBSS)

This section describes the Universal Serial Bus Subsystem (USBSS) in the device.

### Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

<b>12.2.5.1 USB Overview</b> .....	<b>1648</b>
<b>12.2.5.2 USB Environment</b> .....	<b>1651</b>
<b>12.2.5.3 USB Functional Description</b> .....	<b>1653</b>

### 12.2.5.1 USB Overview

The USB 3.1 Gen1 Interface is a general-purpose cable bus, supporting data exchange between a host device and a wide range of simultaneously accessible peripherals, similar to previous versions of USB.

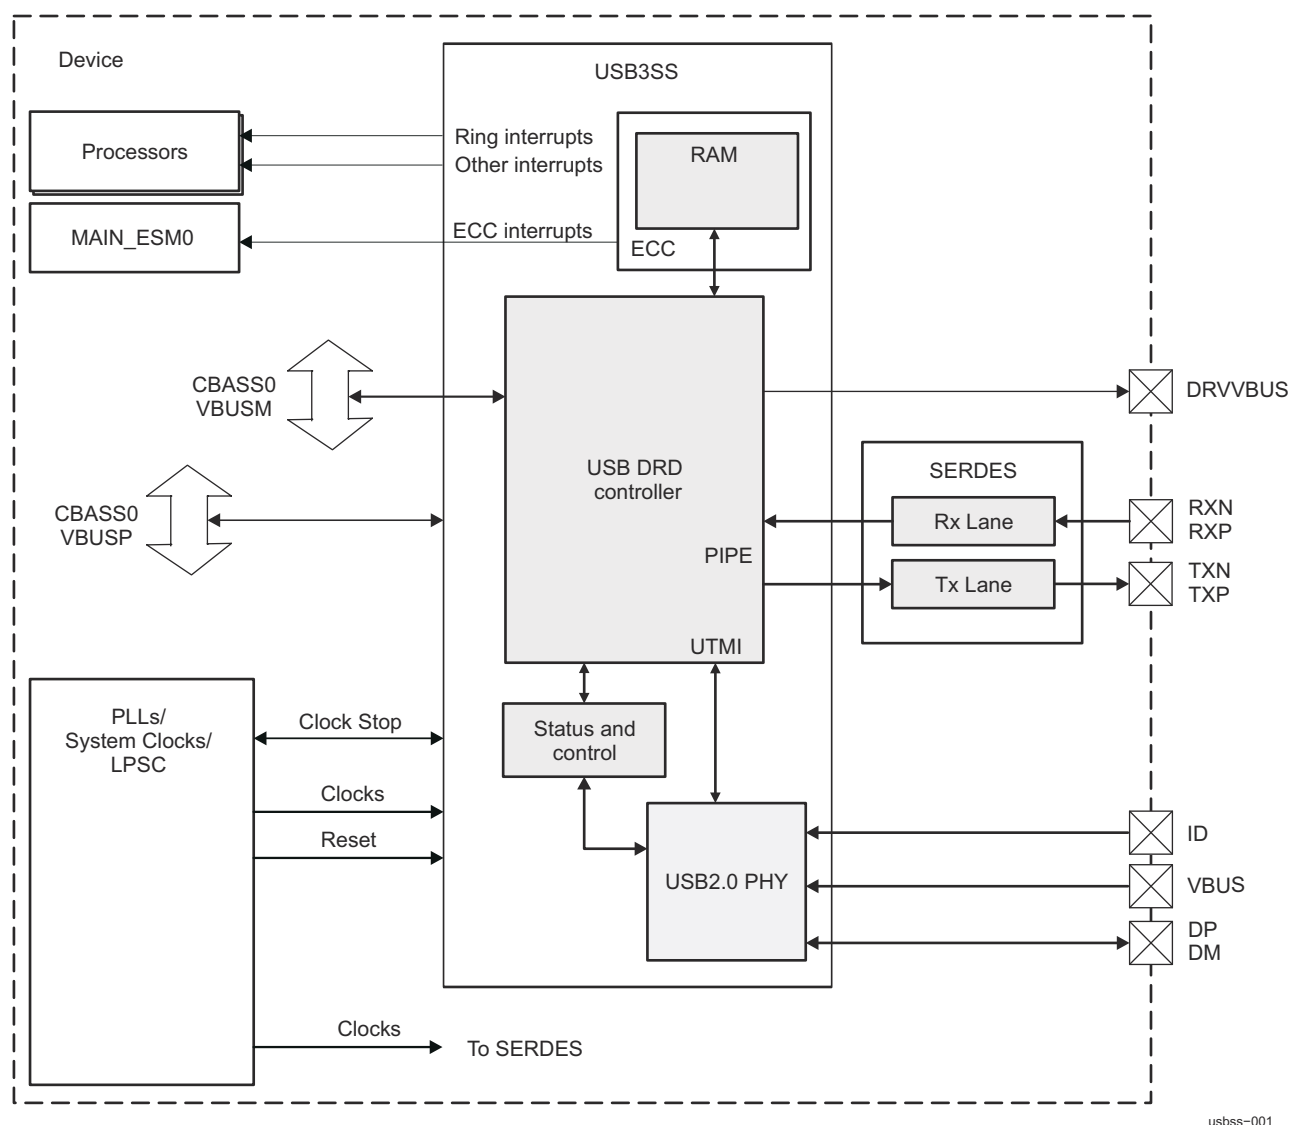

The device supports one USB subsystem integrated in the MAIN domain:

- USB3SS0 is SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with on-chip SS (USB3.0) PHY and HS/FS/LS <sup>2</sup>(USB2.0) PHY

**Table 12-157. USB Allocation Within Device Domains**

Module Instance	Domain	
	MCU	MAIN
USB3SS0	-	✓

Figure 12-135 shows the USB subsystem highlights.

**Figure 12-135. USB Subsystem Overview**

<sup>2</sup> LowSpeed (LS) is supported only in host mode.

### 12.2.5.1.1 USB Features

The USB subsystem supports the following USB Features:

- USB interface:
  - Compliant with USB 3.1 Gen1 specification
  - Compliant with xHCI 1.0 specification
  - Limited USB 2.0 on-the-go support
  - High speed (480 Mbps), and full speed (12Mbps) Device
  - SuperSpeed (5 Gbps), high speed (480 Mbps), full speed (12Mbps), and low speed (1.5 Mbps) Host
  - Single USB2.0 port
  - Single USB3.1 port
  - USB2 L1/L2 support
  - USB3 U1/U2/U3 support
- Dual mode operation:
  - Programmable runtime mode change
  - OTG 2.0 host negotiation protocol (HNP) support
- Host mode:
  - 64 slots supported
  - Up to 32 endpoints per slot
  - 256 primary streams supported
  - Root hub functionality
- USB2 PHY:
  - Fully compliant with UTMI+ Level 3 specification revision 1.0
  - Supports high-speed (480 Mbps), full-speed (12 Mbps) and low-speed (1.5 Mbps) data rates
  - Supports battery charging BC1.2v specification
  - Supports host, peripherals and OTG 2.0 (dual role device) applications
  - Supports D+/D- lane reversal for flexible board integration
  - Supports USB low-power states; namely, suspend and link power management (LPM)
  - Supports internal comparators for monitoring OTG voltage thresholds
  - Supports multiple PLL reference clocks
  - Supports internal PLL for high-speed (480 MHz) clock and data recovery (CDR) operation
  - Integrated termination resistors (45  $\Omega$ , 1.5 K $\Omega$ , and 15 K $\Omega$ )
  - Supports built-in self-test (BIST) for production testing
  - 3.3-V ESD support on VBUS

### 12.2.5.1.2 USB Not Supported Features

The following are USB features which are not supported by the hardware integration of the current device:

**Table 12-158. USBSS0 Unsupported Features**

Feature	Reason
Virtualization (SRIOV or xHCI-IOV or ARM SMMU)	No Support
SuperSpeed (5 Gbps) Device Mode	No Support
Debug Trace for USB	No Support
Attach Detection Protocol (ADP)	This function is not possible because the USB2 PHY implements 3.3v ESD on the VBUS pin.
5 volt compatible VBUS pin	This function is not possible because the USB2 PHY implements 3.3v ESD on the VBUS pin. Note: The VBUS signal should be applied to a 20k/10k voltage divider which divides the potential by 3. This allows the VBUS signal to go up to 10.75 volts before exceeding the VBUS pin maximum of 3.63 volts.
NRDY Event TRB, when operating in host mode	NRDY Event TRB is not supported when operating in host mode.
Halt Endpoint Command TRB, when operating in host mode	Halt Endpoint Command TRB is not supported when operating in host mode.
OTG Protocol, for USB Type-C applications	OTG Protocol is not supported for USB Type-C applications.

**Table 12-158. USBSS0 Unsupported Features (continued)**

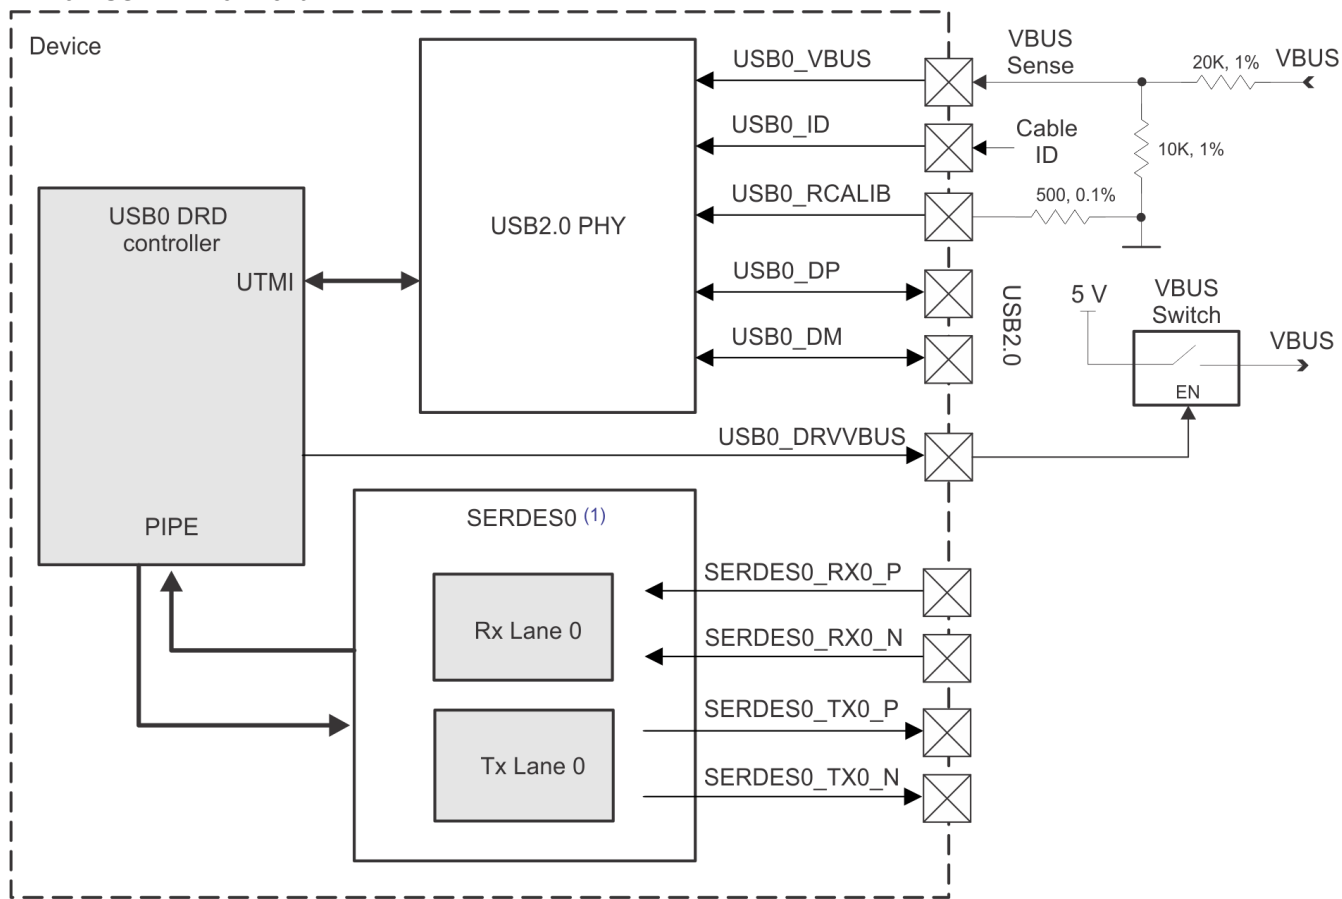

Feature	Reason
Light HC Reset Capability (LHRC)	No Support
xHCI Debug Capability (Debug Port)	No Support
xHCI Save and Restore Operations	No Support
HIMD, when operating in host mode	No Support
Latency Tolerance Messaging	Set Latency Tolerance Value Command is not supported
Negotiate Bandwidth Command	No Support
Number of slots limited to 64	Total for USB2 and USB3
Number of active periodic endpoints limited to 96, when operating in host mode	No Support
Smart ISO	Deprecated in USB 3.2 specification
Secondary Streams	No Support
PTM, when operating in device mode	No Support

### 12.2.5.1.3 USB Terminology

The following acronyms and abbreviations are related to USB.

Term	Definition
<b>ADP</b>	Attach Detection Protocol: detects USB OTG attach/detach events.
<b>DRD</b>	Dual Role Device: USB Host and Peripheral capable.
<b>DS</b>	Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).
<b>EP</b>	Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.
<b>FS</b>	Full-Speed USB data rate (12 Mbps).
<b>HNP</b>	Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.
<b>HS</b>	High-Speed USB data rate (480 Mbps).
<b>ITP</b>	Isochronous Timestamp Packet: USB SS micro-frame boundary packets.
<b>LMP</b>	Link Management Packet.
<b>LS</b>	Low-Speed USB data rate (1.5 Mbps).
<b>OTG</b>	On-The-Go extension to USB protocol.
<b>PHY</b>	Physical Layer Device.
<b>SS</b>	Super-Speed USB data rate. 5 Gbps (USB3.0 or USB3.1 Gen1)
<b>US</b>	Upstream facing from a device (or hub) to the host (or a hub).
<b>USB IF</b>	USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. <a href="http://www.usb.org">http://www.usb.org</a>
<b>xHC</b>	Host Controller, designates the USB hardware that implements the xHCI specification.
<b>xHCI</b>	eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

### 12.2.5.2 USB Environment

(1) See section *SerDes* for details

usbss-003

**Figure 12-136. USB3SS0 Subsystem Environment**

#### 12.2.5.2.1 USB I/Os

Table describes the external signals of the USB3SS0 module.

**Table 12-159. USB3SS0 Input/Output Description**

Device Pin	Module Signal	I/O	Description	Value at Reset
USB0_DP	DP	I/O	DP to USB connector	HiZ
USB0_DM	DM	I/O	DM to USB connector	HiZ
USB0_ID	ID	A/I	ID to USB connector	HiZ
USB0_VBUS	VBUS	A/I	VBUS to USB connector	HiZ
USB0_RTRIM			USB2 PHYreference resistor	
USB0_DRVVBUS	DRVVBUS	O	3.3 Volt LVC MOS Output. Controls VBUS power switch	0
The following pins are implemented through SERDES				
USB0_SSRXN		I	N of differential receive data	HiZ
USB0_SSRXP		I	P of differential receive data	HiZ

**Table 12-159. USB3SS0 Input/Output Description (continued)**

Device Pin	Module Signal	I/O	Description	Value at Reset
USB0_SSTXN		O	N of differential transmit data	HiZ
USB0_SSTXP		O	P of differential transmit data	HiZ
USB0_REFCLKN		I	N of differential reference clock	HiZ
USB0_REFCLKP		I	P of differential reference clock	HiZ
USB0_REXT			SERDES reference resistor	

**12.2.5.2.2 USB Subsystem Application**

As the USB controller modules present in this device are DRD (Dual-Role Devices), they can support operation as either a USB Host or a USB Device. The operational mode determination is made based on the state of the USBn\_ID pin; when this pin is grounded, the controller will operate as a USB Host, when this pin is left floating, the controller assumes the role of a USB Device. For implementations that do not require DRD functionality, the USBn\_ID pin can either be left floating or can be grounded in the board design depending on the static role required. For implementations that do require DRD functionality, the USBn\_ID pin should be connected directly to the corresponding ID pin on a USB Micro-AB socket. In doing so, the USBn\_ID pin will be correctly terminated (open or grounded) depending on the cable attached and the controller will enter Host or Device mode accordingly.

**12.2.5.2.3 VBUS Sense**

The VBUS voltage needs to be monitored for detection of the various valid signals (SESSEND, AVALID, BVALID, and SESSEND).

The voltage of the VBUS signal is scaled down using an external resistor divider (as shown in Figure 12-1796), to limit the voltage applied to the VBUS pin. A zener diode is used to clamp the maximum intermediate voltage to 6.8 volts. The tolerance of resistors used must be less than 1%. The leakage current of the zener diode must be less than 100 nA at 5 V.

### 12.2.5.3 USB Functional Description

#### Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

The USB3SS subsystem contains the USB3.0 Dual Role Device (DRD) controller module and a USB2.0 PHY module. A wrapper module is controlling some top-level functions like Host and Device role switch and reset release.

The USB controller uses USB2PHY for USB2.0 operation and one of the device SERDESeS for USB3.0 speeds.

#### 12.2.5.3.1 USB Controller Reset

USB controller has three resets going in, called preset\_n, pwrup\_rst\_n, and aresetn.

- preset\_n comes from the mod\_g\_rst\_n input coming from LPSC
- pwrup\_rst\_n is PWRUP\_RST\_N register bit in the USB wrapper module (USB3P0SS\_W1). This reset has to be deasserted before accessing controller registers. The default value for pwrup\_rst\_n is 0 (reset asserted). This reset goes to the default asserted state when mod\_g\_rst\_n reset is asserted.
- areset\_n comes from PWRUP\_RST\_N register bit, but the deassertion is synchronized to ACLK.

#### 12.2.5.3.2 Overcurrent Detection

The overcurrent detection circuit is external to the device. Software must specify an overcurrent condition to the controller whenever the overcurrent signal is received from the detection circuit. Software must set the OVERCURRENT\_N bit to 0 in the USB3P0SS\_W1 register when overcurrent was detected.

#### 12.2.5.3.3 Top-Level Initialization Sequence

The following initialization sequence has to be followed before configuring the controller for USB operation:

1. Software must select and configure the SERDES for USB operation. Refer to *Serializer/Deserializer (SerDes)* for more details. USB2.0 PHY contains default configuration that normally does not need change
2. Software must configure the pseudo-static settings in USB3P0SS\_W1 register
3. Software must set PWRUP\_RST\_N to 1 in order to deassert controller reset

After the above sequence, software can access controller registers.

## 12.3 Memory Interfaces

### 12.3.1 Flash Subsystem (FSS)

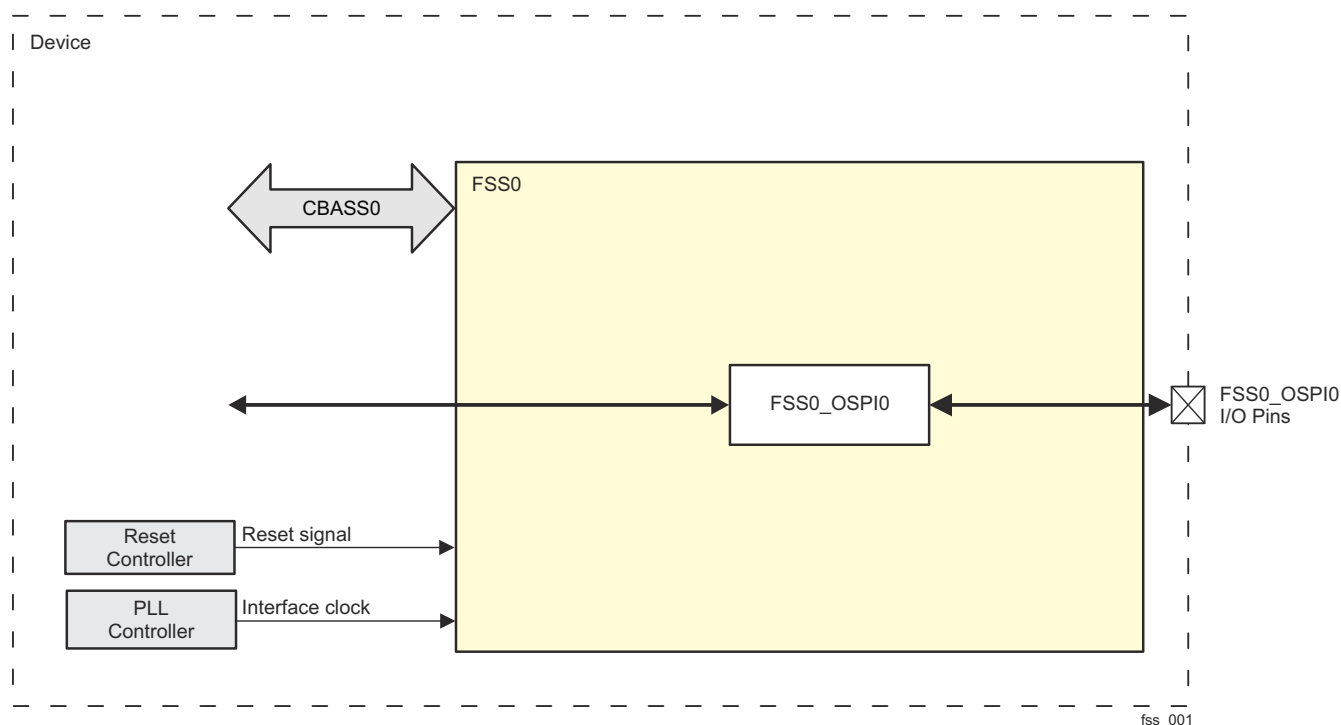

This section describes the Flash Subsystem (FSS) in the device.

#### 12.3.1.1 FSS Overview

The Flash Subsystem (FSS) provides access to external Flash devices via Octal Serial Peripheral Interface (OSPI).

The FSS includes one OSPI. For more information, see *Octal Serial Peripheral Interface (OSPI)*.

Figure 12-137 shows the FSS overview.

**Figure 12-137. FSS Overview**

#### 12.3.1.1.1 FSS Features

For more information, see [Section 12.3.2.1.1, OSPI Features](#).

#### 12.3.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

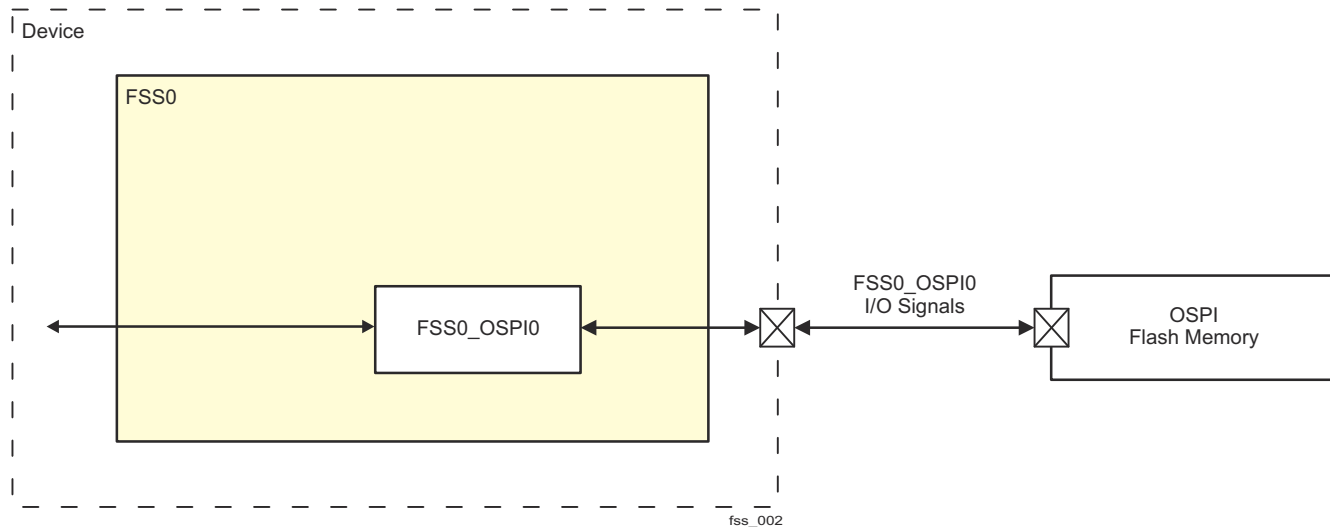

Some features may not be available. See *Module Integration* for more information.

### 12.3.1.2 FSS Environment

The FSS is hereinafter also referred to as FSS0.

#### 12.3.1.2.1 FSS Typical Application

Figure 12-138 shows typical FSS application.

**Figure 12-138. FSS Typical Application**

[Table 12-160](#) describes the FSS I/O signals.

**Table 12-160. FSS I/O Signals**

FSS0 Interface	I/O Signals
FSS0_OSPI0	For more information about OSPI I/O signals, see <i>OSPI I/O Signals</i> .

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

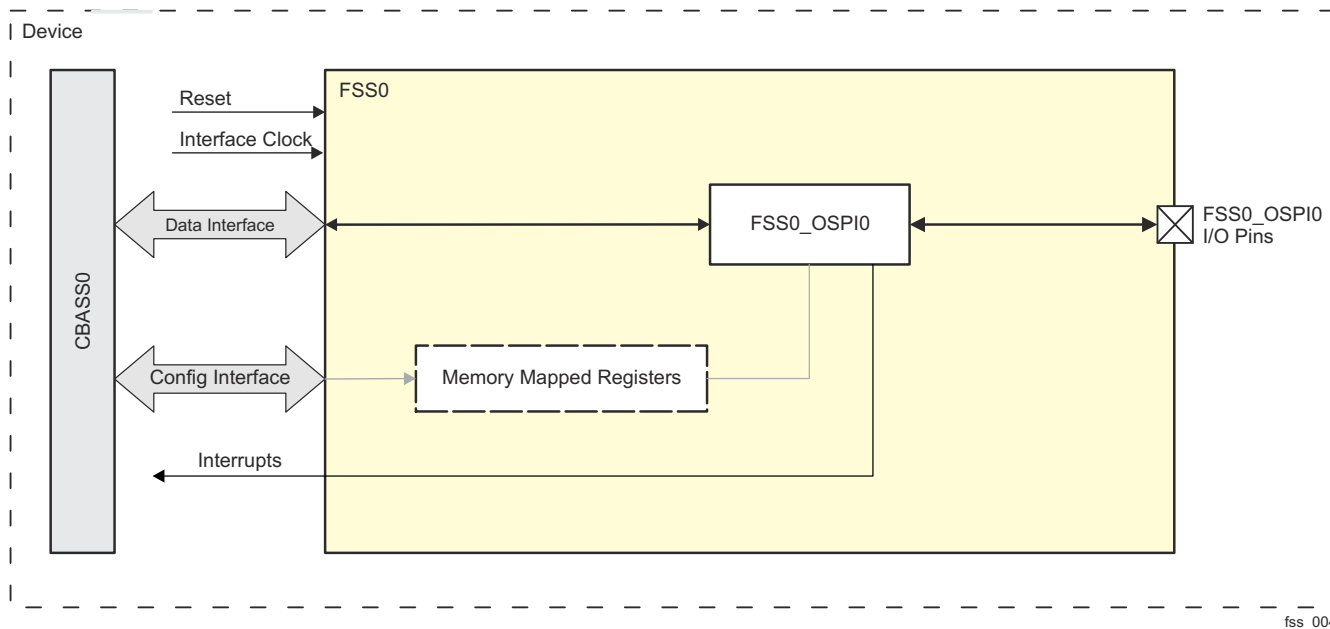

### 12.3.1.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.3.1.4 FSS Functional Description

#### 12.3.1.4.1 FSS Block Diagram

Figure 12-139 shows the FSS block diagram.

**Figure 12-139. FSS Block Diagram**

FSS Blocks:

- CBASS0: The CBASS0 interconnect allows FSS to communicate with the device modules and subsystems.
- Data Interface: It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to the FSS0\_OSPI0.
- Config Interface: It is used for configuration of the memory mapped registers within the FSS.
- Interface Clock and Reset:
  - For more information, see *FSS0 Clocks and Resets*.
  - For more information, see *FSS0\_OSPI Clocks and Resets*.
- Interrupts: For more information, see *FSS0\_OSPI Hardware Requests*.
- Memory Mapped Registers: This block includes the FSS registers. The configuration of these registers defines which FSS features are used. For more information, see *FSS Registers*.
- FSS0\_OSPI0: For more information about OSPI, please see *Octal Serial Peripheral Interface (OSPI)*.
- FSS0\_OSPI0 I/O Pins: For more information, see *OSPI I/O Signals*.

#### 12.3.1.4.2 FSS Regions

##### 12.3.1.4.2.1 FSS Regions Boot Size Configuration

The boot size for FSS defaults to 64 MB but can be configured to be 128 MB. Selection of boot block which will be used is also configurable. For more information see CTRLMMR\_FSS\_CTRL register in *Control Module (CTRL\_MMR)*.

### 12.3.1.4.3 FSS Memory Regions

Table 12-161 shows the FSS memory regions.

**Table 12-161. FSS Memory Regions**

Address Range	Size	Description
0x400000000 - 0x4FFFFFFF	4 GB	External Memory Space (Region 0)
0x060000000 - 0x067FFFFFF	128 MB	Boot Space (Region 1)
0x500000000 - 0x5FFFFFFF	4 GB	External Memory Space (Region 3)

### 12.3.1.5 FSS Programming Guide

#### 12.3.1.5.1 FSS Initialization Sequence

Initialization steps:

- Configure the main boot parameters for FSS (see [Section 12.3.1.4.2.1](#)):
  - Select the boot block to be used.
  - Select the size of the boot block to be used.
- Enable FSS in PSC.
- Configure the FSS0\_OSPI0.
- Enable the FSS0\_OSPI0 in PSC. For more information about OSPI configuration, please see *Octal Serial Peripheral Interface (OSPI)*.

#### 12.3.1.5.2 FSS Power Up/Down Sequence

There are two PSC controls for the FSS: for FSS0 itself and for FSS0\_OSPI0. The CPU enables the FSS0\_OSPI0 before using the FSS. Software should ensure the FSS0\_OSPI0 is enabled prior to FSS transactions.

Normal Power Down Sequence:

- Block any new transaction.
- Power down the FSS0\_OSPI0.
- In the event when the FSS0\_OSPI0 is powered down, the FSS can then be powered down.

## 12.3.2 Octal Serial Peripheral Interface (OSPI)

This section describes the Octal Serial Peripheral Interface (OSPI) module for the device.

### 12.3.2.1 OSPI Overview

The Octal Serial Peripheral Interface (OSPI) module is a kind of Serial Peripheral Interface (SPI) module which allows single, dual, quad or octal read and write access to external flash devices.

The OSPI module is used to transfer data, either in a memory mapped direct mode (for example a processor wishing to execute code directly from external flash memory), or in an indirect mode where the module is set-up to silently perform some requested operation, signaling its completion via interrupts or status registers. For indirect operations, data is transferred between system memory and external flash memory via an internal SRAM which is loaded for writes and unloaded for reads by a device controller at low latency system speeds. Interrupts or status registers are used to identify the specific times at which this SRAM should be accessed using user programmable configuration registers.

shows the OSPI allocation across device domains.

Figure 12-140 shows the OSPI module overview.

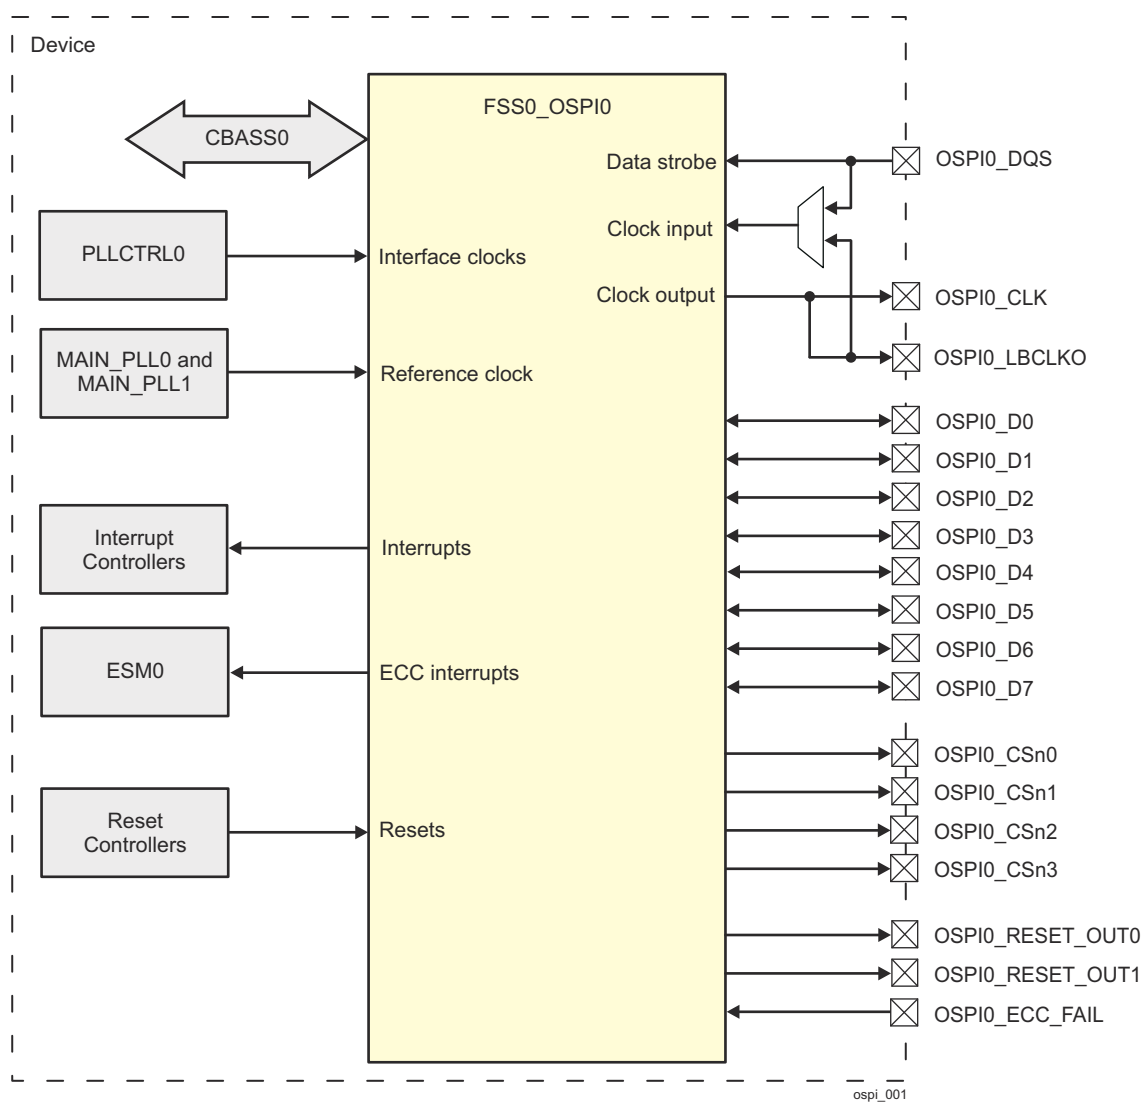

Figure 12-140. OSPI Overview

### 12.3.2.1.1 OSPI Features

The OSPI module has the following features:

- Support for single, dual, quad (QSPI mode) or octal I/O bus widths.
- Memory mapped 'direct' mode of operation for performing flash data transfers and executing code from flash memory.
- Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
- Local SRAM of configurable size to reduce advanced high-performance bus overhead and buffer flash data during indirect transfers.
- Set of software advanced peripheral bus accessible flash control registers to perform any flash command, including data transfers up to 8-bytes at a time.
- Additional addressable memory bank to accommodate more than 8-bytes at a time.
- Support for XIP, sometimes referred to as continuous mode.
- Support for DDR Mode and DTR protocol (including Octal DDR protocol with DQS for Octal-SPI devices)
- Programmable device sizes.
- Programmable write protected regions to block system writes from taking effect.
- Programmable delays between transactions.
- Legacy mode allowing software direct access to low level transmit and receive FIFOs, bypassing the higher layer processes.
- An independent reference clock to decouple bus clock from SPI clock – allows slow system clocks.
- Programmable baud rate generator to generate OSPI clocks.
- Features included to improve high speed read data capture mechanism.
- Option to use adapted clocks or DQS to further improve read data capturing.
- Programmable interrupt generation.
- Up to four external device selects - OSPI and QSPI devices can be mixed
- Programmable data decoder, enables continuous addressing mode for each of the connected devices and auto-detection of boundaries between devices.
- Supports BOOT mode.
- Bidirectional CRC on Multiple-SPI interface.
- Handling ECC errors for flash devices with embedded correction engine.
- Full integration with PHY module dedicated to more flexible and power efficient transfers.
- Supports RESET\_OUT[1-0] and ECC\_FAIL pins for external flash devices where ECC is checked on the flash.

### 12.3.2.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

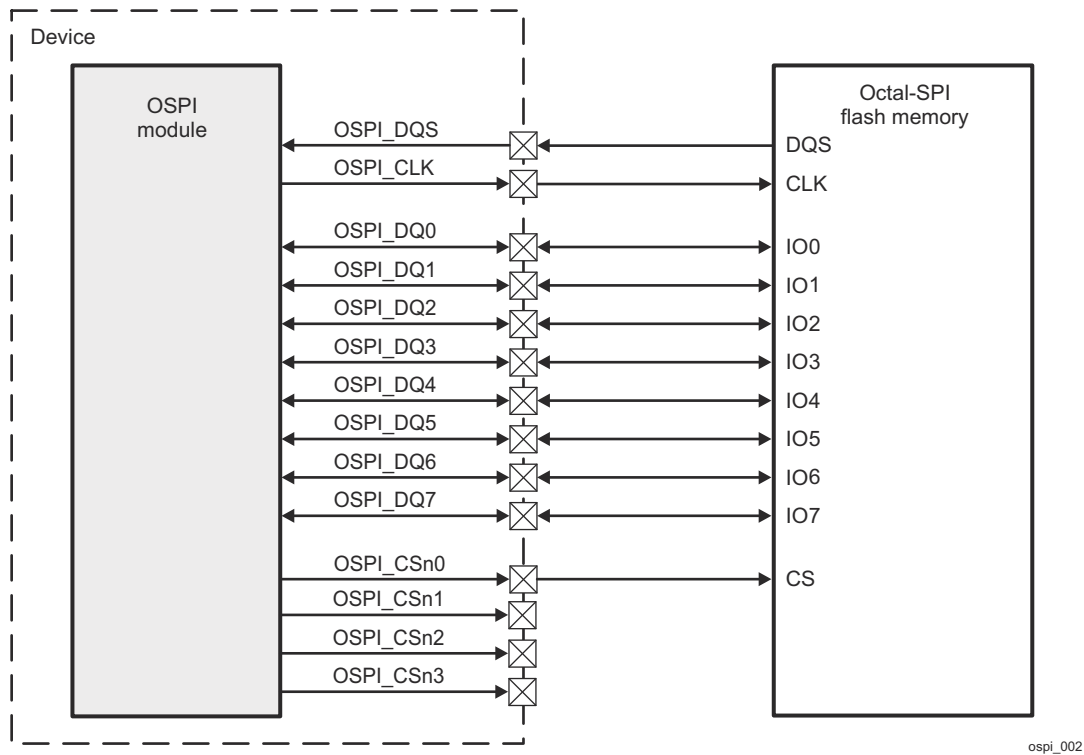

---

### 12.3.2.2 OSPI Environment

The FSS0\_OSPI0 module is hereinafter referred to as OSPI module.

This section describes the OSPI external connections (environment).

The OSPI module is primarily intended for fast booting from Octal- and Quad-SPI flash memories. [Figure 12-141](#) shows a typical connection of the OSPI module to an external Octal-SPI flash memory.

**Figure 12-141. OSPI Connected to an External Octal-SPI Flash Memory**

[Table 12-162](#) lists and describes the FSS0\_OSPI I/O signals.

**Table 12-162. OSPI I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>FSS0_OSPIi<sup>(4)</sup></b>				
DQ0	OSPIi <sup>(4)</sup> _D0	IO	FSS0_OSPIi <sup>(4)</sup> data input/output 0	HiZ

DQ6	IO	Not used	Not used	Not used	Used as SPI data input 6 Used as SPI data output 6
DQ7	IO	Not used	Not used	Not used	Used as SPI data input 7 Used as SPI data output 7
DQS	I <sup>(2)</sup>	Not used	Not used	Not used	Data strobe or loopback clock input
OCLK	O	Output clock or loopback clock output. For more information, see Table 12-162.			
N_SS_OUT0	O	External SPI device chip-select 0			
N_SS_OUT1	O	External SPI device chip-select 1			
N_SS_OUT2	O	External SPI device chip-select 2			
N_SS_OUT3	O	External SPI device chip-select 3			
RESET_OUT0	O	External SPI device reset 0			
RESET_OUT1	O	External SPI device reset 1			
ECC_FAIL	I	External SPI device ECC failure indication			

(1) This is the pin count at the external SPI flash memory side.

(2) When used as an external loopback input, the DQS signal can alternatively be referred to as LBCLKI. The LBCLKI clock input signal is a looped back version of the LBCLKO clock output signal and facilitates easier timing closure at higher speeds. The loopback has to be at board level in order to support higher OSPI speeds. The source of the loopback clock is defined by CTRLMMR\_MCU\_OSPIn\_CLKSEL[4] LOOPCLK\_SEL bit in *Control Module (CTRL\_MMR)*.

---

**Note**

For OSPI0\_CLK, OSPI0\_LBCLKO, and OSPI0\_DQS signals to work properly, the RXACTIVE bit of the appropriate registers should be set to 0x1 because of retiming purposes.

---

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

---

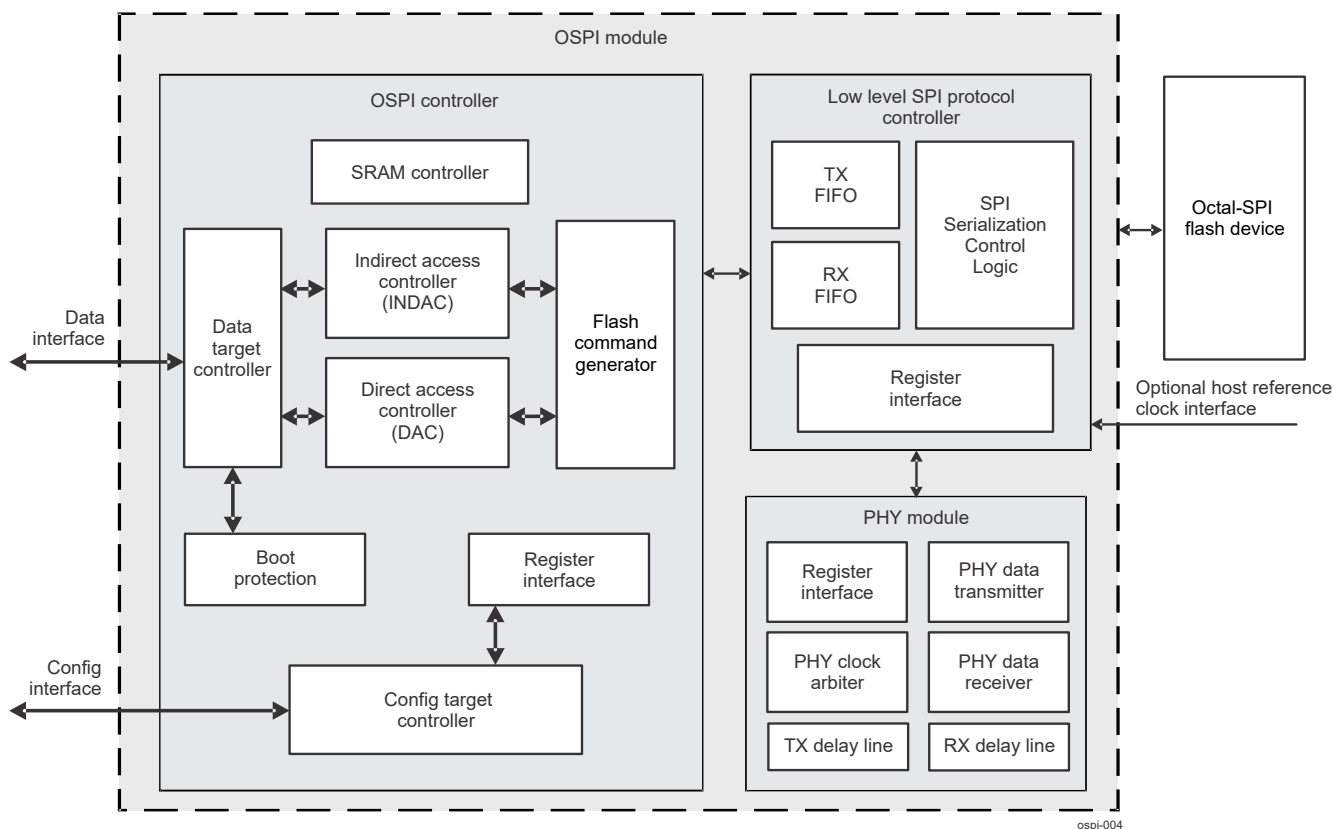

**12.3.2.3 Integration**

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.3.2.4 OSPI Functional Description

#### 12.3.2.4.1 OSPI Block Diagram

Figure 12-142 shows the OSPI module block diagram.

**Figure 12-142. OSPI Block Diagram**

The OSPI module is composed of three main blocks. The first one is the OSPI controller, the second one is the low level SPI protocol controller, and the third one is the integrated PHY.

The OSPI module has the following two target interfaces:

- Data target interface intended for data transfer.
- Configuration target interface intended for accessing the programmable set of registers.

##### 12.3.2.4.1.1 Data Target Interface

The data interface is used for data transfer to external flash devices in direct and indirect mode of operation. The data target controller validates incoming data accesses, responds to invalid requests, performs any required byte and halfword reordering, blocks writes that violate the programmed write protection rules (only for direct access) and forwards the transfer request to either the direct access controller (DAC) or the indirect access controller (INDAC).

The data interface bus is 32-bits wide. Therefore only byte, halfword and word accesses are permitted. When the controller is configured to work in SPI Octal DDR Mode or Octal DDR Protocol (where 2 bytes are collected within single SPI clock cycle what exceeds the size of 1 byte transfer request), 8 bit transfer size is not allowed.

#### Note

Cache line wrap accesses over the data target port should be word aligned.

Data target port doesn't support cache line wrap bursts of 128 bytes.

#### 12.3.2.4.1.2 Configuration Target Interface

The configuration interface is used to configure the OSPI module and perform software controlled flash accesses using the OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG register (for more information refer to [Section 12.3.2.4.11, Software Triggered Instruction Generator \(STIG\)](#)). Depending on the address it routes the incoming interconnect transfer to the Low level SPI protocol controller or to the ECC aggregator. The configuration port is also used to interact with the OSPI configuration and SRAM ECC registers.

##### Note

The configuration interface supports only 32-bit accesses. For single byte or halfword manipulations software should perform read-modify-write operations.

#### 12.3.2.4.1.3 OSPI Clock Domains

The OSPI module has two main clock sources for the Octal-SPI controller.

- For interface clocks
- For reference clock

The source for the interface clocks corresponds to the configuration and data buses. The data bus clock (OSPI\_HCLK) is the main system clock used to transfer data over the data bus between a controller on the system interconnect and the OSPI module. The data bus clock also drives the internal OSPI SRAM. The configuration bus clock (OSPI\_PCLK) is used to access the OSPI configuration register and perform basic configuration and for interrupt handling. The OSPI reference clock (OSPI\_RCLK) drives the SPI transmit and receive logic in the OSPI module. It is also used to generate the output SPI protocol clock (OSPI\_OCLK) and for oversampling of the input data. Using the reference clock (OSPI\_RCLK) allows the OSPI module to decouple the frequency of the SPI flash device from the device system clocks, thereby providing more flexible clocking solution.

##### Note

There is no particular clock ratio requirement between configuration (OSPI\_PCLK) and data bus (OSPI\_HCLK) clocks.

#### 12.3.2.4.2 OSPI Modes

##### Note

Some of the OSPI features described in this section may not be supported on this family of devices. For more information, see *OSPI Not Supported Features*.

The OSPI module supports four SPI modes. These modes are defined through the OSPI\_FLASH\_CFG\_CONFIG\_REG[1] SEL\_CLK\_POL\_FLD and OSPI\_FLASH\_CFG\_CONFIG\_REG[2] SEL\_CLK\_PHASE\_FLD bits. The SEL\_CLK\_POL\_FLD bit defines the clock polarity and the SEL\_CLK\_PHASE\_FLD bit defines the data launch and data capture relation to the OSPI clock edges. [Table 12-164](#) gives a brief description of these modes.

**Table 12-164. OSPI Modes**

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
0	0	0	Clock inactive state: low Data launch edge: clock falling edge Data capture edge: clock rising edge
1	0	1	Clock inactive state: low Data launch edge: clock rising edge Data capture edge: clock falling edge

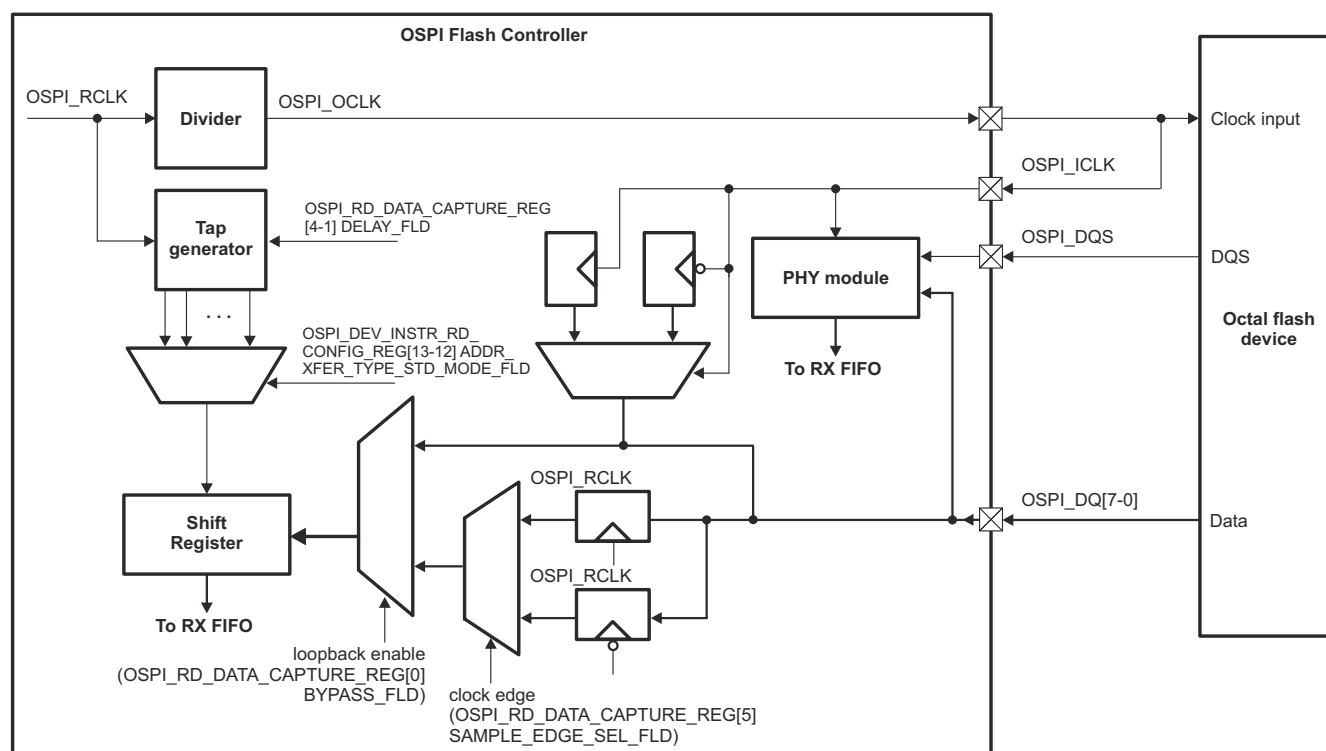

**Table 12-164. OSPI Modes (continued)**

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
2	1	0	Clock inactive state: high Data launch edge: clock rising edge Data capture edge: clock falling edge
3	1	1	Clock inactive state: high Data launch edge: clock falling edge Data capture edge: clock rising edge

Octal flash devices provide DQS signal which allows source synchronous capture, but for Quad flash devices the OSPI module has a loopback mode. In this loopback mode the clock, looped back at board level, is used for registering the input data, and the edge used is same as the launch edge, thus giving a full cycle path (for more information, see [Section 12.3.2.4.2.1, Read Data Capture](#)).

#### 12.3.2.4.2.1 Read Data Capture

Figure 12-143 shows the Read Data Capture Logic in the OSPI module.

ospi-005

**Figure 12-143. Read Data Capture Logic**

The PHY module includes a DLL which allows adjustment of the sampling edge with respect to the incoming data to achieve maximum frequency. There are three sources for the sampling signal:

- The reference clock
- Output SPI clock external loopback
- The DQS (only available in Octal Flash devices)

The loopback mode (only for Quad flash devices) can work in two cases. The first one is when OSPI\_FLASH\_CFG\_CONFIG\_REG[2] SEL\_CLK\_PHASE\_FLD=0. When SEL\_CLK\_PHASE\_FLD=1 there aren't enough clock falling edges for the register pipeline to catch the last data driven, thus causing a functional failure. Additionally, since the capture edge is falling edge, it gives a full cycle input path only in SPI mode 0, that

is when SEL\_CLK\_POL\_FLD=0 and SEL\_CLK\_PHASE\_FLD=0. Thus SPI mode 0 is the first of two modes that support high MHz operation (greater than 50 MHz). The second mode is when SEL\_CLK\_PHASE\_FLD=1 and SEL\_CLK\_PHASE\_FLD=1 (SPI mode 3). In this case the missing clock falling edge is compensated inside the OSPI controller when using the incorporated PHY module by inverting the loopback clock.

The loopback mode is enabled by writing 0x0 to OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[0] BYPASS\_FLD. The taps are selected by programming OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[4-1] DELAY\_FLD field. The taps delay the read data capturing logic by the programmed number of OSPI\_RCLK cycles.

#### **12.3.2.4.2.1.1 Mechanisms of Data Capturing**

There are two mechanisms of data capturing in the OSPI module. They can be combined in some parts to ensure reliable sampling solution independent on the system requirements and the controller configuration. The mechanisms are as follows:

- Data capturing mechanism using taps
- Data capturing mechanism using PHY module.

#### **12.3.2.4.2.1.2 Data Capturing Mechanism Using Taps**

This section describes the data capturing mechanism where sampling point is adjusted for one of the reference clock edges inside divided OSPI clock.

After POR, the adapted loopback clock circuit and the OSPI\_RCLK delay register line both wake in a disabled state. The OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG register provides the control for the mechanism using taps.

OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[5] SAMPLE\_EDGE\_SEL\_FLD bit selects the edge of the reference clock, on which data outputs from flash memory are sampled.

OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[4-1] DELAY\_FLD bit field controls the additional number of read data capture cycles (this is the fast reference clock, running at least x4 of the device clock) that should be applied to the internal read data capture circuit. The large clock-to-out delay of the flash memory together with trace delays as well as other device delays may impose a maximum flash clock frequency which is less than the flash memory device itself can operate at. To compensate, software shall set this register to a value that guarantees robust data captures.

#### **12.3.2.4.2.1.3 Data Capturing Mechanism Using PHY Module**

PHY module is responsible for data capturing. More detailed description of all internal PHY sampling mechanisms is included in [Section 12.3.2.4.16.2, Read Data Capturing by the PHY Module](#).

#### **12.3.2.4.2.1.4 External Pull Down on DQS**

Per the OSPI protocol, the FLASH device drives DQS while CS is asserted. When CS is not asserted the FLASH device presents HiZ on DQS. When configured to use DQS, the controller uses the DQS as a clock, which samples the incoming data into a FIFO. Noise on the DQS when it is HiZ can cause spurious false triggering of the FIFO and filling it with invalid data. There is no way to clear this data except to reset the OSPI module.

To avoid this issue, it is recommended to add a pull down on the DQS line.

During device wakeup, before the IO ring is configured properly, the CS to the FLASH device is HiZ. Depending on the actual level of the CS line the FLASH device might drive the DQS High, Low or HiZ. A pull down on DQS forces the DQS input to Low, but the DQS might still be High or in the presence of noise there might be transitions between Low and High. This again can cause the same issue of capturing garbage data in the Controller FIFO.

To avoid this issue it is recommended to release the OSPI from reset only after the IO ring is configured properly.

### 12.3.2.4.3 OSPI Power Management

#### Note

The OSPI module does not provide any hardware signal for busy or idle status. Software need to ensure that the OSPI module is idle before clocks can be shut off by reading the OSPI\_FLASH\_CFG\_CONFIG\_REG[31] IDLE\_FLD bit.

OSPI\_PCLK and OSPI\_HCLK share the same clock stop request/acknowledge and clock enable/acknowledge interface.

### 12.3.2.4.4 Auto HW Polling

The OSPI controller is capable of automatically testing the Flash device busy bit to guarantee no reads or writes are ignored by the flash when it is busy burning in programmed data.

At the end of a programming transaction, the Flash device goes into a burn-in state and becomes busy.

When Auto HW Polling is enabled, the OSPI controller keeps track of programming transactions and will initiate a Flash status read polling transactions automatically, until Flash indicates it is not busy, before any additional data read or programming operations are sent to the flash device. See OSPI\_FLASH\_CFG\_WRITE\_COMPLETION\_CTRL\_REG register and the associated registers.

The OSPI controller requires that the OSPI\_FLASH\_CFG\_WRITE\_COMPLETION\_CTRL\_REG[23-16] POLL\_COUNT\_FLD field should always be set with values greater or equal to 3 ( $\geq 3$ ).

### 12.3.2.4.5 Flash Reset

OSPI provides Flash reset out ports. These ports are active low and controlled thru OSPI\_FLASH\_CFG\_CONFIG\_REG register.

### 12.3.2.4.6 OSPI Memory Regions

#### Note

For more information about the memory space, see *FSS Memory Regions*.

### 12.3.2.4.7 OSPI Interrupt Requests

The OSPI module generates three interrupts. The ECC interrupts (FSS0\_OSPI\_0\_OSPI\_ECC\_CORR\_LVL\_INTR\_0 and FSS0\_OSPI\_0\_OSPI\_ECC\_UNCORR\_LVL\_INTR\_0) are generated by the OSPI ECC aggregator.

The other interrupt (FSS0\_OSPI\_0\_OSPI\_LVL\_INTR\_0) is generated by the OSPI module.

[Table 12-165](#) lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

**Table 12-165. OSPI Events**

Event Flag	Event Mask	Description
OSPI_FLASH_CFG_IRQ_STATUS_REG[0] MODE_M_FAIL_FLD	OSPI_FLASH_CFG_IRQ_MASK_REG[0] MODE_M_FAIL_MASK_FLD	Event Flag and Event Mask for the OSPI Interrupts.
OSPI_FLASH_CFG_IRQ_STATUS_REG[1] UNDERFLOW_DET_FLD	OSPI_FLASH_CFG_IRQ_MASK_REG[1] UNDERFLOW_DET_MASK_FLD

#### 12.3.2.4.8 OSPI Data Interface

##### 12.3.2.4.8.1 Data Interface Address Remapping

The incoming data interface address, by default, maps directly to the address sent serially to the FLASH device. If the FLASH device has a 24-bit address, then the 24 LSB's of the data address is forwarded. A remap feature is available to remap all incoming data addresses to ADDRESS + N, where N is the value stored in the OSPI\_FLASH\_CFG\_REMAP\_ADDR\_REG[31-0] VALUE\_FLD bit field. It is enabled via the OSPI\_FLASH\_CFG\_CONFIG\_REG[16] ENB\_AHB\_ADDR\_REMAP\_FLD bit. This feature could be used when software needs to move boot code to another FLASH region.

##### 12.3.2.4.8.2 Write Protection

In order to protect the FLASH device, a software controlled write protection feature is supported. Any data write detected (by using DAC), pointing to an area of the FLASH that is protected, is not permitted.

A programmable region of the FLASH device, defined as a number of FLASH 'blocks' starting from a particular block number can be protected. Three programmable registers are provided. The first OSPI\_FLASH\_CFG\_LOWER\_WR\_PROT\_REG register defines the FLASH block that is located at the bottom of the region to be protected. The second OSPI\_FLASH\_CFG\_UPPER\_WR\_PROT\_REG register defines the FLASH block that is located at the top of the region to be protected. The third OSPI\_FLASH\_CFG\_WR\_PROT\_CTRL\_REG register is a control register consisting of 2 bits. The OSPI\_FLASH\_CFG\_WR\_PROT\_CTRL\_REG[0] INV\_FLD bit allows software to invert the region that is being protected, causing the programmed region to become the only areas of FLASH memory that is not protected from writes. The OSPI\_FLASH\_CFG\_WR\_PROT\_CTRL\_REG[1] ENB\_FLD bit is the write protection enable bit. When this bit is set to 0, the FLASH device is unprotected.

For implementation, the data interface must map the incoming address into its associated FLASH block. A block can be between 1 and 65 KB, programmed via the OSPI\_FLASH\_CFG\_DEV\_SIZE\_CONFIG\_REG register.

##### 12.3.2.4.8.3 Access Forwarding

For legal accesses, the data interface will forward all accesses to one of two access controllers - the direct access and the indirect access controllers. Assuming DAC has been enabled via the OSPI\_FLASH\_CFG\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTRL\_FLD bit, then by default all accesses will be forwarded to this controller. Before any accesses can be forwarded to INDAC, it must first be configured by software. This process is fully explained in [Section 12.3.2.4.10, Indirect Controller \(INDAC\)](#). If DAC is disabled,

any incoming access that cannot be forwarded to INDAC will be completed immediately with an error. If DAC is enabled, the same access will be forwarded and serviced by DAC.

#### 12.3.2.4.9 OSPI Direct Access Controller (DAC)

Direct access refers to the operation where data interface accesses directly trigger a read or write to FLASH memory. It is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and will be serviced by the DAC. Note that accesses that use DAC do not use the embedded SRAM. The data transfer stops when read or write burst is carried out. The amount of wait states applied will be dependent on the latency through the controller. Latency is kept to a minimum when the use of XIP read instructions are enabled (see OSPI\_FLASH\_CFG\_CONFIG\_REG[18] ENTER\_XIP\_MODE\_IMM\_FLD and OSPI\_FLASH\_CFG\_CONFIG\_REG[17] ENTER\_XIP\_MODE\_FLD bits).

#### 12.3.2.4.10 OSPI Indirect Access Controller (INDAC)

##### 12.3.2.4.10.1 Indirect Read Controller

The aim of the indirect mode of operation is to read significant numbers of bytes from FLASH memory without requiring a data interface access to trigger it. Instead indirect operations are controlled and triggered by software via specific control/configuration Indirect Read Transfer registers (OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG, OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_WATERMARK\_REG, OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_START\_REG, and OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG). This block will communicate with an embedded low level SPI protocol state machine module to perform an efficient and optimized FLASH read burst, placing the read data into the local SRAM module ready for fast and low latency delivery to any external controller.

By default, the Indirect Read controller is disabled. Before enabling it, software must configure how much data is required and the start address. The start address and total number of bytes to be fetched is defined in OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_START\_REG and OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. For more information refer to [Section 12.3.2.4.10.3, Indirect Access Queuing](#).

The total number of bytes to read in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the size of requests. In the case of SRAM overrun, the controller will back pressure FLASH reads until space becomes available in the SRAM. Back pressuring the reads on the SPI interface is handled by completing any current read burst, waiting until space in the SRAM becomes available and then issuing a new read burst at the address where the previous terminated burst ended.

An external controller will be able to fetch the data that the controller has read from external FLASH memory by issuing data interface reads to the OSPI module. The address of the incoming read access must be in the range of indirect trigger address programmed via the OSPI\_FLASH\_CFG\_IND\_AHB\_ADDR\_TRIGGER\_REG register to indirect trigger address +  $2^{**}(\text{indirect trigger address range}) - 1$ . Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the indirect range to grant SRAM as source. Each valid Indirect Read will cause the internal SRAM to be popped, thereby decoupling the incoming read access address from the FLASH address – that is not direct mapped. Therefore the indirect trigger address does not have any relationship with the FLASH address. It is just to indicate that data should take the SRAM as source instead of the FLASH memory array after triggering of any valid Indirect Read. The FLASH address for Indirect Read is taken from the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_START\_REG register. Assuming the requested data is present in the SRAM at the point the data interface access is received by the OSPI module, then the data will be fetched from the SRAM and the response to the read burst will be achieved with

minimum latency. Once the data has been read from the SRAM, the OSPI module will free up the associated resource in the SRAM.

If a read access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a read access is received whose address is within the range described above but the requested data is not immediately present in the SRAM then wait states will be applied until the data has been read from FLASH and pushed to the SRAM.

If a read burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external controller is only permitted to issue 32-bit data interface reads until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final read, the external controller may issue a 16-bit (Halfword) or byte access to complete the transfer. It is also permitted for the external controller to always issue a 32-bit Word read on the last indirect access. The controller will pad the upper bits of the response with zero. The current expectation is that the SRAM will be kept fairly full while the read operation is carried out. The fill level of the SRAM is directly readable by software reading the OSPI\_FLASH\_CFG\_SRAM\_FILL\_REG register.

An indirect operation may be cancelled at any time by setting 1 to OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG[1] CANCEL\_FLD bit.

Any bus controller should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via configuration registers and then decide for itself when the data should be fetched from the local SRAM. The fill level watermark register (see OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_WATERMARK\_REG register) is provided. When the SRAM fill level passes this watermark, an interrupt is generated. If the watermark value is > 0, the watermark interrupt is also generated when the final byte of data has been read by the OSPI module and placed in the SRAM, even if the actual SRAM fill level has not risen above the watermark. This last feature is useful to avoid software tracking how much data has been read and resetting the watermark value for the last few bytes of an indirect read transfer.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an Indirect Read operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit starts an indirect read operation. OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG[2] RD\_STATUS\_FLD bit is available to check the status.

#### 12.3.2.4.10.1 Indirect Read Transfer Process

The following sequence can be followed:

1. Setup OSPI\_FLASH\_CFG\_CONFIG\_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_START\_REG register.
3. Setup the number of bytes to be transferred in the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG register.
4. Setup the indirect transfer's trigger address in the OSPI\_FLASH\_CFG\_IND\_AHB\_ADDR\_TRIGGER\_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI\_FLASH\_CFG\_INDIRECT\_TRIGGER\_ADDR\_RANGE\_REG register.
6. If the watermark interrupt feature is to be used, set the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_WATERMARK\_REG register which will cause an interrupt to

be generated when the fill level increases beyond the watermark level. Setting the watermark can be useful indication to software when to read the next part of the indirect read transfer. Note that if the watermark is set to a value other than zero, the watermark interrupt will always trigger once the final byte of indirect transfer has been fetched and placed in the embedded SRAM, even if the watermark value is higher than the actual completed fill level.

7. Trigger Indirect Read access by setting the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit to 1.
8. If the watermark interrupt feature is to be used, wait for watermark interrupt. Else poll the SRAM fill level via the OSPI\_FLASH\_CFG\_SRAM\_FILL\_REG register to decide when sufficient data is in the SRAM to trigger data fetches.
9. Read the expected amount of data from SRAM. If there is still more data to fetch in order to complete the indirect read transfer, then loop back to step 8. Otherwise continue to step 10.
10. The completion status of the Indirect Read operation can be polled via the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG[5] IND\_OPS\_DONE\_STATUS\_FLD bit.
11. An Indirect Complete interrupt will be generated when the Indirect read operation has completed.

#### 12.3.2.4.10.2 Indirect Write Controller

The aim of the indirect mode of operation is to perform bulk transfer of data from the processor into a FLASH memory in the most efficient manner. The fewest possible write cycles inside the FLASH device will be carried out for the indirect transfer, thus maximizing the life of the device. Indirect write operation can be thought of from a software perspective as the inverse of the indirect read. It is controlled and triggered by software via specific control/configuration Indirect Write Transfer registers (for more information see the following registers: OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG, OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG, OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_START\_REG, and OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG). This block will await delivery of the write data via the external data interface controller, placing it in the local SRAM before communicating with the existing legacy SPI core to perform an efficient and optimized FLASH write burst.

By default, the indirect write controller is disabled. Before enabling it, the software must configure how much data is required and the start address. The start address and total number of bytes to be written is defined in OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_START\_REG and OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. The Indirect write queuing is very similar to indirect read queuing. For more information refer to [Section 12.3.2.4.10.3, Indirect Access Queuing](#).

The total number of bytes to write in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the amount of data that can be accepted from the external controller. In the case of an SRAM overrun, the controller will back pressure the data interface with wait states. Note the fill level of the SRAM is readable via programmable OSPI\_FLASH\_CFG\_SRAM\_FILL\_REG register and this can be used to avoid this situation.

An external controller will provide the write data and will transfer this to the OSPI module by issuing data interface writes. The address of the incoming write access must be in the range of Indirect trigger address programmed via the OSPI\_FLASH\_CFG\_IND\_AHB\_ADDR\_TRIGGER\_REG register to Indirect trigger address +  $2^{**}(\text{Indirect trigger address range}) - 1$ . Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each write will cause the internal SRAM to be pushed, thereby decoupling the incoming write access address from the FLASH address – that is not direct mapped. Therefore Indirect trigger address does not have any relationship with FLASH address. It is just to indicate that data should take SRAM as source instead of FLASH Memory array after triggering of any valid Indirect Write. The FLASH address for Indirect Write is taken from the

OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_START\_REG register. Assuming the SRAM is not full at the point the data interface access is received by the OSPI module, then the data will be pushed to the SRAM with minimum latency.

If a write access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a write access is received whose address is within the range described above but the SRAM is full then wait states will be applied until some or all of the data has been pushed from the SRAM to the FLASH.

If a write burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller, and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external controller is only permitted to issue 32-bit data interface writes until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final write, the external controller may issue a 32-bit word, 16-bit (halfword) or a byte access to complete the transfer. If the number of bytes to write is less than 4 on the last transfer, the controller is still permitted to issue a 32-bit transfer. In these cases, the extra bytes are discarded by the controller.

When the SRAM holds a number of bytes equal to or greater than the size of a FLASH page (which itself is programmed into the OSPI module, with a default of 256 bytes) or when the SRAM holds all remaining bytes of the currently executing indirect transfer, the OSPI module will initiate a write burst to the flash command generator.

An indirect operation may be cancelled at any time by setting 1 to the OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[1] CANCEL\_FLD bit.

Any bus controller should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be written to the local SRAM. The fill level watermark register (see OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG register) is provided. When the SRAM fill level falls below this watermark, an interrupt is generated.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect write operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit starts an indirect write operation. The OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[2] WR\_STATUS\_FLD bit is available to check the status.

#### **12.3.2.4.10.2.1 Indirect Write Transfer Process**

The following sequence can be followed:

1. Setup OSPI\_FLASH\_CFG\_CONFIG\_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_START\_REG register.
3. Setup the number of bytes to be transferred in the OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG register.
4. Setup the indirect transfer's trigger address in the OSPI\_FLASH\_CFG\_IND\_AHB\_ADDR\_TRIGGER\_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI\_FLASH\_CFG\_INDIRECT\_TRIGGER\_ADDR\_RANGE\_REG register.
6. It is functionally valid for software to simply write all the data to the SRAM in one block transfer. However, if the total number of bytes to write is greater than the size of the partitioned SRAM, then it is quite likely the SRAM will become full causing the OSPI to back-pressure the system data bus for a considerable time. This time is based on the FLASH data-rate and the page-write time of the device. To avoid sending all the write

data in one block transfer, software can make use of the watermark interrupt to identify a convenient time to send data a page at a time to the SRAM module. Alternatively, software can poll the SRAM fill level register directly to identify how empty the SRAM is at any one time in order to make a judgment as to when the most practical time to send the next part of the transfer.

7. If the watermark interrupt feature is to be used, set the OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG register which will cause an interrupt to be generated when the fill level falls below the watermark. The watermark should be set to a number between zero and a page size. That is if the page size is 256 bytes, then setting the watermark to a value between 10 and 250 is reasonable and will cause the interrupt to trigger when the fill level drops below the programmed number. Setting the watermark can be useful to provide an indication to software when to write the next page of data to the SRAM.
8. Trigger Indirect Write access by setting OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit.
9. If the remaining number of bytes still to be transferred into the SRAM for the current indirect transfer is greater than a FLASH page, then write 1 FLASH page worth of data to the SRAM. Otherwise send the remaining data from the indirect transfer to SRAM.
10. If all the data in the indirect transfer has now been sent to the SRAM, then go to 12 and await indirect complete status. Otherwise if there is more data still to be transferred then either:
  - If the watermark interrupt feature is being used, then wait for watermark interrupt.
  - Alternatively the SRAM fill level can be interrogated to identify a convenient time to send more data.
11. Loop back to 9.
12. Optional: The completion status of the Indirect write operation can be polled via OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[5] IND\_OPS\_DONE\_STATUS\_FLD.
13. An Indirect Complete interrupt will be generated when the Indirect write operation has completed.

#### 12.3.2.4.10.3 Indirect Access Queuing

Software is permitted to queue up to two indirect transfers for both the indirect write controller and the indirect read controller. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. Any attempt to queue more than two operations will cause an interrupt to be generated. To take advantage of this feature, software should attempt to keep both indirect programming slots full at all times.

From the software perspective, indirect access queuing is achieved by triggering bit 0 of the indirect transfer control register (OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit or OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit) twice in short succession. The indirect number of bytes register (OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG or OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG register) and the indirect FLASH start address register (OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_START\_REG or OSPI\_FLASH\_CFG\_INDIRECT\_WRITE\_XFER\_START\_REG register) must be setup with the relevant transfer data before START\_FLD bit can be triggered for each transfer. Since these registers will change regularly, the hardware must keep sampled versions of these registers for the duration of the indirect transfer.

The internal register block will only issue an indirect start trigger to the key underlying datapath blocks one at a time. There are 2 independent datapath blocks in the indirect access controller that will receive and independently sample this information. The first is the datapath block on the data bus side of the SRAM. For indirect reads, this is a read interface, for indirect writes, it is a write interface. The second is the datapath block on the FLASH side of the SRAM. For indirect reads, this is a write interface, for indirect writes, it is a read interface. Both blocks will process the indirect transfers at different times. For example, for an indirect read operation, the datapath block on the FLASH side of the SRAM will be able to start processing the second queued transfer as soon as the last byte of the first transfer has been written to the SRAM. Before commencing the second transfer, this block must resample the OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG and OSPI\_FLASH\_CFG\_INDIRECT\_READ\_XFER\_START\_REG registers. Similarly, the datapath block on the bus side will resample the same registers locally when it has forwarded all the FLASH data associated with the first indirect transfer from the SRAM onto the data bus.

#### 12.3.2.4.10.4 Consecutive Writes and Reads Using Indirect Transfers

It is permitted for software to trigger an indirect read operation while an indirect write operation is in progress. Similarly it is permitted to trigger an indirect write while an indirect read operation is in progress. Indirect write operations will take overall precedence.

#### 12.3.2.4.10.5 Accessing the SRAM

The SRAM depth is separated in two segments. The lower segment is reserved for indirect read use. The upper segment is for indirect write use only. The size of each segment is programmable via the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG register. This feature allows to allocate how many bits of the SRAM address bus are allocated to indirect read. By default, this is set so that exactly half of the SRAM is portioned for use by the indirect read controller. To ensure the read data bus is not directly fed by the SRAM read data through combinatorial logic, an extra bank of holding registers is included in the indirect read data path. These registers act as an extra location to be added to the allocated number of SRAM locations for indirect read.

To illustrate how the SRAM (and the extra bank of holding registers) can be allocated between indirect read and write, the following example is provided. The depth of the SRAM in this example is configured to be 8 bits. This is equal to 256 locations.

- If the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x00, then 256 locations are allocated to indirect writes and 1 location to indirect reads.
- If the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x01, then 255 locations are allocated to indirect writes and 2 locations to indirect reads.
- If the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x02, then 254 locations are allocated to indirect writes and 3 locations to indirect reads.
- And so on until.
- If the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFD, then 3 locations are allocated to indirect writes and 254 locations to indirect reads.
- If the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFE, then 2 locations are allocated to indirect writes and 255 locations to indirect reads.
- If the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFF, then 1 location is allocated to indirect writes and 256 locations to indirect reads.

#### Note

A value of 0xFF or 0x00 in the OSPI\_FLASH\_CFG\_SRAM\_PARTITION\_CFG\_REG register should be avoided by software, as only the bottom 8 bits of the SRAM fill level are accessible through software (up to 255 limit) via the OSPI\_FLASH\_CFG\_SRAM\_FILL\_REG register. If the fill level reaches 256 on either the indirect read or write side, it will appear when reading the Fill Level to be 0.

There are four SRAM sources that are arbitrated and muxed onto the single SRAM port. Up to three sources can access this port at any one time. The sources are described as follows:

- Indirect Write, Write source. This is located on the data bus side of the SRAM.
- Indirect Write, Read source. This is located on the FLASH side of the SRAM.
- Indirect Read, Write source. This is located on the FLASH side of the SRAM.
- Indirect Read, Read source. This is located on the data bus side of the SRAM.

A fixed priority arbitration scheme is implemented. [Table 12-166](#) shows priority allocated to these sources.

**Table 12-166. SRAM Access Priority**

SRAM Access Priority		
Indirect Write	Write to SRAM (from System Data Bus)	3rd (exclusive with Data Bus Read Request)
	Read from SRAM (from OSPI Module)	2nd

**Table 12-166. SRAM Access Priority (continued)**

Indirect Read	Write to SRAM (from OSPI Module)	1st
	Read from SRAM (from System Data Bus)	3rd (exclusive with Data Bus Write Request)

#### Note

With the exception of the write port during an Indirect Read operation (on the FLASH side of the SRAM), the logic driving all four sources must not assume single cycle completion. Writes to the SRAM during an indirect read must be allowed to complete immediately to avoid data loss. Therefore this port is given maximum priority.

#### 12.3.2.4.11 OSPI Software-Triggered Instruction Generator (STIG)

The DAC and INDAC are used to transfer data. In order to access the volatile and non-volatile configuration registers, the legacy SPI Status register, other status/protection registers as well as to perform ERASE functions, a separate software controller is required. The software triggered instruction generator (STIG) is controlled using the OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG register by setting up the command to issue to the FLASH device. This is a generic controller and can be used to perform any instruction that the FLASH device supports from the extended SPI protocol. Configuring of instructions which are not compliant with the specification of the FLASH devices could cause unpredicted behavior of the controller. OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD bits should be set different than OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG[7-0] RD\_OPCODE\_NON\_XIP\_FLD and OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG[7-0] WR\_OPCODE\_FLD. The OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[0] CMD\_EXEC\_FLD bit is used to trigger the command. The OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit is used by software to poll the status of the command execution. For reads, when the command has been serviced (OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit toggles from '1' to '0'), up to 8 bytes of read data will be placed in the OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_UPPER\_REG registers. For writes, the write data should be placed in the OSPI\_FLASH\_CFG\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_CFG\_FLASH\_WR\_DATA\_UPPER\_REG registers.

The completion of the STIG request could be also checked by the corresponding interrupt. The occurrence of the interrupt indicates that the controller is ready for accepting a new STIG request. It is important to notice that completion of the STIG request is not equivalent to completion it on SPI side. For example, if STIG is configured to the command composed of data to transmit only, the data is taken from the corresponding STIG register fields and put into TX FIFO. Since all bytes to write are known, another STIG can be queued before serialization of the current one is completed.

There are some commands which require more data to read than 8 bytes (for example READ ID command). The additional STIG Memory Bank is implemented in order to accommodate these data if needed. The STIG Memory Bank (internal component of the controller) is controlled by the OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD bit. If enabled, the number of bytes to read in the STIG is extended to 16 as defined in OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG[18-16] NB\_OF\_STIG\_READ\_BYTES\_FLD bit field. It should be noticed that there are very few commands (excluding Read Array ones which are not intended to handle effectively in STIG Mode but in Direct/Indirect Modes) which return more than 8 bytes to the controller. If the maximum number of bytes to Read using STIG in target application is less than 16, the depth of the STIG Memory Bank can be set smaller what will result in saving noticeable part of the area.

If number of bytes to Read in the STIG as defined in OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG[18-16] NB\_OF\_STIG\_READ\_BYTES\_FLD bit field exceeds the Memory Bank Depth, remaining data will overwrite the STIG Memory Bank locations starting from its first address. OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_UPPER\_REG keep the last 8 bytes read from the Flash Device

by STIG when Memory Bank is enabled. Therefore, for example if the user wants to get just a single byte from the last eight bytes from long continuous read SPI data chain, there is no need to access the STIG Memory Bank since data can be taken from suitable Flash Command Read Data register. In order to access more data, STIG Memory Bank data request should be triggered. It is controlled by the OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG and works analogously for triggering STIG from the functional standpoint.

OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG[0] TRIGGER\_MEM\_BANK\_REQ\_FLD bit is used to trigger the command, bit OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG[1] MEM\_BANK\_REQ\_IN\_PROGRESS\_FLD is used by software to poll the status of the command execution. When MEM\_BANK\_REQ\_IN\_PROGRESS\_FLD bit toggles from "1" to "0", the byte of data (OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG[15-8] MEM\_BANK\_READ\_DATA\_FLD) from corresponding address (OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG[28-20] MEM\_BANK\_ADDR\_FLD bit field) is valid. The address should be set before triggering the STIG Memory Bank access. Each consecutive STIG access overwrites the previous one so that the data in the Bank always fit into byte index fetched by the last STIG access configured to use the Memory Bank (first incoming byte equals first address of the Memory Bank, second one equals the second address and so on).

#### 12.3.2.4.11.1 Servicing a STIG Request

A STIG request will cause the OSPI Flash controller to interrogate the OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG register to determine what and how many bytes it should send to the FLASH device. The OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD field of this register indicate the instruction to be sent and is always pushed first. If there is an address to send, then the address (the size of which is also programmed in the same register) is sent next. The address itself is stored in the OSPI\_FLASH\_CFG\_FLASH\_CMD\_ADDR\_REG register. If Mode bits are enabled by OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[18] ENB\_MODE\_BIT\_FLD bit. OSPI\_FLASH\_CFG\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field are being sent right after address. If OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[18] ENB\_MODE\_BIT\_FLD and OSPI\_FLASH\_CFG\_CONFIG\_REG[29] CRC\_ENABLE\_FLD are both enabled, STIG will replace XIP Mode bits (not applicable for CRC aware SPI interface) for automatically calculated address CRC byte. Therefore, to execute CRC aware STIGs (meaning the commands requiring sending address CRC byte), ENB\_MODE\_BIT\_FLD bit should always be set. If there are any dummy cycles to send (the size of which is also programmed in OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG register) then those are sent next. If there is data to write or read (the size of which is also programmed in OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG register) then for the case of writes, up to 8 bytes can be sent (as stored in the Flash Command Write Data registers, OSPI\_FLASH\_CFG\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_CFG\_FLASH\_WR\_DATA\_UPPER\_REG registers) next. In the read case, when the read data has been collected from the FLASH device, the OSPI Flash Controller stores that in the Flash Command Read Data Registers (OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_UPPER\_REG registers). Up to 8 bytes can be get if OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD bit is disabled or up to 512 when enabled. When the OSPI Flash controller starts to service a STIG request, it sets the OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit to indicate a command execution is in progress. When the OSPI Flash controller is in the auto-polling state, servicing a STIG request is slightly different. Most of devices are largely inaccessible after a program operation until the device has completed that write. Some group of them has a possibility to suspend programming page. It can be controlled by the OSPI\_FLASH\_CFG\_POLLING\_FLASH\_STATUS\_REG[8] DEVICE\_STATUS\_VALID\_FLD bit, which indicate active auto-polling phase. After requesting a STIG, the OSPI Flash Controller immediately issues appropriate OPCODE to Memory. During servicing a STIG (in auto-polling phase) the status bit of command execution remains steady and other parts of transfer such as ADDRESS or DUMMY BITS, and so forth, are disabled (to issued Program Suspend Command is needed OPCODE only). There is a programmable option to add delay between every repetitive poll operation (delay is defined by OSPI\_FLASH\_CFG\_WRITE\_COMPLETION\_CTRL\_REG[31-24] POLL\_REP\_DELAY\_FLD bit field). This feature is implemented to free up SPI bandwidth if needed.

#### 12.3.2.4.12 OSPI Arbitration Between Direct / Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a simple fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

- The Indirect Access Write
- The Direct Access Write
- The STIG
- The Direct Access Read
- The Indirect Access Read

#### 12.3.2.4.13 OSPI Command Translation

Requests issued by the direct access controller, the indirect access controller or the STIG will be translated into a sequence of byte transfers to send downstream (before serialization to the FLASH device). These sequences depend on the requested transfer but an example of a typical 1-byte non sequential READ is shown below:

INSTRUCTION OPCODE -> ADDRESS -> Mode Byte -> Dummy Bytes -> 1 byte of don't care

For sequential accesses, an extra byte of data per read is pushed to the FLASH device on the back of the above sequence assuming it can be done so with no gap between each transferred byte.

When PHY mode is enabled and consequently no clock divider is configured, latency caused by multi domain synchronization may make an extra byte insufficient to avoid the transfer gap. To ensure the sequential access non-interrupted and keep the maximum performance of the controller, PHY Pipeline Mode is implemented. When enabled, number of don't care bytes is calculated based on the configuration.

The actual sequence sent to the FLASH device depends on the requested transfers, whether the transfer is non-sequential or sequential, whether the device has been configured in XIP mode and the state of the main Device Instruction Type programmable registers (OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG).

For writes, the write enable latch (or WEL) within the FLASH device itself must be high before a write sequence can be issued. The OSPI Flash Controller will automatically issue the write enable latch command before triggering a write command via the direct or indirect access controllers (DAC/INDAC) – that is the user does not need to perform this operation. For increasing flexibility and performance user can turn off this feature by setting the OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG[8] WEL\_DIS\_FLD bit. The opcode for WREN is typically 0x06 and is common between devices.

When write requests from the direct or indirect access controllers are no longer being received and all outstanding requests have been sent, the FLASH device will automatically start the page program write cycle. Any incoming request at this time will be held in wait states until the cycle has completed. The OSPI Flash Controller will automatically poll the FLASH device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the RDSR opcode to the FLASH device and waiting until the device itself has indicated the write cycle has completed (until the Write in Progress bit has cleared to zero and the write enable latch bit has also cleared to zero or device is ready bit has set to one). The WREN and the RDSR device instructions are the only ones that are sent by the controller under the hood. For any other specific instruction that the user determines should be sent to the device (for example if the device needs to be unprotected before a write command is issued), these should be handled separately by issuing FLASH commands via the STIG.

There is an option to trigger HOLD or RESET feature on I/Os of the Flash Device. The HOLD one is generally common across the devices and takes an alternative function of DQ3 pin (applicable when device operates neither in Quad SPI mode nor DDR). The transfer can be hold and then resumed by dedicated software trigger field (OSPI\_FLASH\_CFG\_CONFIG\_REG[4] HOLD\_PIN\_FLD). The devices which have the HOLD feature on DQ3 usually need another dedicated pin for hardware reset and ones without HOLD feature usually have alternative reset on DQ3 what makes the additional reset pin being redundant. The controller supports both variants and reset selection register field (OSPI\_FLASH\_CFG\_CONFIG\_REG[6] RESET\_CFG\_FLD) allows the user to configure which hardware reset solution is implemented in the device under usage.

After configuration is done, it is possible to trigger HOLD or RESET features using I/Os (OSPI\_FLASH\_CFG\_CONFIG\_REG[4] HOLD\_PIN\_FLD or OSPI\_FLASH\_CFG\_CONFIG\_REG[5] RESET\_PIN\_FLD bits). After HOLD activation the controller is introduced into waiting state and any other operations should not be requested before de-asserting of HOLD configuration bit. The HOLD feature is useful when any SPI transaction needs to be prolonged in order to adjust it into specific point in time. Note that any HOLD trigger issued during active SPI transaction may be synchronized into reference clock domain at the time the SPI transfer turns to be finished. In this case, there is nothing to hold so the low level SPI logic will not activate HOLD on DQ3. To check if HOLD request suspended the transfer OSPI\_FLASH\_CFG\_CONFIG\_REG[31] IDLE\_FLD bit can be polled for. If SPI is not in the IDLE state, the transfer was successfully suspended. It is important for the software to take care of resetting OSPI\_FLASH\_CFG\_CONFIG\_REG[4] HOLD\_PIN\_FLD bit before newly triggered SPI transaction. In case HOLD request is set before the beginning of the transfer it will be HOLD right after it starts what may not always be a goal. The hardware RESET needs to be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling of OSPI\_FLASH\_CFG\_CONFIG\_REG[31]. If the controller is in the IDLE state and no other transfer requests are queued to perform, the hardware RESET can be triggered. The RESET feature is useful when any write, program or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to being inactive. Triggering HOLD or RESET on DQ3 at the time the device is configured to work in Quad SPI mode or DDR will overwrite transfer data on DQ3 with '0'. This behavior is considered as a software error so it is advisable for the system to make sure that the flash device was introduced to suitable SPI mode (that is by polling its configuration register) before triggering alternative DQ3 function. There are four independent reset outputs implemented to separate between multiple devices connected to the controller (up to 4 are supported). The decision which reset output is to be activated after triggering OSPI\_FLASH\_CFG\_CONFIG\_REG[5] RESET\_PIN\_FLD bit is made based on OSPI\_FLASH\_CFG\_CONFIG\_REG[9] PERIPH\_SEL\_DEC\_FLD and OSPI\_FLASH\_CFG\_CONFIG\_REG[13-10] PERIPH\_CS\_LINES\_FLD bits. Reset output OSPI\_ECC\_VECTOR is to be directly driven into corresponding dedicated RESET pins of the devices with separated RESET pin and alternatively, Reset output OSPI\_ECC\_VECTOR is to be control OSPI\_ECC\_VECTOR of the DQ3 RESET devices enabling separating of DQ3 Controller Outputs on SoC integration level.

The controller supports all combinations of CPHA and CPOL for Serial Clock. It allows the controller to support any SPI target devices not limited to Flash Memories. Multiple-SPI flash devices use just a subset of these combinations depending on the Transfer Mode as defined in [Table 12-167](#).

**Table 12-167. Flash SPI Modes**

(SEL_CLK_POL_FLD, SEL_CLK_PHASE_FLD)	Edge Mode	Support
0x00 (SPI MODE 0)	SDR	Yes
0x01 (SPI MODE 1)	SDR	No
0x10 (SPI MODE 2)	SDR	No
0x11 (SPI MODE 3)	SDR	No
0x00 (SPI MODE 0)	DDR	Yes
0x01 (SPI MODE 1)	DDR	No
0x10 (SPI MODE 2)	DDR	No
0x11 (SPI MODE 3)	DDR	No

#### 12.3.2.4.14 Selecting the Flash Instruction Type

In order to send the correct READ and WRITE opcodes, software should initialize the OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG and the OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the FLASH (default is basic READ and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad or octal pins for address and data transfer. Providing this level of control to the user provides a future proofed generic solution. To ensure the

controller can operate from a reset state, the registers will be reset to an opcode compatible with SIO devices what can be modified using BOOT feature.

Despite being applicable for both READs and WRITES, the OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG[9-8] INSTR\_TYPE\_FLD field only appears once – it is not included in the OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG register. If software sets this to anything other than '0', then the address transfer type and the data transfer type bits of both OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG registers become don't care. It is made available to allow software to support the less common FLASH instructions where the opcode, address and data are sent on 2 or 4 lanes (the opcode from most instructions are sent serially to the FLASH device, even for dual/quad instructions).

There are devices capable to handling Read Operations in Dual Data Rate Mode (DDR) (it is also called Dual Transfer Rate Mode (DTR)). That means they can issue and capture the data on both rising and falling edges during working with dedicated command type. This enables the controller to maintain throughput at twice lower frequency of OSPI clock. The Device Read Instruction Register has DDR enable bit which informs Octal-SPI Flash Controller that opcode written into Read Opcode field is capable with DDR command type. The other field defined in OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[19-16] DDR\_READ\_DELAY\_FLD which enables the controller to shift the transmitted data in DDR mode. By default, data are shifted by 1 clock cycle to ensure hold timing greater than 0 during DDR transactions. It may not be sufficient for high reference clock frequency in accordance with the high dividers.

Table 12-168 shows how software should configure the OSPI module for selected specific READ and WRITE instruction supported by the abovementioned device.

**Table 12-168. READ and WRITE Instruction Configuration**

READ							
OPCODE	OPCODE sent over how many lanes / edge mode?	ADDRESS / DUMMY / MODE sent over how many lanes / edge mode?	DATA bytes sent over how many lanes / edge mode? ---

**Note**

This data are applicable for both 3-byte or 4-byte address variants of the commands if did not indicate otherwise.

---

---

**Note**

In DTR protocol all transfer phases (including opcode) take DDR edge mode independently on the command under execution. DTR protocol is to be enabled by OSPI\_FLASH\_CFG\_CONFIG\_REG[24] ENABLE\_DTR\_PROTOCOL\_FLD bit. It has higher priority than DDR Mode enable bit from OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG[10] DDR\_EN\_FLD.

---

**12.3.2.4.15 OSPI Data Interface**
**12.3.2.4.16 OSPI PHY Module**

OSPI module fully integrates PHY module dedicated to more flexible and power efficient transfers.

The PHY module communicates with the OSPI Flash controller via the aforementioned PHY Interface and handles data transfer on low-level stage of design hierarchy. However, when the OSPI\_RCLK is configured to be equal to the SPI clock instead of alternative approach using clock divider, there is just one OSPI\_RCLK cycle (not 4 or more) within single SPI period or half period for DDR Mode (SPI Control Module works on reference clock). Given that OSPI\_RCLK is the input clock for RX FIFO and the output one for TX FIFO, the PHY solution incurs more restrictive requirement for value of system clock in order to synchronize data without SPI transfer interruption. For example, when the controller operates in DDR 1× octal Mode, 2 bytes of data (equivalent to one RX FIFO location) is gathered within just single OSPI\_RCLK cycle. The controller cannot predict next data access while operating in the Direct Mode (meaning its size or whether it is sequential to the previous one or not). As a result, if the OSPI\_HCLK is not significantly greater than OSPI\_RCLK, the SPI transfer has to be suspended until the Flash Command Generator forwards new data to TX FIFO.

An optional PHY Pipeline Mode is implemented to avoid the necessity of stable clocking of the system clock for the Direct Mode when the PHY mode is enabled and to keep maximum performance while ensuring correct operation of the OSPI controller with the PHY using low frequencies from all its domains. This mode is a trade-off between large software overhead when operating in the Indirect Mode and the described limitations present in the Direct Mode. For more information about PHY Pipeline Mode, see [Section 12.3.2.4.16.1, PHY Pipeline Mode](#).

When DDR 2× Mode is granted based on configuration – SPI transfer is automatically performed using the PHY module even if the OSPI\_FLASH\_CFG\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD is de-asserted. SDR 2× commands are handled with PHY module paths being bypassed. Nevertheless, dividers of 2, 4 or 6 for DDR and divider of 2 for SDR should not be configured based on controller requirements and these configurations are perceived as a software error.

---

**Note**

Please refer to the [OSPI Controller PHY Tuning Algorithm Application Note](#) for additional details related to the OSPI PHY Module and Tuning Algorithm,

---

### 12.3.2.4.16.1 PHY Pipeline Mode

This mode is used for Direct Read Mode of operation. If any other operations are intended to be executed, it is recommended to disable PHY Pipeline Mode and re-enable for subsequent Direct Reads in PHY mode. Since there is comprehensive software mechanism controlling Read data transfers in Indirect Mode, pipeline of data interface accesses is not effective for this mode. Enable PHY Pipeline feature when at least four 4-byte-sized data words are predicted to be read in sequentially. The Flash Command Generator pipelines and puts them into TX FIFO which causes CS to remain active because low level SPI protocol controller controls TX FIFO fill level. In order to correctly trigger Direct Read in Pipeline Mode TX FIFO must be empty. Therefore first polling of OSPI\_FLASH\_CFG\_CONFIG\_REG[31] IDLE\_FLD bit needs to be done. The sequential data transfer will be interrupted when the data target select signal of the data interface is asserted to low. This information is also detected by Data Target Module which informs the Flash Command Generator that the next access is invalid and a TX FIFO locations can be flushed transparently for the system.

In PHY Pipeline Mode it is recommended for Data Controller not to introduce wait states in between consecutive occurrences of the data interface signal that indicates transfer has finished. It will ensure regular transfer rate on data side. Introducing wait states gradually slows data transfer rate down and may finally cause SPI transfer interruption because of TX FIFO data starvation. The system, however, may need to introduce some number of wait states after completion of sequential transfer (composed of 4-byte sized data words) for progressing the data. The dedicated buffer is implemented in Data Target Controller which collects all incoming data during wait states injection. In order to keep SPI transfer uninterrupted, number of wait states should be as little as possible. The higher the OSPI\_HCLK/ OSPI\_RCLK ratio the more wait states can be introduced without SPI transfer interruption. In case the system is able to launch a new transfer before wait states overflow, buffered data transfer to the host will continue. It compensates slowed down transfer by introducing wait states. In case the system is not able to launch a new transfer before wait states overflow, next incoming transfer is considered non-sequential and is executed after all pipelined data is flushed.

This mode can be enabled when following conditions are met:

- OSPI\_HCLK > OSPI\_RCLK (Comparing the slow data clock with the fast reference one makes Pipeline Mode ineffective – Suspend of SPI Transfer would be possible. Consequently, this condition has to be met to operate in this mode.)
- Only 4-byte sized Data Words are permitted (This ensures more data clock cycles for synchronization of FIFOs between consecutive pulses of the signal indicating transfer has finished.)
- The transfer with introduced wait states or non-sequential transfers can only be triggered in between at least four 4-byte sized Data Bursts sequential accesses (16 Bytes) to be sure that Data Controller can trust buffered incoming data during wait states injection.
- Do not use Pipeline Mode along with Continuous Mode (XIP). Benefit of XIP is limited for bulk data transfers intended to execute in Pipeline Mode.

### 12.3.2.4.16.2 Read Data Capturing by the PHY Module

Read Data Capturing by the PHY module is useful, as the user is not responsible for the design dedicated DLL being compatible with the Octal-SPI Flash Controller. Another benefit is an option to adjust both SPI clock and sampling clock in a very wide range to fit them into individual requirements of any system. If loopback clock (OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[0] BYPASS\_FLD) and PHY mode (OSPI\_FLASH\_CFG\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD) are both enabled, the loopback clock is driven into RX DLL instead of gated reference clock. Because of the architecture of DLL, loopback clock needs to be provided in SPI Mode 0. If DQS (OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG[8] DQS\_ENABLE\_FLD) and PHY mode (OSPI\_FLASH\_CFG\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD) are both enabled, the DQS is driven into RX DLL instead of gated reference clock.

### 12.3.2.5 OSPI Programming Guide

#### 12.3.2.5.1 Configuring the OSPI Controller for Use After Reset

The OSPI controller has been designed to wake up in a state that is suitable for performing basic reads and writes using the direct access controller. The BASIC read (opcode 0x03) and BASIC write (opcode 0x02) instructions are operations supported by all target devices. The controller also wakes up with a baud rate divider setting of divide-by-32. Assuming the reference clock is operating at 400 MHz after reset, then this means the effective SPI clock is just 12.5 MHz. This should be slow enough to meet all timing requirements of all target devices without any further device programming.

If the target device does not use 3 address bytes, the device size configuration register must be modified to the appropriate size.

If software plans to write to the device, and the number of bytes per device page is not equal to 256, then the device size configuration register must also be modified.

While not a requirement, it is prudent for software to enable the write protect feature prior to enabling the OSPI controller. This will block any data writes from taking effect. To do so, the protection registers (OSPI\_FLASH\_CFG\_LOWER\_WR\_PROT\_REG, OSPI\_FLASH\_CFG\_UPPER\_WR\_PROT\_REG and OSPI\_FLASH\_CFG\_WR\_PROT\_CTRL\_REG) should be setup and the number of bytes per device block in the device size configuration register should also be setup.

After Power-on Reset (POR), software can read from and write to the FLASH device (albeit slowly). Enabling/Disabling the controller and DAC is achieved with just one write to corresponding fields of the OSPI\_FLASH\_CFG\_CONFIG\_REG register. User shall take note to maintain the default values of the baud rate divisor and the default state of SEL\_CLK\_POL\_FLD/ SEL\_CLK\_PHASE\_FLD bits of this register. A write data value of 0x00780081 is recommended.

#### 12.3.2.5.2 Configuring the OSPI Controller for Optimal Use

##### Note

When using the OSPI Controller, the opcodes in OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG[7-0] RD\_OPCODE\_NON\_XIP\_FLD, OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG[7-0] WR\_OPCODE\_FLD and OSPI\_FLASH\_CFG\_WRITE\_COMPLETION\_CTRL\_REG[7-0] OPCODE\_FLD bit fields shall not match the opcode in the OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD bit field.

For high speed transfers PHY mode can be enabled and for optimal configuration PHY Pipeline mode is recommended. For more information, see [Section 12.3.2.4.16.1, PHY Pipeline Mode](#).

To access the flash optimally, software must configure the controller accurately:

1. Wait until any pending STIG or INDAC operation has completed or poll OSPI\_FLASH\_CFG\_CONFIG\_REG[31] IDLE\_FLD bit.
2. Disable the DAC through OSPI\_FLASH\_CFG\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTLR\_FLD bit. It is permitted, but not necessary to also disable the OSPI controller completely via OSPI\_FLASH\_CFG\_CONFIG\_REG[0] ENB\_SPI\_FLD bit.
3. Update the OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_FLASH\_CFG\_DEV\_INSTR\_WR\_CONFIG\_REG registers for the instruction type you wish to use for indirect and direct writes and reads.
4. Update the OSPI\_FLASH\_CFG\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field if mode bits have been enabled in the OSPI\_FLASH\_CFG\_DEV\_INSTR\_RD\_CONFIG\_REG[20] MODE\_BIT\_ENABLE\_FLD bit.
5. Update the OSPI\_FLASH\_CFG\_DEV\_SIZE\_CONFIG\_REG if the contents are incorrect. Note parts or all of this register may have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing

any write. The number of bytes per device block is only required if the write protect feature is used. If the default values are correct for the target device, or if some of the values (not including the number address bytes) were incorrect but device writes were not permitted.

6. Update the OSPI\_FLASH\_CFG\_DEV\_DELAY\_REG. This register allows the user to tweak how the chip select is driven after each FLASH access. This is required as each device may have different timing requirements. As the serial clock frequency is increased, these timing requirements become more important. Note the numbers programmed in this register are based on the period of reference clock. Example: A device needs 50ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the controller will only provide a minimum of 1 SCLK period. When the device is operating at 100 MHz, the SCLK period is only 10ns, so 40ns extra is required. Since the register defines the number of reference clock cycles to add, and reference clock is running at 400 MHz (2.5ns period), then the user should program a value of at least 16 to the OSPI\_FLASH\_CFG\_DEV\_DELAY\_REG[31-24] D\_NSS\_FLD. This delay can be extended during auto-polling phase. There is possibility to define the polling repetition delay in the OSPI\_FLASH\_CFG\_WRITE\_COMPLETION\_CTRL\_REG[31-24] POLL\_REP\_DELAY\_FLD bit field.
7. Update the OSPI\_FLASH\_CFG\_REMAP\_ADDR\_REG register, if required. Affects DAC path only.
8. Setup and enable write protection registers (OSPI\_FLASH\_CFG\_LOWER\_WR\_PROT\_REG, OSPI\_FLASH\_CFG\_UPPER\_WR\_PROT\_REG and OSPI\_FLASH\_CFG\_WR\_PROT\_CTRL\_REG) if they are required and if they have not already been setup from post initialization.
9. Enable required interrupts via the OSPI\_FLASH\_CFG\_IRQ\_MASK\_REG register.
10. Setup the baud rate divisor in the OSPI\_FLASH\_CFG\_CONFIG\_REG[22-19] MSTR\_BAUD\_DIV\_FLD to define the required clock frequency of the target device.
11. Update the OSPI\_FLASH\_CFG\_RD\_DATA\_CAPTURE\_REG register. This register will delay when the read data is captured and can help when the read data path from the device to the controller is long and the device clock frequency is high. An update to this register may not be necessary.
12. Enable the OSPI controller and the DAC via the OSPI\_FLASH\_CFG\_CONFIG\_REG.

### 12.3.2.5.3 Using the Flash Command Control Register (STIG Operation)

The OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG register provides software means to access the FLASH device in a flexible and programmable manner. This is known as a STIG operation (Software Triggered Instruction Generator). The instruction opcode, number of address bytes (if any), the address itself, number of dummy cycles (if any), number of write data bytes (if any), the write data itself and the number of read data bytes (if any) can be programmed. Once these have been programmed, software can trigger the command via OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[0] CMD\_EXEC\_FLD bit and wait for its acceptance by polling OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit. When CMD\_EXEC\_STATUS\_FLD bit turns de-asserted, another STIG can be triggered. This method of accessing the FLASH is the typical mechanism that software would use to access the FLASH device's registers, as well as for performing ERASE operations. It can also be used to access the FLASH array itself, although the maximum of 8 data bytes may be read or written at any one time, defined in the Flash Command Write and Read Data registers (OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_LOWER\_REG, OSPI\_FLASH\_CFG\_FLASH\_RD\_DATA\_UPPER\_REG, OSPI\_FLASH\_CFG\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_CFG\_FLASH\_WR\_DATA\_UPPER\_REG). This number of bytes can be extended for Read Data commands using additional STIG Memory Bank controlled by OSPI\_FLASH\_CFG\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD and OSPI\_FLASH\_CFG\_FLASH\_COMMAND\_CTRL\_MEM\_REG.

Commands issued using this interface have a higher priority than all other READ accesses coming from data interface, and will therefore interrupt any READ commands being requested by the indirect or direct controllers.

### 12.3.2.5.4 Using SPI Legacy Mode

SPI legacy mode allows software to access the internal TX-FIFO and RX-FIFO directly, thus bypassing the direct, indirect and STIG controllers.

Legacy mode allows the user to issue any FLASH instruction to the device, but does place a heavy software overhead in order to manage the fill levels of the FIFO's effectively. This is because the legacy SPI core is bi-directional in nature, with data continuously being transferred in either direction while the chip select is

enabled. Even if the driver only wishes to read data from the FLASH device, dummy data must be written out to ensure the chip select stays active, and vice versa for write transactions.

Since the TX-FIFO and RX-FIFO are of limited depth, software has a responsibility to maintain the FIFO levels to ensure the TX-FIFO does not become exhausted during the instruction execution and the RX-FIFO doesn't overflow. This can place a lot of overhead on software. Interrupts are provided to indicate when the fill levels pass programmable watermarks, which are themselves programmable registers `OSPI_FLASH_CFG_TX_THRESH_REG` and `OSPI_FLASH_CFG_RX_THRESH_REG`.

The limited depth may impose the limitation over execution of some specific SPI commands in legacy mode. Note that the controller interprets all transmitted bytes as valid. For example, if the Flash Device was configured to return valid data after many dummy cycles, the TX FIFO could become full before the controller sends all of dummy data.

#### 12.3.2.5.5 Entering XIP Mode from POR

XIP is a mode that can be entered in a non-volatile way if the device has XIP enabled as a non-volatile configuration setting. Software will not be able to discover the state of XIP from POR via FLASH status register reads as the only operation a FLASH device will recognize when XIP mode is enabled is an XIP read operation.

If it is already known that the device will enter XIP from POR, then the `OSPI_FLASH_CFG_MODE_BIT_CONFIG_REG[7-0] MODE_FLD` and `OSPI_FLASH_CFG_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD` bits should be set in initial boot.

If it is not already known that the device will enter XIP from POR, and XIP from POR may be supported by the attached FLASH device, then software can attempt to exit XIP mode by issuing an XIP exit command using a STIG command (via the `OSPI_FLASH_CFG_FLASH_CMD_CTRL_REG` register). To do this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

#### 12.3.2.5.6 Entering XIP Mode Otherwise

XIP mode is supported in most FLASH devices. Some of them use signature bits that are sent to the device immediately following the address bytes, other use signature bits and also require a FLASH device configuration register write to enable XIP. For the FLASH devices that must be compliant to the OSPI controller, the following steps can be taken by software to enter XIP mode:

1. Disable the DAC and INDAC (`OSPI_FLASH_CFG_CONFIG_REG[7] ENB_DIR_ACC_CTLR_FLD`) to ensure no new data read accesses will be sent to the FLASH device.
2. (Optional) Configure the `OSPI_FLASH_CFG_FLASH_CMD_CTRL_REG` to issue a VCR write to FLASH memory, because XIP mode must first be enabled for some devices.
3. Configure the XIP mode bits in the `OSPI_FLASH_CFG_MODE_BIT_CONFIG_REG[7-0] MODE_FLD` bit field.
4. Enable the local controllers XIP mode by setting `OSPI_FLASH_CFG_CONFIG_REG[17] ENTER_XIP_MODE_FLD` bit.
5. Re-enable the DAC and, if required, the INDAC.

#### 12.3.2.5.7 Exiting XIP Mode

To exit XIP mode, software should first disable the DAC and INDAC to ensure no new data read accesses will be sent to the FLASH device. It should then set mode bits to other than the established in the corresponding Flash Device specifications. These are dependent on the FLASH device and manufacturer. Software should then reset `OSPI_FLASH_CFG_CONFIG_REG[17] ENTER_XIP_MODE_FLD`.

Note the FLASH device must see a READ instruction before it can disable its internal XIP mode state, so this means XIP mode will internally stay active until the next READ instruction is serviced. User must take care to ensure that XIP mode is disabled before the end of any READ sequence.

### 12.3.3 General-Purpose Memory Controller (GPMC)

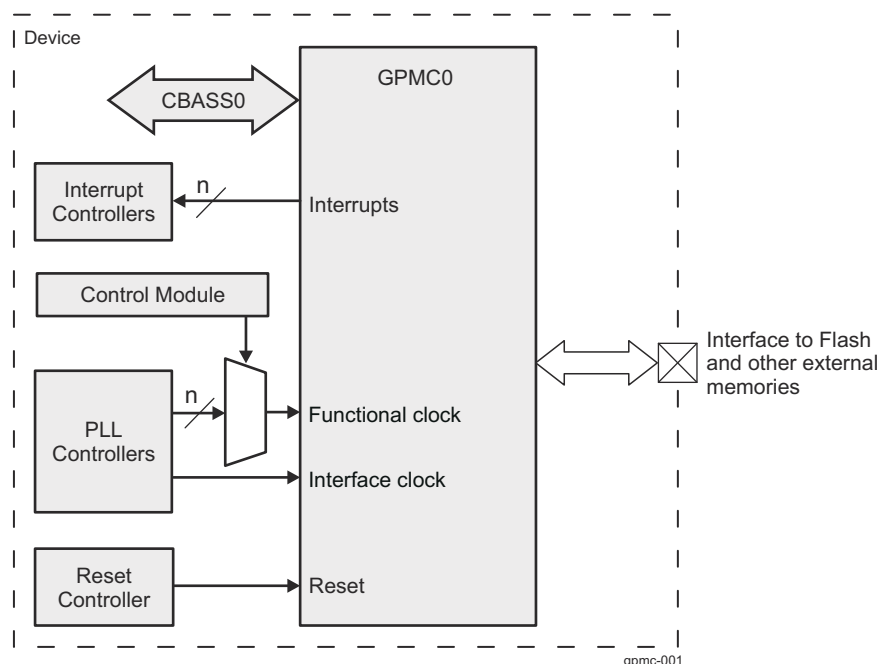

This section describes the General-Purpose Memory Controller (GPMC) for the device.

#### 12.3.3.1 GPMC Overview

The General-Purpose Memory Controller is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in non-multiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

Figure 12-144 shows the GPMC0 module overview.

**Figure 12-144. GPMC0 Overview**

#### 12.3.3.1.1 GPMC Features

The main features of the GPMC are:

- 8-, 16- or 32-bit-wide data path to external memory device
- Supports up to 4 chip select regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) ( $t = 4, 8, \text{ or } 16$ ) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth usage
- The clock to the external memory is provided from GPMC\_FCLK divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters with a timing granularity of one GPMC\_FCLK clock cycle.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pin monitoring

- Support bus keeping
- Support bus turnaround
- Prefetch and write-posting engine associated with DMA controller at system level to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access
- 32-bit interconnect target interface which supports non-wrapping and wrapping burst of up to 16x32 bits.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16-32 Word16, 4-8-16 Word32)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4-8-16-32 Word16, 4-8-16 Word32)
- Synchronous read/write burst access with wrap capability (4-8-16-32 Word16, 4-8-16 Word32)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little-endian access only

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External asynchronous or synchronous 32-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16- and 32-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit and 32-bit pseudo-SRAM (pSRAM) device

---

**Note**

Page mode is available only in non-multiplexed mode.

---

#### **12.3.3.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

### 12.3.3.2 GPMC Environment

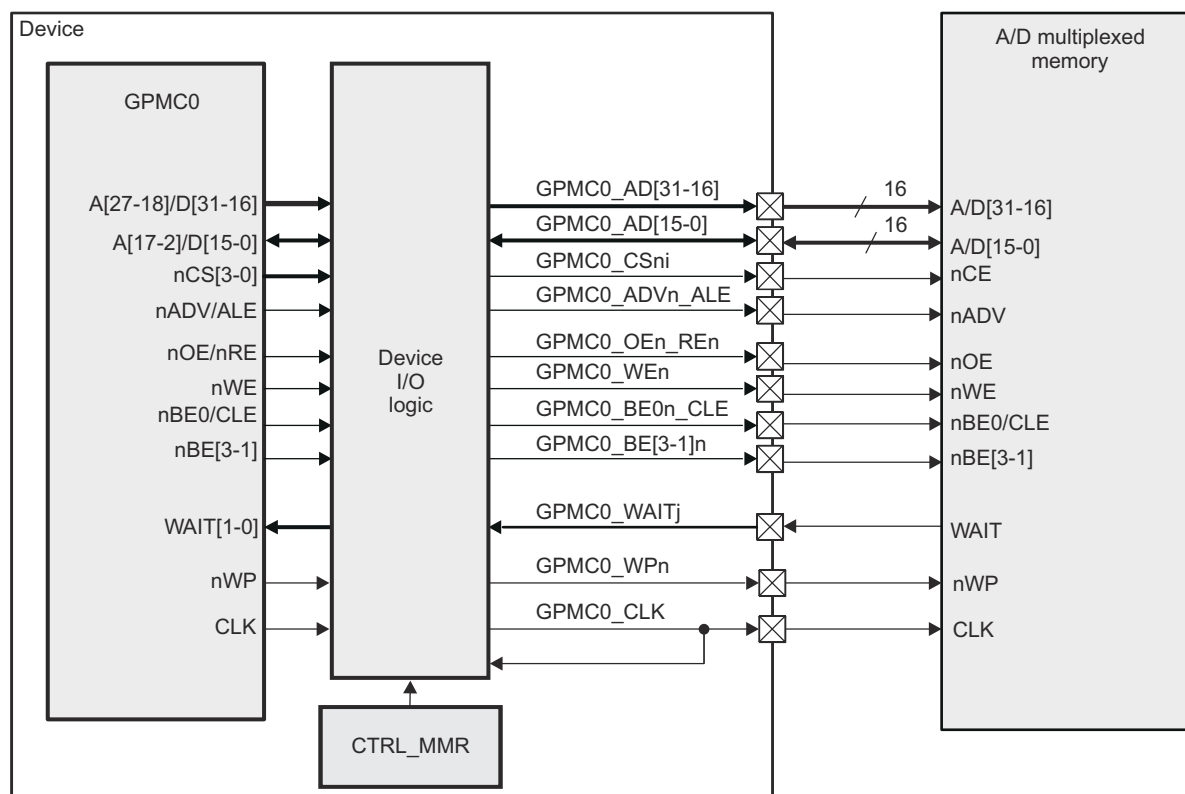

The GPMC0 module is hereinafter referred to as GPMC.

This section describes the GPMC0 external connections (environment).

#### 12.3.3.2.1 GPMC Modes

This section shows four GPMC0 external connection options:

- [Figure 12-145](#) shows a connection between the GPMC0 and a 32-bit synchronous address/data-multiplexed external memory device.
- [Figure 12-146](#) shows a connection between the GPMC0 and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed but this protocol uses fewer address pins) external memory device.
- [Figure 12-147](#) shows a connection between the GPMC0 and a 16-bit synchronous non-multiplexed external memory device.
- [Figure 12-148](#) shows a connection between the GPMC0 and an 8-bit synchronous non-multiplexed external memory device.
- [Figure 12-149](#) shows a connection between the GPMC0 and an 8-bit NAND device.

### 12.3.3.2.2 GPMC I/O Signals

Table 12-169 lists the GPMC subsystem input/output (I/O) pins.

**Table 12-169. GPMC I/O Signals (Controller Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>GPMC0</b>				
A[22-0]	GPMC0_A[22-0]	O	23-bit output address bus	-
A[27-2]/D[31-0]	GPMC0_AD[31-0]	I/O	Multiplexed address/data	-
nCS[3-0]	GPMC0_CS[n][3-0]	O	Chip-selects (active low)	-
CLK	GPMC0_CLK	O	Clock generated for the external memory or device. For more information, see <i>GPMC0 Integration</i> .	-
CLKLB				
N/A	GPMC0_FCLK_MUX	O	Free running clock. GPMC functional clock (GPMC0_FCLK) propagated on a device pad. For more information on the GPMC0_FCLK_MUX integration, see <i>GPMC0 Integration</i> .	-
nADV/ALE	GPMC0_ADV[n]_ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.	-
nOE/nRE	GPMC0_OE[n]_RE[n]	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.	-
nWE	GPMC0_WEn	O	Write enable (active low)	-
nBE0/CLE	GPMC0_BE0[n]_CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.	-
nBE[3-1]	GPMC0_BE[3-1][n]	O	Upper-byte enable (active low)	-

**Table 12-169. GPMC I/O Signals (Controller Mode) (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
WAIT[1-0]	GPMC0_WAIT[1-0]	I	External wait signal for NOR and NAND protocol memories. Can be mapped on any of the chip-selects.	-
nWP	GPMC0_WPn	O	Write protect (active low)	-
DIR	GPMC0_DIR	O	This signal can be used to control an external buffer direction. Also controls the signal direction of D[15-0]. Low during transmit (for write access: data OUT from GPMC0 to memory). High during receive (for read access: data IN from memory to GPMC0).	-

(1) I = Input; O = Output; I/O - Bidirectional

(2) HiZ = High Impedance

### Note

For GPMC output clock signal (CLK) to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

Table 12-170 shows the use of address and data GPMC pins based on the type of external device.

**Table 12-170. GPMC Pin Multiplexing Options**

GPMC Pin	Multiplexed Address Data 32-Bit Device	Multiplexed Address Data 16-Bit Device	non-multiplexed Address Data 16-Bit Device (incomplete 28-bit address range)	non-multiplexed Address Data 8-Bit Device (incomplete 28-bit address range)	16-Bit NAND Device	8-Bit NAND Device

(1) Used to effectively address 8-bit (only) non-multiplexed memories

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x0.

Address mapping supports address/data-multiplexed 16- or 32-bit-wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit field (where i = 0 to 3).

### 12.3.3.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.3.3.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the four configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external WAIT pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

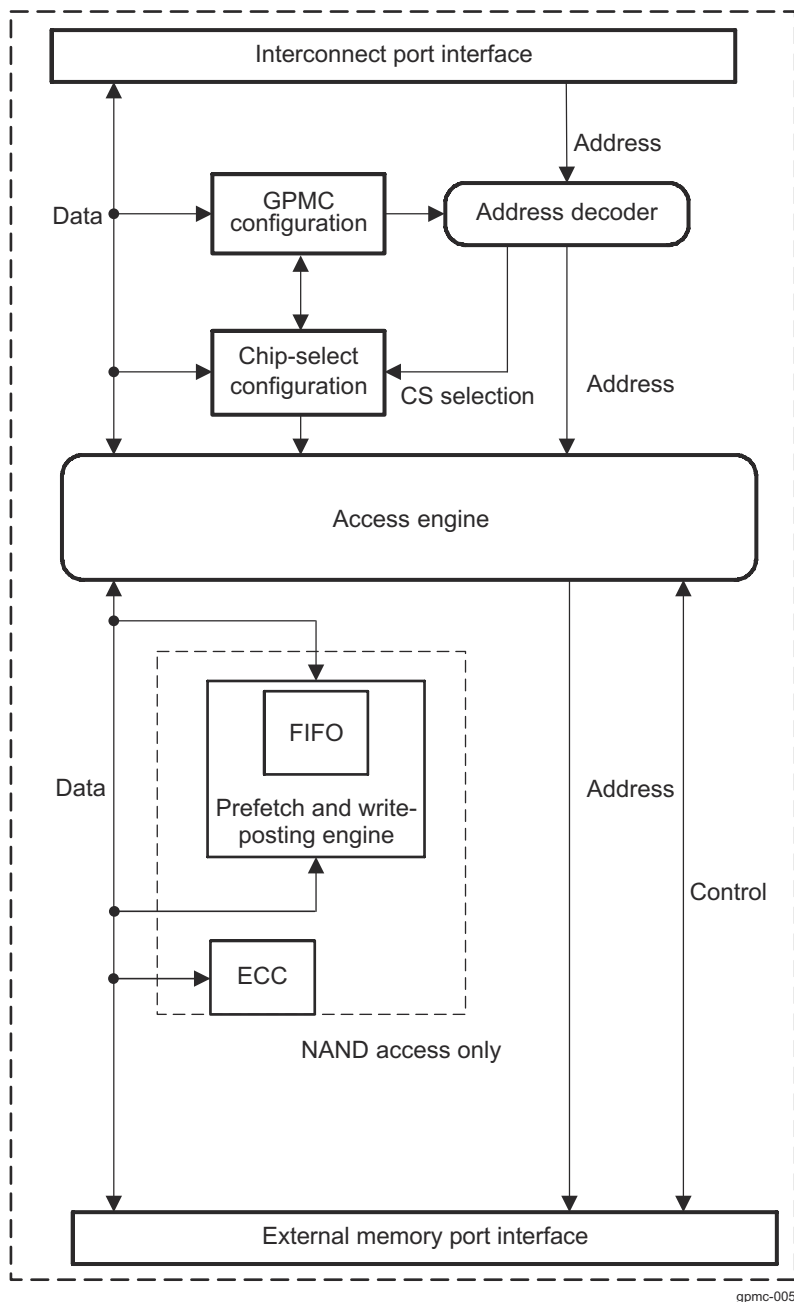

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC\_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

##### 12.3.3.4.1 GPMC Block Diagram

Figure 12-150 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

**Figure 12-150. GPMC Block Diagram**

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

#### 12.3.3.4.2 GPMC Clock Configuration

Table 12-171 describes the GPMC clocks.

**Table 12-171. GPMC Clocks**

Signal	I/O <sup>(1)</sup>	Description
GPMC_FCLK	I	Functional clock
GPMC_ICLK	I	Interface clock
CLK (GPMC_CLKOUT pin)	O	External clock provided to synchronous external memory devices and to DCC5 in the device.

(1) I = Input; O = Output; I/O - Bidirectional

The GPMC output clock (CLK) is generated by the GPMC from the internal GPMC\_FCLK clock. The source of the GPMC\_FCLK is described in *GPMC0 Clocks*. The GPMC output clock is configured using the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), as shown in [Table 12-172](#).

**Table 12-172. GPMC Output Clock Configuration**

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC Output Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

When using synchronous interface protocols, the GPMC output clock (CLK), toggles only during the read or write access cycle. In some applications, it may be desirable to have a continuous clock running at the GPMC interface clock frequency for clocking attached devices. This option is enabled by an optional clock path from the GPMC functional clock input (GPMC\_FCLK) to the GPMC\_FCLK\_MUX pin. This output clock, to GPMC\_FCLK\_MUX pin, can be selected through the standard MUXMODE selection of the GPMC\_FCLK\_MUX pin PADCONFIG control register.

Note that when using such synchronous interface protocols with the continuous clock option, user should ensure that the GPMC outputs are timed to the same frequency (GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0).

#### 12.3.3.4.3 GPMC Power Management

[Table 12-173](#) describes the local power-management features available for the GPMC module.

**Table 12-173. GPMC Local Power-Management Features**

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_ICLK clock upon the internal activity.
Target idle modes	GPMC_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle and smart-idle modes are available.

#### 12.3.3.4.4 GPMC Interrupt Requests

The GPMC generates one interrupt request (see *GPMC0 Hardware Requests*).

[Table 12-174](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 12-174. GPMC Interrupt Events**

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.

**Table 12-174. GPMC Interrupt Events (continued)**

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0.
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

#### 12.3.3.4.5 GPMC Interconnect Port Interface

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The GPMC interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the *GPMC\_CONFIG1*\_*i*[24-23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the *GPMC\_CONFIG1*\_*i*[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

#### 12.3.3.4.6 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-non-multiplexed memories or devices is supported with an address range of 256MB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.

- 8-bit-wide NOR devices do not use GPMC I/O: GPMC\_AD[15-8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: GPMC\_A[22-0].
- 8-bit-wide NAND devices do not use GPMC I/O: GPMC\_A[22-0] and GPMC I/O: GPMC\_AD[15-8].

#### 12.3.3.4.6.1 GPMC I/O Configuration Setting

##### Note

In this section and the following sections, the *i* in GPMC\_CONFIGx\_i stands for the GPMC chip-select *i*, where *i* = 0 to 3.

To select a NAND device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b10
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b01

To select an address/data-non-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b00

#### 12.3.3.4.7 GPMC Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and four sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

##### 12.3.3.4.7.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 128MB address space. For more information, see *Memory Map*.

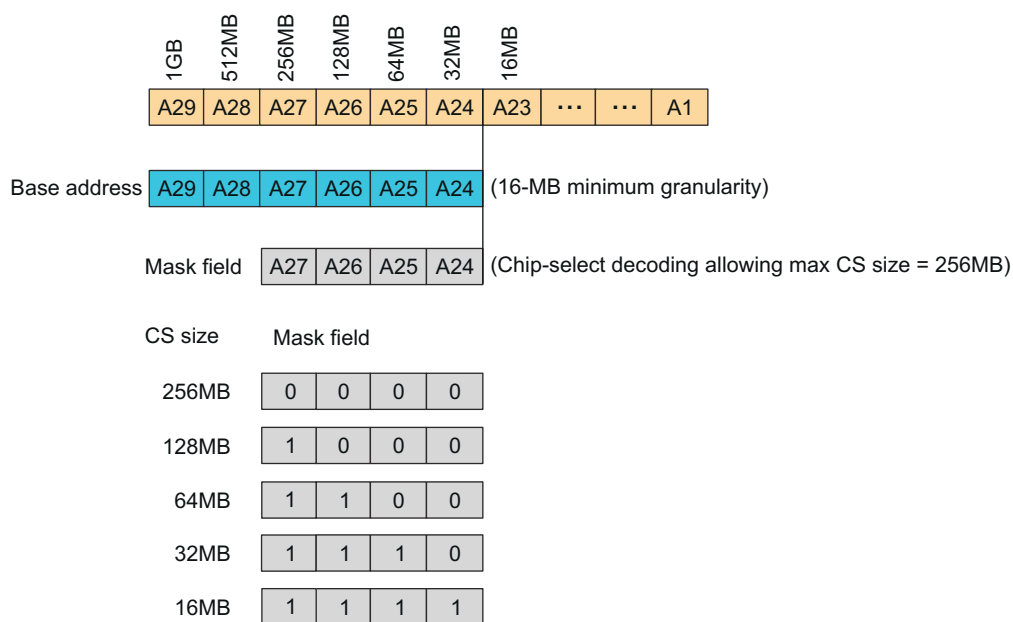

##### Note

Even though GPMC supports total address space of 1GB, only 128MB are physically available in this device.

The GPMC 128MB address space can be divided into a maximum of four chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MB to 256MB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in [Figure 12-151](#) (with A0 as the device system byte-address line). The base address is programmed through the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC\_CONFIG7\_i[11-8] MASKADDRESS bit field.

gpmc-006

**Figure 12-151. Chip-Select Address Mapping and Decoding Mask**

For example, to map the 128MB address space (from 2000 0000h to 27FF FFFFh), the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field should be set to 20h.

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC\_CONFIG7\_i[6] CSVALID bit (where i stands for the GPMC chip-select i, where i = 0 to 3). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

### CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines at the value specified in the device-specific Datasheet.

#### 12.3.3.4.7.2 Access Protocol

##### 12.3.3.4.7.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the *GPMC\_CONFIG1\_i*[11-10] DEVICETYPE parameter (where *i* = 0 to 3) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

### Note

For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 12.3.3.4.11](#), *GPMC NAND Device Basic Programming Model*, and [Section 12.3.3.4.11.1](#), *NAND Memory Device in Byte or Word16 Stream Mode*.

#### 12.3.3.4.7.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the *GPMC\_CONFIG1\_i*[13-12] DEVICESIZE bit field (where *i* = 0 to 3) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

##### 12.3.3.4.7.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the *GPMC\_CONFIG1\_i*[9-8] MUXADDDATA bit field (where *i* = 0 to 3). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See *Module Integration*.

### Note

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See [Section 12.3.3.4.11](#), *NAND Device Basic Programming Model*.

#### 12.3.3.4.7.3 External Signals

##### 12.3.3.4.7.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external GPMC\_WAIT pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features two input WAIT pins: GPMC\_WAIT1, and GPMC\_WAIT0. These pins allow control of external devices with different WAIT pin polarity. They also allow the overlap of WAIT pin assertion from different devices without affecting access to devices for which the WAIT pin is not asserted.

- The GPMC\_CONFIG1\_i[17-16] WAITPINSELECT bit field (where *i* = 0 to 3) selects which input GPMC\_WAIT pin is used for the device attached to the corresponding chip-select.

- The polarity of the WAIT pin is defined through the WAITxPINPOLARITY bit of the GPMC\_CONFIG register. A WAIT pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a WAIT pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the WAIT pin of the external memory device, based on the access type: read or write.

- The GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit defines whether or not the WAIT pin must be monitored during read accesses.
- The GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit defines whether or not the WAIT pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the WAIT pin of the external memory device asynchronously or synchronously with the GPMC output clock, depending on the access type: synchronous or asynchronous (the GPMC\_CONFIG1\_i[29] READTYPE and GPMC\_CONFIG1\_i[27] WRITETYPE bits).

#### 12.3.3.4.7.3.1.1 Wait Monitoring During Asynchronous Read Access

When WAIT pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with WAIT pin monitoring enabled, the WAIT pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through WAIT pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the WAIT pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

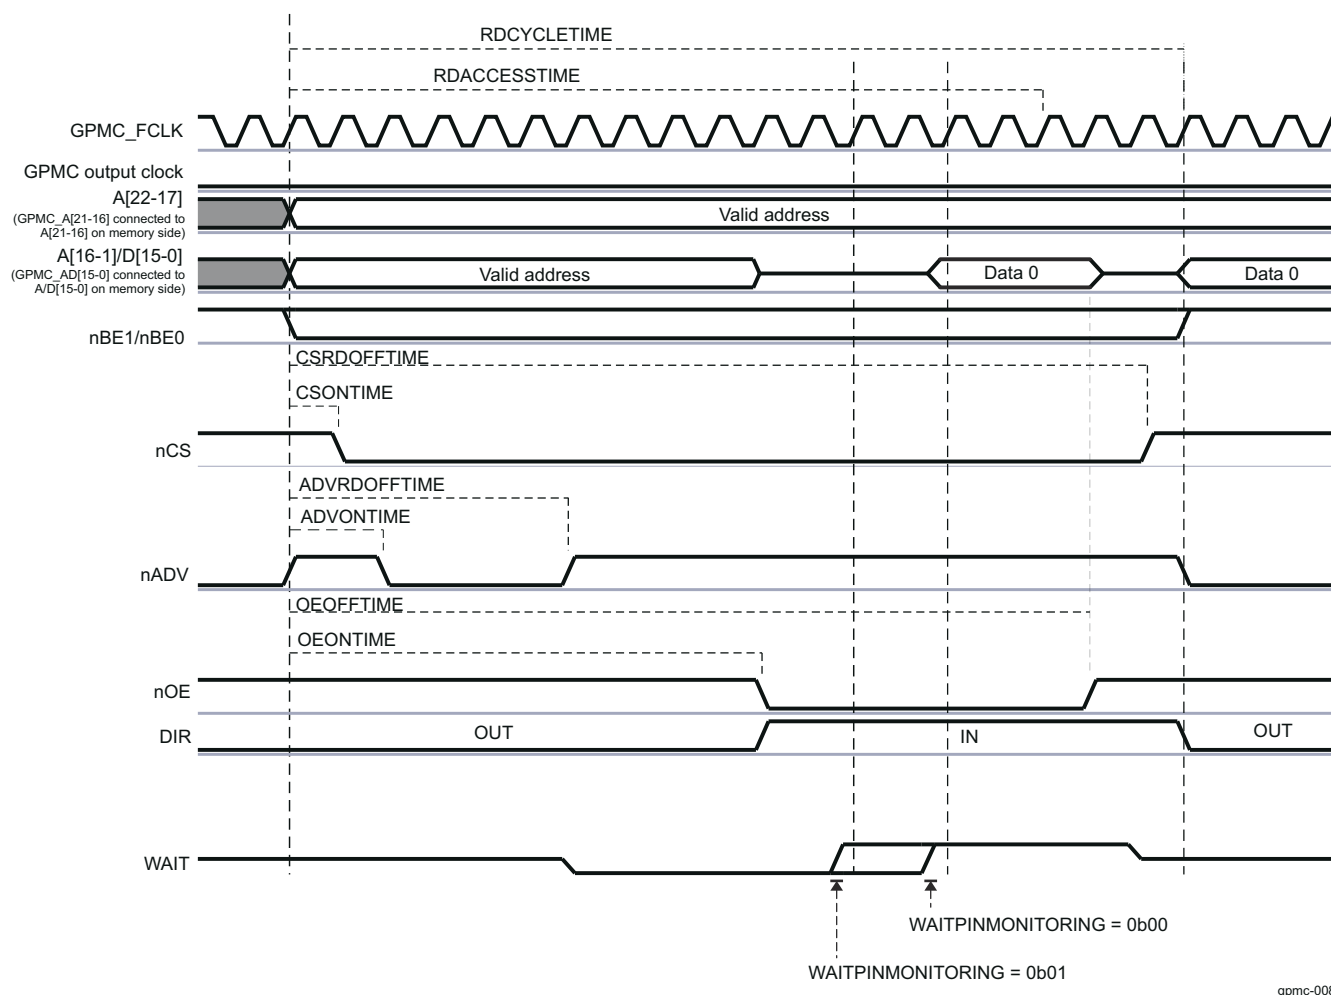

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

#### Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and no GPMC output clock is provided to the external device. Still, because GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 12-152 shows wait behavior during an asynchronous single read access.

**Figure 12-152. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

### Note

The WAIT signal is active low. *GPMC\_CONFIG1*\_*i*[19-18] WAITMONITORINGTIME = 0b00, or 0b01.

#### 12.3.3.4.7.3.1.2 Wait Monitoring During Asynchronous Write Access

When WAIT pin monitoring is enabled for write accesses (*GPMC\_CONFIG1*\_*i*[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the WAIT pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write

time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the `GPMC_CONFIG1_i[19-18]` WAITMONITORINGTIME bit field (where  $i = 0$  to 3).

#### Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the `GPMC_CONFIG1_i[1-0]` GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

#### 12.3.3.4.7.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with WAIT pin monitoring enabled, the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC output clock cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the `GPMC_CONFIG1_i[19-18]` WAITMONITORINGTIME bit field (where  $i = 0$  to 3), and is expressed as a number of GPMC output clock cycles.

In synchronous mode, when WAIT pin monitoring is enabled (the `GPMC_CONFIG1_i[22]` WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

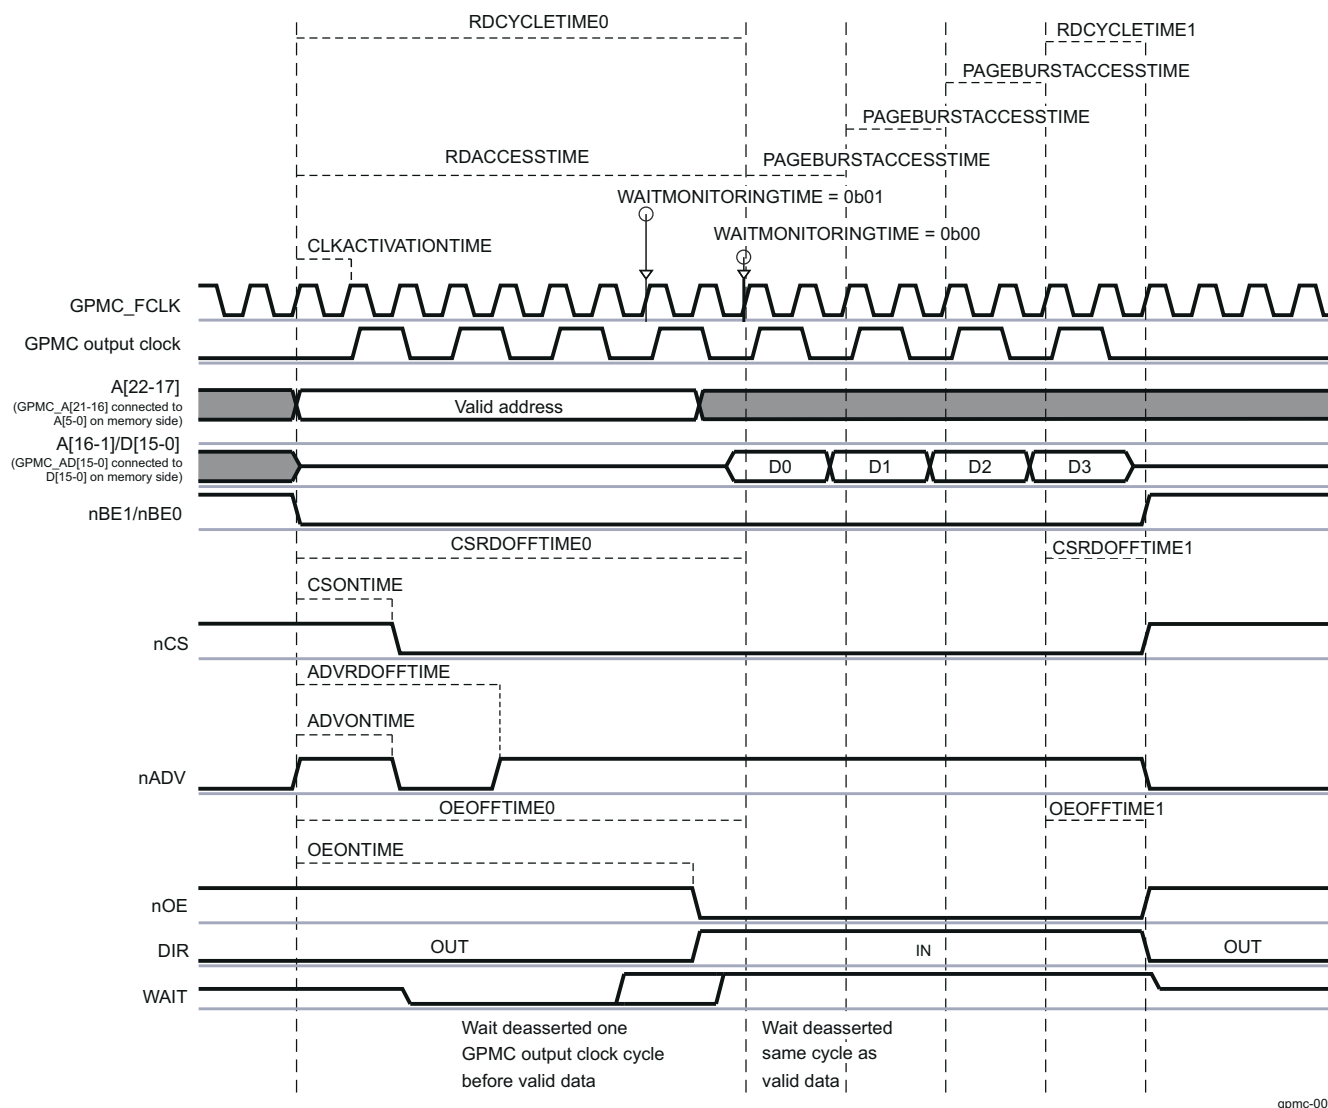

Depending on the programmed value of WAITMONITORINGTIME, the WAIT pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 12-153 shows wait behavior during a synchronous read burst access.

**Figure 12-153. Wait Behavior During a Synchronous Read Burst Access**

### Note

The WAIT signal is active low. WAITMONITORINGTIME = 0b00, 0b01.

#### 12.3.3.4.7.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with WAIT pin monitoring enabled (the *GPMC\_CONFIG1*\_[21] WAITWRITEMONITORING bit), the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

If enabled, external WAIT pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC output clock capture edge of the effective memory device.

WAIT-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

#### Note

WAIT monitoring is supported for all configurations except *GPMC\_CONFIG1\_*[19-18] WAITMONITORINGTIME = 0x0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (the *GPMC\_CONFIG1\_*[1-0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

#### 12.3.3.4.7.3.1.5 Wait With NAND Device

For information about the use of the WAIT pin for communication with a NAND flash external device, see [Section 12.3.3.4.11.2, NAND Device-Ready Pin](#).

#### 12.3.3.4.7.3.1.6 Idle Cycle Control Between Successive Accesses

##### 12.3.3.4.7.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the *GPMC\_CONFIG6\_*[3-0] BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

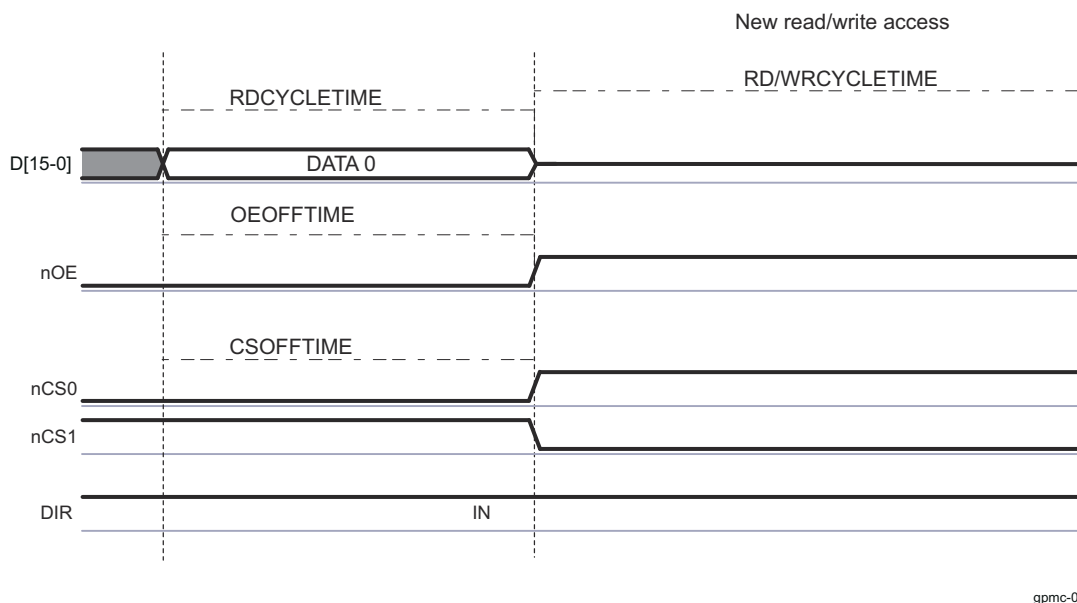

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

#### Note

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with *GPMC\_CONFIG6\_*[3-0] CYCLE2CYCLEDELAY bit field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see [Figure 12-154](#) through [Figure 12-156](#)).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

**Figure 12-154. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)**

**Figure 12-155. Read-to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround**

**Figure 12-156. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround**

#### 12.3.3.4.7.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The *GPMC\_CONFIG6*\_*i*[7] CYCLE2CYCLESAMECSSEN bit (where *i* = 0 to 3) enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the *GPMC\_CONFIG6*\_*i*[11-8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (*GPMC\_CONFIG1*\_*i*[30] READMULTIPLE = 0 or *GPMC\_CONFIG1*\_*i*[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock (CLK)) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 12.3.3.4.7.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the *GPMC\_CONFIG6*\_*i*[6] CYCLE2CYCLEDIFFCSSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select.

CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

### Note

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the *GPMC\_CONFIG6\_i* registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see [Section 3.3.4.7.3.1.6.1](#), *Bus Turnaround (BUSTURNAROUND)*.

[Table 12-175](#) describes the configuration required for idle cycle insertion.

**Table 12-175. Idle Cycle Insertion Configuration**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

#### 12.3.3.4.7.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the `GPMC_CONFIG1_i[4]` TIMEPARAGRANULARITY bit (where *i* stands for the GPMC chip-select *i*, where *i* = 0 to 3). Increasing all access timing parameters allows support of slow devices.

#### 12.3.3.4.7.3.2 DIR Pin

The DIR pin is used to control I/O direction on the GPMC data bus `GPMC_D[15-0]`. Depending on pad multiplexing, this signal can be output and used externally to the device, if required. The DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the DIR pin goes from OUT to IN at `nOE` assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the DIR pin goes from IN to OUT at `RDACCESSTIME + 1 GPMC_FCLK` cycle or when `RDCYCLETIME` completes, whichever occurs last.
  - After a synchronous read access, the DIR pin goes from IN to OUT at `RDACCESSTIME + 2 GPMC_FCLK` cycles or when `RDCYCLETIME` completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the DIR pin is OUT (see [Section 12.3.3.4.8.10, Bus Keeping Support](#)). In non-multiplexed devices, the DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

#### 12.3.3.4.7.3.3 Reset

No reset signal is sent to the external memory device by the GPMC.

`GPMC_RST` is the reset signal for the GPMC module. It is connected and controlled by LPSC8 in `VD_CORE`. That reset signal initializes the internal state-machine and the internal configuration registers.

#### 12.3.3.4.7.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The `nWP` output pin value is controlled through the `GPMC_CONFIG[4]` `WRITEPROTECT` bit which is common for all chip selects.

#### 12.3.3.4.7.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (`nBE1/nBE0`) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses.

#### 12.3.3.4.7.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the `GPMC_ERR_TYPE` register and the address of the illegal access is stored in the `GPMC_ERR_ADDRESS` register. The GPMC keeps only the first error abort information until the `GPMC_ERR_TYPE` register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the `GPMC_ERR_TYPE[0]` `ERRORVALID` bit.

- `ERRORNOTSUPPADD` occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.

- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the interconnect interface.
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the `GPMC_TIMEOUT_CONTROL` register and enabled with the `GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE` bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

#### 12.3.3.4.8 GPMC Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about `GPMC_CLKOUT` and `GPMC_FCLK`, see [Section 12.3.3.4.8.6, GPMC\\_CLKOUT](#).

#### Note

In the following sections, the start access time refers to the time at which the access begins.

##### 12.3.3.4.8.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The `GPMC_CONFIG5_i[4-0] RDCYCLETIME` and `GPMC_CONFIG5_i[12-8] WRCYCLETIME` bit fields (where  $i = 0$  to 3) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC output clock between accesses, `RDCYCLETIME` and `WRCYCLETIME` are expressed in `GPMC_FCLK` cycles and must be multiples of the GPMC output clock cycle. The `RDCYCLETIME` and `WRCYCLETIME` bit fields can be set with a granularity of 1 or 2 through the `GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY` bit.

When `RDCYCLETIME` or `WRCYCLETIME` completes, if they are not already deasserted, all control signals (`nCS`, `nADV/ALE`, `nOE/RE`, `nWE`, and `BE0/CLE`) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

#### Note

All control signals (`CS`, `ADV#/ALE`, `BE0#/CLE`, `WE#`, and GPMC output clock) are kept inactive (`ADV#/ALE`, `BE0#/CLE`, and GPMC output clock at low level; and `CS`, `OE#/RE`, and `WE` at high level) during the idle `GPMC_FCLK` cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (`GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0` or `GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0`, where  $i = 0$  to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (`nCS`, `nADV/ALE`, `nBE0/CLE`, `nWE`, and `nOE/RE`) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, `CYCLE2CYCLESAMECSEN = 1` or `CYCLE2CYCLEDIFFCSEN = 1`), the control signals are forced to their respective default reset values for the number of `GPMC_FCLK` cycles defined in `CYCLE2CYCLEDELAY`.

#### **12.3.3.4.8.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)**

The GPMC\_CONFIG2\_i[3-0] CSONTIME bit field (where i = 0 to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME (read access) and GPMC\_CONFIG2\_i[20-16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG2\_i[7] CSEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. CSEXTRADELAY is especially useful in configurations where GPMC output clock and GPMC\_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **12.3.3.4.8.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)**

The GPMC\_CONFIG3\_i[3-0] ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME (read access) and GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG3\_i[7] ADVEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC output clock and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME, GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME, and GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV

pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see [Section 12.3.3.4.11](#), *GPMC NAND Access Description*.

#### **12.3.3.4.8.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)**

The GPMC\_CONFIG4\_i[3-0] OEONTIME bit field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user must ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[7] OEEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **Note**

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

#### **12.3.3.4.8.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)**

The GPMC\_CONFIG4\_i[19-16] WEONTIME bit field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[23] WEEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### 12.3.3.4.8.6 GPMC\_CLKOUT

The GPMC output clock generated for external synchronous memory or device is GPMC\_CLKOUT.

- The GPMC\_CLKOUT clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device-specific Datasheet.
- The GPMC\_CLKOUT clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLKOUT activation.
- The GPMC\_CLKOUT clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLKOUT clock is kept low when access is defined as asynchronous.

#### CAUTION

When the cycle time completes, the GPMC\_CLKOUT may be high because of the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLKOUT clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

#### Note

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

#### 12.3.3.4.8.7 GPMC Output Clock and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC output clock edge can be controlled in the following ways:

- For the GPMC output clock signal, the GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC output clock allows setup and hold control of the control-signal assertion and deassertion times.
- When the GPMC output clock runs at the GPMC\_FCLK frequency so that GPMC output clock edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by a half-GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

#### 12.3.3.4.8.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME and GPMC\_CONFIG6\_i[28-24] WRACCESSTIME bit fields (where i = 0 to 3). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

#### 12.3.3.4.8.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field (where i = 0 to 3) defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from the start access time to the GPMC\_FCLK rising edge corresponding to the GPMC output clock rising edge used for the first data capture.

GPMC output clock, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC output clock.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see [Section 12.3.3.4.7.3.1, WAIT Pin Monitoring Control](#).

#### 12.3.3.4.8.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC\_CONFIG6\_i[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the GPMC\_WAIT pin is at a valid state two GPMC output clock cycles before WRACCESSTIME completes. For more information about wait monitoring, see [Section 12.3.3.4.7.3.1, WAIT Pin Monitoring Control](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from the start access time to the GPMC output clock rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC output clock edge for a synchronous write access. For more information about wait monitoring, see [Section 12.3.3.4.7.3.1, WAIT Pin Monitoring Control](#).

#### 12.3.3.4.8.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field (where i = 0 to 3) can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

##### 12.3.3.4.8.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access. For more information about wait monitoring, see [Section 12.3.3.4.7.3.1, WAIT Pin Monitoring Control](#).

##### 12.3.3.4.8.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC output clock edge in synchronous write mode. For more information about wait monitoring, see [Section 12.3.3.4.7.3.1, WAIT Pin Monitoring Control](#).

#### **12.3.3.4.8.10 Bus Keeping Support**

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

#### **12.3.3.4.9 GPMC NOR Access Description**

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC\_CONFIG1\_i[29] READTYPE bit (where i = 0 to 3). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC\_CONFIG1\_i[27] WRITETYPE bit where (i = 0 to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC\_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC output clock (CLK), RdAccessTime, WrAccessTime, and WAIT pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

---

#### **Note**

The address bus and nBE[1-0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

---

#### **12.3.3.4.9.1 Asynchronous Access Description**

This section describes:

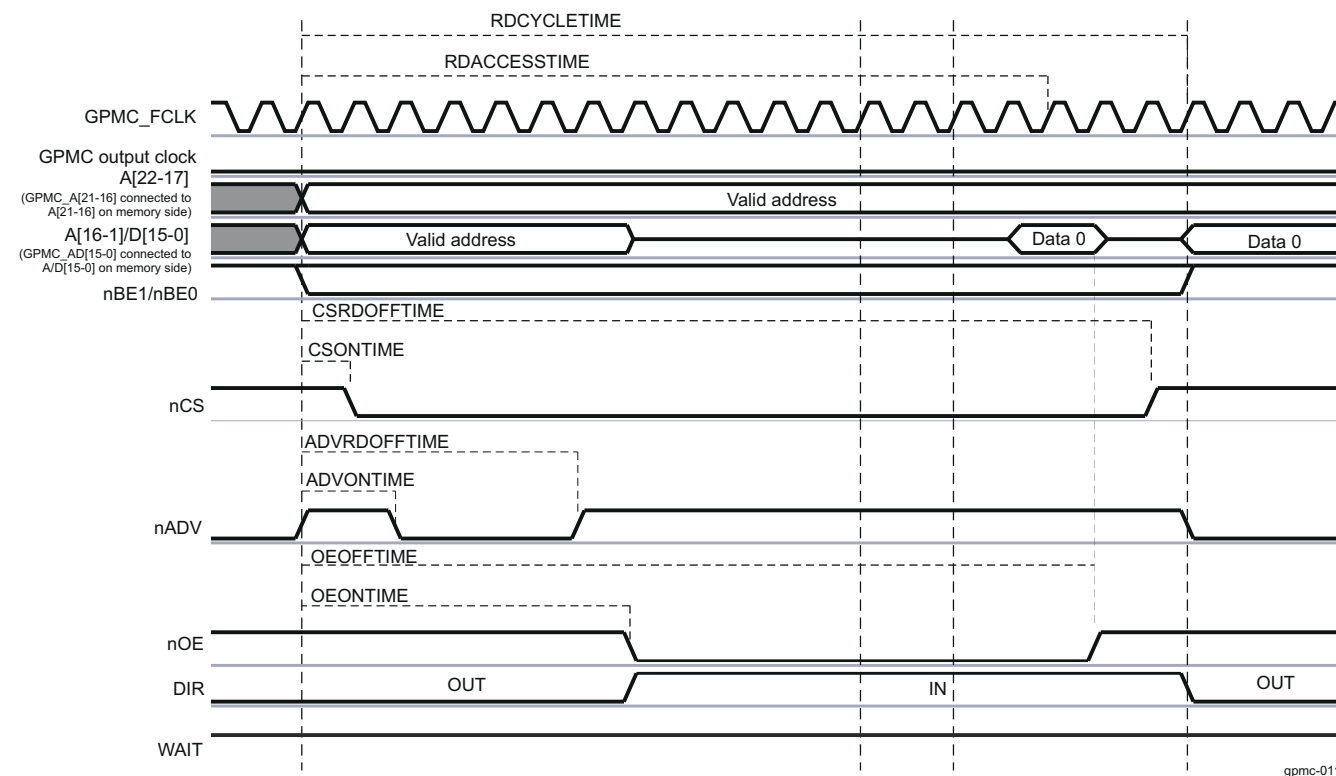

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC output clock is not provided outside the GPMC and is kept low.

##### **12.3.3.4.9.1.1 Access on Address/Data Multiplexed Devices**

##### **12.3.3.4.9.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device**

[Figure 12-157](#) shows an asynchronous single read operation on an address/data-multiplexed device.

**Figure 12-157. Asynchronous Single Read on an Address/Data-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-215](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

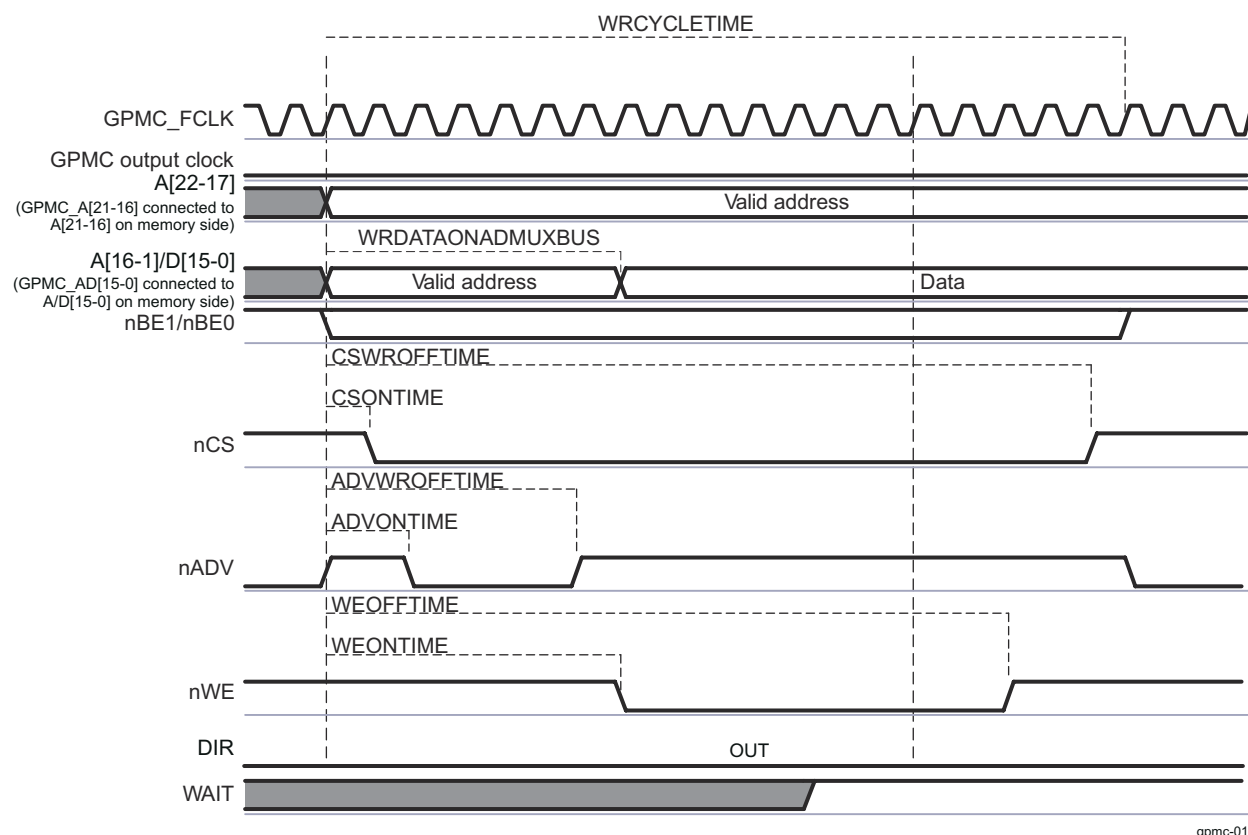

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.3.4.7.2.3, Address/Data-Multiplexing Interface](#).

Address bits (A[16-1] from a GPMC perspective, A[15-0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC\_A[22-16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the *GPMC\_CONFIG2\_i[3-0]* CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the *GPMC\_CONFIG2\_i[12-8]* CSROFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the *GPMC\_CONFIG3\_i[3-0]* ADVONTIME bit field.
  - nADV deassertion time is controlled by the *GPMC\_CONFIG3\_i[12-8]* ADVRD OFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the *GPMC\_CONFIG4\_i[3-0]* OEONTIME bit field.
  - nOE deassertion time is controlled by the *GPMC\_CONFIG4\_i[12-8]* OE OFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the *GPMC\_CONFIG5\_i[20-16]* RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the
- *GPMC\_CONFIG5\_i[4-0]* RDCYCLETIME parameter.

gpmc-013

**Figure 12-159. Asynchronous Single-Write on an Address/Data-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-215](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 12.3.3.4.7.2.3, Address/Data-Multiplexing Interface](#).

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC\_CONFIG5\_i[12-8] WRCYCLETIME parameter.

Address bits A[16-1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[22-17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS time.

### Note

Multiple write access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 12.3.3.4.8.10, Bus Keeping Support](#).

### 12.3.3.4.9.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

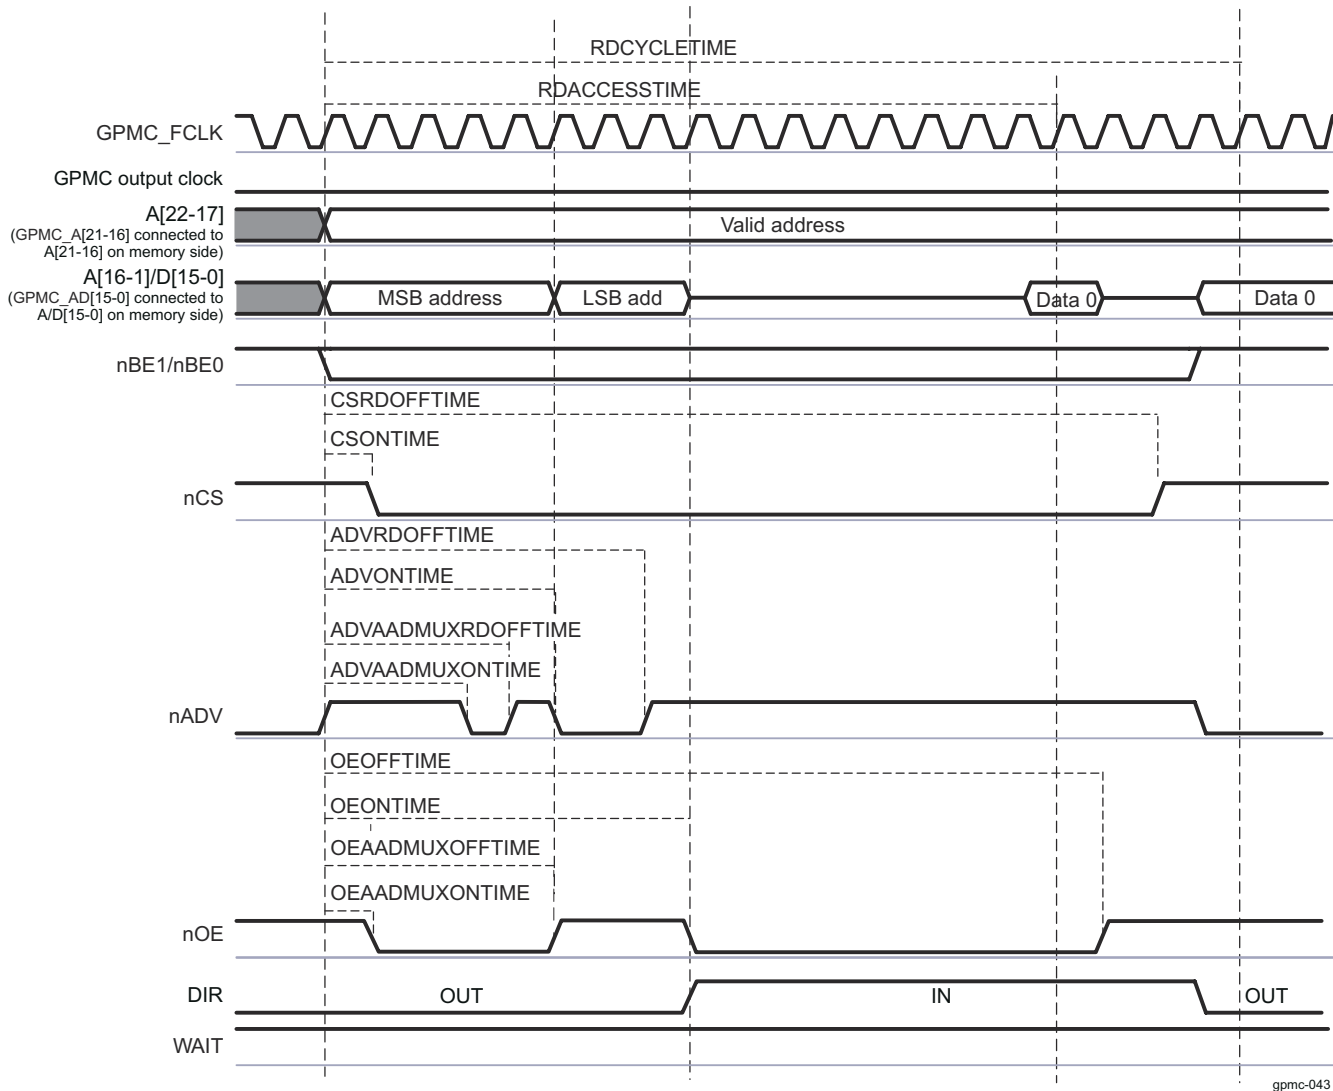

If the `GPMC_CONFIG1_i[28]` `WRITEMULTIPLE` bit is enabled (0x1) with the `GPMC_CONFIG1_i[27]` `WRITETYPE` bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.3.4.9.3, Asynchronous and Synchronous Accesses in non-multiplexed Mode](#).

### 12.3.3.4.9.1.2 Access on Address/Address/Data-Multiplexed Devices

#### 12.3.3.4.9.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 12-160 shows an asynchronous single-read operation on an AAD-multiplexed device.

**Figure 12-160. Asynchronous Single Read on an AAD-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-215](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE

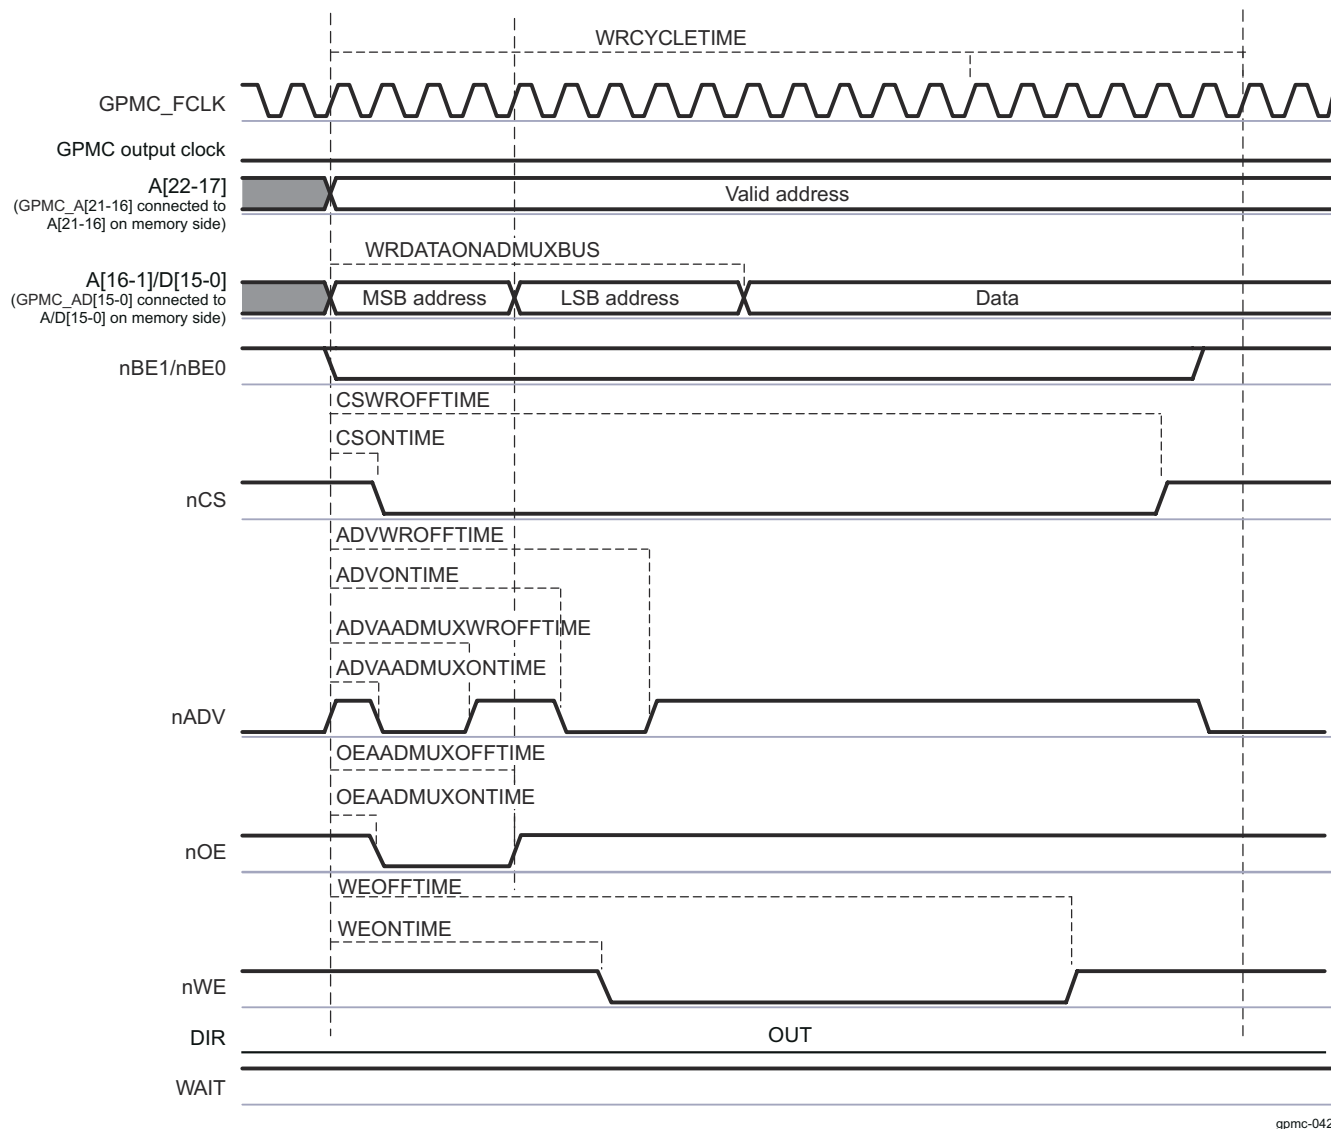

driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the *GPMC\_CONFIG3\_i*[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the *GPMC\_CONFIG3\_i*[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the *GPMC\_CONFIG3\_i*[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the *GPMC\_CONFIG3\_i*[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the *GPMC\_CONFIG4\_i*[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the *GPMC\_CONFIG3\_i*[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the *GPMC\_CONFIG4\_i*[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the *GPMC\_CONFIG4\_i*[12-8] OEOFFTIME bit field.

#### 12.3.3.4.9.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 12-161 shows an asynchronous single-write operation on an AAD-multiplexed device.

gpmc-042

**Figure 12-161. Asynchronous Single Write on an AAD-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-215](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See [Table 12-206, NAND Memory Type](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the *GPMC\_CONFIG3\_i*[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the *GPMC\_CONFIG3\_i*[30-28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the *GPMC\_CONFIG3\_i*[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the *GPMC\_CONFIG3\_i*[20-16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:

- nOE assertion time is controlled by the *GPMC\_CONFIG4\_i*[6-4] OEAADMUXONTIME bit field.
- nOE deassertion time is controlled by the *GPMC\_CONFIG3\_i*[15-13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the *GPMC\_CONFIG6\_i*[19-16] WRDATAONADMUXBUS parameter.

#### 12.3.3.4.9.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the *GPMC\_CONFIG1\_i*[28] WRITEMULTIPLE bit is enabled (0x1) with the *GPMC\_CONFIG1\_i*[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.3.4.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

#### 12.3.3.4.9.2 Synchronous Access Description

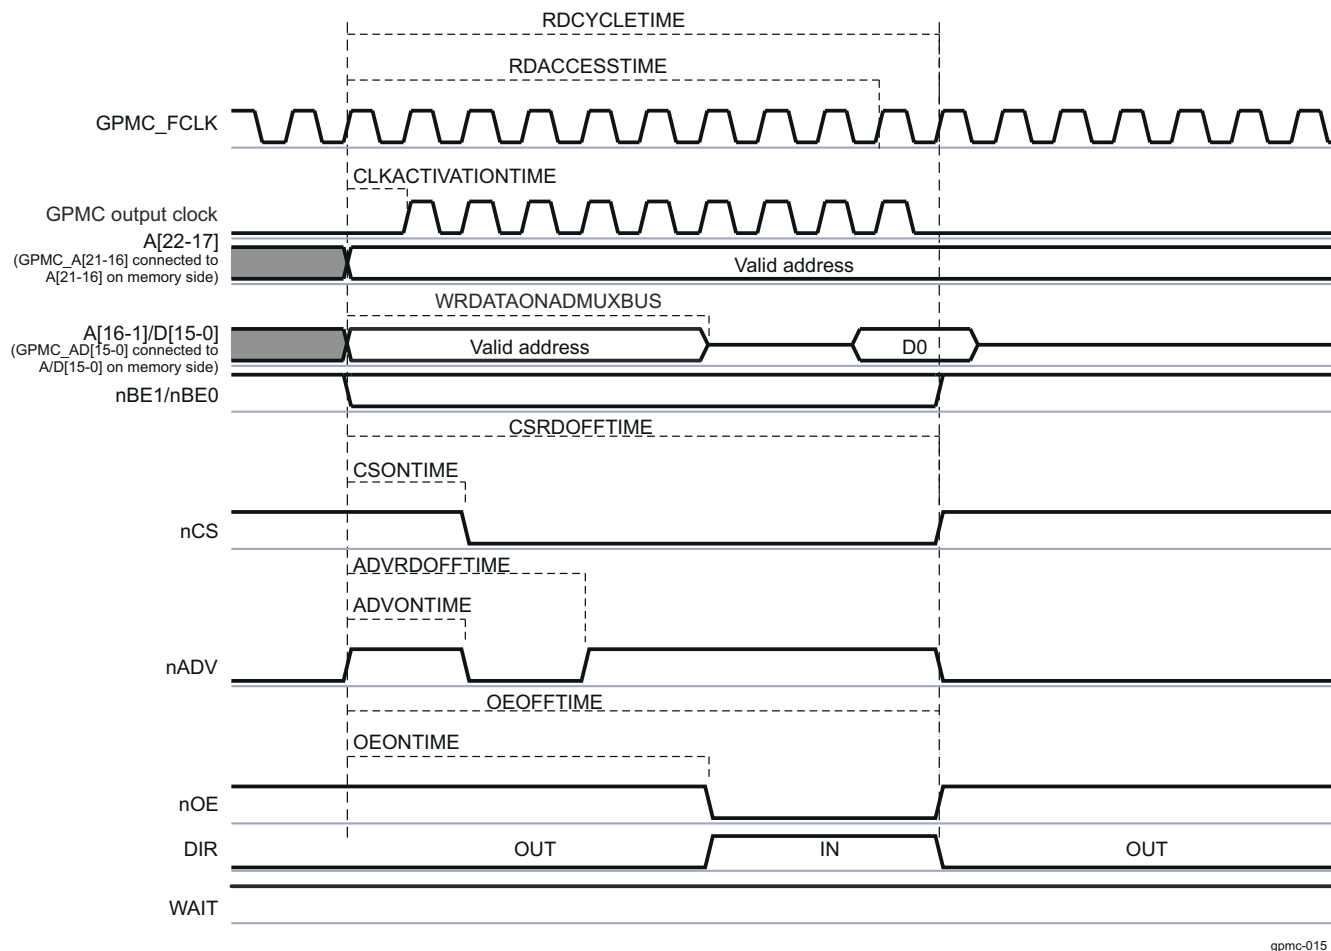

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (non-multiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on non-multiplexed devices, see [Section 12.3.3.4.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

In synchronous operations:

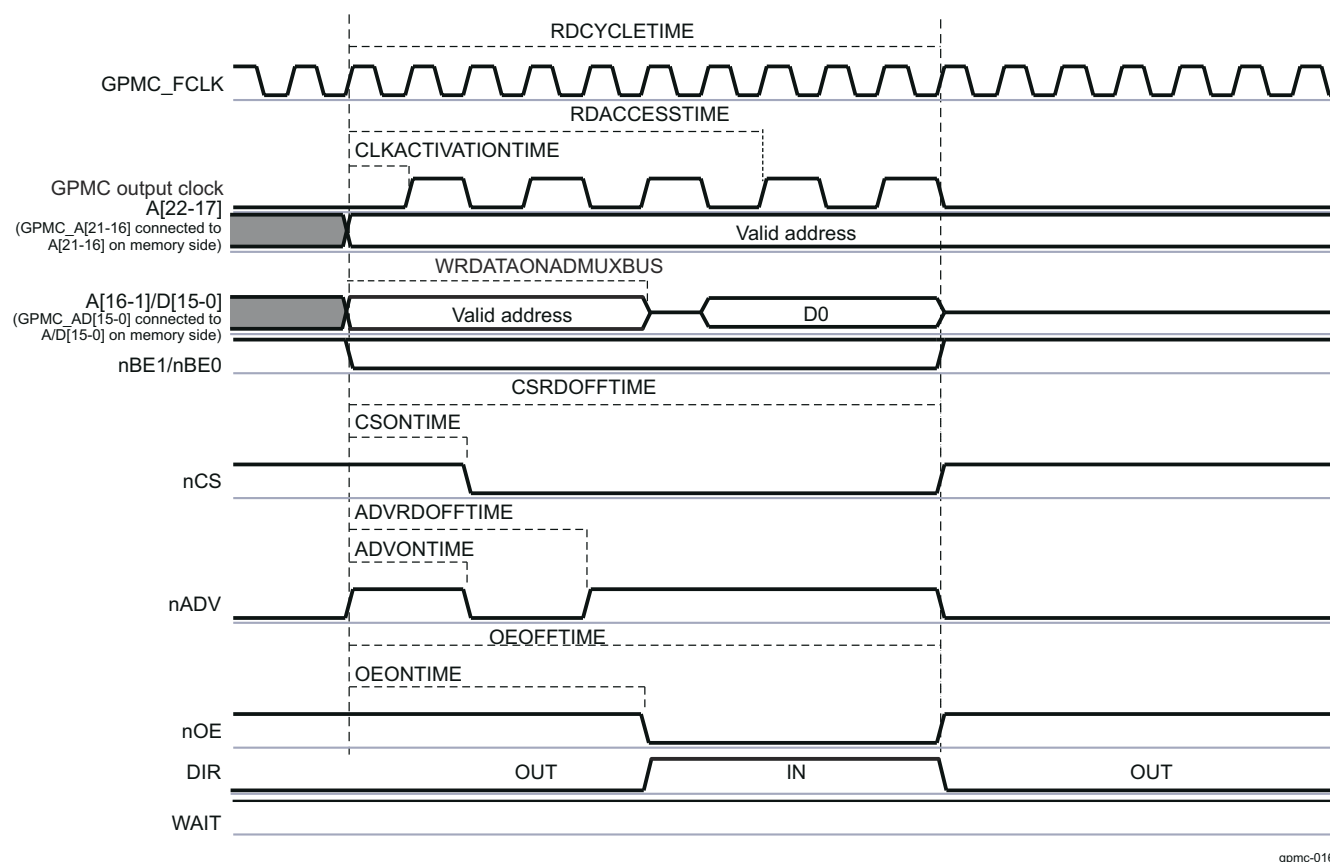

- The GPMC\_CLKOUT clock is provided outside the GPMC when accessing the memory device.
- The GPMC\_CLKOUT clock is derived from the GPMC\_FCLK clock using the *GPMC\_CONFIG1\_i*[1-0] GPMCFCLKDIVIDER bit field. In the following section *i* stands for the chip-select number, *i* = 0 to 3.
- The *GPMC\_CONFIG1\_i*[26-25] CLKACTIVATIONTIME bit field specifies that the GPMC\_CLKOUT is provided outside the GPMC for 0 to 2 GPMC\_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

##### 12.3.3.4.9.2.1 Synchronous Single Read

[Figure 12-162](#) and [Figure 12-163](#) show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

**Figure 12-162. Synchronous Single Read (GPMCCLKDIVIDER = 0)**

**Figure 12-163. Synchronous Single Read (GPMCFCLKDIVIDER = 1)**

For formulas to calculate timing parameters, see [Section 12.3.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-215](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.3.4.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSOFTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CSRD OFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEQOFTIME bit field.
- Initial latency for the first read data is controlled by GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRD OFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.3.4.8.10](#), *Bus Keeping Support*.

#### **12.3.3.4.9.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)**

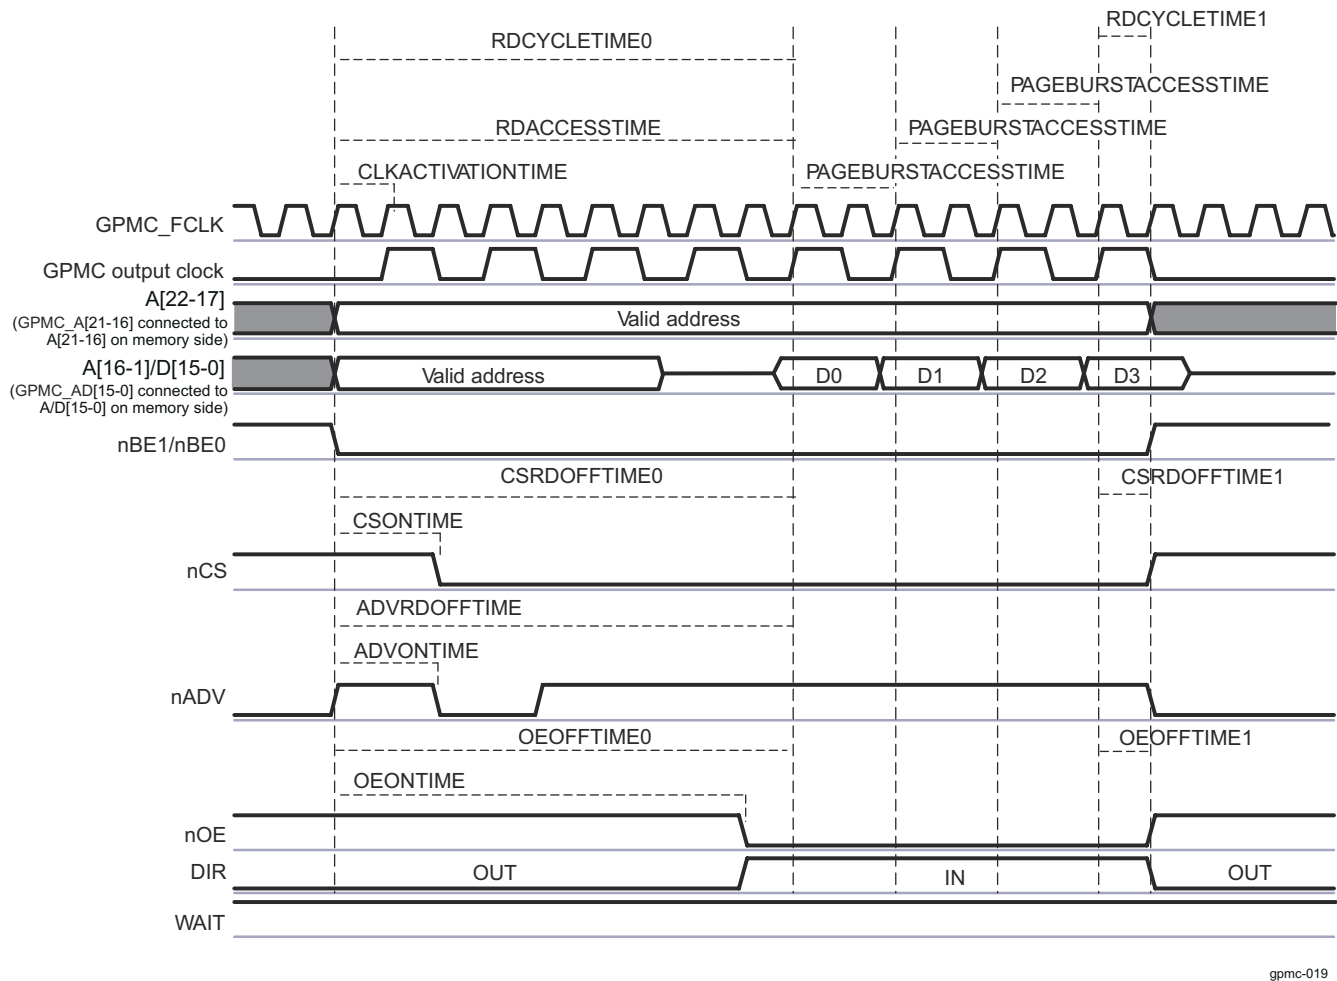

[Figure 12-164](#) and [Figure 12-165](#) show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

gpmc-018

**Figure 12-164. Synchronous Multiple (Burst) Read (GPMCCLKDIVIDER = 0)**

**Figure 12-165. Synchronous Multiple (Burst) Read (GPMCCLKDIVIDER = 1)**

When the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See [Table 12-201, NOR Memory Type](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC\_CLKOUT cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC\_CONFIG1\_i[1-0] GPMCCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

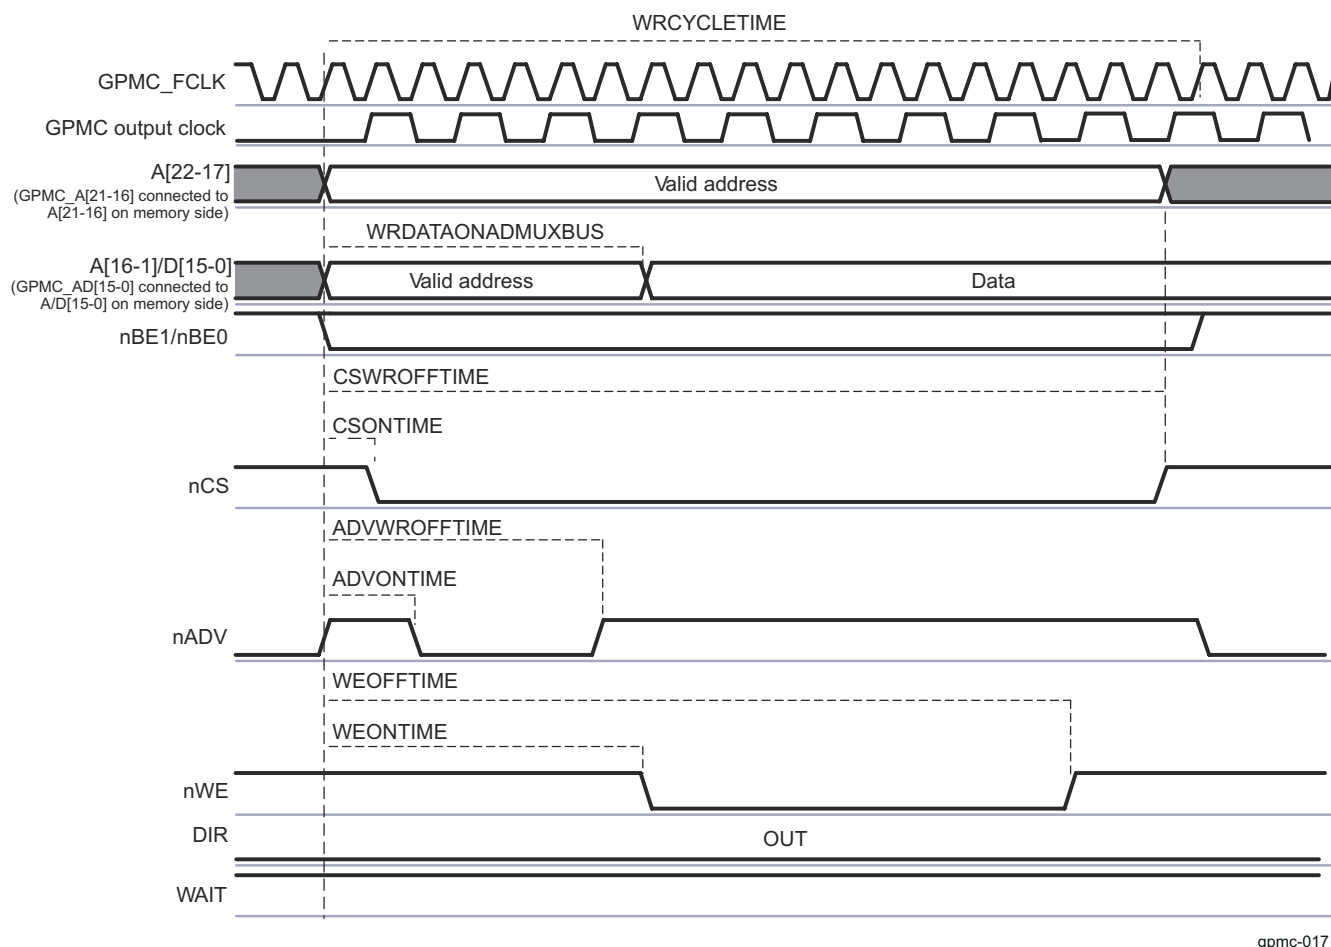

Total access time GPMC\_CONFIG5\_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-165](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.3.4.8.10, Bus Keeping Support](#).

Burst wraparound is enabled through the GPMC\_CONFIG1\_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word linear burst access to wrap within its burst-length boundary through the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field.

### 12.3.3.4.9.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

gpmc-017

**Figure 12-166. Synchronous Single Write on an Address/Data-Multiplexed Device**

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16-1]) until the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

### 12.3.3.4.9.2.4 Synchronous Multiple (Burst) Write

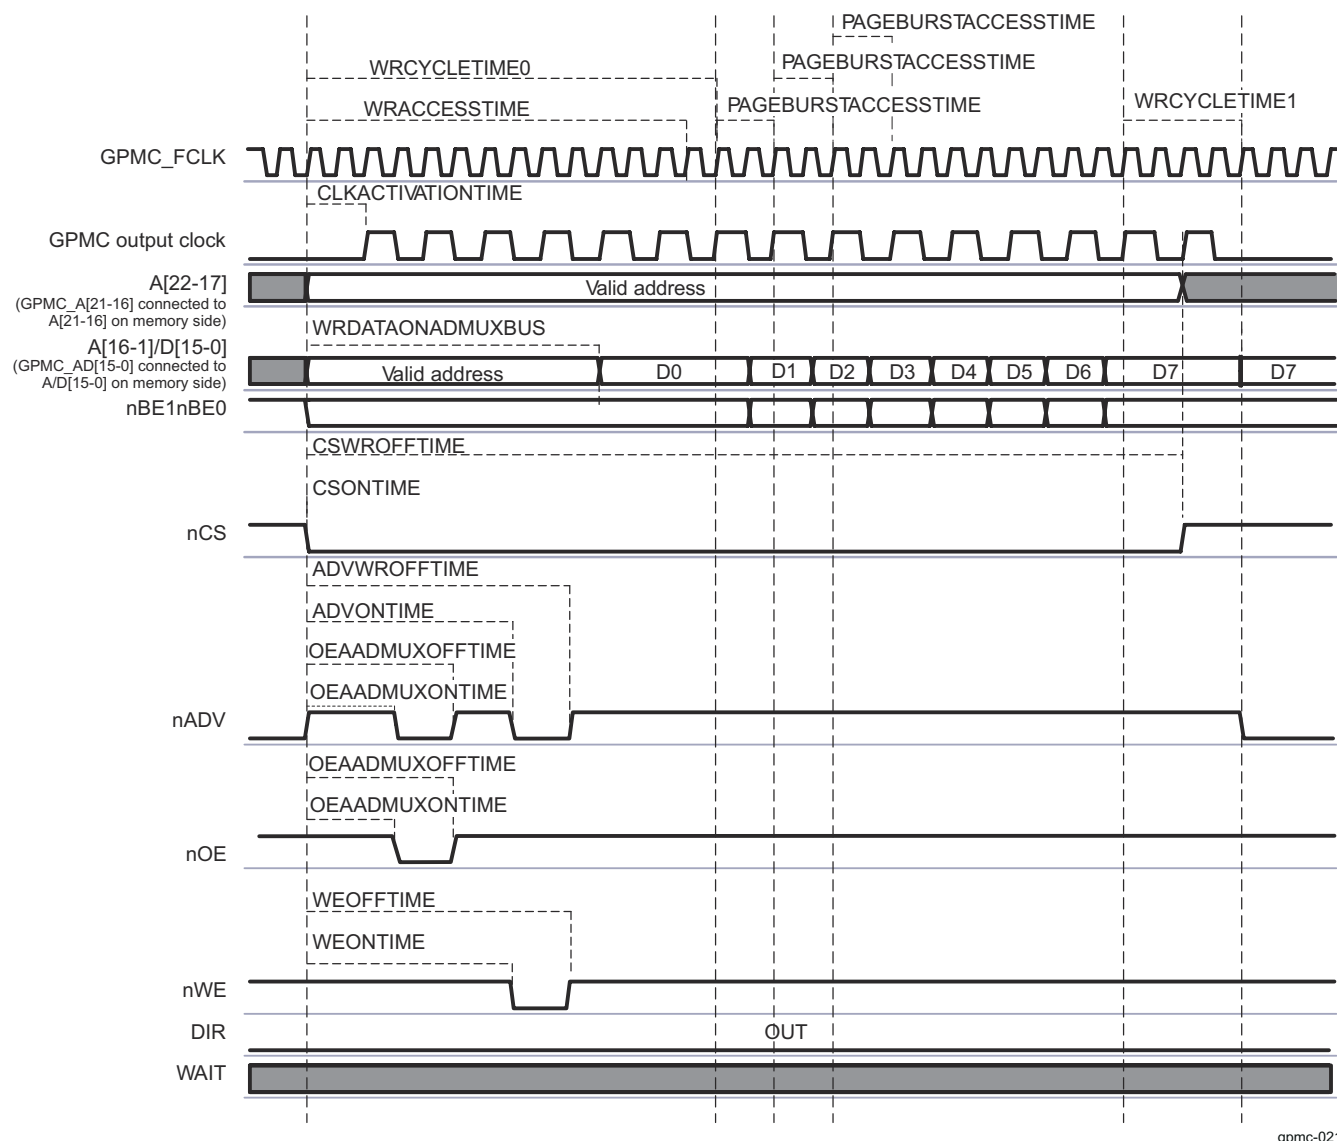

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 12-167 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 12-167. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

Figure 12-168 shows the same synchronous burst write access when the chip-select is configured in address/ address/data-multiplexed (AAD-multiplexed) mode.

**Figure 12-168. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode**

The first data of the burst is driven on the A/D bus at the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS bit field.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.3.4.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field (where i = 0 to 3) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC\_CONFIG2\_i[20-16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME bit field.

- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field.

#### Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG4\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until GPMC\_CONFIG5\_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC\_CONFIG6\_i[28-24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC\_CONFIG5\_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-167](#), the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 12.3.3.4.8.10, Bus Keeping Support](#).

#### 12.3.3.4.9.3 Asynchronous and Synchronous Accesses in non-multiplexed Mode

Page mode is available only in non-multiplexed mode.

- Asynchronous single-read operation on a non-multiplexed device
- Asynchronous single-write operation on a non-multiplexed device
- Asynchronous multiple- (page mode) read operation on a non-multiplexed device
- Synchronous operations on a non-multiplexed device

##### 12.3.3.4.9.3.1 Asynchronous Single-Read Operation on non-multiplexed Device

[Figure 12-169](#) shows an asynchronous single-read operation on a non-multiplexed device.

**Figure 12-169. Asynchronous Single Read on an Address/Data-non-multiplexed Device**

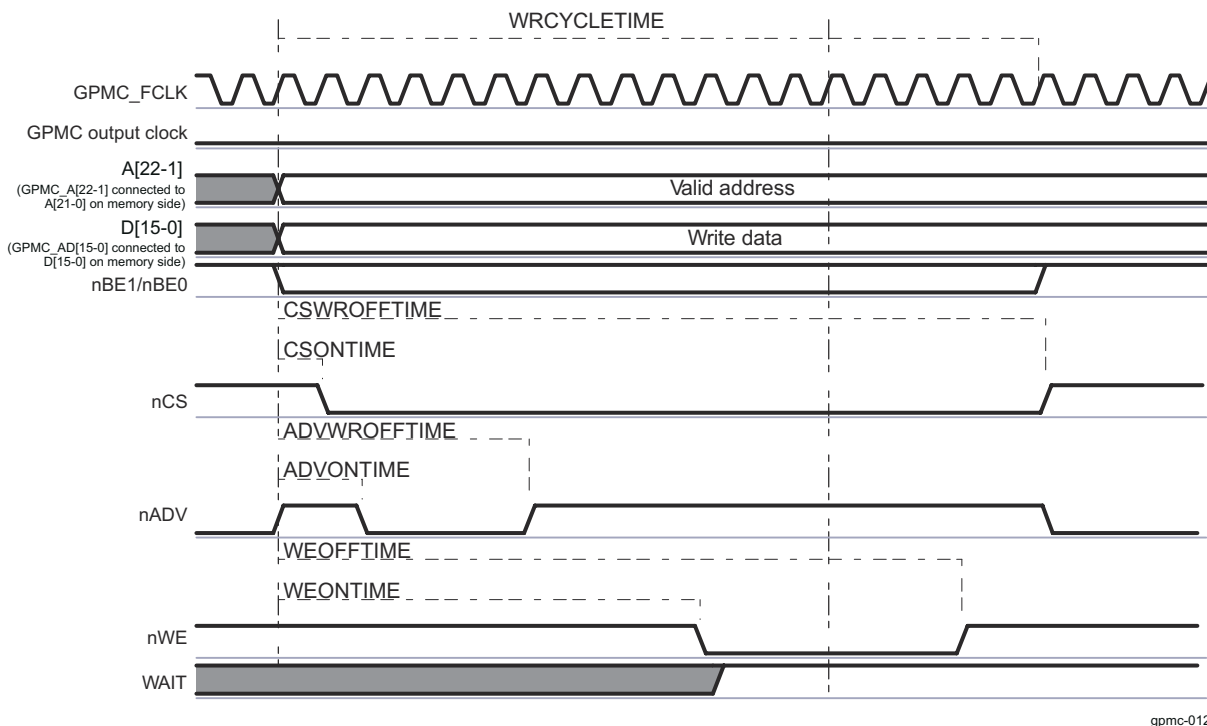

The 22-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[22-1] and the 16-bit data is driven onto the data bus D[15-0].

Read data is latched at GPMC\_CONFIG1\_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC\_CONFIG1\_5[4-0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-206, NAND Memory Type](#)).

#### 12.3.3.4.9.3.2 Asynchronous Single-Write Operation on non-multiplexed Device

[Figure 12-170](#) shows an asynchronous single-write operation on a non-multiplexed device.

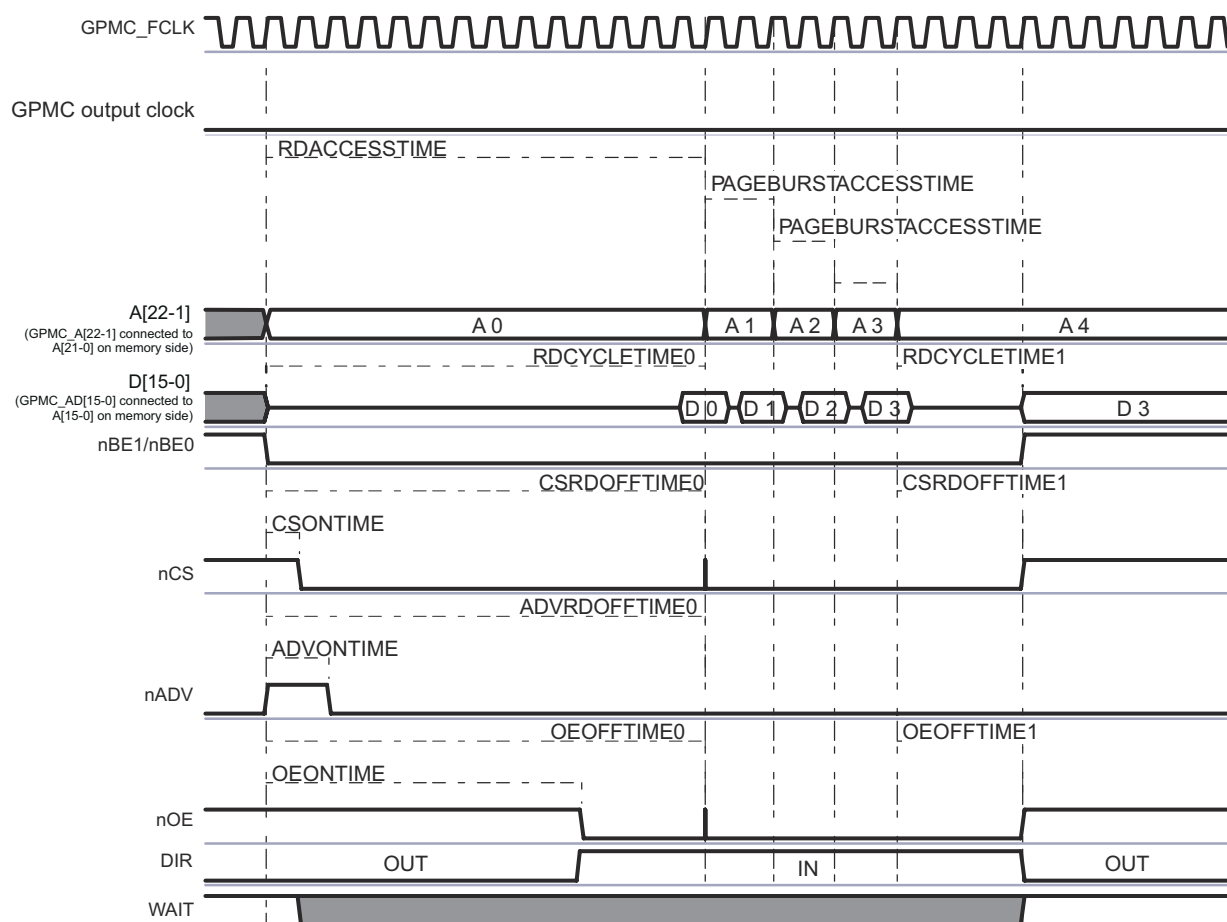

**Figure 12-170. Asynchronous Single Write on an Address/Data-non-multiplexed Device**

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-206](#)).

#### 12.3.3.4.9.3.3 Asynchronous Multiple (Page Mode) Read Operation on non-multiplexed Device

[Figure 12-171](#) shows an asynchronous multiple-read operation on a non-multiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

gpmc-014

**Figure 12-171. Asynchronous Multiple (Page Mode) Read**

### Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-206](#)).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at  $GPMC\_CONFIG5\_i[20-16]$  RDACCESSTIME completion time (where  $i = 0$  to 3). The end of the access is defined by the  $GPMC\_CONFIG5\_i[4-0]$  RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the  $GPMC\_CONFIG5\_i[27-24]$  PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the  $GPMC\_CONFIG5\_i[4-0]$  RDCYCLETIME bit field.

- In [Figure 12-171](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

#### 12.3.3.4.9.3.4 Synchronous Operations on a non-multiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 12.3.3.5.3](#), *GPMC Configuration in NOR Mode*.

#### 12.3.3.4.9.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC\_CONFIG1\_i[30] READMULTIPLE and GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bits (where i = 0 to 3) are associated with the READTYPE and WRITETYPE parameters.

#### Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

#### 12.3.3.4.9.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 3). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC\_CONFIG1\_i[31] WRAPBURST bit (where i = 0 to 3) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only

fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the `GPMC_CONFIG1_i[24-23]` `ATTACHEDDEVICEPAGELENGTH` bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of `ATTACHEDDEVICEPAGELENGTH`. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), `WAIT` pin monitoring must be enabled to dynamically control data access completion within the burst.

#### Note

When the system burst request length is less than the value of `ATTACHEDDEVICEPAGELENGTH`, the GPMC proceeds with the required accesses.

#### 12.3.3.4.10 GPMC pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The `GPMC_CONFIG1_i[11-10]` `DEVICETYPE` bit field (where  $i = 0$  to 3) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its `WAIT` signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional `WAIT` signal capability or a minimum `nCS` high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

#### 12.3.3.4.11 GPMC NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

### 12.3.3.4.11.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model depends on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

#### 12.3.3.4.11.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC\_CONFIG7\_i register (where i = 0 to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

#### CAUTION

To allow correct command, address, and data-access controls, the GPMC\_CONFIG1\_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in [Table 12-176](#). Failure to comply with these settings corrupts the NAND interface protocol.

**Table 12-176. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] <sup>(1)</sup>	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26-25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24-23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19-18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17-16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13-12]	0b00 or 0b01	8- or 16-bit interface

**Table 12-176. Chip-Select Configuration for NAND Interfacing (continued)**

Bit Field	Register	Value	Comments
DEVICETYPE	GPMC_CONFIG1_i[11-10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9-8]	0b00	non-multiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1-0]	Don't care	Asynchronous mode

(1)  $i = 0$  to 3

The GPMC\_CONFIG1\_i to GPMC\_CONFIG4\_i registers (where  $i = 0$  to 3) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

#### 12.3.3.4.11.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i register locations (where  $i = 0$  to 3) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i register locations must be posted for faster operations (where  $i = 0$  to 3). The GPMC\_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC\_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i registers (where  $i = 0$  to 3) are 32-bit word locations, which means any 32- or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC\_NAND\_COMMAND\_i and a GPMC\_NAND\_ADDRESS\_i (where  $i = 0$  to 3) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

#### 12.3.3.4.11.1.3 Command Latch Cycle

Writing data at the GPMC\_NAND\_COMMAND\_i location (where  $i = 0$  to 3) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.

- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 12-172 shows the NAND command latch cycle.

**Figure 12-172. NAND Command Latch Cycle**

#### Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

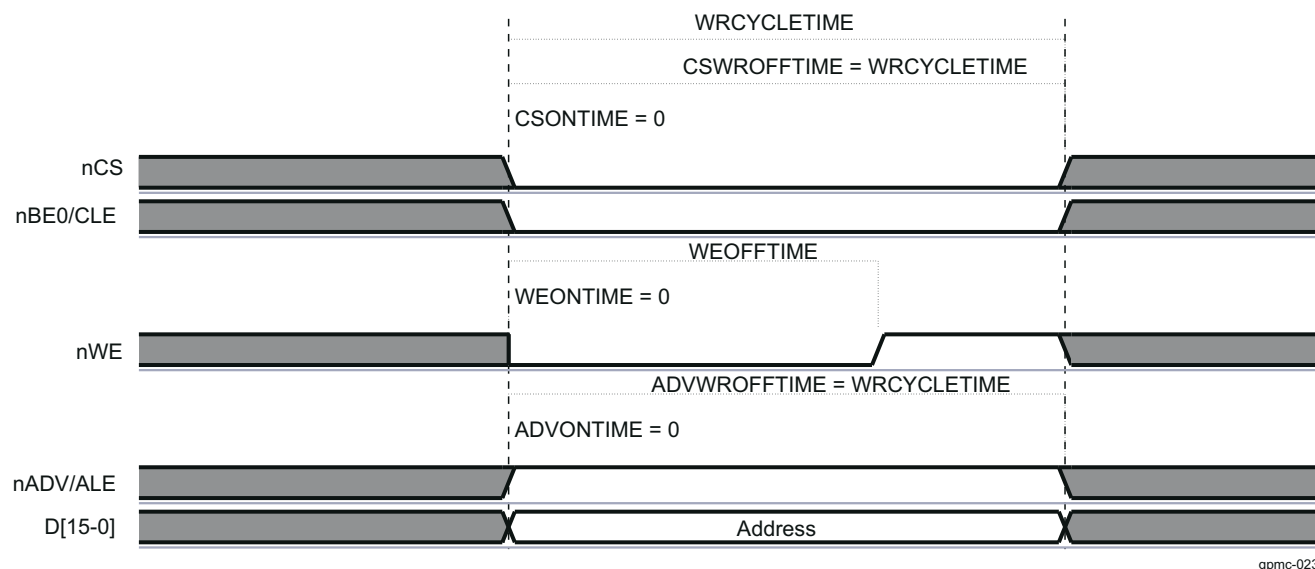

NAND flash memories do not use byte-enable signals.

#### 12.3.3.4.11.1.4 Address Latch Cycle

Writing data at the *GPMC\_NAND\_ADDRESS\_i* location (where *i* = 0 to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 12-173 shows the NAND address latch cycle.

**Figure 12-173. NAND Address Latch Cycle**

### Note

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

#### 12.3.3.4.11.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC\_NAND\_DATA\_i location (where i = 0 to 3) mapped in the chip-select-associated control register region. GPMC\_NAND\_DATA\_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC\_NAND\_DATA\_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 12-174 shows the NAND data read cycle.

**Figure 12-174. NAND Data Read Cycle**

Writing data to the GPMC\_NAND\_DATA\_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- **nCS** is controlled by the **CSONTIME** and **CSWROFFTIME** timing parameters.
- **nWE** is controlled by the **WEONTIME** and **WEOFFTIME** timing parameters.
- **ALE**, **CLE**, and **nRE** (**nOE**) are maintained inactive.

Figure 12-175 shows the NAND data write cycle.

**Figure 12-175. NAND Data Write Cycle**

#### 12.3.3.4.11.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by **nCS**-to-data-valid timing and has faster **nRE**-to-data-valid timing. Successive accesses with **nCS** deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that **nCS** always stays low between two accesses to the same chip-select. Moreover, an **nCS** deassertion time between the same chip-select NAND accesses is likely to be required as follows: the **nCS** deassertion requires programming **CYCLETIME** and **RDACCESSTIME** according to the **nCS**-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see [Section 12.3.3.4.11.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

#### **12.3.3.4.11.1.7 Read and Write Access Size Adaptation**

##### **12.3.3.4.11.1.7.1 8-Bit-Wide NAND Device**

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

##### **12.3.3.4.11.1.7.2 16-Bit-Wide NAND Device**

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

#### 12.3.3.4.11.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

#### Note

If a read access to a NAND flash is done using WAIT monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the WAIT pin monitoring for read and write accesses (that is, set the `GPMC_CONFIG1_i[21]` WAITWRITEMONITORING and `GPMC_CONFIG1_i[22]` WAITREADMONITORING bits to 0, where  $i = 0$  to 3), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where  $x = 0$  to 1) of the `GPMC_STATUS`.
- Configure an interrupt that is generated on the WAIT signal change (through the `GPMC_IRQENABLE` register bits[11-8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the `GPMC_STATUS` register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

##### 12.3.3.4.11.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the `GPMC_STATUS[9-8]` WAITxSTATUS bit (where  $x = 0$  to 1). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

##### 12.3.3.4.11.2.2 Ready Pin Monitored by Hardware Interrupt

Each GPMC\_WAIT input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the `GPMC_CONFIG[9-8]` WAITxPINPOLARITY bits (where  $x = 0$  to 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where  $x = 0$  to 1) of the `GPMC_IRQSTATUS` register according to the GPMC\_WAIT pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the `GPMC_IRQENABLE` register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the `GPMC_IRQSTATUS` register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the `GPMC_IRQSTATUS` register according to the GPMC\_WAIT pin used for NAND device ready signal monitoring.

### 12.3.3.4.11.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the `GPMC_ECC_CONFIG[16]` ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhuri-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the `GPMC_ECC_CONFIG[3-1]` ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

#### 12.3.3.4.11.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

#### 12.3.3.4.11.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (`GPMC_ECCj_RESULT`, where  $j = 1$  to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the `GPMC_ECCj_RESULT` register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The *GPMC\_ECC\_CONTROL*[3-0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the *GPMC\_ECCj\_RESULT* register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the *GPMC\_ECCj\_RESULT* register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The *GPMC\_ECC\_CONTROL*[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each *GPMC\_ECCj\_RESULT* register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZ bits (where j = 1 to 9) in the *GPMC\_ECC\_SIZE\_CONFIG* register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the *GPMC\_ECCj\_RESULT* register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine *GPMC\_ECCj\_RESULT* registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZ bits are set to 0, and the ECC9RESULTSIZ bit is set to 1.

#### 12.3.3.4.11.3.1.2 ECC Enabling

The *GPMC\_ECC\_CONFIG*[3-1] ECCCS bit field selects the allocated chip-select. The *GPMC\_ECC\_CONFIG*[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZ (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 12-177 describes the ECC enable settings.

**Table 12-177. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	<i>GPMC_ECC_CONFIG</i>	0–3	Selects the chip-select where ECC is computed
ECC16B	<i>GPMC_ECC_CONFIG</i>	0/1	Selects column number for ECC calculation
ECCCLEAR	<i>GPMC_ECC_CONTROL</i>	0–7	Clears all ECC result registers
ECCPOINTER	<i>GPMC_ECC_CONTROL</i>	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

**Table 12-177. ECC Enable Settings (continued)**

Bit Field	Register	Value	Comments
ECSSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECSSIZE1
ECSSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECSSIZE0
ECCjRESULTSIZEn (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

### 12.3.3.4.11.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 12-176 and Figure 12-177. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

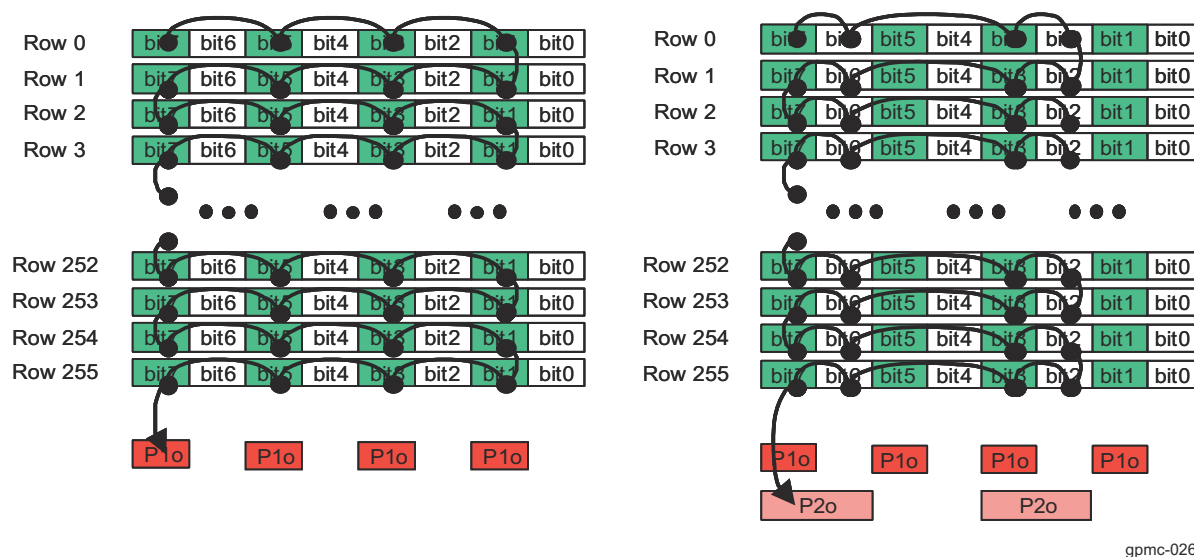

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

**Figure 12-176. Hamming Code Accumulation Algorithm (1/2)**

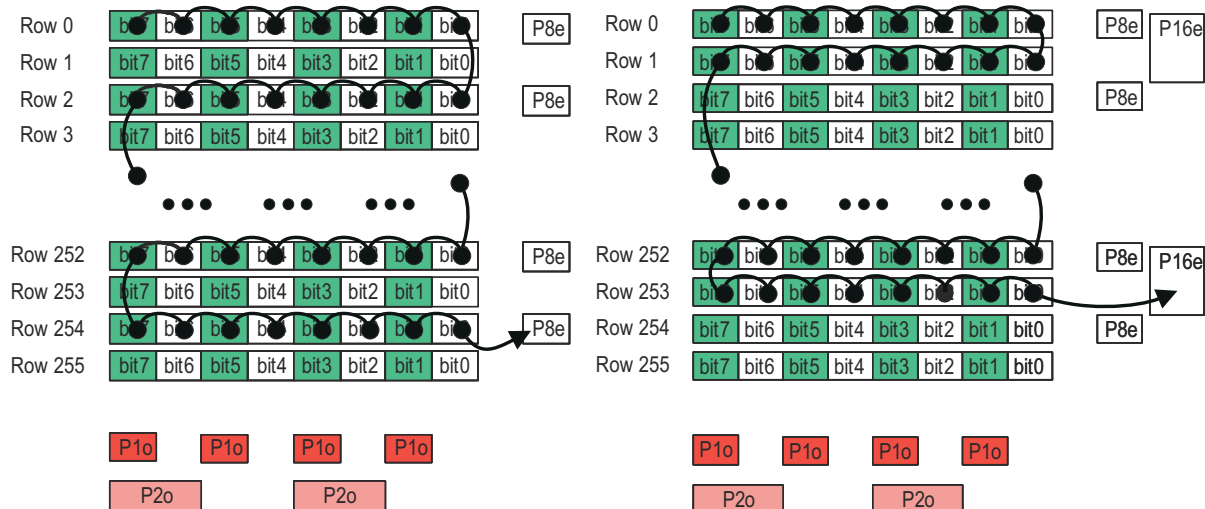

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

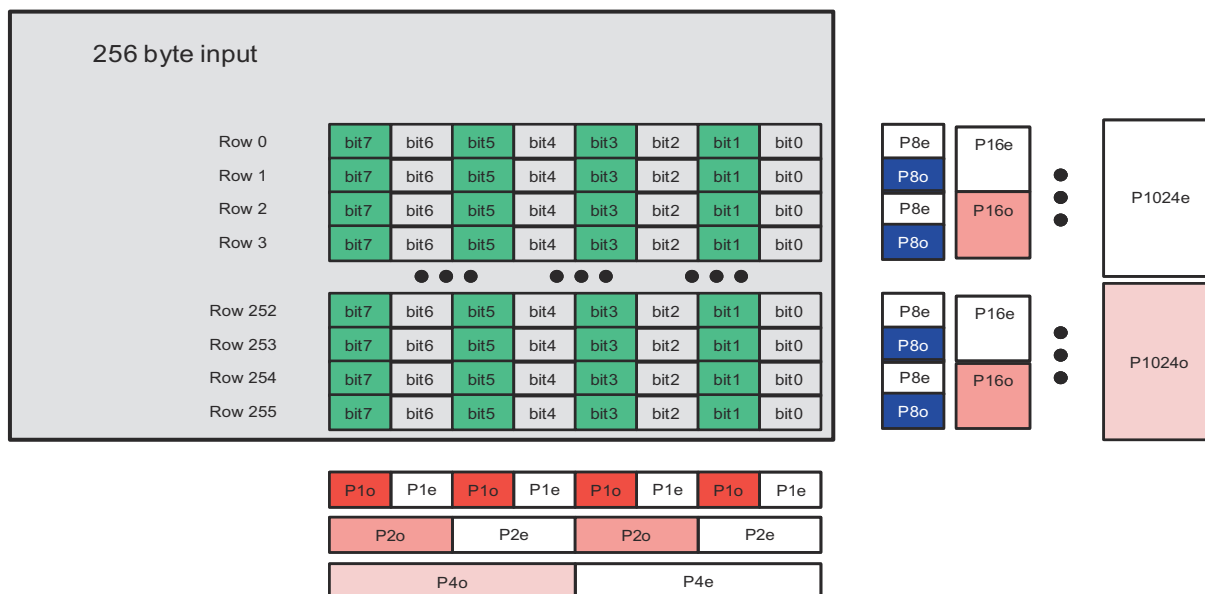

gpmc-027

**Figure 12-177. Hamming Code Accumulation Algorithm (2/2)**

Unused parity bits in the result registers are set to 0.

Figure 12-178 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

gpmc-028

**Figure 12-178. ECC Computation for a 256-Byte Data Stream (Read or Write)**

Figure 12-179 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o - P2048o for odd parities, and P8e-P16e-P32e--P1024e - P2048e for even parities).

gpmc-029

**Figure 12-179. ECC Computation for a 512-Byte Data Stream (Read or Write)**

For a 2-KB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the `GPMC_ECCj_RESULT` registers (where  $j = 1$  to 9).

#### 12.3.3.4.11.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

#### 12.3.3.4.11.3.1.5 ECC Calculation Based on 8-Bit Word

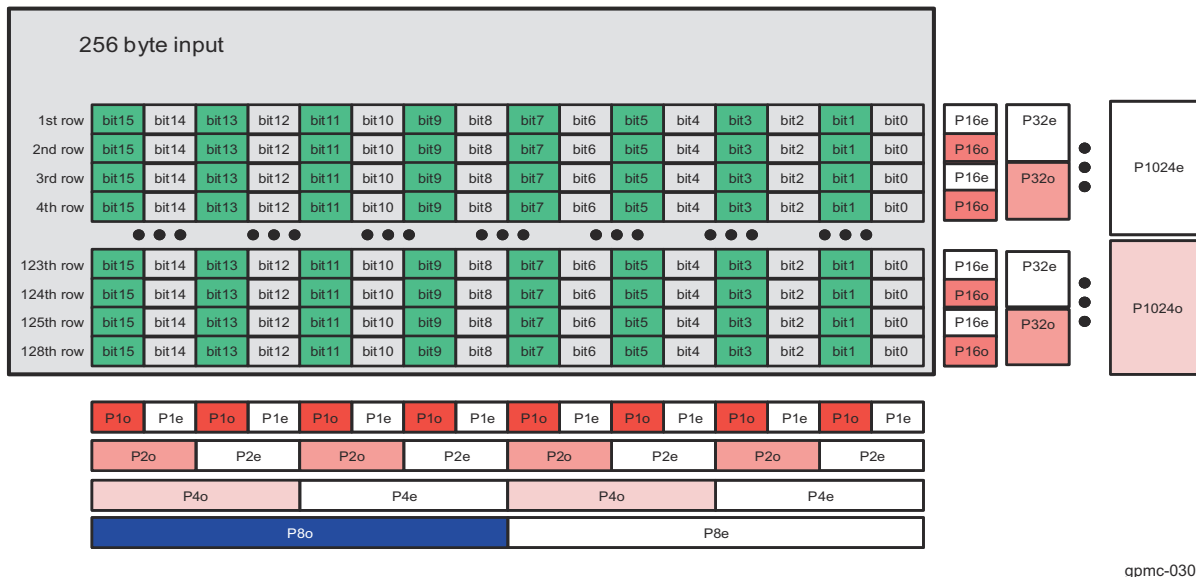

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

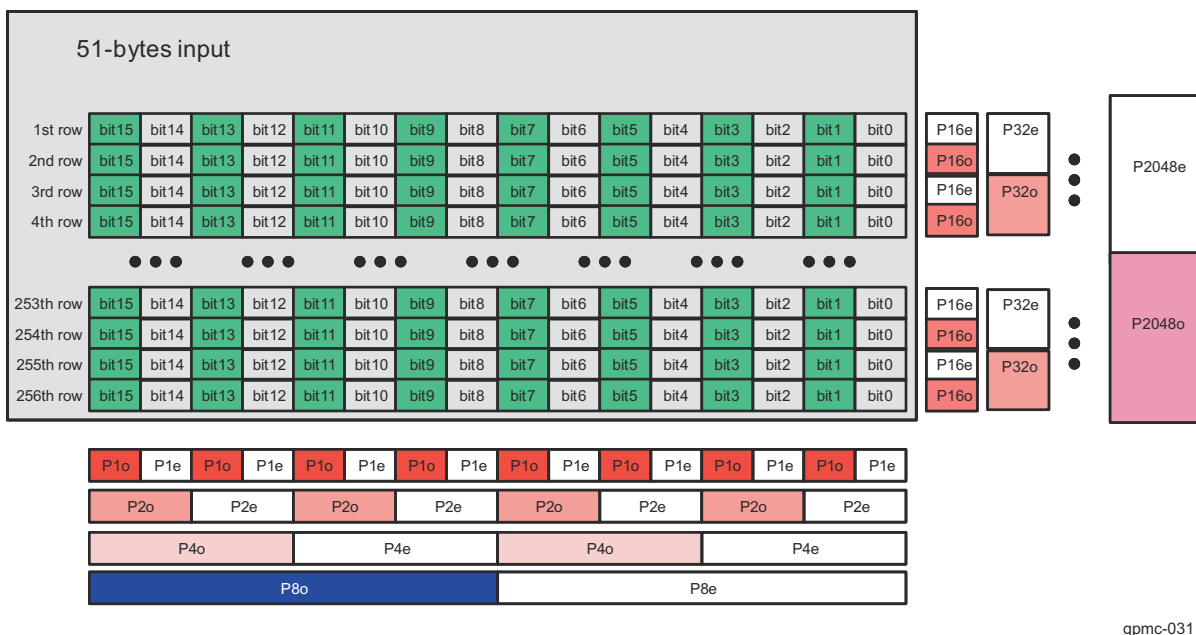

#### 12.3.3.4.11.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the `GPMC_ECC_CONFIG[7] ECC16B` bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. [Figure 12-180](#) and [Figure 12-181](#) show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

**Figure 12-180. 128 Word16 ECC Computation**

**Figure 12-181. 256 Word16 ECC Computation**

#### 12.3.3.4.11.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

##### 12.3.3.4.11.3.2.1 Requirements

- Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
  - Typical page write sequence:
    - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.
- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.
- 2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
- 3. Each page can hold up to 4KB of data, spare bytes not included. This means up to  $8 \times 512$ -byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
- 5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

#### 12.3.3.4.11.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In a standard case, 512 bytes of data (that is,  $2^{12}$  bits = 4096 bits) are seen as a polynomial of degree  $2^{12} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$ , as described in [Table 12-178](#).

**Table 12-178. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

	Message $M(x)$			ECC $R(x)$		
Bit Number	$M_{4095}$	...	$M_0$	$R_{103}$	...	$R_0$

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) \times 8) - 1 = 4119$ , for a total of  $3 + 13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where  $i = 0$  to 3):

- GPMC\_BCH\_RESULT\_0\_i
- GPMC\_BCH\_RESULT\_1\_i
- GPMC\_BCH\_RESULT\_2\_i
- GPMC\_BCH\_RESULT\_3\_i

#### 12.3.3.4.11.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LSB) represents a segment of polynomial  $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

### Note

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 12-179 and Table 12-180 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset module 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2<sup>12</sup>–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

**Table 12-179. Aligned Message Byte Mapping in 8-Bit NAND**

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

**Table 12-180. Aligned Message Byte Mapping in 16-Bit NAND**

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 12-181 through Table 12-186 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

**Table 12-181. Aligned Nibble Mapping of Message in 8-Bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

**Table 12-182. Misaligned Nibble Mapping of Message in 8-Bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
(S + 1) / 2 – 2	Nibble 2	Nibble 1

**Table 12-182. Misaligned Nibble Mapping of Message in 8-Bit NAND (continued)**

Byte Offset	8-Bit Word
$(S + 1) / 2 - 1$	Nibble 0 (LSB)

**Table 12-183. Aligned Nibble Mapping of Message in 16-Bit NAND**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$S/2 - 4$	Nibble 5	Nibble 4	Nibble 7	Nibble 6
$S/2 - 2$	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

**Table 12-184. Misaligned Nibble Mapping of Message in 16-Bit NAND (1 Unused Nibble)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S + 1) / 2 - 4$	Nibble 4	Nibble 3	Nibble 6	Nibble 5
$(S + 1) / 2 - 2$	Nibble 0 (LSB)		Nibble 2	Nibble 1

**Table 12-185. Misaligned Nibble Mapping of Message in 16-Bit NAND (2 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S + 2) / 2 - 4$	Nibble 3	Nibble 2	Nibble 5	Nibble 4
$(S + 2) / 2 - 2$			Nibble 1	Nibble 0 (LSB)

**Table 12-186. Misaligned Nibble Mapping of Message in 16-Bit NAND (3 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S + 3) / 2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S + 3) / 2 - 2$			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

### 12.3.3.4.11.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword

(concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 12.3.3.4.11.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see [Section 12.3.3.4.11.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

##### 12.3.3.4.11.3.2.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC\_ECC\_SIZE\_CONFIG[31-22] ECCSIZE1. In the same example, 5 nibbles to process + 3 to discard = 8 nibbles =  $2 \times 16$ -bit accesses. Software must set:

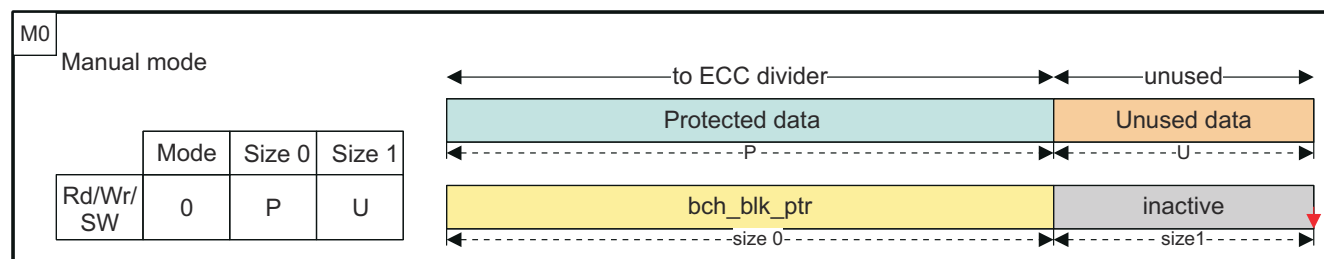

- GPMC\_ECC\_SIZE\_CONFIG[21-12] ECCSIZE0 = 0x5
- GPMC\_ECC\_SIZE\_CONFIG[31-22] ECCSIZE1 = 0x3

---

#### Note

In the following figures, size and size0 are the same parameter.

---

gpmc-032

**Figure 12-182. Manual Mode Sequence and Mapping**

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

#### 12.3.3.4.11.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.3.4.11.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

#### 12.3.3.4.11.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.3.4.11.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.3.4.11.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.3.4.11.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

#### 12.3.3.4.11.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.3.4.11.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

#### 12.3.3.4.11.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.3.4.11.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

#### 12.3.3.4.11.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.3.4.11.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 3.3.4.11.3.2.2.1, Memory Mapping of Data Message](#).

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 12-183](#) through [Figure 12-185](#), the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of  $n = 2^{13} - 1 = 8191$  bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

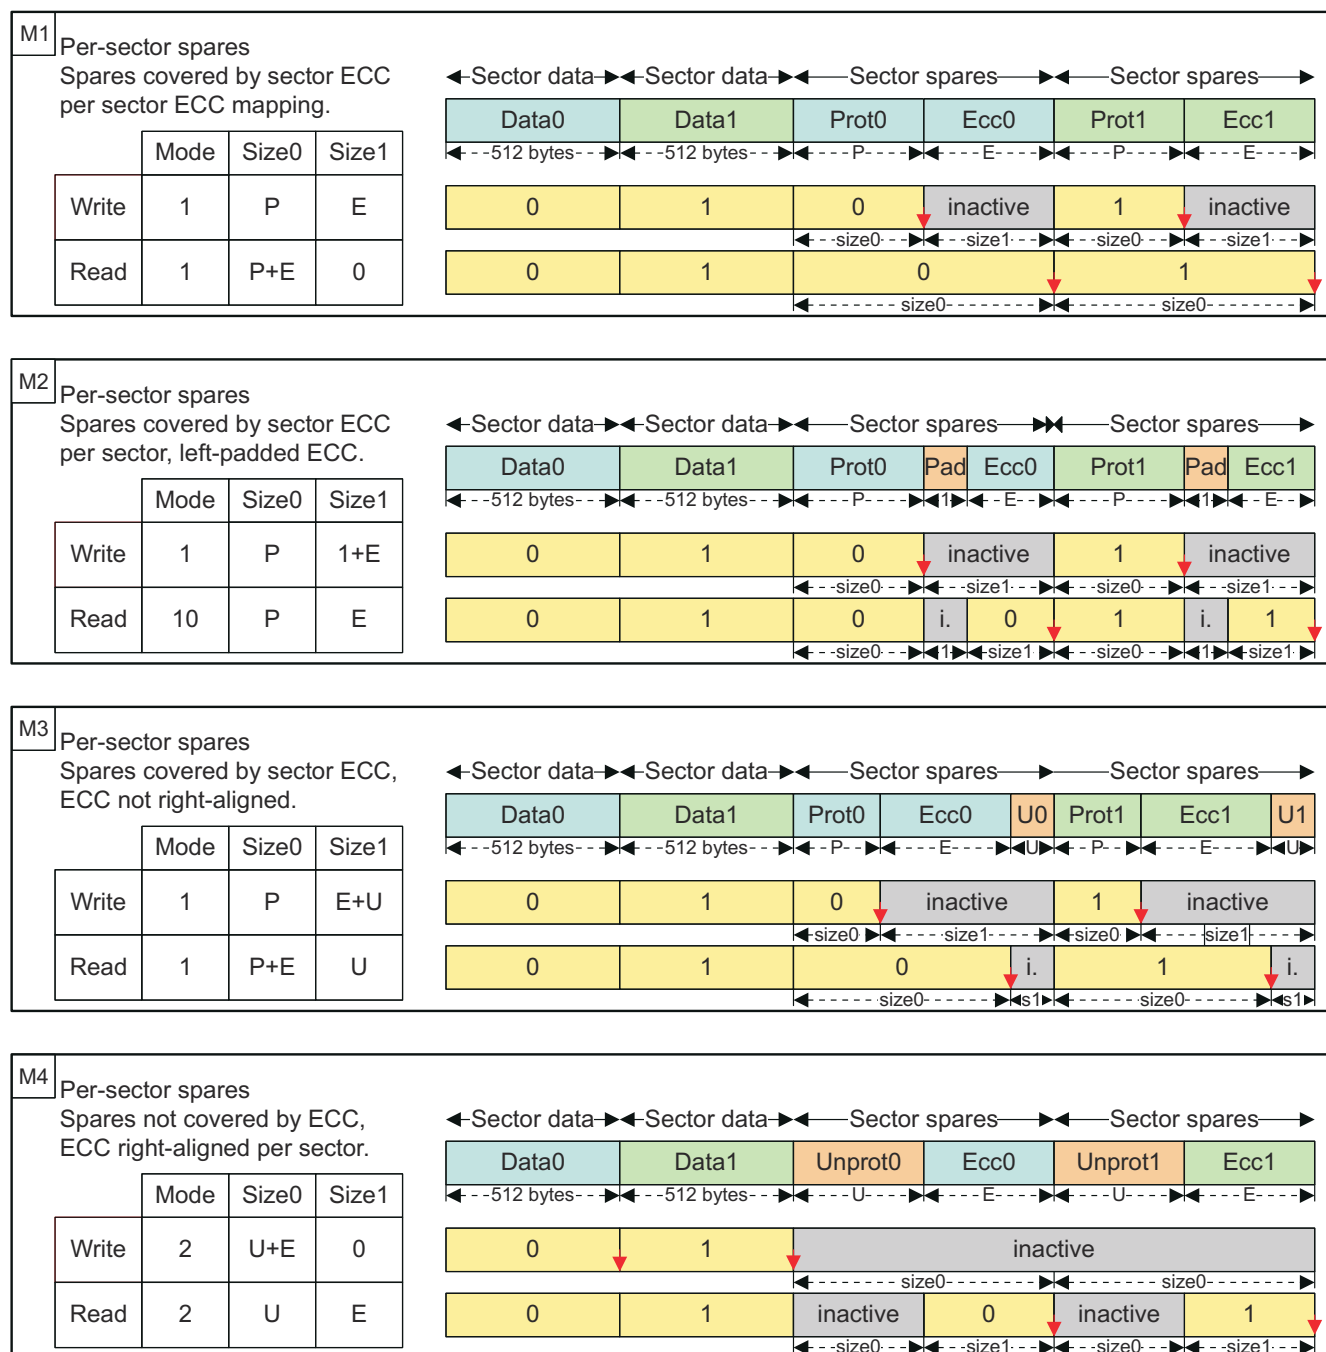

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors:  $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword:  $(512) + P + E$
  - Other sectors:  $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords  $(512) + E$

#### **12.3.3.4.11.3.2.3.1 Per-Sector Spare Mappings**

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

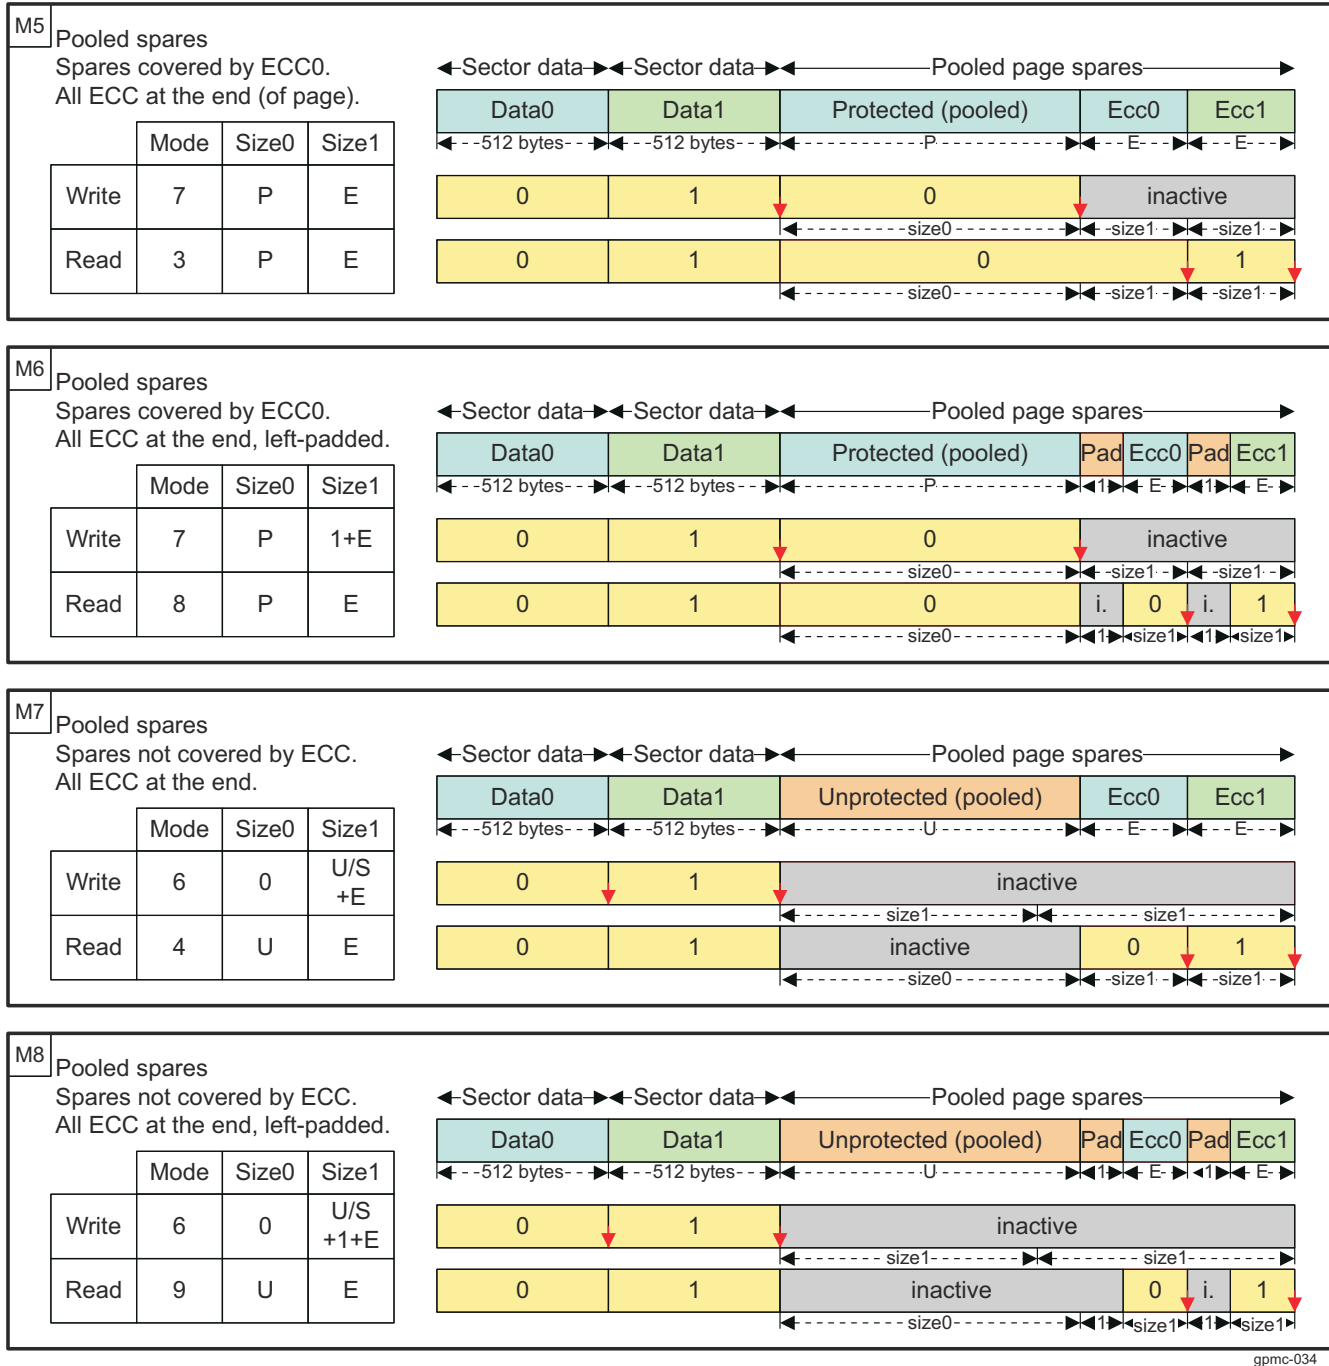

gpmc-033

**Figure 12-183. NAND Page Mapping and ECC: Per-Sector Schemes**

#### 12.3.3.4.11.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

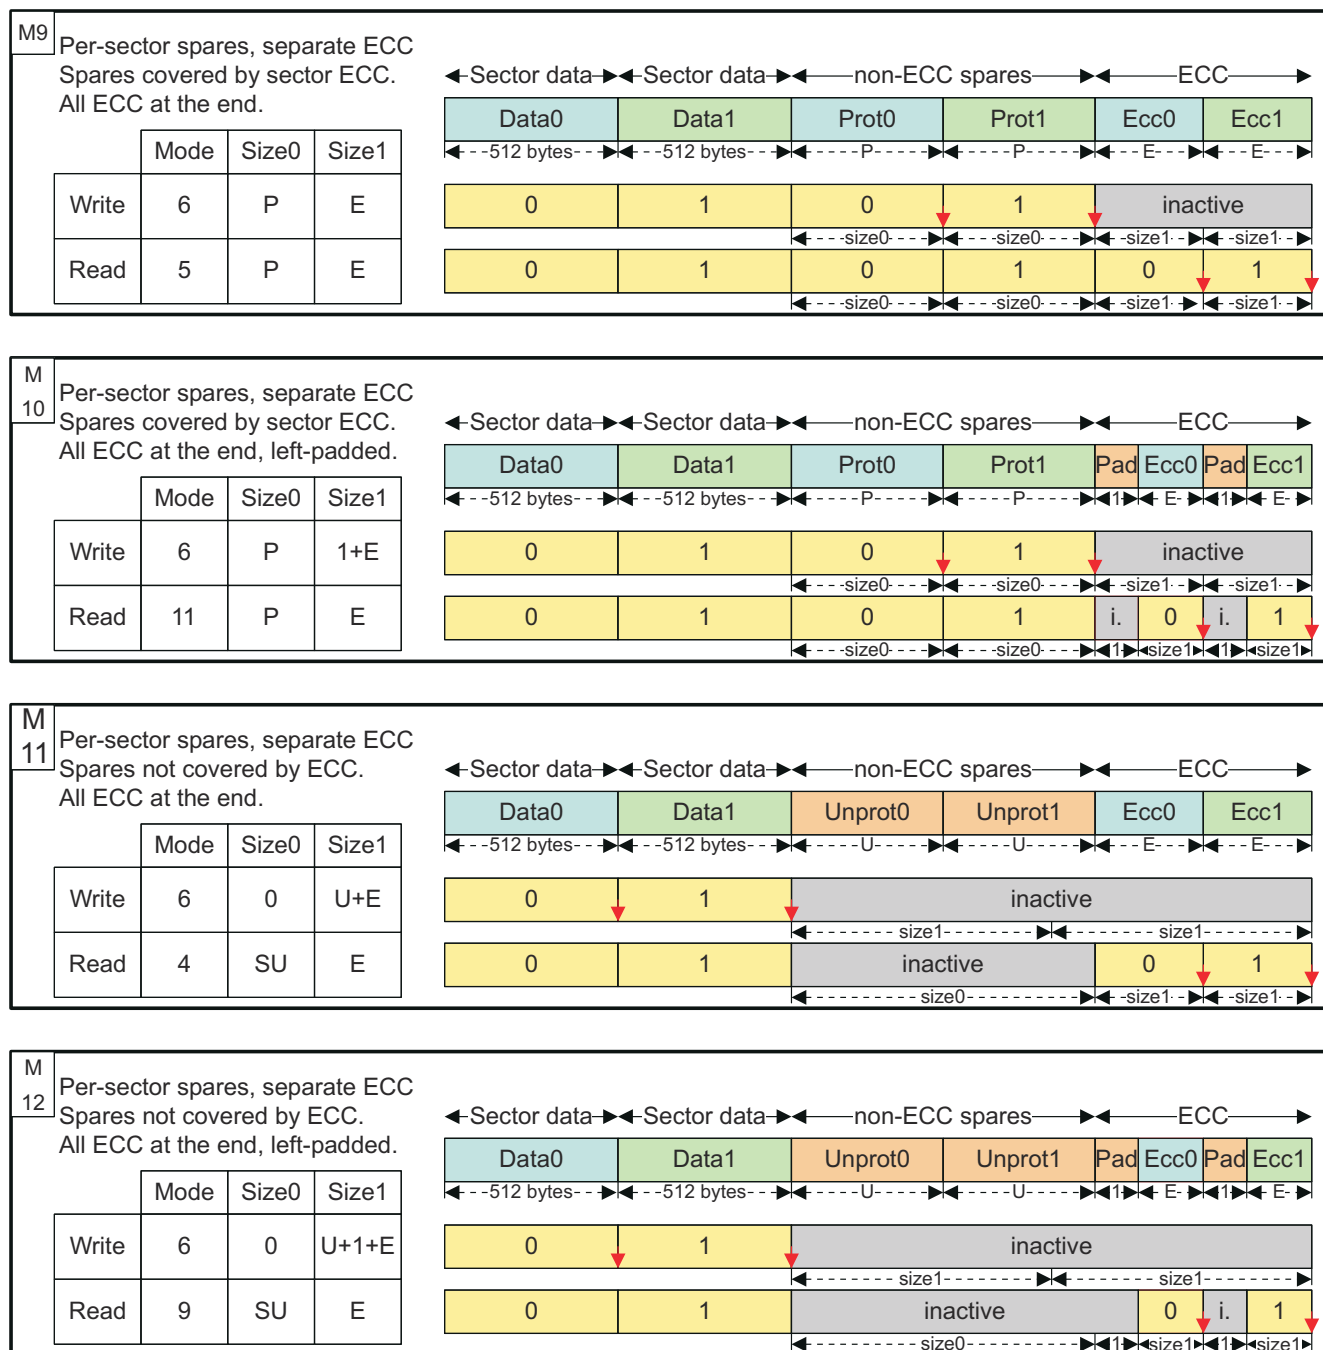

**Figure 12-184. NAND Page Mapping and ECC: Pooled Spare Schemes**

#### 12.3.3.4.11.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

gpmc\_035

**Figure 12-185. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC**

#### 12.3.3.4.11.4 Prefetch and Write-Posting Engine

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

NAND device data access cycles are usually much slower than the CPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long

read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the interconnect interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine depends on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the `GPMC_PREFETCH_CONFIG1[23]` `PFPWENROUNDROBIN` bit is enabled, the arbitration grants the prefetch and write-posting engine access to the GPMC bus for a number of requests programmed in the `GPMC_PREFETCH_CONFIG1[19-16]` `PFPWWWEIGHTEDPRIO` bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

#### Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

#### 12.3.3.4.11.4.1 General Facts About the Engine Configuration

The engine can be configured only if the `GPMC_PREFETCH_CONTROL[0]` `STARTENGINE` bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the `GPMC_PREFETCH_CONFIG1[26-24]` `ENGINECSSELECTOR` bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC\_PREFETCH\_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 3):

- GPMC\_NAND\_COMMAND\_i
- GPMC\_NAND\_ADDRESS\_i
- GPMC\_NAND\_DATA\_i

The FIFO entry on the interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC\_PREFETCH\_STATUS[30-24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

#### 12.3.3.4.11.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see [Section 12.3.3.4.11.2.2, Ready Pin Monitored by Hardware Interrupt](#)). The GPMC\_PREFETCH\_CONFIG1[5-4] WAITPINSELECTOR bit field selects which GPMC\_WAIT pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT bit field.

Table 12-187 describes the prefetch mode configuration.

**Table 12-187. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17-16]	0 to 1	Selects WAIT pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 12.3.3.4.11.4.6, <i>Optimizing NAND Access Using the Prefetch and Write-Posting Engine</i> .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 12.3.3.4.11.4.3 FIFO Control in Prefetch Mode

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC\_PREFETCH\_STATUS[30-24] FIFOPOINTER bit field or through the GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must

be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

### Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 12.3.3.4.11.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor

the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 12-188 describes the write-posting configuration.

**Table 12-188. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 12.3.3.4.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine</a> .
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 12.3.3.4.11.4.5 FIFO Control in Write-Posting Mode

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

### Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, DMA or CPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

#### 12.3.3.4.11.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC\_NAND\_DATA\_i location, where i = 0 to 3) are never optimized.

The GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION bit field defines the number of GPMC\_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 12-186 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION bit field.

gpmc-036

**Figure 12-186. NAND Read Cycle Optimization Timing Description**

#### 12.3.3.4.11.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the *GPMC\_PREFETCH\_CONFIG1*[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the *GPMC\_PREFETCH\_CONFIG1*[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

### 12.3.3.4.12 GPMC Use Cases and Tips

#### 12.3.3.4.12.1 How to Set GPMC Timing Parameters for Typical Accesses

##### 12.3.3.4.12.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or non-multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

##### 12.3.3.4.12.1.2 Typical GPMC Setup

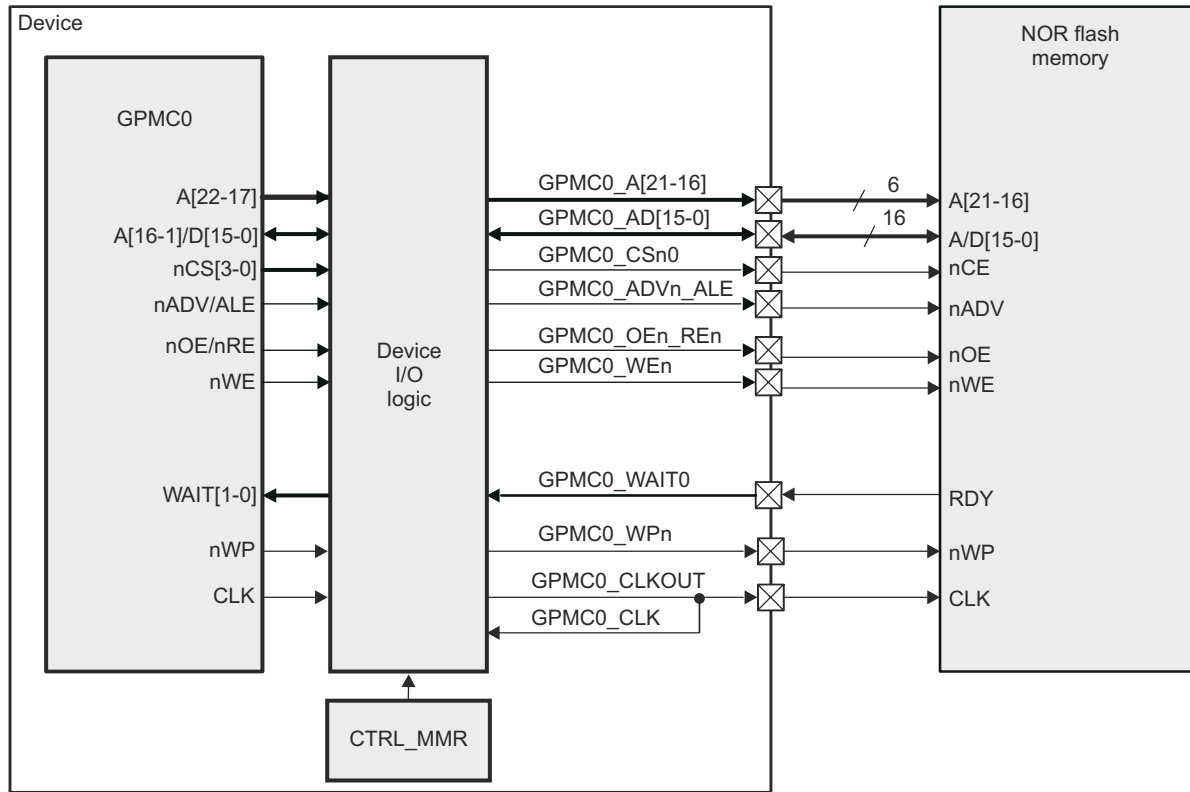

[Table 12-189](#) lists some of the I/Os of the GPMC module.

**Table 12-189. Typical GPMC Setup Signals**

Module Pin	I/O <sup>(1)</sup>	Description
GPMC0_FCLK	Internal	Functional clock. Acts as the time reference.
GPMC0_ICLK	Internal	Interface clock. Acts as the time reference.
GPMC0_CLKOUT	O	External clock provided to the external device for synchronous operations
GPMC0_A[21-16]	O	Address
GPMC0_AD[15-0]	I/O	Data-multiplexed with addresses A[16-1] on memory side
GPMC0_CSn[3-0]	O	Chip-selects
GPMC0_ADVn_ALE	O	Address valid enable
GPMC0_OEn_REn	O	Output enable (read access only)
GPMC0_WEn	O	Write enable (write access only)
GPMC0_WAIT[1-0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) I = Input; O = Output

[Figure 12-187](#) shows the typical connection between the GPMC module and an attached NOR Flash memory.

gpmc-037

**Figure 12-187. GPMC Connection to an External NOR Flash Memory**

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

#### 12.3.3.4.12.1.2.1 GPMC Configuration for Synchronous Burst Read Access

##### Note

The examples in [Section 12.3.3.4.12.1.2.1](#) through [Section 12.3.3.4.12.1.2.3](#) are based on a clock rate of 104 MHz. See the device-specific Datasheet for the maximum frequency appropriate for this device and the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9.615 \text{ ns}$ ).

[Table 12-190](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 12-191](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 12-188](#) shows the synchronous burst read access.

**Table 12-190. Useful Timing Parameters on the Memory Side**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tlACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5.2

**Table 12-190. Useful Timing Parameters on the Memory Side (continued)**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ( $T = 9.615$  ns). The read access time between two bursts of data is  $tBACC = 5.2$  ns. Therefore, data setup time is a clock period –  $tBACC = 4.415$  ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

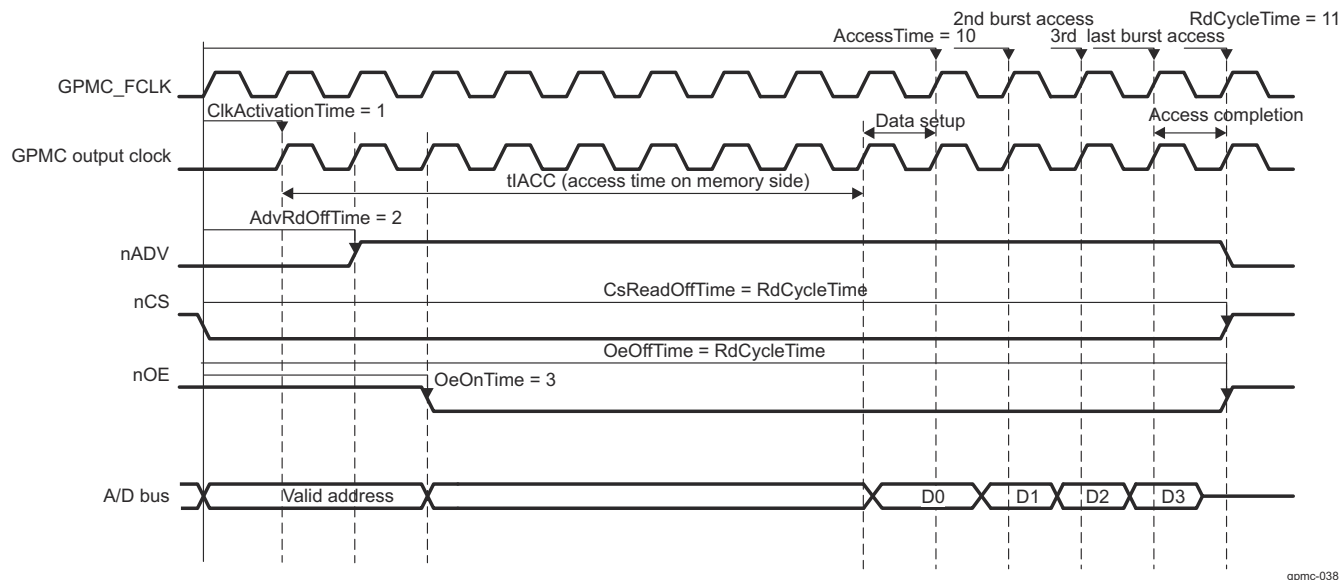

**Table 12-191. Calculating GPMC Timing Parameters**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	$\min(tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94.03: (9.615 + 80 + 4.415)	10: $\text{roundmax}(94.03 / 9.615)$	RDACCESSTIME = 0xA
PageBurst RdAccessTime	$\text{roundmax}(tBACC)$	$\text{roundmax}(5.2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{RdAccess time} + \max(tCEZ, tOEZ)$	101.03: (94.03 + 7)	11	RDCYCLETIME = 0xB
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	–	11	CSRDOFFTIME = 0xB
AdvOnTime	tAVC <sup>(1)</sup>	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC <sup>(2)</sup>	12	2	ADVRDOFFTIME = 0x2
OeOnTime <sup>(3)</sup>	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime}(\text{ClkActivationTime} + tIACC)$	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0xB

(1) The external clock provided to the NOR flash is not yet available.

(2)  $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$ ; thus,  $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$ .

(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

**Figure 12-188. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

#### 12.3.3.4.12.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9.615 \text{ ns}$ ).

Table 12-192 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-193 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-189 shows the asynchronous read access.

**Table 12-192. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 12-192: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

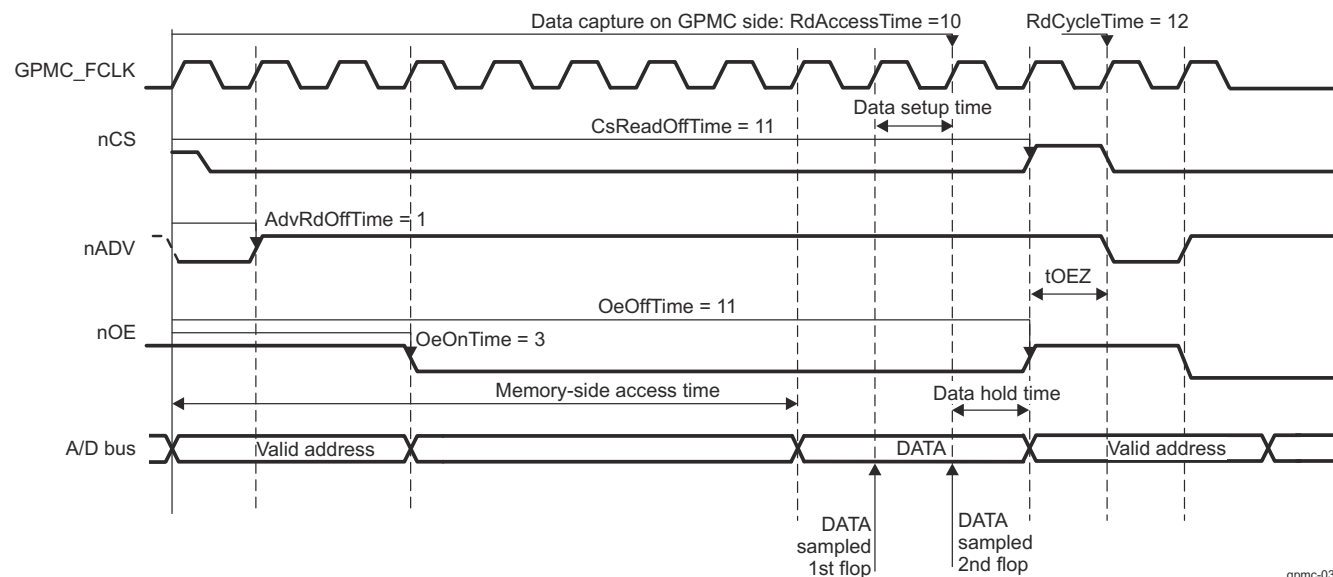

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).
4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.

5. Addresses can now be relatched and a new read cycle begun.

**Table 12-193. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0xA
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1 cycle + tOEZ	96.615	12	RDCYCLETIME = 0xC
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89.615	11	CSRDOFFTIME = 0xB
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x1
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1 cycle	89.615	11	OEOFFTIME = 0xB

**Figure 12-189. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

#### 12.3.3.4.12.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9.615 ns).

Table 12-195 shows how to calculate timings for the GPMC using the memory parameters.

Table 12-194 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 12-190 shows the synchronous burst write access.

**Table 12-194. AC Characteristics for Asynchronous Single Write (Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20

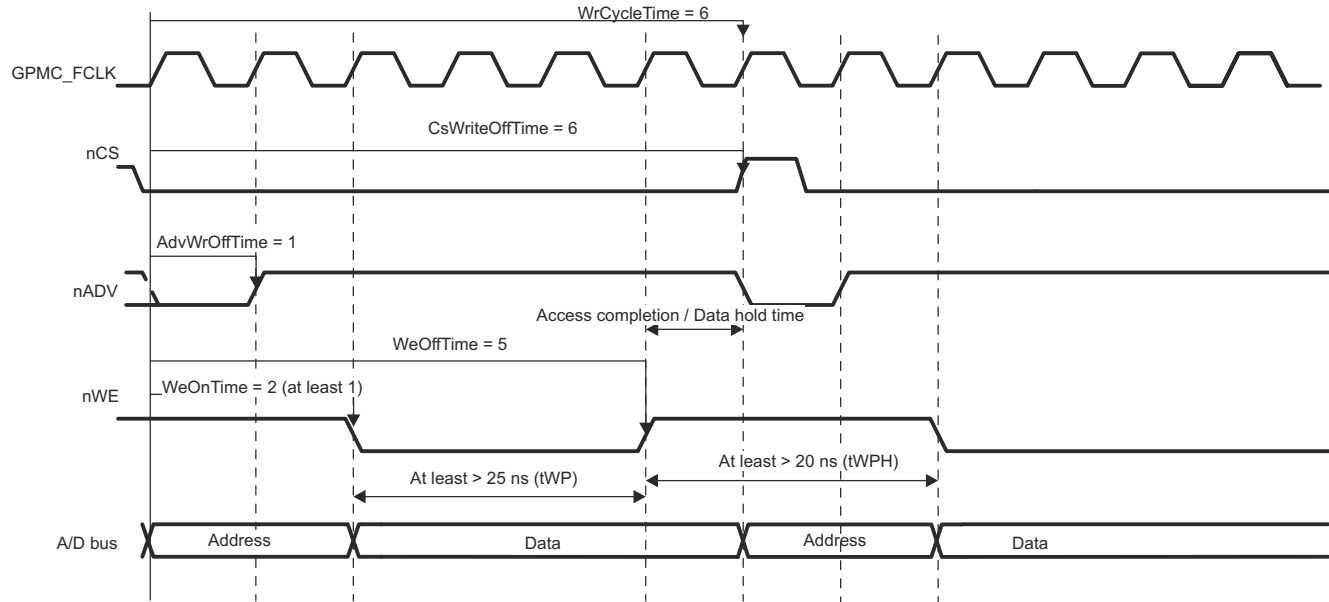

**Table 12-194. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is  $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$ . For the AccessCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device-specific Datasheet.

**Table 12-195. GPMC Timing Parameters for Asynchronous Single Write**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		N/A (asynchronous mode)		
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		N/A (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57.615	6	WRCYCLETIME = 0x6
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57.615	6	CSWROFFTIME = 0x6
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x1
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x5

gpmc-040

#### 12.3.3.4.12.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

### 12.3.3.4.12.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, and so on)
- 8- and 16-bit NAND flash devices

#### 12.3.3.4.12.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

**Table 12-196. Supported Memory Interfaces**

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash <sup>(1)</sup>	16-Bit NAND	8-Bit NAND

GPMC_AD[11]	D11 or A12	IO11	
GPMC_AD[10]	D10 or A11	IO10	
GPMC_AD[9]	D9 or A10	IO9	
GPMC_AD[8]	D8 or A9	IO8	
GPMC_AD[7]	D7 or A8		IO7
GPMC_AD[6]	D6 or A7		IO6
GPMC_AD[5]	D5 or A6		IO5
GPMC_AD[4]	D4 or A5		IO4

**Table 12-196. Supported Memory Interfaces (continued)**

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash <sup>(1)</sup>	16-Bit NAND	8-Bit NAND
GPMC_AD[3]	D3 or A4		IO3
GPMC_AD[2]	D2 or A3		IO2
GPMC_AD[1]	D1 or A2		IO1
GPMC_AD[0]	D0 or A1		IO0
GPMC_CLKOUT	CLK		
GPMC_CSn0	nCS0 (chip-select)		nCE0 (chip-enable)
GPMC_CSn1	nCS1		nCE1
GPMC_CSn2	nCS2		nCE2
GPMC_CSn3	nCS3		nCE3
GPMC_ADVn_ALE	nADV (address valid)		ALE (address latch enable)
GPMC_OEn_REn	nOE (output enable)		nRE (read enable)
GPMC_WEn	nWE (Write enable)		nWE (write enable)
GPMC_BE0n_CLE	nBE0 (byte enable)		CLE (command latch enable)
GPMC_BE1n	nBE1		
GPMC_WAIT0	WAIT0		R/nB0 (ready/busy)
GPMC_WAIT1	WAIT1		R/nB1
GPMC_WPn	nWP (Write Protect)		nWP (Write Protect)

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

#### 12.3.3.4.12.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 12-197 summarizes the NAND interface signals level applied to external device or memories.

**Table 12-197. NAND Interface Bus Operations Summary**

Bus Operation	CLE	ALE	nCE	nWE <sup>(1)</sup>	nRE <sup>(1)</sup>	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H <sup>(2)</sup>	H <sup>(2)</sup>	H <sup>(2)</sup>	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L

(1) RE stands for rising edge; FE stands for falling edge

(2) Can be nCE high, or WE and nRE high.

### 12.3.3.4.12.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

[Table 12-198](#) summarizes the level of the NOR interface signals applied to external devices or memories.

**Table 12-198. NOR Interface Bus Operations Summary**

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15-0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

### 12.3.3.4.12.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

FPGA (Field-Programmable Gate Array) is a low-power integrated circuit based on an array of programmable logic blocks.

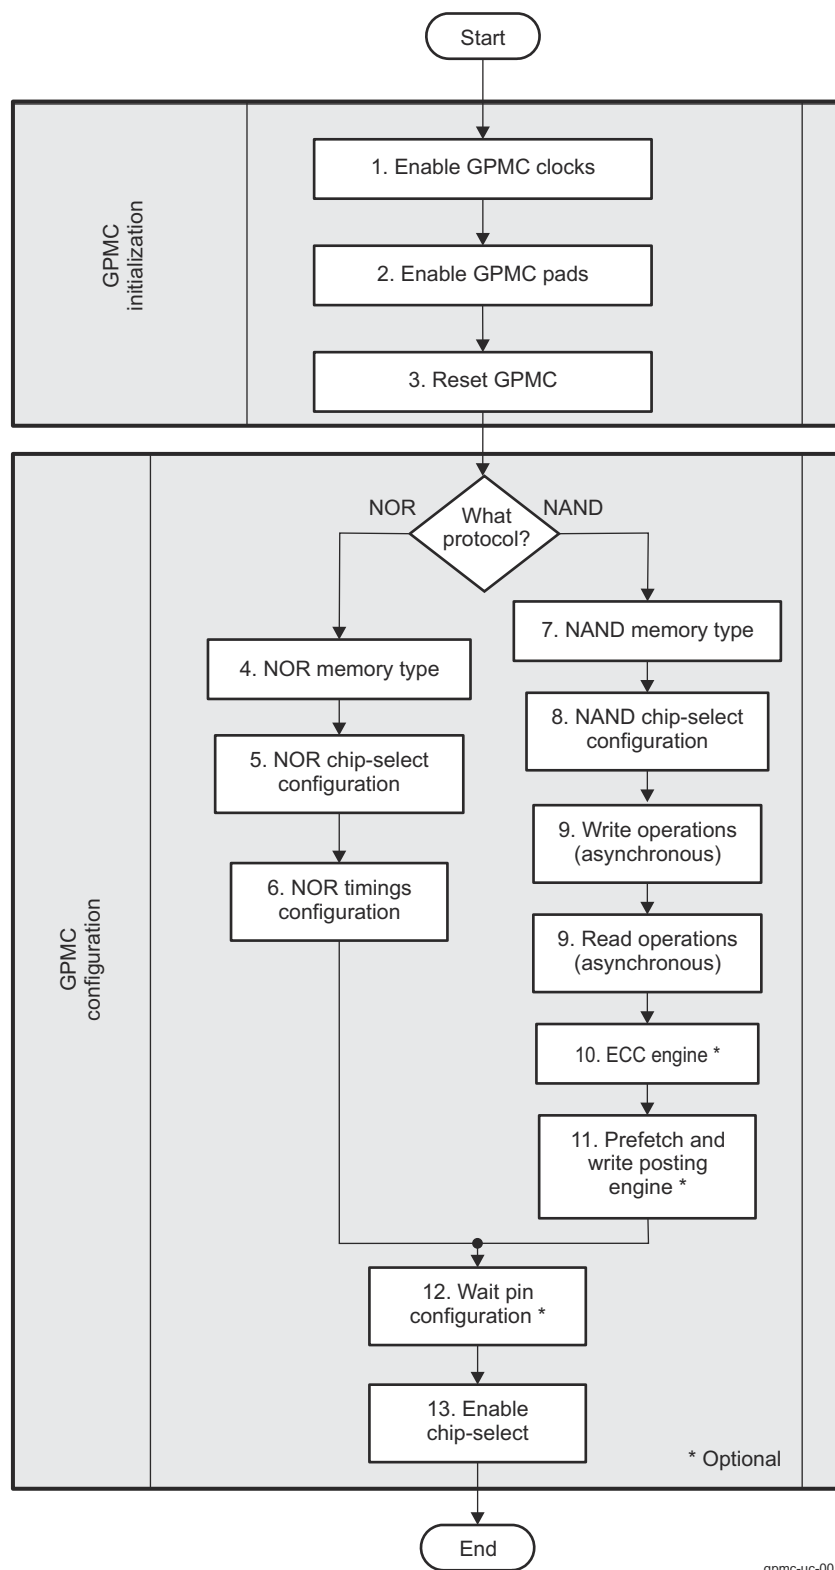

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It has synchronous write capability.

### 12.3.3.5 GPMC Basic Programming Model

#### 12.3.3.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

[Figure 12-191](#) and [Table 12-199](#) through [Table 12-200](#) show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

**Figure 12-191. Programming Model Top-Level Diagram**
**Table 12-199. GPMC Configuration in NOR Mode**

Step	Description
NOR Memory Type	See <a href="#">Table 12-201</a> .

**Table 12-199. GPMC Configuration in NOR Mode (continued)**

Step	Description
NOR Chip-Select Configuration	See <a href="#">Table 12-202</a> .
NOR Timings Configuration	See <a href="#">Table 12-203</a> .
WAIT Pin Configuration	See <a href="#">Table 12-211</a> .
Enable Chip-Select	See <a href="#">Table 12-212</a> .

**Table 12-200. GPMC Configuration in NAND Mode**

Step	Description
NAND Memory Type	See <a href="#">Table 12-206</a> .
NAND Chip-Select Configuration	See <a href="#">Table 12-207</a> .
Write Operations (Asynchronous)	See <a href="#">Table 12-208</a> .
Read Operations (Asynchronous)	See <a href="#">Table 12-208</a> .
ECC Engine	See <a href="#">Table 12-209</a> .
Prefetch and Write-Posting Engine	See <a href="#">Table 12-210</a> .
WAIT Pin Configuration	See <a href="#">Table 12-211</a> .
Enable Chip-Select	See <a href="#">Table 12-212</a> .

### 12.3.3.5.2 GPMC Initialization

GPMC can be reset via software bit in LPSC. For more information, see *Reset*.

### 12.3.3.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

**Table 12-201. NOR Memory Type**

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency <sup>(1)</sup> .	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time <sup>(1)</sup> .	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations <sup>(1)</sup> .	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or non-multiplexed asynchronous for multiple access one)

**Table 12-202. NOR Chip-Select Configuration**

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 12-203. NOR Timings Configuration**

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See <i>GPMC Timing Parameters</i>	

**Table 12-204. WAIT Pin Configuration**

Subprocess Name	Register/Bit Field	Value
Enable or disable WAIT pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable WAIT pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a WAIT pin monitoring time.	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input WAIT pin for the chip-select.	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

**Table 12-205. Enable Chip-Select**

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

#### 12.3.3.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

#### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

**Table 12-206. NAND Memory Type**

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See <a href="#">Section 12.3.3.5.5, Set Memory Access</a> .	x

**Table 12-207. NAND Chip-Select Configuration**

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16MB).	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 12-208. Asynchronous Read and Write Operations**

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See <a href="#">Section 12.3.3.5.6, GPMC Timing Parameters</a> .	

**Table 12-209. ECC Engine**

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x <sup>(2)</sup>
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 and [31-22] ECCSIZE1	x <sup>(1)</sup>
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x

**Table 12-209. ECC Engine (continued)**

Subprocess Name	Register/Bit Field	Value
Select the chip-select where ECC is computed.	<i>GPMC_ECC_CONTROL</i> [3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	<i>GPMC_ECC_CONTROL</i> [16] ECCALGORITHM	x
Select word size for ECC calculation.	<i>GPMC_ECC_CONTROL</i> [7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	<i>GPMC_ECC_CONTROL</i> [13-12] ECCBCHTSEL and <i>GPMC_ECC_CONTROL</i> [6-4] ECCTOPSECTOR	x
Enable the ECC computation.	<i>GPMC_ECC_CONTROL</i> [0] ECCENABLE	0x1

(1) Depends on the size of each sector in the NAND page

(2) This parameter depends on the numbers of sectors in a page.

**Table 12-210. Prefetch and Write-Posting Engine**

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	<i>GPMC_PREFETCH_CONTROL</i> [0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	<i>GPMC_PREFETCH_CONFIG1</i> [26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	<i>GPMC_PREFETCH_CONFIG1</i> [0] ACCESSMODE	x
Select the threshold used to issue an interrupt request.	<i>GPMC_PREFETCH_CONFIG1</i> [14-8] FIFOTHRESHOLD	x
Select interrupt synchronization mode.	<i>GPMC_PREFETCH_CONFIG1</i> [2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	<i>GPMC_PREFETCH_CONFIG1</i> [3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	<i>GPMC_PREFETCH_CONFIG1</i> [5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	<i>GPMC_PREFETCH_CONFIG1</i> [30-28] CYCLOPTIMIZATION	x
Enable the prefetch postwrite engine.	<i>GPMC_PREFETCH_CONFIG1</i> [7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	<i>GPMC_PREFETCH_CONFIG2</i> [13-0] TRANSFERCOUNT	x
Start the prefetch engine.	<i>GPMC_PREFETCH_CONTROL</i> [0] STARTENGINE	0x1

**Table 12-211. WAIT Pin Configuration**

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	<i>GPMC_PREFETCH_CONFIG1</i> [3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	<i>GPMC_PREFETCH_CONFIG1</i> [5-4] WAITPINSELECTOR	x

**Table 12-212. Enable Chip-Select**

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	<i>GPMC_CONFIG7_1</i> [6] CSVALID	x

### 12.3.3.5.5 Set Memory Access

#### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

This section describes the bit field to configure to set the GPMC in various memory modes. [Table 12-213](#) and [Table 12-214](#) provide check lists for mode parameters and access type parameters, respectively.

**Table 12-213. Mode Parameters Check List**

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
<i>GPMC_CONFIG1_i</i>	30	READMULTIPLE	0x0	Don't care	0x1 <sup>(1)</sup>	Not Supported	0x0	Don't care	0x1	Don't care
<i>GPMC_CONFIG1_i</i>	29	READTYPE	0x0	Don't care	0x0 <sup>(1)</sup>	Not Supported	0x1	Don't care	0x1	Don't care
<i>GPMC_CONFIG1_i</i>	28	WRITEMULTIPLE	Don't care	0x0	- <sup>(1)</sup>	Not Supported	Don't care	0x0	Don't care	0x1
<i>GPMC_CONFIG1_i</i>	27	WRITETYPE	Don't care	0x0	- <sup>(1)</sup>	Not Supported	Don't care	0x1	Don't care	0x1

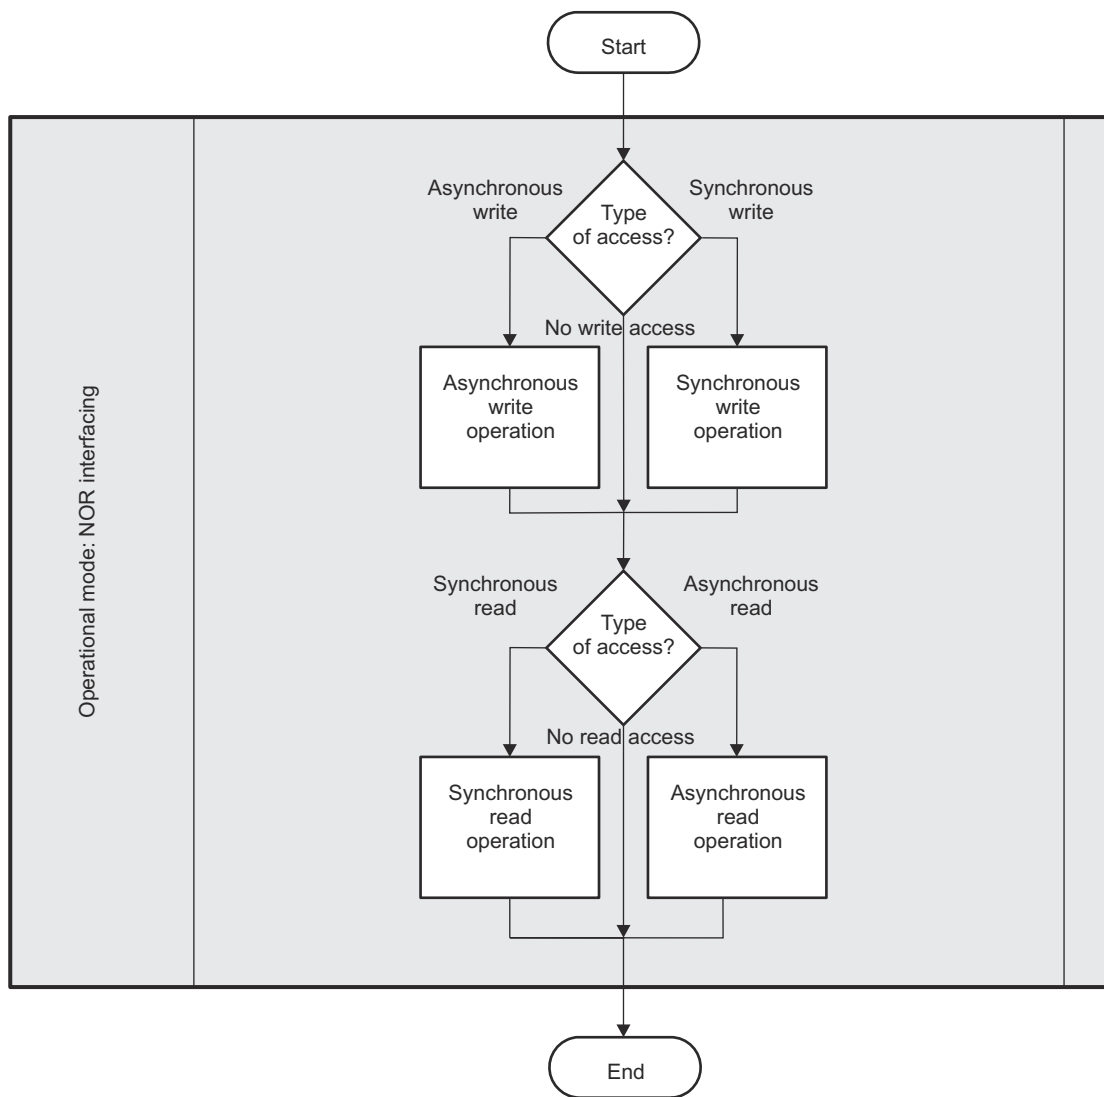

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in non-multiplexed mode.

**Table 12-214. Access Type Parameters Check List**

Register	Bit	Name	Access Type		
			non-multiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
<i>GPMC_CONFIG1_i</i>	9-8	MUXADDDATA	0x0	0x2	0x1

### 12.3.3.5.6 GPMC Timing Parameters

Figure 12-192 shows a programming model diagram for the NOR interfacing timing parameters.

gpmc-uc-002

**Figure 12-192. NOR Interfacing Timing Parameters Diagram**

Table 12-215 lists the bit fields to configure adequate timing parameters in various memory modes.

**Table 12-215. Timing Parameters**

Register	Bit	Name	Asynchronous			Synchronous				Access Type		
			Single Read Accesses	Single Write Accesses	Multiple Read (Page) accesses	Single Read Accesses	Single Write Accesses	Multiple Read (Burst) Accesses	Multiple Write (Burst) Accesses	Non-multiplexed	Addresses/Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	27	WRITETYPE		y			y		y	y	y	y
GPMC_CONFIG1_i	28	WRITEMULTIPLE		y			y		y	y	y	y
GPMC_CONFIG1_i	31	WRAPBURST						y	y	y	y	y

**Table 12-215. Timing Parameters (continued)**

			Asynchronous			Synchronous				Access Type		
GPMC_CONFIG1_i	26-25	CLKACTIVATIONTIME				y	y	y	y	y	y	y
GPMC_CONFIG1_i	19-18	WAITMONITORINGTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	4	TIMEPARAGRANULARITY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG2_i	20-16	CSWROFFTIME		y			y		y	y	y	y
GPMC_CONFIG2_i	12-8	CSRDOFFTIME	y		y	y		y		y	y	y
GPMC_CONFIG2_i	7	CSEXTRADELAY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG2_i	3-0	CSONTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG3_i	30-28	ADVAADMUXWROFFTIME		y			y		y			y
GPMC_CONFIG3_i	30-29	ADVAADMUXRDOFFTIME	y		y	y		y				y
GPMC_CONFIG3_i	6-4	ADVAADMUXONTIME	y	y	y	y	y	y	y			y
GPMC_CONFIG3_i	20-16	ADVWROFFTIME		y			y		y	y	y	y
GPMC_CONFIG3_i	12-8	ADVRDOFFTIME	y		y	y		y		y	y	y
GPMC_CONFIG3_i	7	ADVEXTRADELAY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG3_i	3-0	ADVONTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG4_i	15-13	OEAADMUXOFFTIME	y	y	y	y	y	y	y			y
GPMC_CONFIG4_i	6-4	OEAADMUXONTIME	y	y	y	y	y	y	y			y
GPMC_CONFIG4_i	28-24	WEOFFTIME		y			y		y	y	y	y
GPMC_CONFIG4_i	23	WEEXTRADELAY		y			y		y	y	y	y
GPMC_CONFIG4_i	19-16	WEONTIME		y			y		y	y	y	y
GPMC_CONFIG4_i	12-8	OEOFFTIME	y		y	y		y		y	y	y
GPMC_CONFIG4_i	7	OEEXTRADELAY	y		y	y		y		y	y	y
GPMC_CONFIG4_i	3-0	OEONTIME	y		y	y		y		y	y	y
GPMC_CONFIG5_i	27-24	PAGEBURSTACCESSTIME			y			y	y	y	y	y
GPMC_CONFIG5_i	20-16	RDACCESSTIME	y		y	y		y		y	y	y
GPMC_CONFIG5_i	12-8	WRCYCLETIME		y			y		y	y	y	y
GPMC_CONFIG5_i	4-0	RDCYCLETIME	y		y	y		y		y	y	y
GPMC_CONFIG6_i	28-24	WRACCESSTIME		y			y		y	y	y	y
GPMC_CONFIG6_i	19-16	WRDATAONADMUXBUS		y			y		y		y	y
GPMC_CONFIG6_i	11-8	CYCLE2CYCLEDELAY	y	y	y	y	y	y	y	y	y	y

### 12.3.3.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device-specific Datasheet.

#### 12.3.3.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x2. [Table 12-216](#) describes the NAND timing parameters.

**Table 12-216. NAND Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_WEn valid time
B	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
C	ns	Delay time – GPMC_BE0n_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time – GPMC_AD[15-0] valid to GPMC_WEn valid
E	ns	Delay time – GPMC_WEn invalid to GPMC_AD[15-0] invalid
F	ns	Delay time – GPMC_WEn invalid to GPMC_BE0n_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time – GPMC_WEn invalid to GPMC_CS invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
J	ns	Setup time – GPMC_AD[15-0] valid to GPMC_OEn_REn invalid
K	ns	Pulse duration – GPMC_OEn_REn valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – GPMC_OEn_REn invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

$$\begin{aligned}
 A &= (\text{WEOffTime} - \text{WEOnTime}) * (\text{TimeParaGranularity} + 1) * \text{GPMC\_FCLK period} \\
 B &= ((\text{WEOnTime} - \text{CSOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{WEEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC\_FCLK period} \\
 C &= ((\text{WEOnTime} - \text{ADVOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{WEEExtraDelay} - \text{ADVExtraDelay})) * \text{GPMC\_FCLK period} \\
 D &= (\text{WEOnTime} * (\text{TimeParaGranularity} + 1) + 0.5 * \text{WEEExtraDelay}) * \text{GPMC\_FCLK period} \\
 E &= (\text{WrCycleTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) - 0.5 * \text{WEEExtraDelay}) * \text{GPMC\_FCLK period} \\
 F &= (\text{ADVWrOffTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{ADVExtraDelay} - \text{WEEExtraDelay})) * \text{GPMC\_FCLK period} \\
 G &= (\text{CSWrOffTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSEExtraDelay} - \text{WEEExtraDelay})) * \text{GPMC\_FCLK period} \\
 H &= \text{WrCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period} \\
 I &= ((\text{OEOnTime} - \text{CSOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{OEEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC\_FCLK period} \\
 J &= ((\text{RdAccessTime} - \text{OEOffTime}) * (\text{TimeParaGranularity} + 1) - 0.5 * \text{OEEExtraDelay}) * \text{GPMC\_FCLK period} \\
 K &= (\text{OEOffTime} - \text{OEOnTime}) * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period} \\
 L &= \text{RdCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period} \\
 M &= (\text{CSRdOffTime} - \text{OEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSEExtraDelay} - \text{OEEExtraDelay})) * \text{GPMC\_FCLK period}
 \end{aligned}$$

[Figure 12-193](#) shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

**Figure 12-193. NAND Command Latch Cycle Timing Simplified Example**

#### 12.3.3.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_[11-10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to synchronous mode. [Table 12-217](#) describes the synchronous NOR formulas.

**Table 12-217. Synchronous NOR Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – address bus valid to CLK first edge Delay time – nBE0 / nBE1 valid to CLK first edge
C	ns	Pulse duration – nBE0 / nBE1 low
D	ns	Delay time – CLK rising edge to nBE0 / nBE1 invalid Delay time – CLK rising edge to nADV/ALE invalid
E	ns	Delay time – CLK rising edge to nCS invalid Delay time – CLK rising edge to nOE/nRE invalid
F	ns	Delay time – CLK rising edge to nCS transition
G	ns	Delay time – CLK rising edge to nADV/ALE transition
H	ns	Delay time – CLK rising edge to nOE/nRE transition
I	ns	Delay time – CLK rising edge to nWE transition
J	ns	Delay time – CLK rising edge to A[16-1]/D[15-0] data bus transition Delay time – CLK rising edge to nBE0 / nBE1 transition
K	ns	Pulse duration – nADV/ALE low
L	ns	Delay time – WAIT invalid to first data latching CLK edge

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

- For single read accesses:

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$C = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$D = (\text{RDCYCLETIME} - \text{RDACCESSTIME}) * \text{GPMC\_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - \text{RDACCESSTIME}) * \text{GPMC\_FCLK period}$$

2. For burst read accesses (where n is the page burst access number):
 
$$A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$C = (\text{RDCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$D = (\text{RDCYCLETIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC\_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC\_FCLK period}$$
3. For burst write accesses (where n is the page burst access number):
 
$$A = (\text{CSWROFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$C = (\text{WRCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$D = (\text{WRCYCLETIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC\_FCLK period}$$

$$E = (\text{CSWROFFTIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC\_FCLK period}$$
4. For all accesses:
 

For nCS falling edge (chip-select activated):

  - Case where  $\text{GPMC\_CONFIG1\_}[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$
  - Case where  $\text{GPMCFCLKDIVIDER} = 0x1$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$ , when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)  
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$  otherwise.
  - Case where  $\text{GPMCFCLKDIVIDER} = 0x2$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$ , when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3  
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$ , when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3  
 $F = (2 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$ , when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nCS rising edge (chip-select deactivated) in reading mode:

  - Case where  $\text{GPMC\_CONFIG1\_}[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$
  - Case where  $\text{GPMCFCLKDIVIDER} = 0x1$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$ , when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)  
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$  otherwise.
  - Case where  $\text{GPMCFCLKDIVIDER} = 0x2$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$ , when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3  
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$ , when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3  
 $F = (2 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$ , when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nCS rising edge (chip-select deactivated) in writing mode:

  - Case where  $\text{GPMC\_CONFIG1\_}[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$
  - Case where  $\text{GPMCFCLKDIVIDER} = 0x1$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$ , when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)  
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$  otherwise.
  - Case where  $\text{GPMCFCLKDIVIDER} = 0x2$ :  
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC\_FCLK period}$ , when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3

$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period, when  $(CSWROFFTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3

$F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period, when  $(CSWROFFTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3

For nADV falling edge (nADV activated):

- Case where  $GPMC\_CONFIG1\_i[1-0]$  GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $ADVONTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $ADVONTIME$  are even)  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when  $(ADVONTIME - CLKACTIVATIONTIME)$  is a multiple of 3  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when  $(ADVONTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3  
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when  $(ADVONTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where  $GPMC\_CONFIG1\_i[1-0]$  GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $ADVRDOFFTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $ADVRDOFFTIME$  are even)  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when  $(ADVRDOFFTIME - CLKACTIVATIONTIME)$  is a multiple of 3  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when  $(ADVRDOFFTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3  
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when  $(ADVRDOFFTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where  $GPMC\_CONFIG1\_i[1-0]$  GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $ADVWROFFTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $ADVWROFFTIME$  are even)  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when  $(ADVWROFFTIME - CLKACTIVATIONTIME)$  is a multiple of 3  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when  $(ADVWROFFTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3  
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when  $(ADVWROFFTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3

For nOE falling edge (nOE activated):

- Case where  $GPMC\_CONFIG1\_i[1-0]$  GPMCFCLKDIVIDER = 0x0:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $OEONTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $OEONTIME$  are even)

- $$H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$$
- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x2$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nOE rising edge (nOE deactivated):

- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are even})$   
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nWE falling edge (nWE activated):

- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are even})$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nWE rising edge (nWE deactivated):

- Case where  $GPMC\_CONFIG1\_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are even})$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV low pulse duration:

- Read operation:

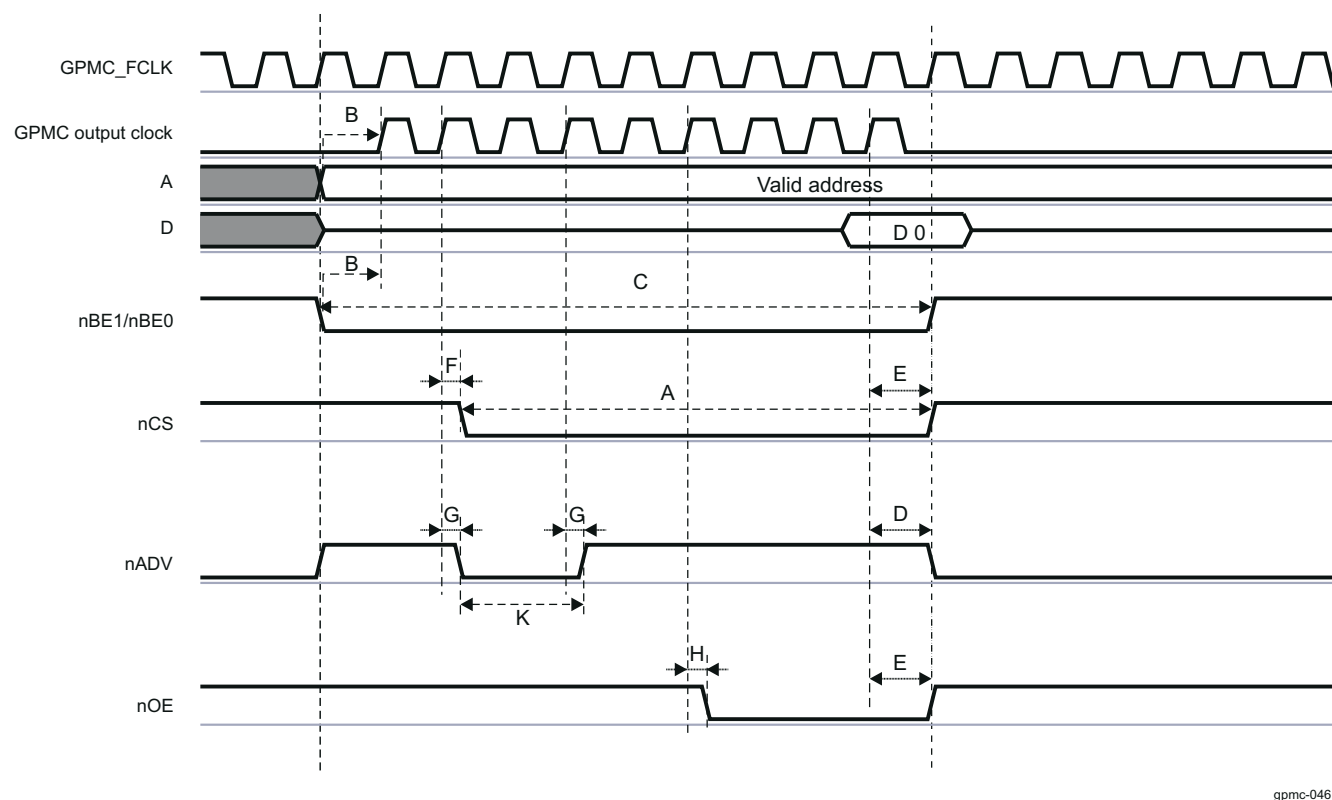

- $$K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$$
- Write operation:  

$$K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$$

For WAIT invalid to first data latching GPMC output clock edge:

- $$L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC\_FCLK \text{ period} + GPMC \text{ output clock period}$$

Figure 12-194 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

gpmc-046

**Figure 12-194. Synchronous NOR Single Read Simplified Example**

### 12.3.3.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when *GPMC\_CONFIG1\_1[11-10]* DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 12-218 describes the asynchronous NOR formulas.

**Table 12-218. Asynchronous NOR Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – nCS valid to nADV/ALE invalid
C	ns	Delay time – nCS valid to nOE/nRE invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – nCS valid to nWE valid
F	ns	Delay time – nCS valid to nWE invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before nOE/nRE high

**Table 12-218. Asynchronous NOR Formulas Description (continued)**

Configuration Parameter	Unit	Description
I	ns	Delay time – nCS valid to nOE/nRE invalid (burst read)
J	ns	Delay time – address bus valid to nCS valid
		Delay time – data bus valid to nCS valid
		Delay time – nBE0 / nBE1 valid to nCS valid
K	ns	Delay time – nCS valid to nADV/ALE valid
L	ns	Delay time – nCS valid to nOE/nRE valid
M	ns	Delay time – nCS valid to first data latching edge
N	ns	Pulse duration – nBE0 / nBE1 valid time
O	ns	Delay time – nCS valid to nADV/ALE valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device-specific Datasheet.

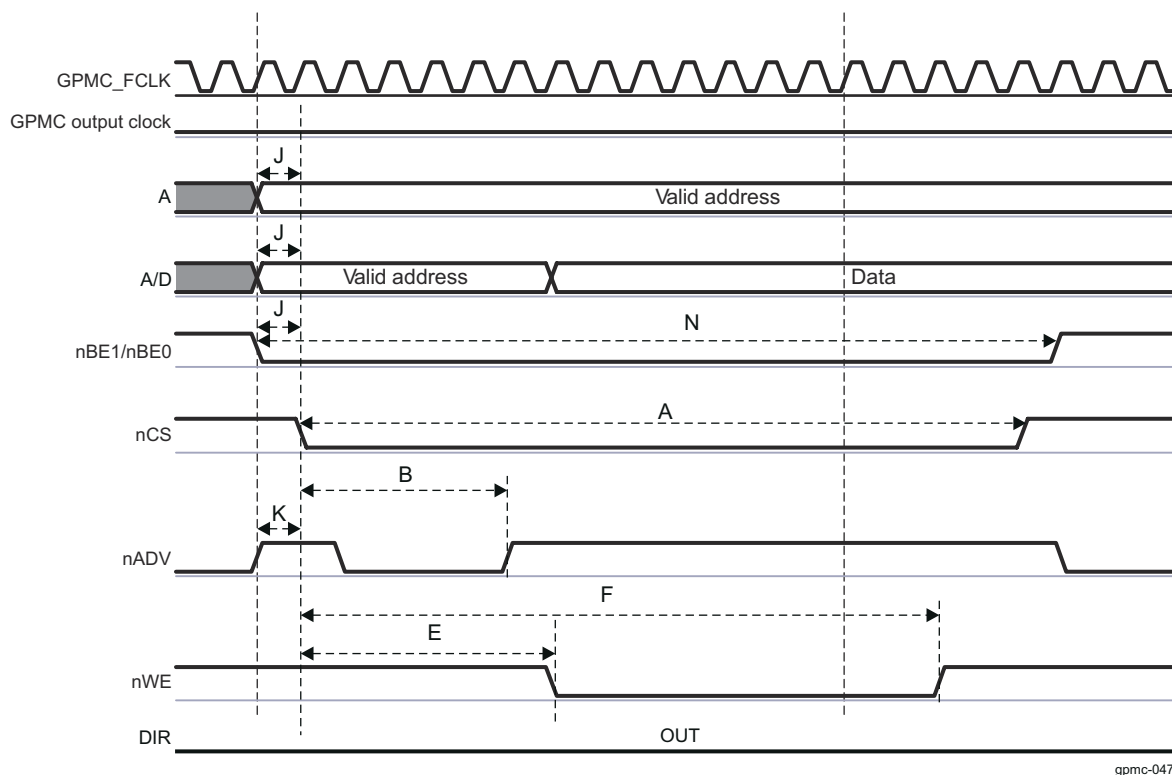

- nCS low pulse:  
For single read:  $A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
For burst read:  $A = (CSRDOFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number  
For single write:  $A = (CSWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$   
For burst write:  $A = (CSWROFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number
- nCS valid to nADV/ALE invalid delay:  
For reading:  $B = ((ADVRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$   
For writing:  $B = ((ADVWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $C = ((OEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$
- $E = ((WEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $F = ((WEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $G = CYCLE2CYCLEDELAY * GPMC\_FCLK \text{ period}$
- $H = ((OEOFFTIME - RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period}$
- $I = ((OEOFFTIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$ , where N = page burst access number
- $J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$
- $K = ((ADVONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $L = ((OEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$
- $M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) - 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period}$
- nBE0 /nBE1 pulse:  
For single read:  $N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$

For burst read:  $N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where  $N$  = page burst access number

For burst write:  $N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where  $N$  = page burst access number

- $O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$

Figure 12-195 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

**Figure 12-195. Asynchronous NOR Single Write Simplified Example**

### Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

### 12.3.4 Error Location Module (ELM)

This section describes the Error Location Module (ELM) for the device.

#### 12.3.4.1 ELM Overview

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller. ELM can be also used to support parallel NOR flash or NAND flash.

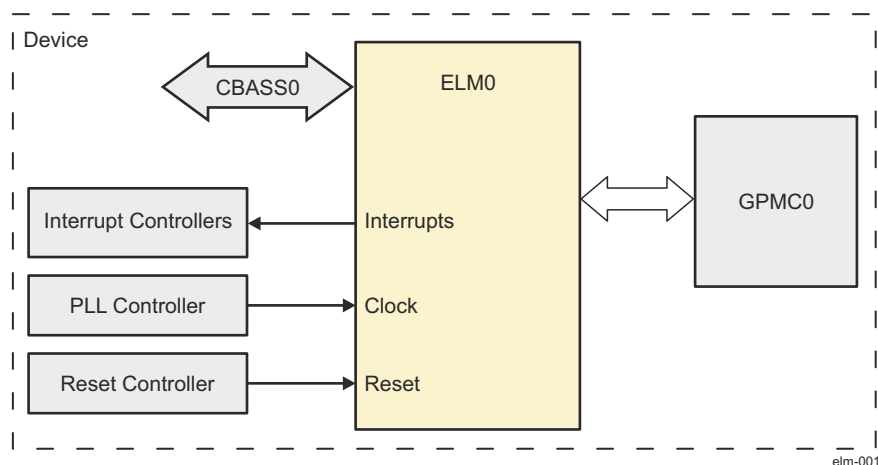

The General-Purpose Memory Controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM depends on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

Figure 12-196 shows the ELM0 module overview.

**Figure 12-196. ELM0 Overview**

#### 12.3.4.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode.

#### 12.3.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 12.3.4.2 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.3.4.3 ELM Functional Description

The ELM0 module is hereinafter referred to as ELM.

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

#### 12.3.4.3.1 ELM Software Reset

To perform a software reset, set the ELM\_SYSCONFIG[1] SOFTRESET bit to 1. The ELM\_SYSSTS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM\_SYSCONFIG[1] SOFTRESET bit is automatically reset.

#### 12.3.4.3.2 ELM Power Management

##### Note

Some of the ELM features described in this section may not be supported on this family of devices. See the *Module Integration* section for more information about Unsupported Features.

Table 12-219 describes the power-management features available to the ELM.

**Table 12-219. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FICLK clock upon the interface activity.
Idle modes	ELM_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained.

#### 12.3.4.3.3 ELM Interrupt Requests

Table 12-220 lists the event flags, and their masks, that can cause module interrupts asserting the signal.

**Table 12-220. ELM Events**

Event Flag	Event Mask	Description
ELM_IRQSTS[8] PAGE_VALID	ELM_IRQEN[8] PAGE_MASK	Page interrupt
ELM_IRQSTS[7] LOC_VALID_7	ELM_IRQEN[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTS[6] LOC_VALID_6	ELM_IRQEN[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTS[5] LOC_VALID_5	ELM_IRQEN[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTS[4] LOC_VALID_4	ELM_IRQEN[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTS[3] LOC_VALID_3	ELM_IRQEN[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3

#### 12.3.4.3.4 ELM Processing Initialization

ELM\_LOCATION\_CONFIG global setting parameters must be set before using the error-location engine. The ELM\_LOCATION\_CONFIG[1-0] ECC\_BCH\_LEVEL bit field defines the error-correction level used (4-, 8-, or 16-bit error correction). The ELM\_LOCATION\_CONFIG[26-16] ECC\_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM\_PAGE\_CTRL[i] SECTOR\_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM\_IRQEN[i] LOCATION\_MASK\_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM\_IRQEN[8] PAGE\_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM\_SYNDROME\_FRAGMENT\_0\_i to ELM\_SYNDROME\_FRAGMENT\_6\_i. The first six registers can be written in any order, but ELM\_SYNDROME\_FRAGMENT\_6\_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit).

As soon as one validity bit is asserted (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM\_LOCATION\_STS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM\_IRQSTS[i] LOC\_VALID\_i bit is set.

#### 12.3.4.3.5 ELM Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM\_LOCATION\_STS\_i[8] ECC\_CORRECTABLE bit is set to 1 and the ELM\_LOCATION\_STS\_i[4-0] ECC\_NB\_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM\_LOCATION\_STS\_i[8] ECC\_CORRECTABLE bit is set to 0 while the ELM\_LOCATION\_STS\_i[4-0] ECC\_NB\_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC\_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC\_ERROR\_LOCATION bit field. The first error detected is logged in the ELM\_ERROR\_LOCATION\_0\_i[12-0] ECC\_ERROR\_LOCATION bit field; the second is logged in the ELM\_ERROR\_LOCATION\_1\_i[12-0] ECC\_ERROR\_LOCATION bit field, and so on.

Table 12-221 describes the ELM\_LOCATION\_STS\_i value decoding.

**Table 12-221. ELM\_LOCATION\_STS\_i Value Decoding**

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
-----------------------	---------------------	--------	---------------------------	-----------------

**Table 12-221. ELM\_LOCATION\_STS\_i Value Decoding (continued)**

1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

#### 12.3.4.3.6 ELM Processing Completion

When the processing for a given syndrome polynomial completes, its ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit is reset. It must not be set again until the exit status registers, ELM\_LOCATION\_STS\_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM\_IRQSTS[i] LOC\_VALID\_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM\_LOCATION\_STS\_i register, and error locations are stored in order in the ECC\_ERROR\_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM\_PAGE\_CTRL are reset), an interrupt is triggered whenever a ELM\_IRQSTS[i] LOC\_VALID\_i bit is asserted. Software must read the ELM\_IRQSTS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM\_LOCATION\_STS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i). When done, software must clear the corresponding ELM\_IRQSTS[i] LOC\_VALID\_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM\_IRQSTS[8] PAGE\_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM\_IRQEN[i] LOCATION\_MASK\_i bits are cleared. A page is defined using the ELM\_PAGE\_CTRL register. Each SECTOR\_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM\_IRQSTS[i] LOC\_VALID\_i bits. The module triggers an ELM\_IRQSTS[8] PAGE\_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM\_IRQSTS register must be cleared by using a single atomic-write access.

#### Note

Do not modify page setting parameters in the ELM\_PAGE\_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM\_PAGE\_CTRL[i] SECTOR\_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM\_IRQSTS bits to check for their status.

### 12.3.4.4 ELM Basic Programming Model

#### 12.3.4.4.1 ELM Low-Level Programming Model

##### 12.3.4.4.1.1 Processing Initialization

**Table 12-222. ELM Processing Initialization**

Step	Register/Bit Field/Programming Model	Value
Resets the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTS[0] RESETDONE	0x1
Configure the target interface power management.	ELM_SYSCONFIG[4-3] SIDLEMODE	Set value
Defines the error-correction level used.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length.	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode.	ELM_PAGE_CTRL	Set value
<b>IF</b> continuous mode is used:	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enable interrupt for syndrome polynomial i.	ELM_IRQEN[i] LOCATION_MASK_i	0x1
<b>ELSE</b> (page mode is used):	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQEN[i] LOCATION_MASK_i = 0x0 and ELM_IRQEN[8] PAGE_MASK = 0x1	Set value
<b>ENDIF</b>		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

##### 12.3.4.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 12-223](#) and [Table 12-224](#) describe the processing completion for continuous and page modes, respectively.

**Table 12-223. ELM Processing Completion for Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTS[i] LOC_VALID_i	0x1
<b>IF</b> the process fails (too many errors): It is software dependant.	ELM_LOCATION_STS_7[8] ECC_CORRECTABLE	0x0
<b>ELSE</b> (process successful, the engine completes):	ELM_LOCATION_STS_7[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STS_7[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_7[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_7[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_7[12-0] ECC_ERROR_LOCATION	
<b>ENDIF</b>		
Clear the corresponding i interrupt.	ELM_IRQSTS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (

ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x0) and after the exit status register check (ELM\_LOCATION\_STS\_i

**Table 12-224. ELM Processing Completion for Page Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTS[8] PAGE_VALID	0x1
<b>Repeat</b> the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	
<b>IF</b> the process fails (too many errors):	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
<b>ELSE</b> (process successful, the engine completes):	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
<b>ENDIF</b>		
<b>End Repeat</b>		
Clear the ELM_IRQSTS register.	ELM_IRQSTS	0x1FF

#### 12.3.4.4.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTS[i] LOC\_VALID\_i = 0x1 for all syndrome polynomials i used in the page).

#### 12.3.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see [Table 12-225](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980.

**Table 12-225. Use Case: Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Reset the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSTS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 8 bits.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x1
Define the maximum buffer length: 528 bytes (2 × 528 = 1056).	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in continuous mode.	ELM_PAGE_CTRL	0
Enable interrupt for syndrome polynomial 0.	ELM_IRQEN[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A

**Table 12-225. Use Case: Continuous Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Initiate the computation process.	<i>ELM_SYNDROME_FRAGMENT_6_i</i> [16] SYNDROME_VALID (where i = 0)	0x1
Wait until process is complete for syndrome polynomial 0: is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	<i>ELM_IRQSTS</i> [0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	<i>ELM_LOCATION_STS</i> [8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	<i>ELM_LOCATION_STS</i> [4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	<i>ELM_ERROR_LOCATION_0_i</i> (where i = 0)	0x1AF
	<i>ELM_ERROR_LOCATION_1_i</i> (where i = 0)	0x426
	<i>ELM_ERROR_LOCATION_2_i</i> (where i = 0)	0x775
	<i>ELM_ERROR_LOCATION_3_i</i> (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	<i>ELM_IRQSTS</i> [0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 12-226](#) are given in decimal format.

**Table 12-226. 16-Bit NAND Sector Buffer Address Map**

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176

50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to

correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

#### 12.3.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for a 16-bit error-correction capability in page mode (see [Table 12-227](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

**Table 12-227. Use Case: Page Mode**

Step	Register/Bit Field/Programming Model	Value
Reset the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSCONFIG[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2

	<i>ELM_ERROR_LOCATION_1_i</i> (where <i>i</i> = 0)	0x617
	<i>ELM_ERROR_LOCATION_2_i</i> (where <i>i</i> = 0)	0x650
	<i>ELM_ERROR_LOCATION_3_i</i> (where <i>i</i> = 0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	<i>ELM_ERROR_LOCATION_0_i</i> (where <i>i</i> = 1)	0x4
	<i>ELM_ERROR_LOCATION_1_i</i> (where <i>i</i> = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	<i>ELM_ERROR_LOCATION_0_i</i> (where <i>i</i> = 1)	0x3E8
Clear the <i>ELM_IRQSTS</i> register.	<i>ELM_IRQSTS</i>	0x1FF

### 12.3.5 Multi-Media Card Secure Digital (MMCSD) Interface

This section describes the MMCSD modules in the device.

#### 12.3.5.1 MMCSD Overview

This device contains one or more MMCSD module instances. Each MMCSD instance includes one MMCSD Host Controller.

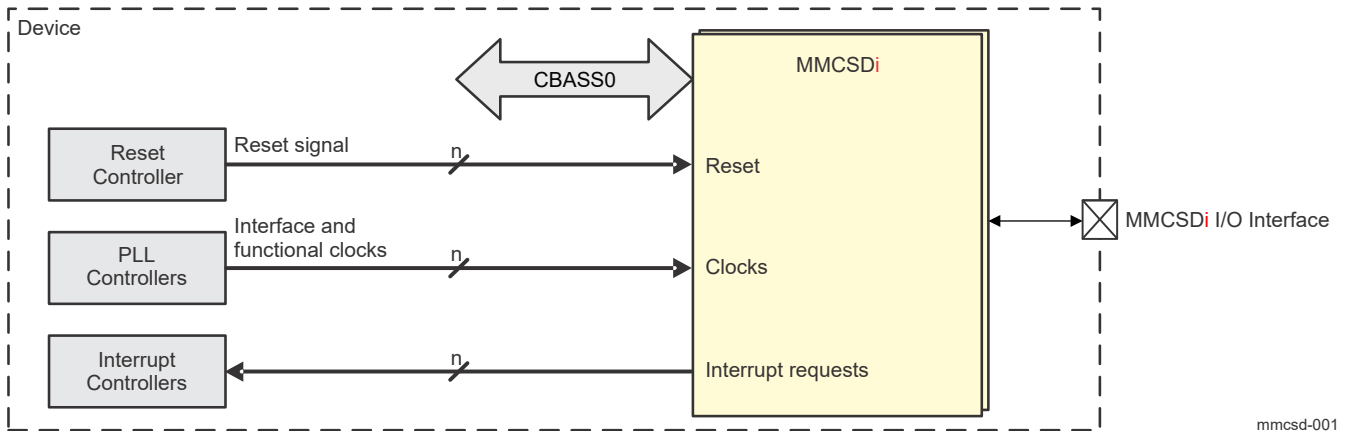

An instance supports either an 8-bit or 4-bit wide data bus.

A host controller can support eMMC and/or SD/SDIO. See the device specific datasheet for interfaces supported by the controller.

The MMCSD Host Controller provides an interface to eMMC 5.1 (embedded Multi-Media Card), SD 4.10 (Secure Digital), and SDIO 4.0 (Secure Digital IO) devices. The MMCSD Host Controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit insertion, and checking for syntactical correctness.

The MMCSD Host Controller provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method. In programmed IO method, the device CPU transfers data using the Buffer Data Port register (MMCSDi\_DATA\_PORT). In DMA data transfer method, the MMCSD Host Controller can read or write memory without device CPU intervention.

Figure 12-197 shows the MMCSDi module overview (where i represents a valid instance of MMCSD in a domain. Consult the device specific datasheet for available domains and instances).

A. i represents a valid instance of MMCSD in a domain.

**Figure 12-197. MMCSDi Module Overview**

### 12.3.5.1.1 MMCSD Features

**Table 12-228. MMCSD Features**

Feature		MMCSD (8-bit)	MMCSD (4-bit)
Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level (See the device specific data sheet for supported interfaces, if applicable)			✓
Controller			
eMMC5.1 Host Specification (JESD84-B51)		✓	✓
Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3 (for more information about ADMA support, see <a href="#">Section 12.3.5.4.4, Advanced DMA</a> )		✓	✓
System Bus Interface			
64-bit data width (host interface)		✓	✓
48-bit address		✓	✓
Clock asynchronous to eMMC clock (MMCi_CLK)		✓	
Clock asynchronous to eMMC/SD clock (MMCi_CLK)			✓
Little endian only		✓	✓
Configuration Bus Interface			
32-bit data width (target interface)		✓	✓
Linear incrementing addressing mode		✓	✓
32-bit aligned accesses only		✓	✓
Little endian only		✓	✓
Multi-Media Card Support			
eMMC Electrical Standard 5.1 (JESD84-B51)		✓	✓
Backward compatible with earlier eMMC standards		✓	✓
Legacy MMC SDR	8-bit bus width, 0-25 MHz, 25 MBps	1.8v	3.3/1.8v
	4-bit bus width, 0-25 MHz, 12.5 MBps		
	1-bit bus width, 0-25 MHz, 3.125 MBps		
High Speed SDR	8-bit bus width, 0-50 MHz, 50 MBps	1.8v	3.3/1.8v
	4-bit bus width, 0-50 MHz, 25 MBps		
	1-bit bus width, 0-50 MHz, 6.25 MBps		
High Speed DDR	8-bit bus width, 0-50 MHz, 100 MBps	1.8v	3.3/1.8v
	4-bit bus width, 0-50 MHz, 50 MBps		
HS200 SDR	0-200 MHz, 8-bit bus width, 200 MBps	1.8v	1.8v
	0-200 MHz, 4-bit bus width, 100 MBps		
HS400 DDR	0-200 MHz, 8-bit bus width, 400 MBps	1.8v	
Secure Digital Card Support			
Backward compatible with earlier SD card specifications			✓
SD Host Controller Standard Specification 4.10 and SD Physical Layer Specification v3.01		✓	✓
SDIO Specification v3.00		✓	✓
Default Speed mode	3.3 V signaling, frequency up to 25 MHz, up to 12.5 MBps		✓
High Speed mode	3.3 V signaling, frequency up to 50 MHz, up to 25 MBps		✓
SDR12	UHS-I 1.8 V signaling, frequency up to 25 MHz, up to 12.5 MBps	✓	✓
SDR25	UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 25 MBps	✓	✓
SDR50	UHS-I 1.8 V signaling, frequency up to 100 MHz, up to 50 MBps	✓	✓
DDR50	UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 50 MBps	✓	✓
SDR104	UHS-I 1.8 V signaling, frequency up to 200 MHz, up to 100 MBps	✓	✓

#### 12.3.5.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

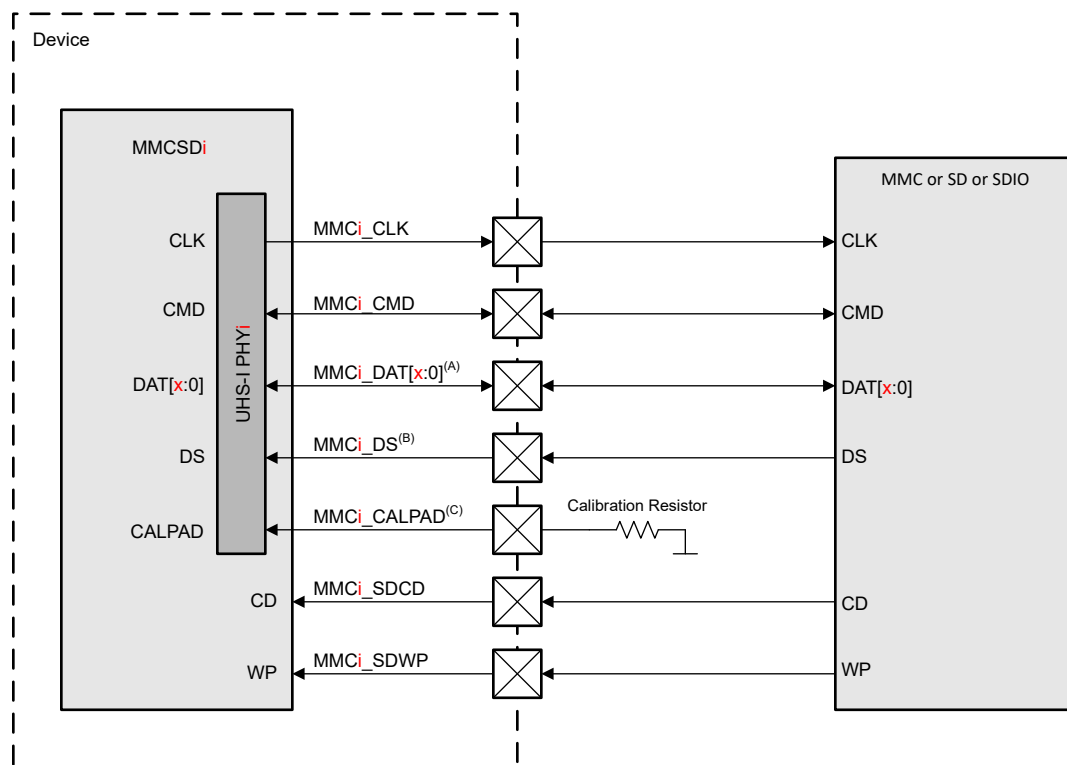

### 12.3.5.2 MMCSD Environment

The MMCSD instance is hereinafter referred to as MMCSDi module.

This section describes the MMCSDi external connections (environment).

The MMCSD (see the device specific datasheet for supported instances) can be used for connection to 1, 4, or 8-bit devices (dedicated for connection to eMMC devices). The MMCSD (see the device specific datasheet for supported instances) can be used for connection to 1 or 4-bit devices (dedicated for connection to SD or SDIO devices). For each MMCSD an integrated UHS-I PHY provides interface to external device.

Figure 12-198 shows the MMCSDi (where i represents a valid instance of MMCSD in a domain. See the device specific datasheet for available domains and MMCSD instances) connected to MMC, SD, or SDIO device.

- A. x=7 for MMCSD (8-bit wide data bus); x=3 for MMCSD (4-bit wide data bus)
- B. Used for HS400 mode (See the device specific datasheet for valid instances)
- C. Used for PHY Calibration Resistor (See the device specific datasheet for valid instances)

**Figure 12-198. MMCSDi Connected to MMC, SD, or SDIO Device**

Table 12-229 describes the MMCSDi I/O signals.

**Table 12-229. MMCSDi I/O Signals**

Module Pin <sup>(4)</sup>	Device Level Signal	I/O <sup>(1)</sup>	Description
<b>MMCSDi<sup>(3)</sup></b>			
CLK	MMCi <sup>(3)</sup> _CLK	O	External Clock
CMD	MMCi <sup>(3)</sup> _CMD	I/O	Command Line
DAT[x:0] <sup>(5)</sup>	MMCi <sup>(3)</sup> _DAT[x:0]	I/O	Data Signals
DS	MMCi <sup>(3)</sup> _DS	I	Data Strobe
CALPAD	MMCi <sup>(3)</sup> _CALPAD <sup>(2)</sup>	A	PHY Calibration Resistor
WP	MMCi <sup>(3)</sup> _SDWP	I	SD Card Write Protect
CD	MMCi <sup>(3)</sup> _SDCD	I	SD Card Detect

(1) I = Input; O = Output; HiZ = High Impedance; A = Analog

(2) An external 10 kΩ ±1% resistor must be connected between this pin and VSS. No external voltage should be applied to this pin.

(3) i represents an MMC instance. See the device datasheet for available domains and MMC instances.

(4) Some pins may not be pinned out or relevant to this device. See the device datasheet for specifics.

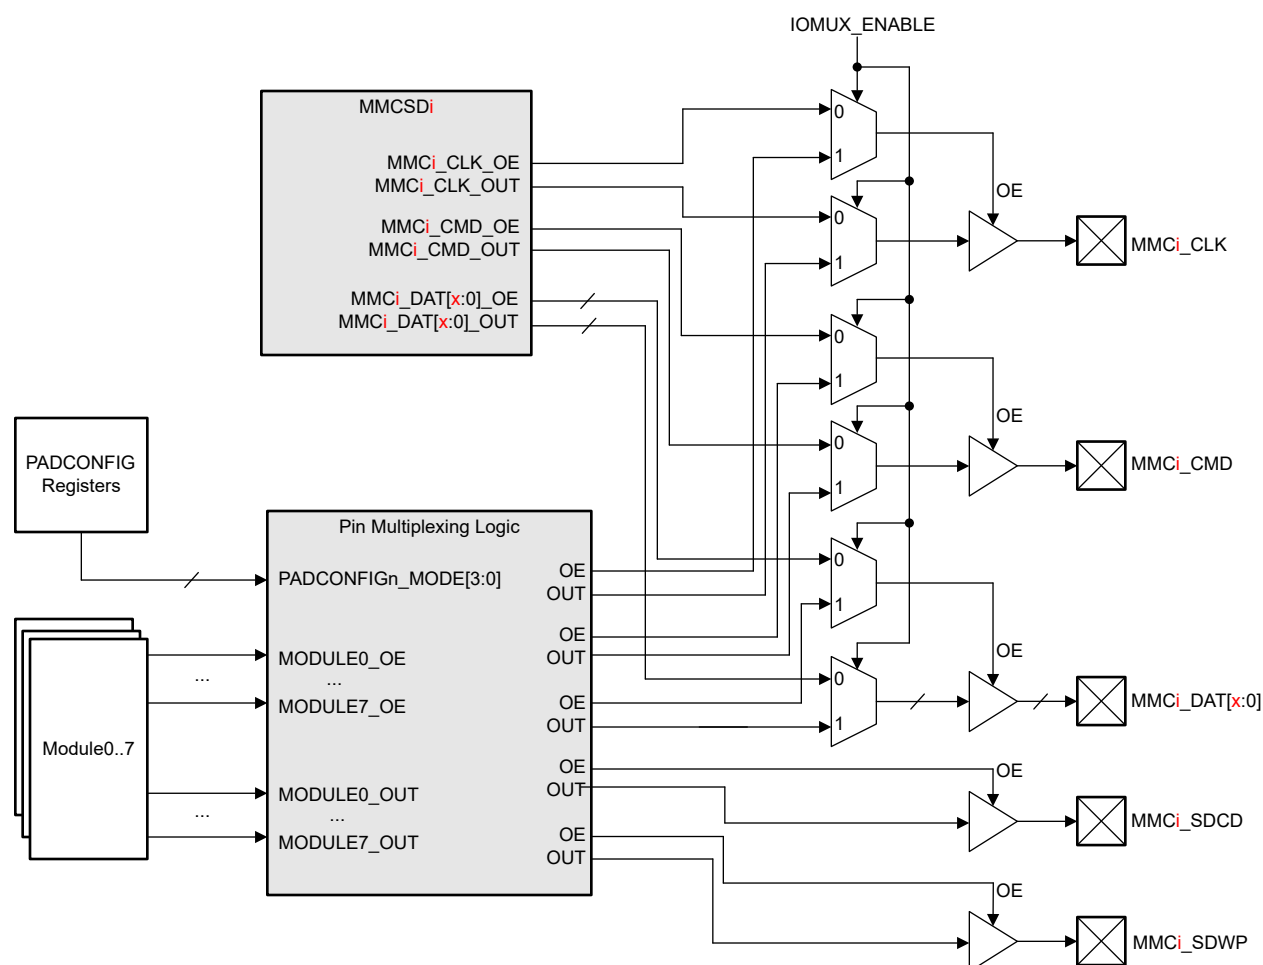

(5) x=7 for MMCSD (8-bit wide data bus); x=3 for MMCSD (4-bit wide data bus)

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), refer to the device-specific Datasheet.

### 12.3.5.2.1 MMCSD IO Multiplexer

Figure 12-199 describes the IOMUX\_ENABLE multiplexer, which is controlled by the MMC\_SSCFG\_PHY\_CTRL\_1\_REG[31] IOMUX\_ENABLE bit.

- A. i represents a valid instance of 4-bit MMCSD only. See the device data sheet for specifics.
- B. x=3 for MMCSD (4-bit wide data bus)
- C. Only MMCi\_CLK, MMCi\_CMD and MMCi\_DAT[n:0] are routed through the IOMUX\_ENABLE multiplexer. MMCi\_SD CD and MMCi\_SD WP are not routed through the IOMUX\_ENABLE multiplexer.
- D. The IOMUX\_ENABLE multiplexer does not affect the signal functions selected from the respective PADCONFIG register for the MMCi\_SD CD or MMCi\_SD WP pins.

**Figure 12-199. MMCSD IOMUX\_ENABLE Multiplexer**

### 12.3.5.2.2 Protocol and Data Format

The bus protocol between the MMCSd Host Controller and the card is message-based. Each message is represented by one of the following parts:

- **Command:** A command starts an operation. The command is transferred serially from the MMCSd Host Controller to the card on the CMD line.
- **Response:** A response is an answer to a command. The response is sent from the card to the MMCSd Host Controller. It is transferred serially on the CMD line.
- **Data:** Data are transferred from the MMCSd Host Controller to the card or from the card to the MMCSd Host Controller using the data lines.
- **Busy:** The DAT[0] signal is maintained low by the card as far as it is programming the data received.
- **CRC status:** The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

#### 12.3.5.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

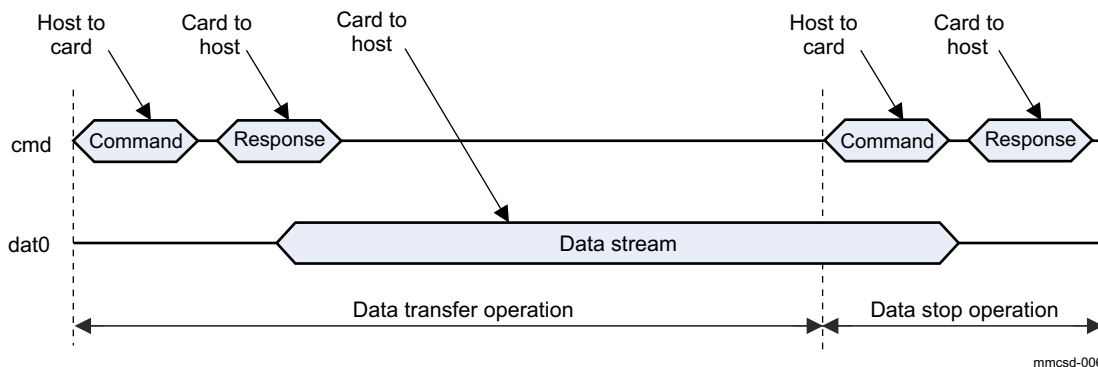

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO devices, see the *Multi-Media Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 12-200 and Figure 12-201 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the CMD line.

#### Note

Stream commands are supported only by MMCs.

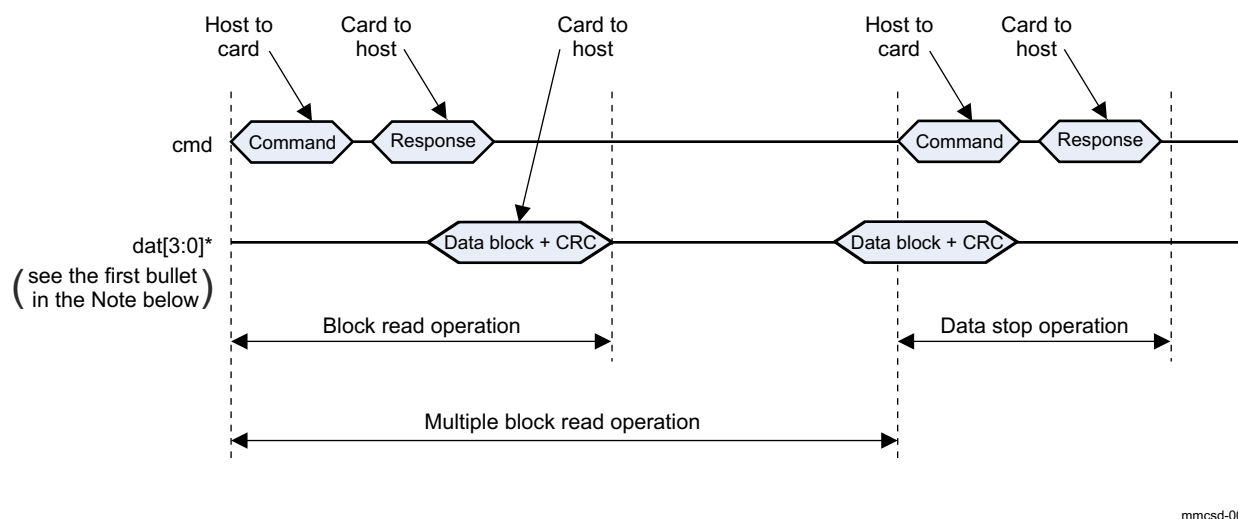

**Figure 12-200. Sequential Read Operation (MMCs Only)**

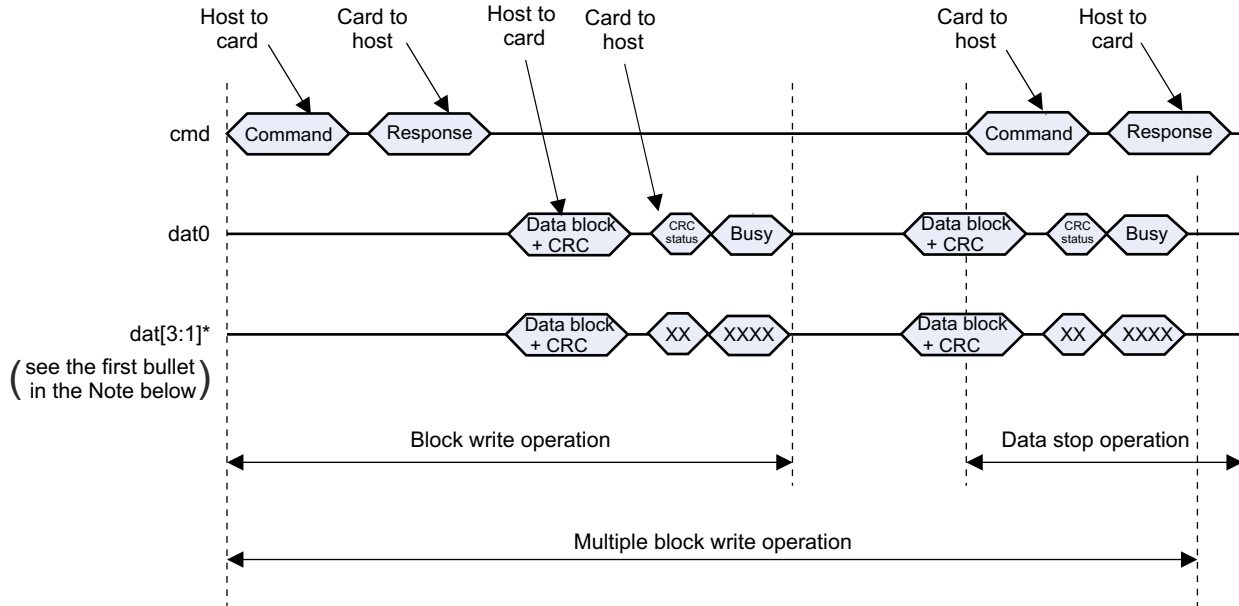

**Figure 12-201. Sequential Write Operation (MMCs Only)**

Figure 12-202 and Figure 12-203 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the CMD line. These operations are available for all kinds of devices (MMC, SD, SDIO).

**Figure 12-202. Multiple Block Read Operation**

**Figure 12-203. Multiple Block Write Operation With Card Busy Signal**

**Note**

- The card busy signal is not always generated by the card. Refer to [Figure 12-202](#) and [Figure 12-203](#), that show a particular case.
- Software must perform a software reset (see MMCS0\_SOFTWARE\_RESET / MMCS1\_SOFTWARE\_RESET register) after a data time-out to ensure that MMCi\_CLK is stopped.
- For multiblock transfer, and especially for MMC devices, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMCs supports this feature).

**12.3.5.2.2.2 Data Format**

**12.3.5.2.2.2.1 Coding Scheme for Command Token**

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 12-204](#)).

**Figure 12-204. Command Token Format**

**12.3.5.2.2.2.2 Coding Scheme for Response Token**

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see [Figure 12-205](#) and [Figure 12-206](#)). Depending on the type of commands sent to the card, the MMCS0\_COMMAND / MMCS1\_COMMAND register must be configured differently to

avoid false CRC or index errors to be flagged on command response (see [Table 12-230](#)). For more information about response types, see the *Multi-Media Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

**Figure 12-205. Response Token Format (R1/R1b, R3, R4, R5/R5b, R6, R7)**

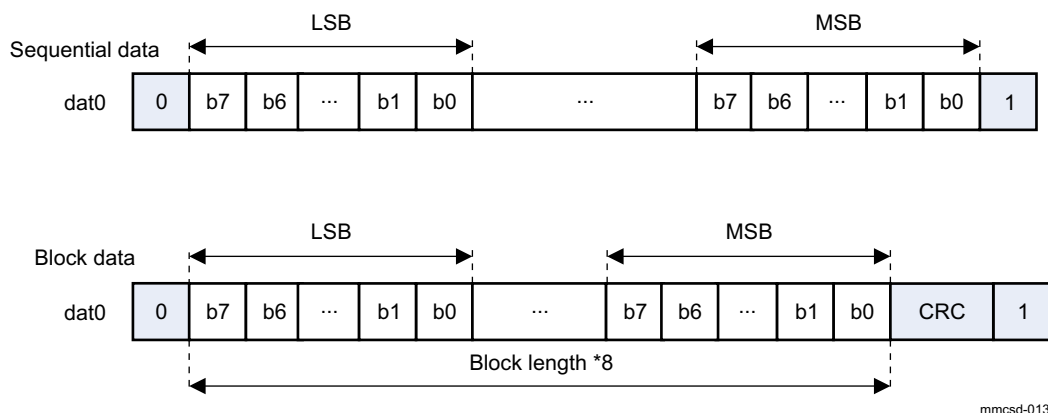

**Figure 12-206. Response Token Format (R2)**

**Table 12-230. Relationship Between Configuration and Name of Response Type**

Response Type MMCSD0_COMMAND[1-0] RESP_TYPE_SEL / MMCSD1_COMMAND[1-0] RESP_TYPE_SEL	Index Check Enable MMCSD0_COMMAND[4] CMD_INDEX_CHK_ENA / MMCSD1_COMMAND[4] CMD_INDEX_CHK_ENA	CRC Check Enable MMCSD0_COMMAND[3] CMD_CRC_CHK_ENA / MMCSD1_COMMAND[3] CMD_CRC_CHK_ENA	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

### 12.3.5.2.2.2.3 Coding Scheme for Data Token

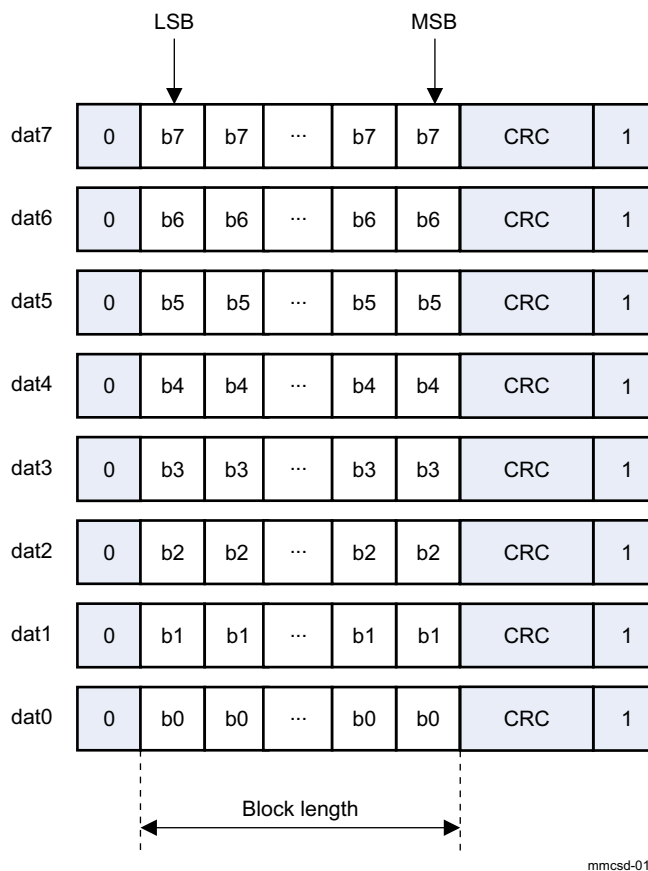

Data tokens always start with 0 and end with 1 (see [Figure 12-207](#) through [Figure 12-209](#)).

**Figure 12-207. Data Token Format for 1-Bit Transfers**

**Figure 12-208. Data Token Format for 4-Bit Transfers**

**Figure 12-209. Data Token Format for 8-Bit Transfers**

### 12.3.5.3 Integration

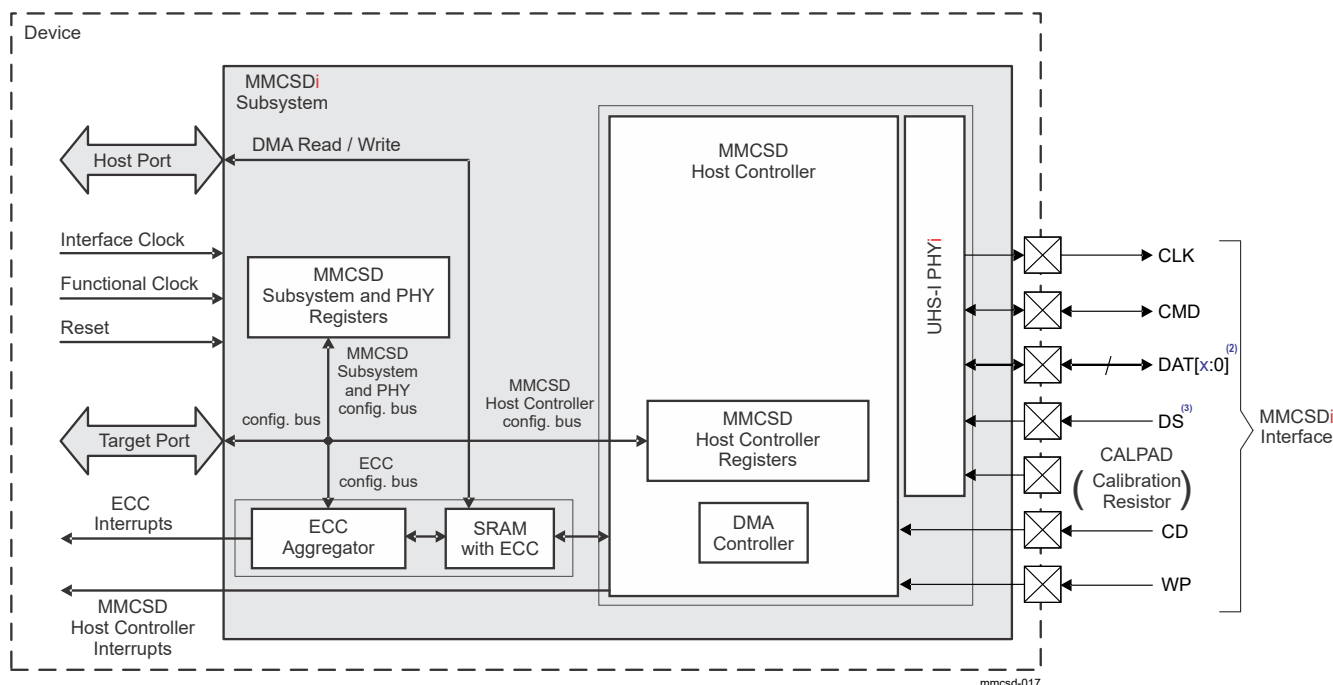

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.3.5.4 MMCSD Functional Description

#### 12.3.5.4.1 Block Diagram

Figure 12-210 shows the MMCSDi module block diagram (where i represents a valid instance of MMCSD in a domain).

- A. (1) i represents a valid instance of MMCSD in a domain. Consult the device specific datasheet for available domains and MMCSD instances.
- B. (2) x = the maximum number of available DAT signals for an instance of MMCSD in a domain.
- C. (3) Used for HS200 mode (Consult the datasheet for supported devices).

**Figure 12-210. MMCSDi Module Block Diagram**

#### Basic Blocks:

- **MMCSD Host Controller:** The MMCSD Host Controller is situated in the MMCSD Subsystem and provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method.
- **UHS-I PHY:** The integrated UHS-I PHY provides an interface between the MMCSD Host Controller and external MMC/SD/SDIO devices.
- **MMCSDi Interface:** The MMCSDi Interface includes all used interface pins (for more information, see [Table 12-229](#)).
- **Host Port:** Provides a 64-bit wide read/write interface between the device and the MMCSD Subsystem internal SRAM.
- **Target Port:** Provides a 32-bit wide interface between the device and the MMCSD Subsystem and MMCSD Host Controller parts.
- **MMCSD Host Controller Registers:** This block includes set of all MMCSD Host Controller registers.
- **MMCSD Subsystem and PHY Registers:** This block implements memory-mapped registers at the MMCSD Subsystem level and memory-mapped registers to control and program the MMCSD PHY.
- **ECC Aggregator:** The ECC Aggregator block facilitates aggregating and reporting internal SRAM ECC errors (for more information, see *ECC Support*).
- **Internal SRAM with ECC:** The internal SRAM block is used for data storage during read/write transactions.
- **DMA Controller:** Manages the data transfer between the device memory and the MMCSD Subsystem internal SRAM.

- System Clocks: There are asynchronous relationship between the interface (system) clock and functional clock (for more information, see *MMCSD Clocks*).
- System Reset: The reset to the MMCSD Subsystem provides reset to the all MMCSD Subsystem parts (for more information, see *MMCSD Clocks*).
- Interrupts: The MMCSD Subsystem sources one MMCSD Host Controller interrupt and four ECC Aggregator interrupts (for more information, see *MMCSD Hardware Requests* and *Interrupt Requests*).

For more information about all MMCSD registers, see *MMCSD Registers*.

The MMCSD Host Controller can use a Programmed IO method (PIO) or DMA data transfer method to access external MMC/SD/SDIO devices.

The target port is used for device CPU access to the MMCSD Host Controller register set. The MMCSD Host Controller register set provides the communication between the device CPU and the MMCSD Host Controller. In PIO method the device CPU transfers data using the MMCSD0\_DATA\_PORT / MMCSD1\_DATA\_PORT register. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the target port, the MMCSD0\_DATA\_PORT / MMCSD1\_DATA\_PORT register in the MMCSD Host Controller, and the PHY.

The host port is used for connection to the DMA controller (for more information about ADMA support, see *Advanced DMA* and MMCSD0\_CAPABILITIES / MMCSD1\_CAPABILITIES register). In DMA data transfer method the DMA controller uses the host port to transfer data between the device memory and the MMCSD Subsystem internal SRAM. The other side of the internal SRAM is connected to the MMCSD Host Controller. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the host port, internal SRAM, MMCSD Host Controller, and the PHY. The DMA controller manages the read/write operations from/to the internal SRAM without device CPU intervention.

#### 12.3.5.4.2 Interrupt Requests

Each MMCSD instance sources one active high level MMCSD Host Controller interrupt and four active high level ECC Aggregator interrupts (see *Module Integration*). The MMCSD Host Controller interrupt is generated based on the bit values in the MMCSD0\_NORMAL\_INTR\_STS / MMCSD1\_NORMAL\_INTR\_STS and MMCSD0\_NORMAL\_INTR\_STS\_ENA / MMCSD1\_NORMAL\_INTR\_STS\_ENA registers. The ECC Aggregator interrupts are generated based on the ECC errors - single and double bit errors (for more information about ECC Aggregator interrupts, see *ECC Support*).

#### 12.3.5.4.3 ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

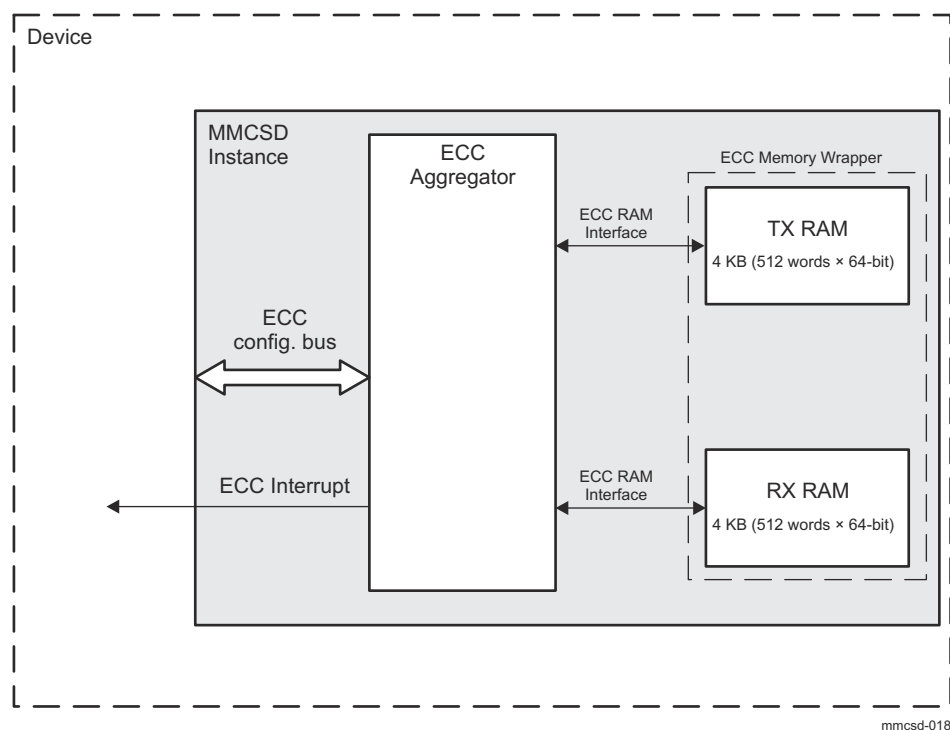

There are two SRAM memories (transmit SRAM and receive SRAM) within each MMCSD instance. These two memories are ECC protected.

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

##### 12.3.5.4.3.1 ECC Aggregator

There are two SRAMs (each with size 4 KB - 512 words × 64-bit) in each MMCSD Subsystem. One SRAM dedicated for transmit and one SRAM dedicated for receive operations.

Figure 12-211 shows the ECC Aggregator block diagram.

**Figure 12-211. ECC Aggregator Block Diagram**

#### Note

For more information about ECC Aggregator Registers, refer to *MMCSD Registers*.

#### 12.3.5.4.4 Advanced DMA

The MMCSD modules support SD Advanced DMA – ADMA2 and ADMA3.

#### Note

For more information, refer to the SD Association specification titled "*SD Host Controller Simplified Specification, Part A2, Version 4.10*".

### 12.3.5.5 MMCSD Programming Guide

#### 12.3.5.5.1 Sequences

This section defines basic sequence flow chart divided into several sub sequences.

#### Note

UHSII is not supported. For more information, see *Not Supported Features*.

"Wait for interrupts" is used in the flow chart. This means the Host Driver waits until specified interrupts are asserted. If already asserted, then fall through that step in the flow chart. Timeout checking shall be always required to detect no interrupt generated but this is not described in the flow chart.

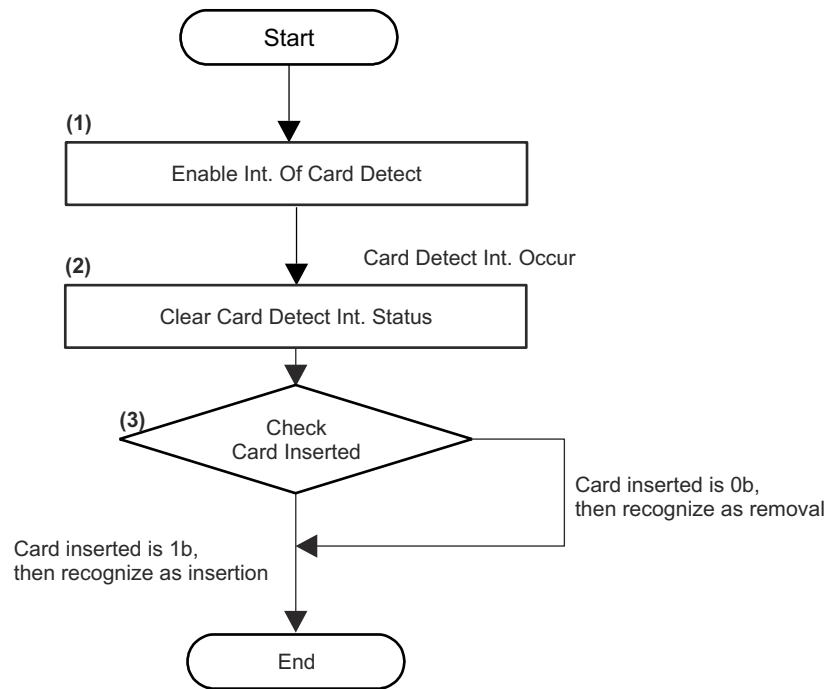

This specification uses the double box like [Figure 12-212](#), (the step (1) in [Figure 12-216](#)), it means that the other flows, which already are shown, shall be performed. Therefore, the interrupt may be included in the other flows.

mmcsd-019

**Figure 12-212. Double Box Notation**

#### 12.3.5.5.1.1 SD Card Detection

mmcsd-020

**Figure 12-213. SD Card Detect Sequence**

The flow chart for detecting a SD card is shown in [Figure 12-213](#).

Each step is executed as follows:

To enable interrupt for card detection, write 1 to the following bits:

- MMCSD0\_NORMAL\_INTR\_STS\_ENA[6] CARD\_INSERTION
- MMCSD0\_NORMAL\_INTR\_SIG\_ENA[6] CARD\_INSERTION

- MMCSD0\_NORMAL\_INTR\_STS\_ENA[7] CARD\_REMOVAL
- MMCSD0\_NORMAL\_INTR\_SIG\_ENA[7] CARD\_REMOVAL

(1) When the Host Driver detects the card insertion or removal, clear its interrupt statuses. If Card Insertion interrupt is generated, write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[6] CARD\_INSERTION bit. If Card Removal interrupt is generated, write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[7] CARD\_REMOVAL bit.

(2) Check MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit. In the case where MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit is 1, the Host Driver can supply the power and the clock to the SD card. In the case where MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit is 0, the other executing processes of the Host Driver shall be immediately closed.

If miniSD adaptor is used for standard SD slot and miniSD card is inserted or extracted from the adaptor, card detect interrupt may not be generated. When host does not receive response to any commands, miniSD card is extracted or in idle state, the host should try to re-initialize the card. In this case, all card information shall be re-loaded.

### 12.3.5.5.1.2 SD Clock Control

#### 12.3.5.5.1.2.1 Internal Clock Setup Sequence

**Figure 12-214. Internal Clock Setup Sequence**

The sequence for supplying SD Clock to a SD card is described in [Figure 12-214](#). From Version 4.10, MMCS0\_CLOCK\_CONTROL[3] PLL\_ENA bit is added. This sequence is also applicable to prior versions which do not support MMCS0\_CLOCK\_CONTROL[3] PLL\_ENA bit.

(1) Calculate a divisor to determine SD Clock frequency for legacy IF or RCLK frequency for UHS-II IF by reading MMCS0\_CAPABILITIES[15-8] BASE\_CLK\_FREQ and MMCS0\_CAPABILITIES[55-48] CLOCK\_MULTIPLIER bit fields. If non-zero value is set to MMCS0\_CAPABILITIES[55-48] CLOCK\_MULTIPLIER bit field, Programmable Clock Mode can be used (for more information, see MMCS0\_CLOCK\_CONTROL[5] CLKGEN\_SEL bit). If MMCS0\_CAPABILITIES[15-8] BASE\_CLK\_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0\_CLOCK\_CONTROL[15-8] SDCLK\_FRQSEL bit field and MMCSD0\_CLOCK\_CONTROL[5] CLKGEN\_SEL bit in accordance with the calculated result of step (1).

If MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set, these bits are set by Host Controller automatically as specified in the Preset Value register (MMCSD0\_PRESET\_VALUE0 - MMCSD0\_PRESET\_VALUE10).

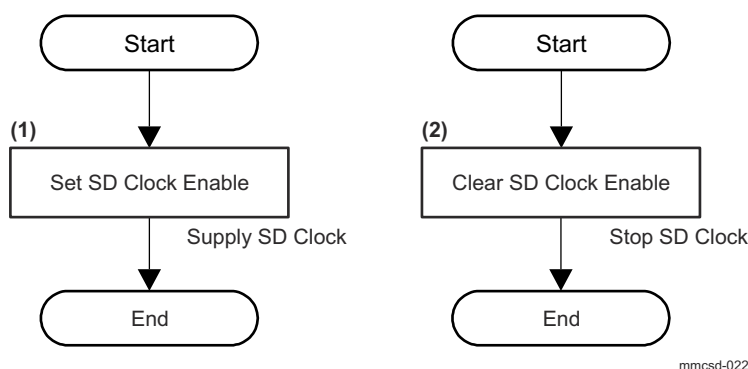

(3) Set MMCSD0\_CLOCK\_CONTROL[0] INT\_CLK\_ENA bit.

(4) Check MMCSD0\_CLOCK\_CONTROL[1] INT\_CLK\_STABLE bit. Repeat this step until this status is 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

(5) Set MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit. This step does not affect Host Controllers which do not support MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit.

(6) If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is supported, PLL locked may be checked by this status (if MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this status is supposed to indicate 1 by step (3)). Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

#### 12.3.5.5.1.2.2 SD Clock Supply and Stop Sequence

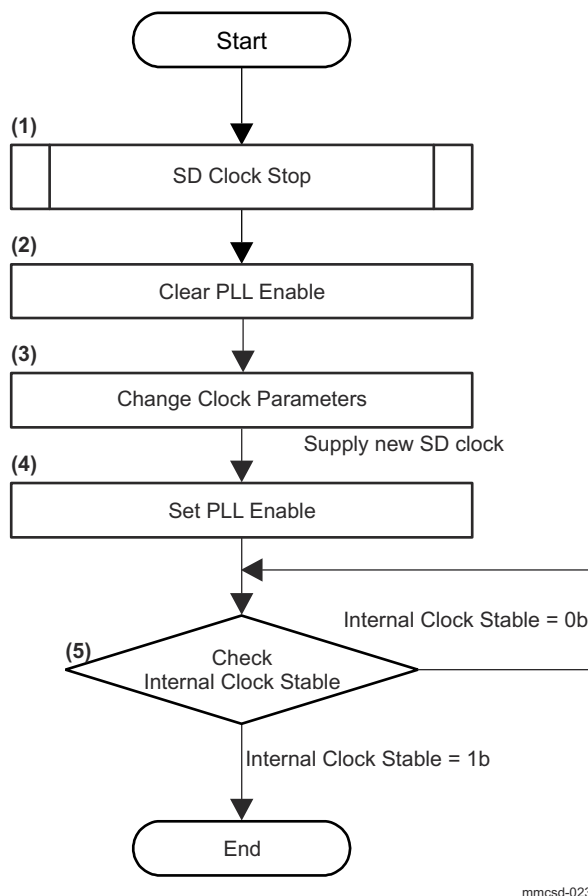

**Figure 12-215. SD Clock Supply and Stop Sequence**

The flow chart for stopping the SD Clock is shown in [Figure 12-215](#). The Host Driver shall not stop the SD Clock when a SD transaction is occurring on the SD Bus -- namely, when either MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT or MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is set to 1.

(1) Setup Internal Clock (see [Figure 12-214](#)). Then set MMCSD0\_CLOCK\_CONTROL[2] SD\_CLK\_ENA bit to 1. Then, the Host Controller starts supplying the SD Clock.

(2) Set MMCSD0\_CLOCK\_CONTROL[2] SD\_CLK\_ENA bit to 0. Then, the Host Controller stops supplying the SD Clock. Internal Clock is still oscillating.

### 12.3.5.5.1.2.3 SD Clock Frequency Change Sequence

**Figure 12-216. SD Clock Change Sequence**

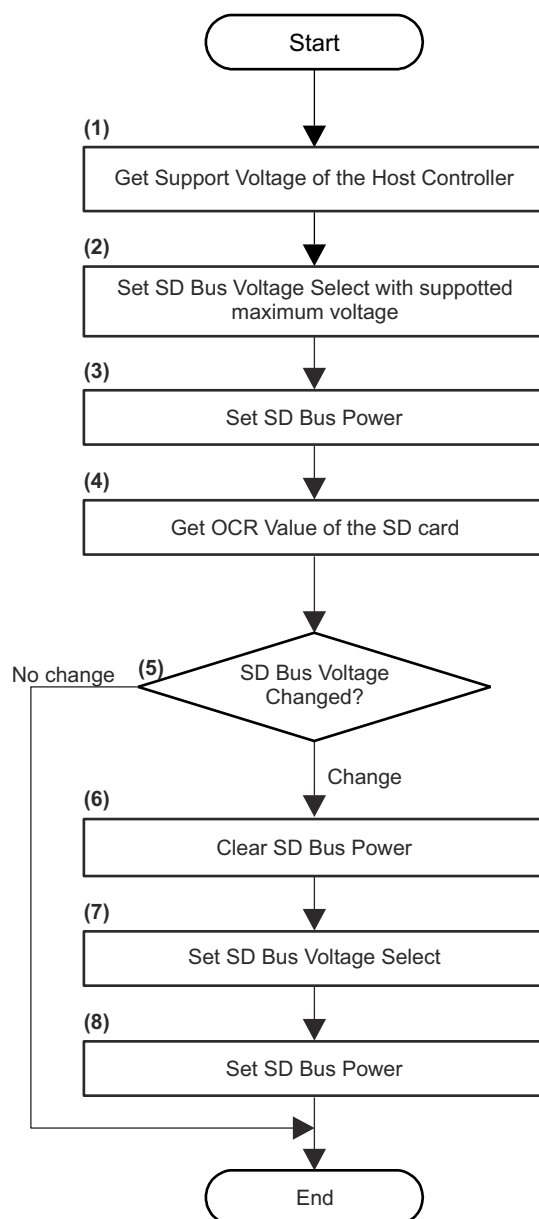

The sequence for changing SD Clock frequency is shown in [Figure 12-216](#).

- (1) Execute the SD Clock Stop Sequence (see [Figure 12-215](#)). If SD Clock supply to card is already stopped, skip this step.
- (2) Clear MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit to 0. If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this step has no effect and may be skipped.
- (3) When MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set to 0, change clock parameters in the MMCSD0\_CLOCK\_CONTROL register. When MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set to 1, select Bus Speed Mode as described.
- (4) Set MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit to 1. If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this step this step has no effect and may be skipped.
- (5) Wait until MMCSD0\_CLOCK\_CONTROL[1] INT\_CLK\_STABLE bit is set to 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms. SD Clock Supply Sequence is required to provide clock to device (see [Figure 12-215](#)).

### 12.3.5.5.1.3 SD Bus Power Control

The sequence for controlling the SD Bus Power is described in [Figure 12-217](#).

mmcsd-024

**Figure 12-217. SD Bus Power Control Sequence**

- (1) By reading the MMCSDB0\_CAPABILITIES register, get the support voltage of the Host Controller.
- (2) Set MMCSDB0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field with maximum voltage that the Host Controller supports.
- (3) Set MMCSDB0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit to 1.
- (4) Get the OCR value of all function internal of SD card.
- (5) Judge whether SD Bus voltage needs to be changed or not. In case where SD Bus voltage needs to be changed, go to step (6). In case where SD Bus voltage does not need to be changed, go to "End".
- (6) Set MMCSDB0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit to 0 for clearing this bit. The card requires voltage rising from 0 volt to detect it correctly. The Host Driver shall

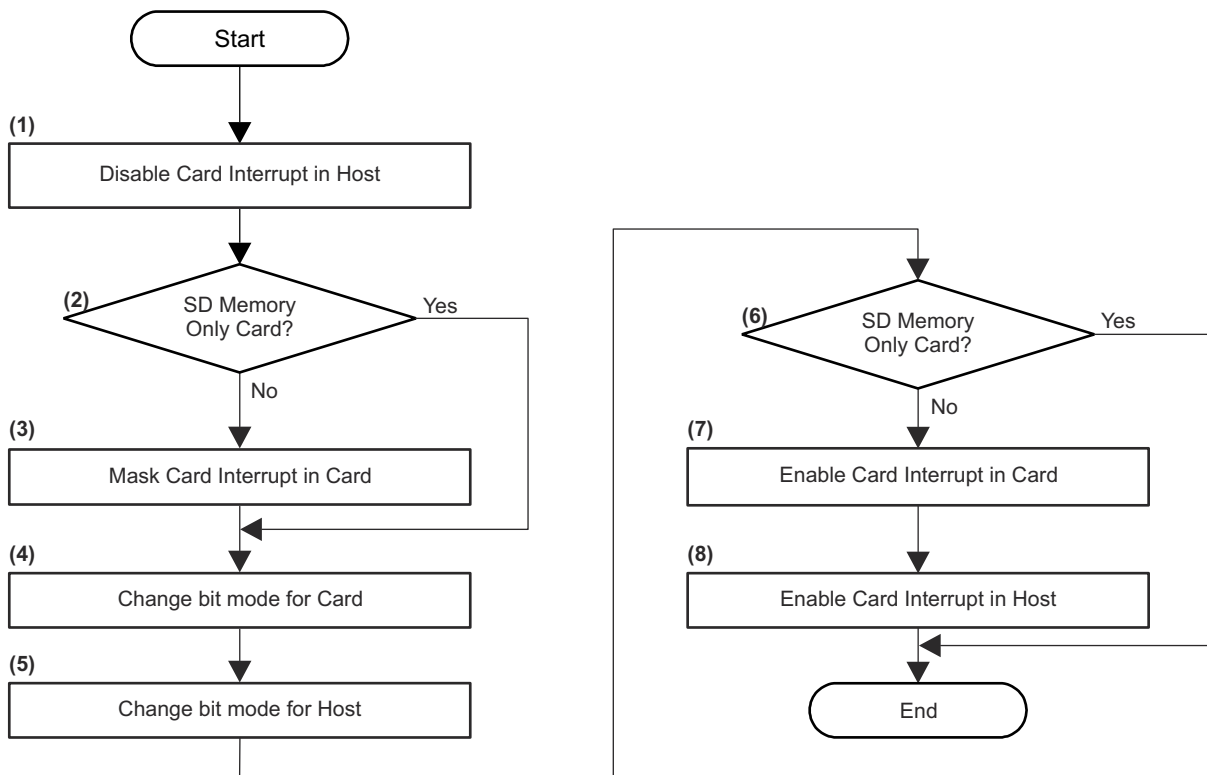

clear MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit before changing voltage by setting MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field.

(7) Set MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field.

(8) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER to 1.

**Note:** Step (2) and step (3) can be executed at same time. And also, step (7) and step (8) can be executed at same time.

#### 12.3.5.5.1.4 Changing Bus Width

mmcsd-025

**Figure 12-218. Change Bus Width Sequence**

The sequence for changing bit mode on SD Bus is shown in [Figure 12-218](#).

(1) Set MMCSD0\_NORMAL\_INTR\_STS\_ENA[8] CARD\_INTERRUPT bit to 0 for masking incorrect interrupts that may occur while changing the bus width.

(2) In case of SD memory only card, go to step (4). In case of other card, go to step (3).

(3) Set "IENM" of the CCCR in a SDIO or SD combo card to 0 by CMD52.

(4) Change the bus width mode for a SD card. SD Memory Card bus width is changed by ACMD6 and SDIO card bus width is changed by setting Bus Width of Bus Interface Control register in CCCR.

(5) In case of changing to 4-bit mode, set MMCSD0\_HOST\_CONTROL1[1] DATA\_WIDTH bit to 1. In another case (1-bit mode), set this bit to 0.

(6) In case of SD memory only card, go to the "End". In case of other card, go to step (7).

(7) Set "IENM" of the CCCR in a SDIO or SD combo card to 1 by CMD52.

(8) Set MMCSD0\_NORMAL\_INTR\_STS\_ENA[8] CARD\_INTERRUPT bit to 1.

Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

#### 12.3.5.5.1.5 Timeout Setting on DAT Line

mmcsd-026

**Figure 12-219. Timeout Setting Sequence**

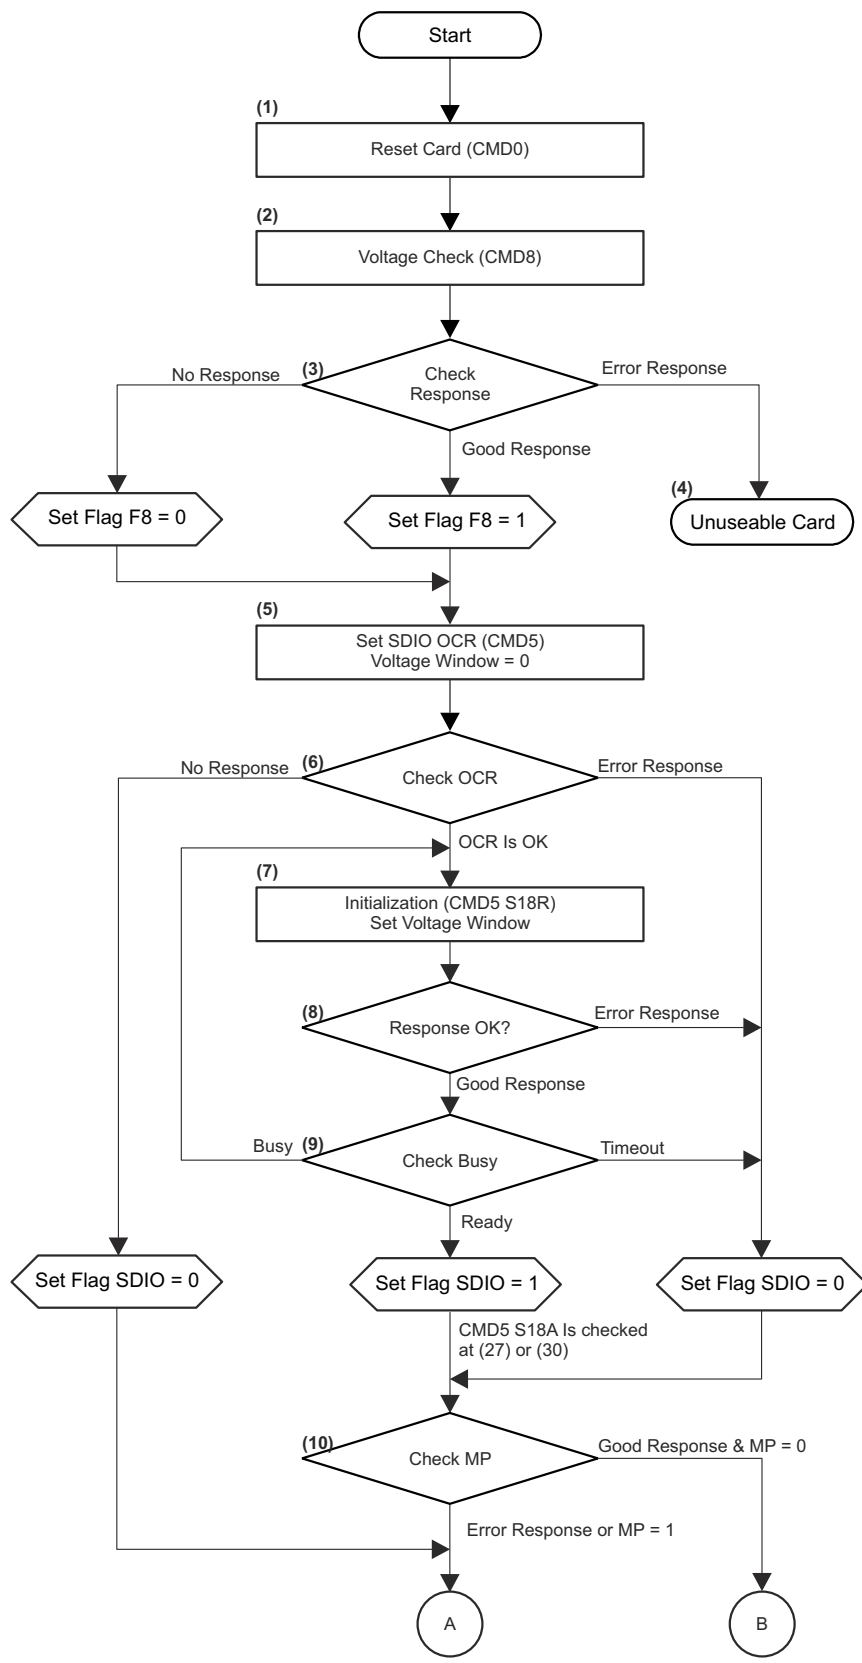

In order to detect timeout errors on DAT line, the Host Driver shall execute the following two steps before any SD transaction. For more information regarding SD transactions:

(1) Calculate a divisor to detect timeout errors by reading MMCSD0\_CAPABILITIES[5-0] TIMEOUT\_CLK\_FREQ bit field and MMCSD0\_CAPABILITIES[7] TIMEOUT\_CLK\_UNIT bit. If MMCSD0\_CAPABILITIES[5-0] TIMEOUT\_CLK\_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0\_TIMEOUT\_CONTROL[3-0] COUNTER\_VALUE bit field in accordance with the value from step (1) above.

#### 12.3.5.5.1.6 Card Initialization and Identification (for SD I/F)

Figure 12-220 and Figure 12-221 shows initialization and card identification sequence for the Standard Capacity SD Memory Card (SDSC), the High Capacity SD Memory Card (SDHC) and the Extended Capacity SD Memory Card (SDXC) that was based on the Physical Layer Version 3.01. Refer to the latest sequence.

mmscd-027

**Figure 12-220. Card Initialization and Identification (1)**

mmscd-028

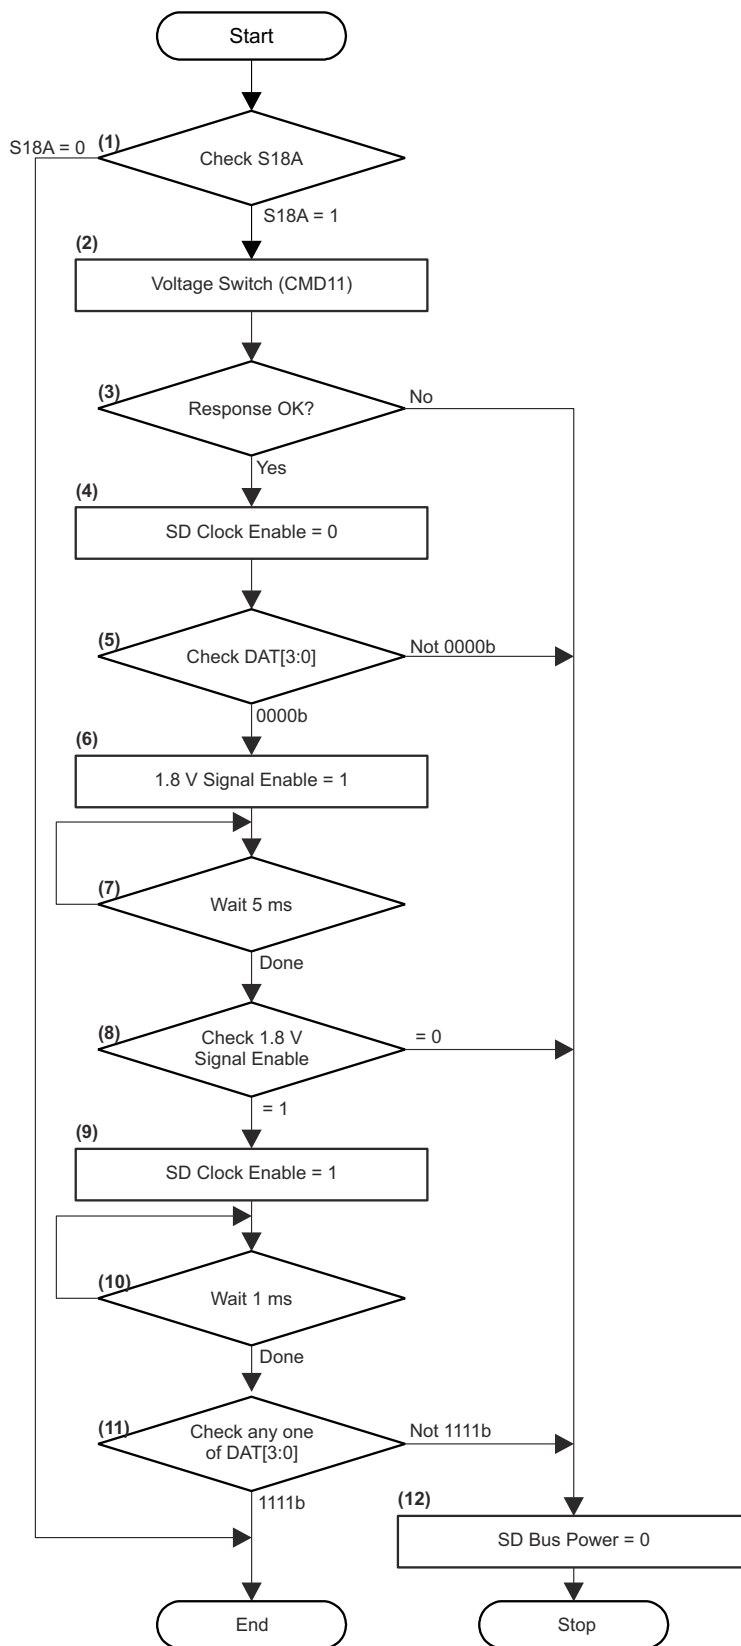

**Figure 12-221. Card Initialization and Identification (2)**

- (1) SD Bus mode is selected by CMD0 (Keep Pin 1 to high during CMD0 execution).
- (2) New CMD8 shall be issued after CMD0 to support High Capacity SD Memory Card.

- (3) Voltage check command enables the Hosts to support future low voltage specification. However, at this time, only one voltage is defined. Legacy cards and Not SD cards do not respond to CMD8. In this case, set F8 to 0 (F8 is CMD8 valid flag used in step (11)) and go to Step (5). Only Version 2.00 or higher cards can respond to CMD8. The host needs to check whether CRC of the response is valid and whether VHS and check pattern in the argument are equal to VCA and check pattern in the response. Passing all these checks results in CMD8 response OK. In this case, set F8 to 1 and go to step (5). If one of the checks is failed, go to step (4).
- (4) Initialization is stopped by CMD8 fails. The Host Driver should retry step (1) to (3) one more time (this is not described in the figure).
- (5) SDIO OCR is available by issuing CMD5 with setting voltage window (bit 23 to 0) in the argument to 0. SDIO initialization is not started.
- (6) No response means the card does not have SDIO function. Set SDIO flag to 0 and go to step (11). If the card responds to CMD5 and the response is OK, go to step (7). If the response is error, set SDIO flag to 0 and go to step (10). SDIO flag indicates whether SDIO functions are initialized or not.
- (7) The SDIO portion starts initialization by CMD5 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.
- (8) If no response or error response is receive, set SDIO flag to 0 and go to step (10). If good response is received, go to step (9).
- (9) Check busy status in the response. If busy is released, set SDIO flag to 1 and go to step (10). Repeat from step (7) while busy is indicated. Detecting timeout of 1 second exits the loop. In this case, set SDIO flag to 0 and go to step (10).
- (10) Good response in this step means that all responses received at (6) and (8) are valid. When response is good, MP (memory present) flag in the response can be checked. If the response valid and MP = 0, go to step (28). Otherwise, go to step (11).
- (11) Check F8 flag set in step (3). If CMD8 is executed correctly (F8 = 1), go to step (19). Otherwise, go to step (12).
- (12) OCR is available by issuing ACMD41 with the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. The response of CMD55 (ACMD41) may indicate illegal command error due to some SD cards do not recognized CMD8. The Host Driver should ignore this error or issue CMD0 before ACMD41 to clear this error status.
- (13) If response of CMD55 is not received, the card is not SD cards and goes to (17). If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (14). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.
- (14) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.
- (15) If no response or error response is received, go to step (28). If good response is received, go to step (16).
- (16) Check busy status in the response. If busy is released, go to step (18). Repeat from step (14) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).
- (17) The host recognizes that the card is not SD memory card and quits SD card initialization.
- (18) The host recognizes that the card is Version 1.xx Standard Capacity SD Memory Card. Go to Step (30).
- (19) OCR is available by issuing ACMD41 with setting the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. Setting of HCS does not affect this operation.

- (20) If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (21). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.
- (21) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the host can supply more than 150mA, XPC is set to 1. HCS in the argument is set to 1, which indicates supporting High Capacity Memory Card. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.
- (22) If no response or error response is received, go to step (28). If good response is received, go to step (23).
- (23) Check busy status in the response. If busy is released, go to step (24). Repeat from step (21) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).
- (24) CCS in the response is valid after busy is released. If CCS = 0, it indicates the Standard Capacity SD Memory Card and go to step (25). If CCS = 1, it indicates the High Capacity SD Memory Card or Extended Capacity Memory Card and go to Step (26).
- (25) The host recognizes that the card is Ver2.00 or Ver3.00 Standard Capacity SD Memory Card. Optimal functions defined in Version 2.00 or higher are available. Go to Step (32).
- (26) The host recognizes that the card is the High Capacity SD Memory Card or Extended Capacity Memory Card.
- (27) Perform the signal voltage switch procedure and go to step (32).
- (28) Check SDIO flag. If SDIO = 1, go to step (28). Otherwise, go to step (31).
- (29) The host recognizes that the card is SDIO only card and go to step (30).
- (30) Perform the signal voltage switch procedure and go to step (33).
- (31) The host recognizes that the card is unusable.
- (32) In case of memory card, CMD2 is issued to get CID and Go to Step (31).
- (33) CMD3 is issued to get RCA. If the RCA number is 0, the Host should issue CMD3 again.

### 12.3.5.5.1.6.1 Signal Voltage Switch Procedure (for UHS-I)

mmscd-029

**Figure 12-222. Signal Voltage Switch Procedure**

- (1) If S18A of CMD5 or S18A of ACMD41 is set to 1, signal voltage switch is performed according to the following steps. Otherwise, exits from this procedure.
- (2) Issue CMD11.
- (3) Check response and if an error is detected, go to step (12).
- (4) Stop providing SD clock to the card.
- (5) Check DAT[3:0] level. If the level is 0000b, the card is ready to start voltage switch sequence. Otherwise, go to (12) to quit the sequence.
- (6) Set MMCSD0\_HOST\_CONTROL2[3] V1P8\_SIGNAL\_ENA bit.
- (7) Wait 5 ms. 1.8 V voltage regulator shall be stable within this period.
- (8) If MMCSD0\_HOST\_CONTROL2[3] V1P8\_SIGNAL\_ENA bit is cleared by Host Controller, go to step (12).
- (9) Provide SD Clock to the card again.
- (10) Wait 1 ms.
- (11) Check DAT[3:0] level. If the level is 1111b, switch to 1.8 V signal level is completed successfully. Otherwise, go to (12).
- (12) If an error occurs during voltage switch procedure, stop providing the power to the card. In this case, Host Driver should retry initialization procedure by setting S18R to 0 at step (7) and (21) in [Figure 12-220](#) and [Figure 12-221](#).

#### **12.3.5.5.1.7 SD Transaction Generation**

This section describes the sequences how to generate and control various kinds of SD transactions. SD transactions are classified into three cases:

- (1) Transactions that do not use the DAT line.
- (2) Transactions that use the DAT line only for the busy signal.
- (3) Transactions that use the DAT line for transferring data.

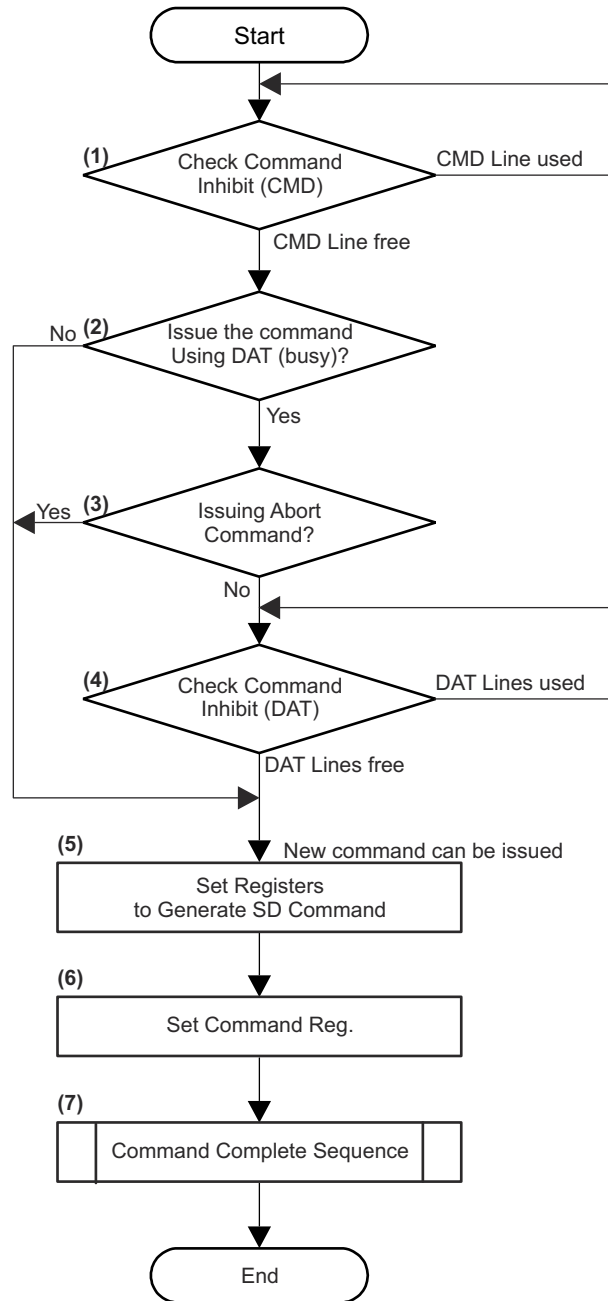

In this specification the first and the second case's transactions are classified as "Transaction Control without Data Transfer using DAT Line", the third case's transaction is classified as "Transaction Control with Data Transfer using DAT Line". Refer to the latest SD Physical Layer Specification and SDIO Specification for more detail about SD commands specification.

##### **12.3.5.5.1.7.1 Transaction Control without Data Transfer Using DAT Line**

In this section, the sequence for how to issue SD Command and how to complete SD Command is explained. [Figure 12-223](#) shows the sequence to issue a SD Command and [Figure 12-224](#) shows the sequence to finalize a SD Command.

##### **12.3.5.5.1.7.1.1 The Sequence to Issue a SD Command**

The sequence to issue the SD Command is detailed in [Figure 12-223](#).

mmcsd-030

**Figure 12-223. SD Command Issue Sequence**

(1) Check MMCSDB0\_PRESENTSTATE[0] INHIBIT\_CMD bit. Repeat this step until MMCSDB0\_PRESENTSTATE[0] INHIBIT\_CMD bit is 0. That is, when MMCSDB0\_PRESENTSTATE[0] INHIBIT\_CMD bit is 1, the Host Driver shall not issue a SD Command.

(2) If the Host Driver issues a SD Command using DAT lines including busy signal, go to step (3). If without using DAT lines including busy signal, go to step (5).

(3) If the Host Driver is issuing an abort command, go to step (5). In the case of nonabort command, go to step (4).

(4) Check MMCSDB0\_PRESENTSTATE[1] INHIBIT\_DAT bit. Repeat this step until MMCSDB0\_PRESENTSTATE[1] INHIBIT\_DAT bit is set to 0.

(5) Set registers except the MMCSD0\_COMMAND register.

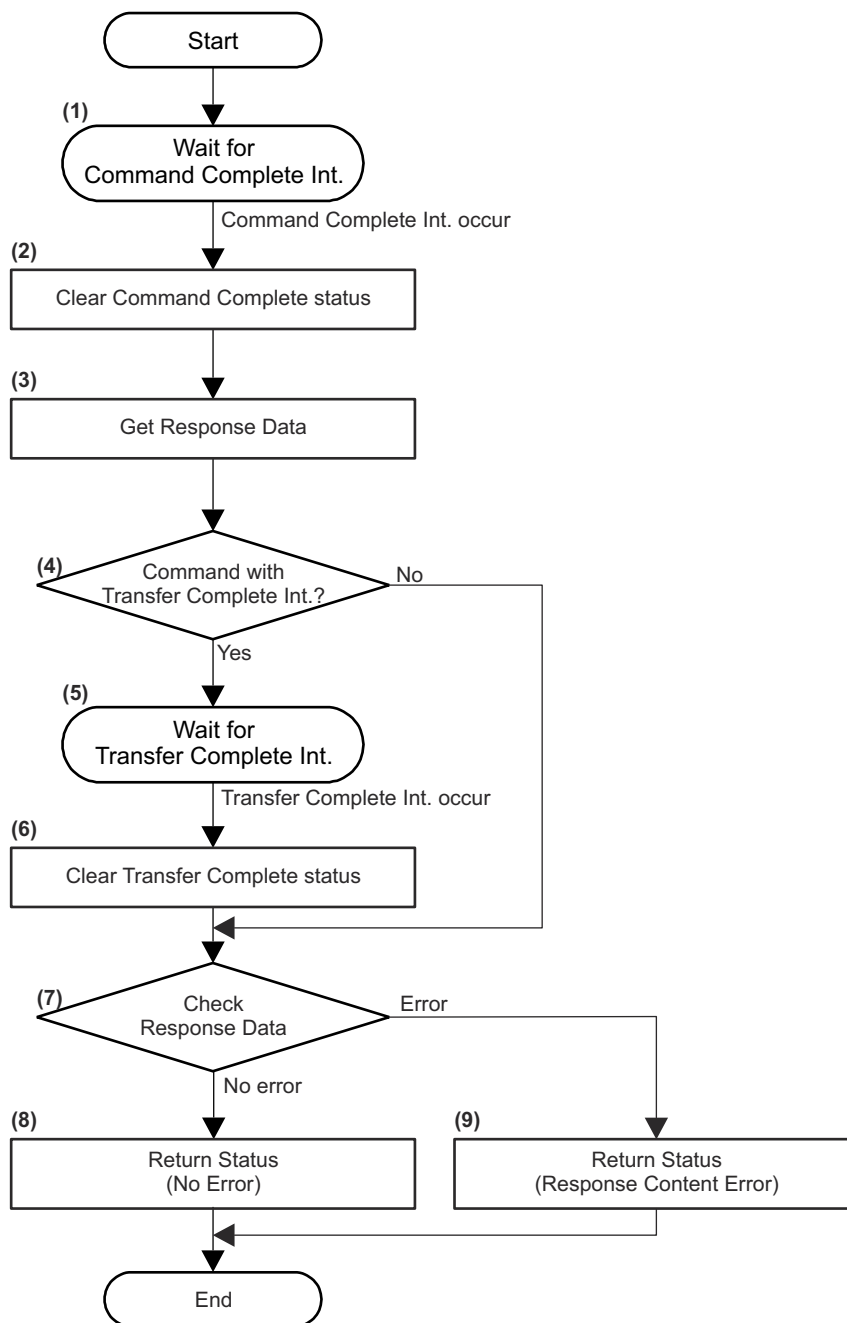

(6) Set the MMCSD0\_COMMAND register.

**Note:** Writing the upper byte [3] in the MMCSD0\_COMMAND register causes the Host Controller to issue a SD command to the SD card.

(7) Perform Command Completion Sequence in accordance.

#### **12.3.5.5.1.7.1.2 The Sequence to Finalize a Command**

[Figure 12-224](#) shows the sequence to finalize a SD Command when response check is disabled. There is a possibility that some errors (Command Index/End bit/CRC/Timeout Error) occur during this sequence. If response check is enabled, error is indicated by Response Error Interrupt.

mmcsd-031

**Figure 12-224. Command Complete Sequence**

#### 12.3.5.5.1.7.1.3

(1) If MMCSDD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit is set to 1 (response check is enabled), go to stop (4) else wait for the Command Complete Interrupt (MMCSDD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE). If the Command Complete Interrupt has occurred, go to step (2).

(2) Write 1 to MMCSDD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(3) Read the Response register (see MMCSDD0\_RESPONSE\_0 - MMCSDD0\_RESPONSE\_7) and get necessary information of the issued command.

- (4) Judge whether the command uses the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) or not. If it uses Transfer Complete, go to step (5). If not, go to step (7).
- (5) Wait for the Transfer Complete Interrupt. If the Transfer Complete Interrupt has occurred, go to step (6).
- (6) Write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to clear this bit.
- (7) Check for errors in Response Data (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7). If there is no error, go to step (8). If there is an error, go to step (9).
- (8) Return Status of "No Error".
- (9) Return Status of "Response Contents Error".

**Note1:** While waiting for the Transfer Complete interrupt, the Host Driver shall only issue commands that do not use the busy signal.

**Note2:** The Host Driver shall judge the Auto CMD12 complete by monitoring Transfer Complete.

**Note3:** When the last block of un-protected area is read using memory multiple block read command (CMD18), OUT\_OF\_RANGE error may occur even if the sequence is correct. The Host Driver should ignore it. This error will appear in the response of Auto CMD12 or in the response of the next memory command.

#### **12.3.5.5.1.7.2 Transaction Control with Data Transfer Using DAT Line**

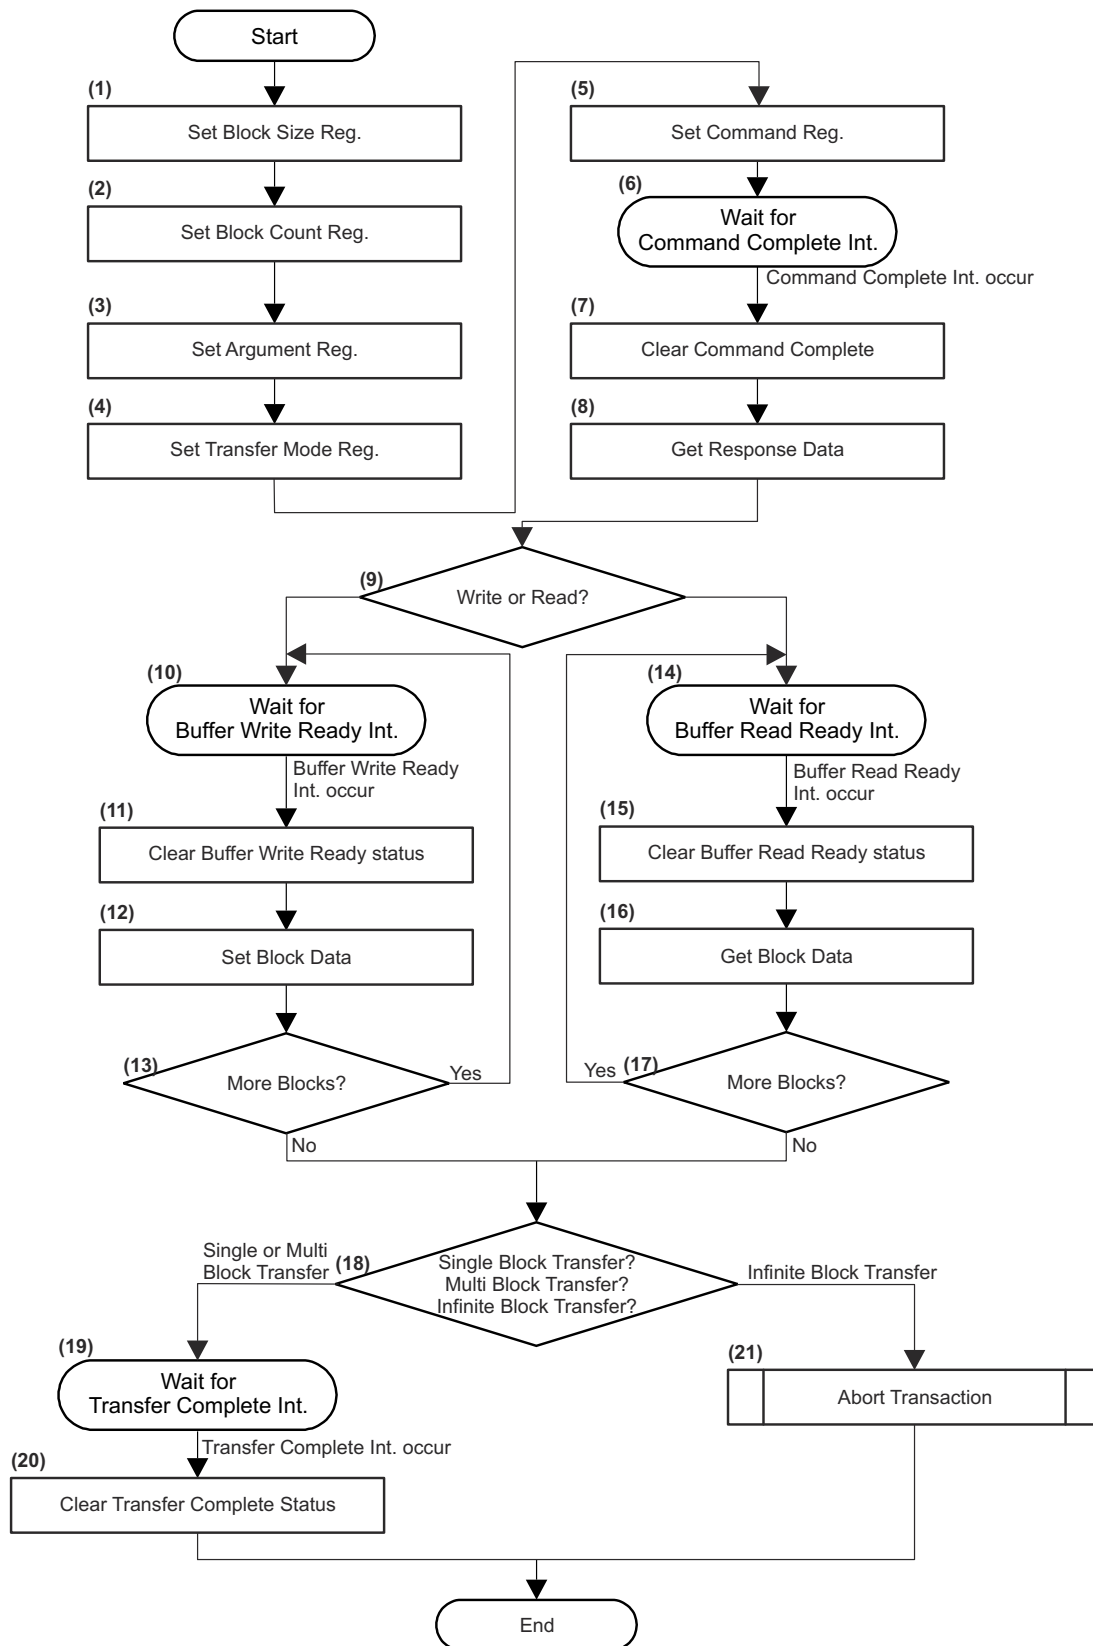

Depending on whether DMA (optional) is used or not, there are two execution methods.

In addition, the sequences for SD transfers are classified into following three kinds according to how the number of blocks is specified:

- (1) Single Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified is always one.
- (2) Multiple Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified shall be one or more.
- (3) Infinite Block Transfer: The number of blocks is not specified to the Host Controller before the transfer. This transfer is continued until an abort transaction is executed. This abort transaction is performed by CMD12 in the case of a SD memory card and by CMD52 in the case of a SDIO card.

##### **12.3.5.5.1.7.2.1 Not using DMA**

The sequence for not using DMA is shown in [Figure 12-225](#).

mmscd-032

**Figure 12-225. Transaction Control with Data Transfer Using DAT Line Sequence (Not using DMA)**

- (1) Set the value corresponding to the executed data byte length of one block to the MMCSD0\_BLOCK\_SIZE register.
- (2) Set the value corresponding to the executed data block count to the MMCSD0\_BLOCK\_COUNT register in accordance with *Determination of Transfer Type*.
- (3) Set the argument value to Argument register (MMCSD0\_ARGUMENT1\_LO and MMCSD0\_ARGUMENT1\_HI).
- (4) Set the value to the MMCSD0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*.

If response check is enabled (MMCSD0\_TRANSFER\_MODE[7] RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5 (MMCSD0\_TRANSFER\_MODE[6] RESP\_TYPE).

- (5) Set the value to MMCSD0\_COMMAND register.

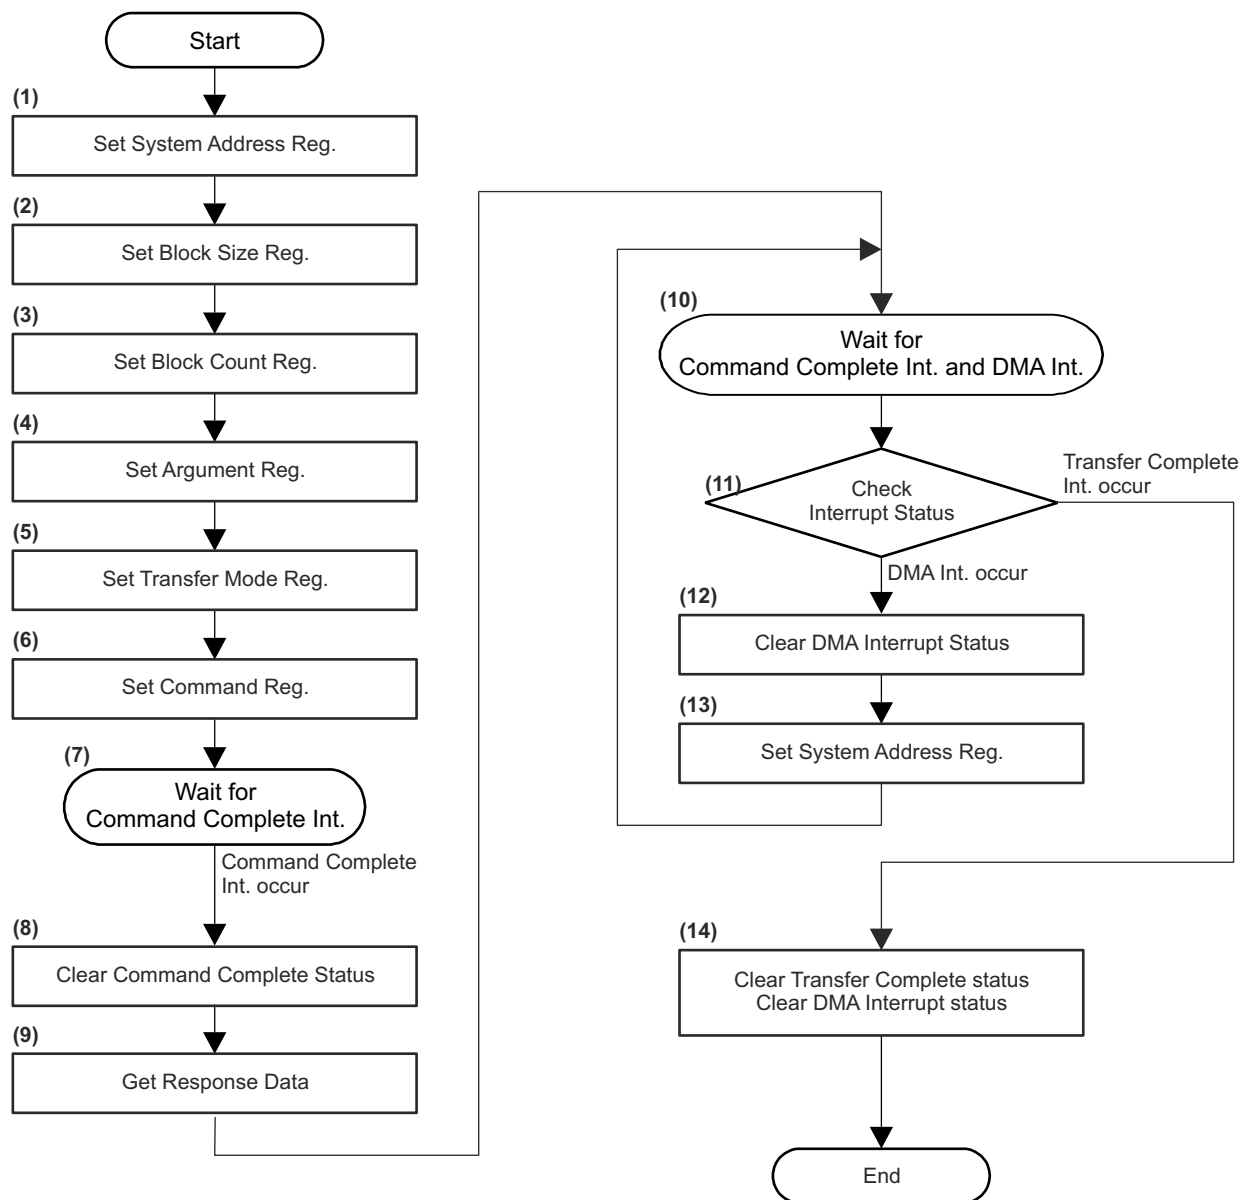

**Note:** When writing the upper byte [3] of MMCSD0\_COMMAND register, SD command is issued.

- (6) If response check is enabled, go to stop (9) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).
- (7) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit for clearing this bit.
- (8) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.
- (9) In the case where this sequence is for write to a card, go to step (10). In case of read from a card, go to step (14).
- (10) Then wait for Buffer Write Ready Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[4] BUF\_WR\_READY).
- (11) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[4] BUF\_WR\_READY bit for clearing this bit.
- (12) Write block data (in according to the number of bytes specified at the step (1)) to MMCSD0\_DATA\_PORT register.
- (13) Repeat until all blocks are sent and then go to step (18).
- (14) Then wait for the Buffer Read Ready Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[5] BUF\_RD\_READY).
- (15) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[5] BUF\_RD\_READY bit for clearing this bit.
- (16) Read block data (in according to the number of bytes specified at the step (1)) from the MMCSD0\_DATA\_PORT register.
- (17) Repeat until all blocks are received and then go to step (18).
- (18) If this sequence is for Single or Multiple Block Transfer, go to step (19). In case of Infinite Block Transfer, go to step (21).
- (19) Wait for Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (20) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit for clearing this bit.
- (21) Perform the sequence for Abort Transaction in accordance with [Section 12.3.5.5.1.8, Abort Transaction](#).

**Note:** Step (1) and Step (2) can be executed at same time. Step (4) and Step (5) can be executed at same time.

#### 12.3.5.5.1.7.2.2 Using SDMA

The sequence for using SDMA is shown in [Figure 12-226](#).

mmcsd-033

**Figure 12-226. Transaction Control with Data Transfer Using DAT Line Sequence (Using SDMA)**

(1) Data location of system memory is set to the SDMA System Address register if MMCS0\_HOST\_CONTROL2[12] HOST\_VER40\_ENA = 0 or set to the MMCS0\_ADMA\_SYS\_ADDRESS register if MMCS0\_HOST\_CONTROL2[12] HOST\_VER40\_ENA = 1.

(2) Set the value corresponding to the executed data byte length of one block in the MMCS0\_BLOCK\_SIZE register.

(3) Set the value corresponding to the executed data block count in the MMCS0\_BLOCK\_COUNT register in accordance with *Determination of Transfer Type*.

(4) Set the argument value to the Argument register (MMCS0\_ARGUMENT1\_LO and MMCS0\_ARGUMENT1\_HI).

(5) Set the value to the MMCS0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the

MMCSD0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCSD0\_TRANSFER\_MODE[7] RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5.

(6) Set the value to the MMCSD0\_COMMAND register.

**Note:** When writing to the upper byte [3] of the MMCSD0\_COMMAND register, the SD command is issued and SDMA is started.

(7) If response check is enabled, go to stop (10) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

(8) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(9) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.

(10) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) and DMA Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT).

(11) If MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is set to 1, go to Step (14) else if MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit is set to 1, go to Step (12). The MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is higher priority than the MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit.

(12) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit to clear this bit.

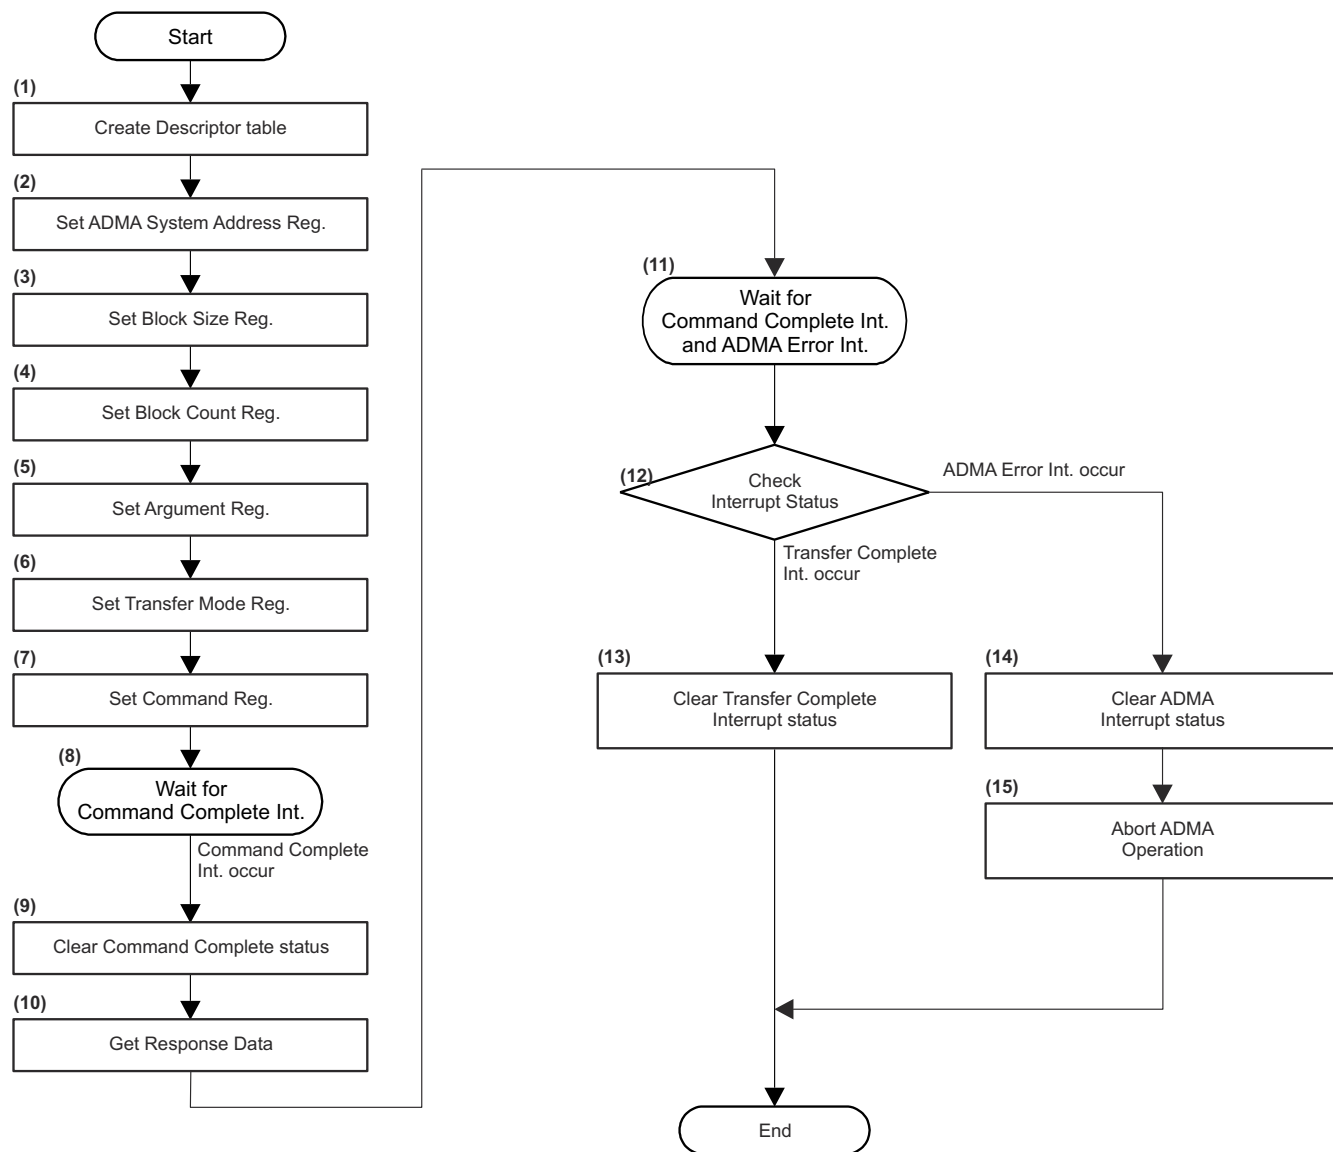

(13) Set the next system address of the next data position to the System Address register (MMCSD0\_ADMA\_SYS\_ADDRESS) and go to Step (10).

(14) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit and MMCSD0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit to clear this bit.

**Note:** Step (2) and Step (3) can be executed simultaneously. Step (5) and Step (6) can also be executed simultaneously.

#### 12.3.5.5.1.7.2.3 Using ADMA

The sequence for using ADMA is shown in [Figure 12-227](#).

mmcsd-034

**Figure 12-227. Transaction Control with Data Transfer Using DAT Line Sequence (Using ADMA)**

- (1) Create Descriptor table for ADMA in the system memory.
- (2) Set the Descriptor address for ADMA in the MMCSDB0\_ADMA\_SYS\_ADDRESS register.
- (3) Set the value corresponding to the executed data byte length of one block in the MMCSDB0\_BLOCK\_SIZE register.
- (4) Set the value corresponding to the executed data block count in the MMCSDB0\_BLOCK\_COUNT register in accordance with *Determination of Transfer Type*.
- (5) Set the argument value to the Argument register (MMCSDB0\_ARGUMENT1\_LO and MMCSDB0\_ARGUMENT1\_HI).
- (6) Set the value to the MMCSDB0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSDB0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCSDB0\_TRANSFER\_MODE[7]

RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5 (MMCSD0\_TRANSFER\_MODE[6] RESP\_TYPE).

(7) Set the value to the MMCSD0\_COMMAND register.

**Note:** When writing to the upper byte [3] of the MMCSD0\_COMMAND register, the SD command is issued and DMA is started.

(8) If response check is enabled, go to stop (11) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

(9) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(10) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.

(11) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) and ADMA Error Interrupt (MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE).

(12) If MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is set to 1, go to Step (13) else if MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE bit field is set to 1, go to Step (14).

(13) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to clear this bit.

(14) Write 1 to the MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE bit field to clear this bit.

(15) Abort ADMA operation. SD card operation should be stopped by issuing abort command. If necessary, the Host Driver checks MMCSD0\_ADMA\_ERR\_STATUS register to detect why ADMA error is generated.

**Note:** Step (3) and Step (4) can be executed simultaneously. Step (6) and Step (7) can also be executed simultaneously.

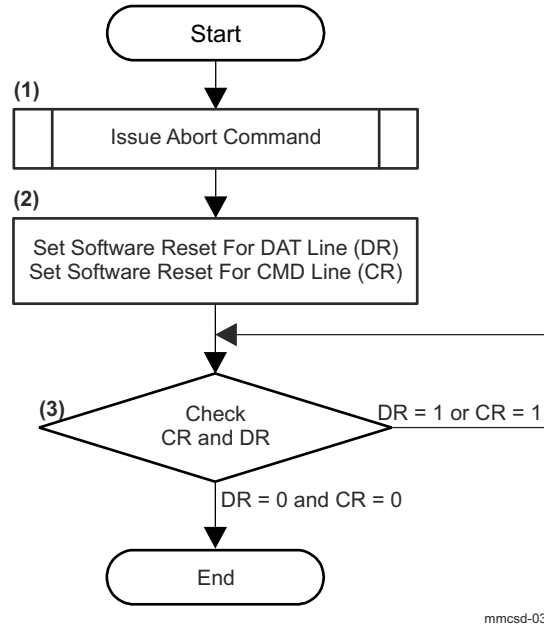

#### 12.3.5.5.1.8 Abort Transaction

An abort transaction is performed by issuing CMD12 for a SD memory card and by issuing CMD52 for a SDIO card. There are two cases where the Host Driver needs to do an Abort Transaction. The first case is when the Host Driver stops Infinite Block Transfers. The second case is when the Host Driver stops transfers while a Multiple Block Transfer is executing.

There are two ways to issue an Abort Command. The first is an asynchronous abort. The second is a synchronous abort. In an asynchronous abort sequence, the Host Driver can issue an Abort Command at any time unless MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is set to 1. In a synchronous abort, the Host Driver shall issue an Abort Command after the data transfer stopped by using MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

##### 12.3.5.5.1.8.1 Asynchronous Abort

The sequence for Asynchronous Abort is shown in [Figure 12-228](#).

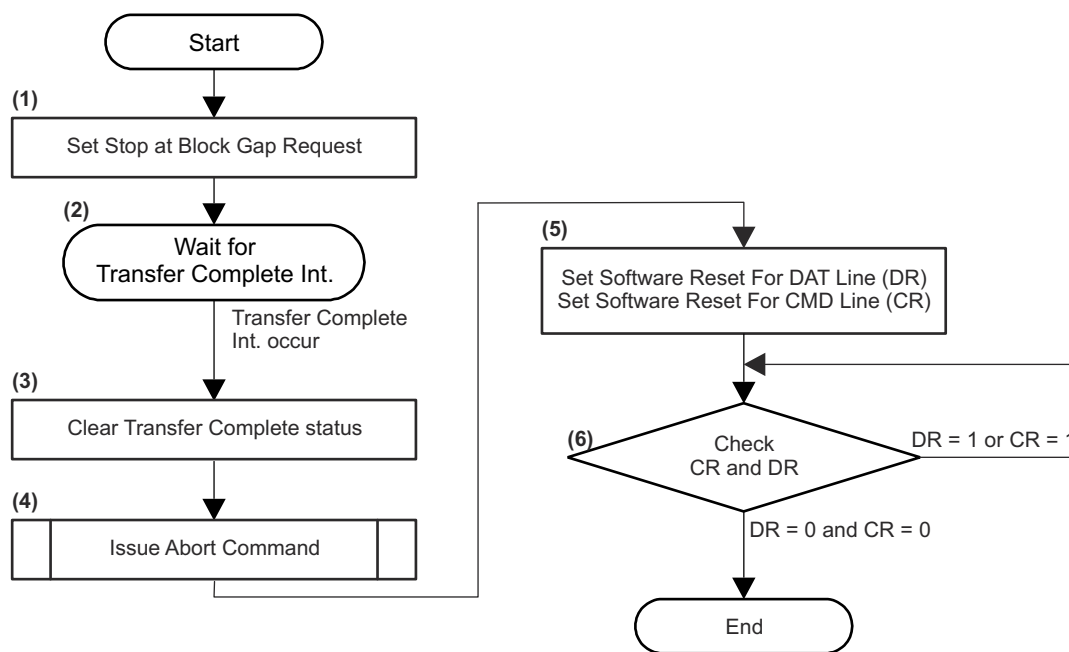

mmcsd-035

**Figure 12-228. Asynchronous Abort Sequence**

- (1) Issue Abort Command in accordance.
- (2) Set both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 to do software reset.
- (3) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit are 0, go to "End". If either MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit or MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 1, go to step (3).

### 12.3.5.5.1.8.2 Synchronous Abort

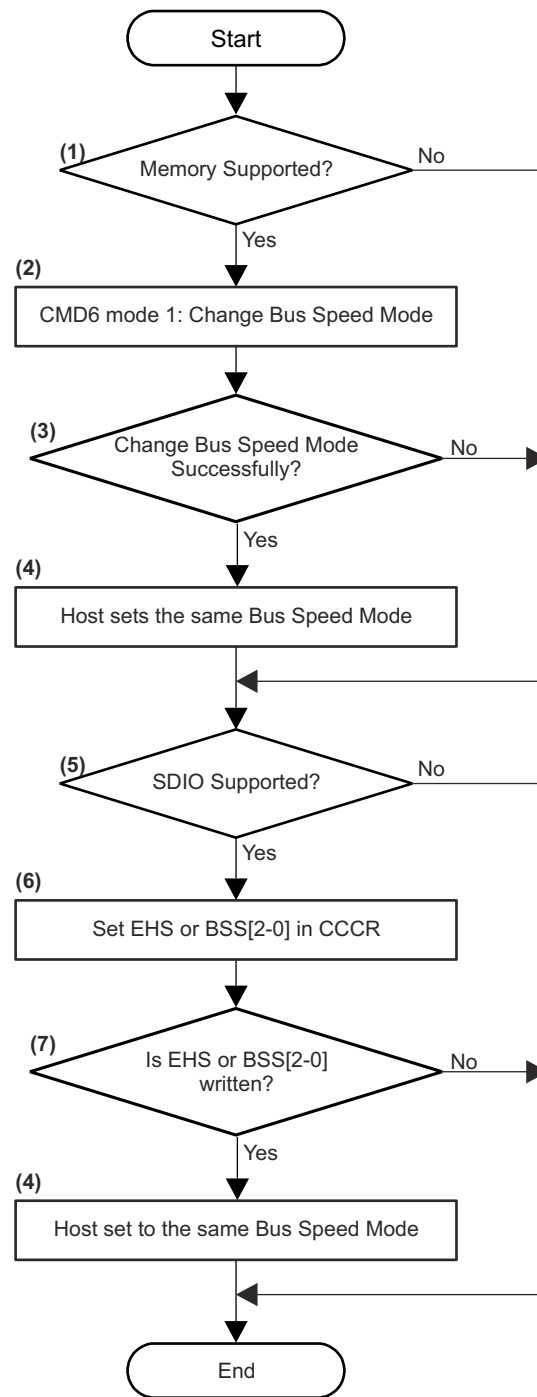

mmcsd-036

**Figure 12-229. Synchronous Abort Sequence**

- (1) Set the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 1 to stop SD transactions.
- (2) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (3) Set the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (4) Issue the Abort Command
- (5) Set both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 to do software reset.
- (6) Check both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit are 0, go to "End". If either MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit or MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 1, go to step (6).

### 12.3.5.5.1.9 Changing Bus Speed Mode

This section describes the sequence for switching the bus speed mode: Default Speed, High Speed mode and UHS-I mode. The switch command (CMD6) is used to change memory card bus speed mode. The EHS bit (SDIO Version 2.00) or BSS[2-0] bits (SDIO Version 3.00) in the CCCR register is used to change the bus speed mode for SDIO card. In case of Combo card, either of the switch method changes both memory and IO bus speed mode. This means the first switch is effective. Refer to the Physical Layer Specification Version 3.0x and the SDIO Specification Version 3.00 for more information about switching bus speed. [Figure 12-230](#) shows the sequence for switching bus speed mode for Combo Card. Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

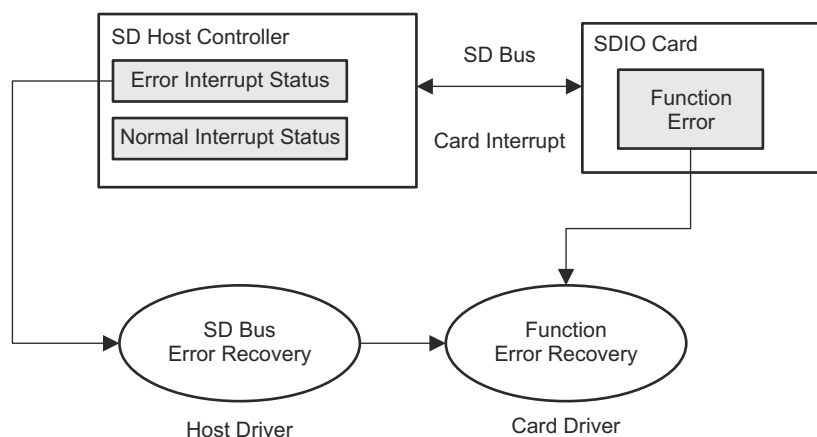

mmcsd-037

**Figure 12-230. Changing Bus Speed Mode**

- (1) The Host Driver checks if the card supports memory. If not supported, go to (5).
- (2) Issue CMD6 with mode 1 to change bus speed mode (Default, High Speed mode or UHS-I mode).
- (3) Check the response of CMD6. If the card does not supports CMD6 (no response) or bus speed is not changed successfully, go to step (5). In this case, the card is in Default Speed mode.
- (4) The Host Driver changes the Host Controller bus speed mode to the same mode.

- (5) The Host Driver checks if the card supports SDIO. If not supported, go to the end.
- (6) Issue CMD52 to write EHS bit or BSS[2-0] bits in CCCR to change bus speed mode (the same bus speed mode of (2) shall be set).
- (7) If EHS or BSS[2-0] are not changed successfully, go to the end.
- (8) The Host Driver changes the Host Controller bus speed to the same mode. In case of Combo card, bus speed is already changed at step (4) and this step does not affect changing bus speed.

#### 12.3.5.5.1.10 Error Recovery

mmcsd-038

**Figure 12-231. Error Report and Recovery**

Figure 12-231 shows concept of error report and its recovery. The Host Controller has 2 interrupt status registers. If an error occurs in the SD Bus transaction, one of the bits is set in the MMCS0\_ERROR\_INTR\_STS register. If the function errors occur in the SDIO card, the card interrupt informs these function errors and the Card interrupt is set in the MMCS0\_NORMAL\_INTR\_STS\_ENA register (the Card Interrupt is used to inform not only error statuses but also normal information. For example, to inform function ready). The Card Driver shall do function error recovery because the Host Driver does not know how to control the function. In the case that function error occurs due to SD Bus error, SD Bus error recovery is required before function error recovery. Abort command is used to recover SD Bus, and then the Host Driver should save error statuses related to SD Bus errors before issuing abort command and transfer these statuses to the Card Driver. These statuses may be used to recover function error. Following explanations are related to SD Bus error recovery. This specification does not specify the function error recovery.

When an error occurs during data transfer in 2L-HD UHS-II mode, there will be the case that Host Controller cannot drive D0 lane in input mode due to DIR LSS for retrieving lane direction is not detected. In this case, Host Driver cannot issue abort command for recovery. Then if DIR LSS is not detected, Host Controller sets MMCS0\_UHS2\_ERR\_INTR\_STS[17] DEADLOCK\_TIMEOUT bit. Host Driver should execute power cycle if MMCS0\_UHS2\_ERR\_INTR\_STS[17] DEADLOCK\_TIMEOUT bit is detected to recover from this error. Furthermore, if this type of error is detected several times in 2L-HD, Host Driver should use FD mode rather than using 2L-HD.

Implementation Note:

If the Card Driver cannot recover the function errors, the Host Driver should try following methods.

- (9) Using IOEx for SDIO card

IOEx may be used as the reset per function basis. Sequence is as follows:

Clear IOEx = 0 and wait until IORx = 0 and then set IOEx = 1 again. SDIO may be recovered when IORx = 1.

- (10) Using reset command for memory and SDIO card Re-initialization sequence is required.

(11) Off and on power supply for the SD Bus.

The card may be recovered by the power on reset. Re-initialization sequence is required.

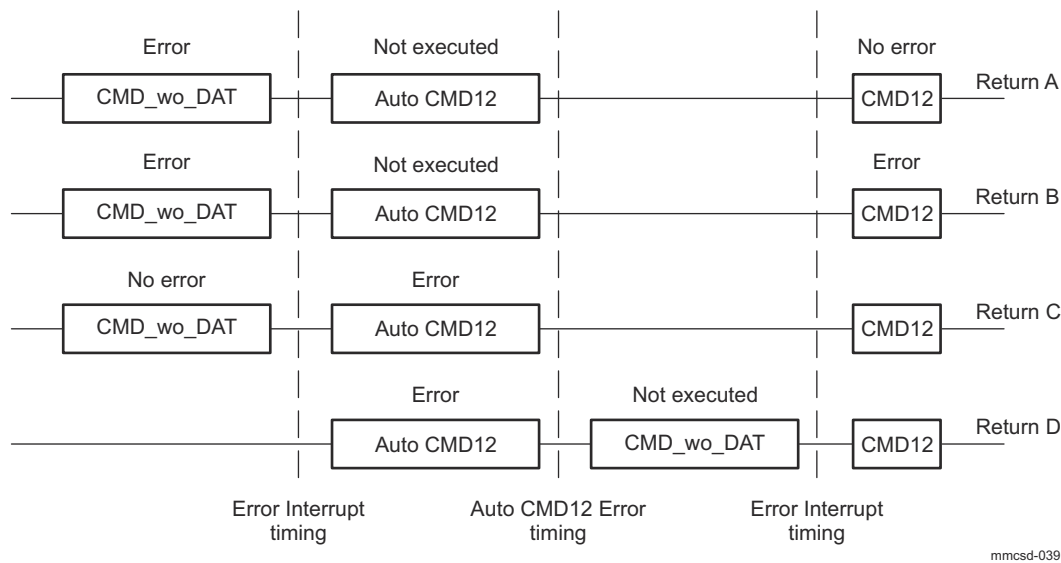

The two cases where the Host Driver needs the "Error Recovery" sequence are classified as follows:

(1) Error Interrupt Recovery:

If error interrupt is indicated by the MMCSD0\_ERROR\_INTR\_STS register, the Host Driver shall apply this sequence.

(2) Auto CMD12 Error Recovery:

If there are errors in Auto CMD12, the Host Driver shall apply this sequence. In terms of Return Status, Auto CMD12 Error Recovery is classified into 4 cases. It is shown in Figure 12-232. If error occurs during memory write transfer, strongly recommend using ACMD22 and then in the following recovery sequence, retry to send remaining blocks not written.

**Figure 12-232. Return Status of Auto CMD12 Error Recovery**

Implementation Note:

Abort command is used to recover from SD Bus error. SDIO transaction abort using CMD52 returns response but in the case of memory transaction abort using CMD12, response returns depending on the memory card state. If no response returns after issue CMD12, the Host Driver should check card state using CMD13. If the state is "tran" in the CURRENT\_STATE, consider CMD12 is successful.

Implementation Note:

The following sequence is one possible error recovery flow. There may be another methods, sometimes using interrupts or polling. It can be possible to use another flows, based on Host System requirements.

In these error recovery sequences, return statuses for the next sequence. When the Host Controller cannot issue the next command due to SD Bus error, the error recovery sequences return "Non-recoverable" status. In this case, the Host System may cut off power to the SD Bus and then power on SD Bus and initialize both the Host Controller and the SD card again.

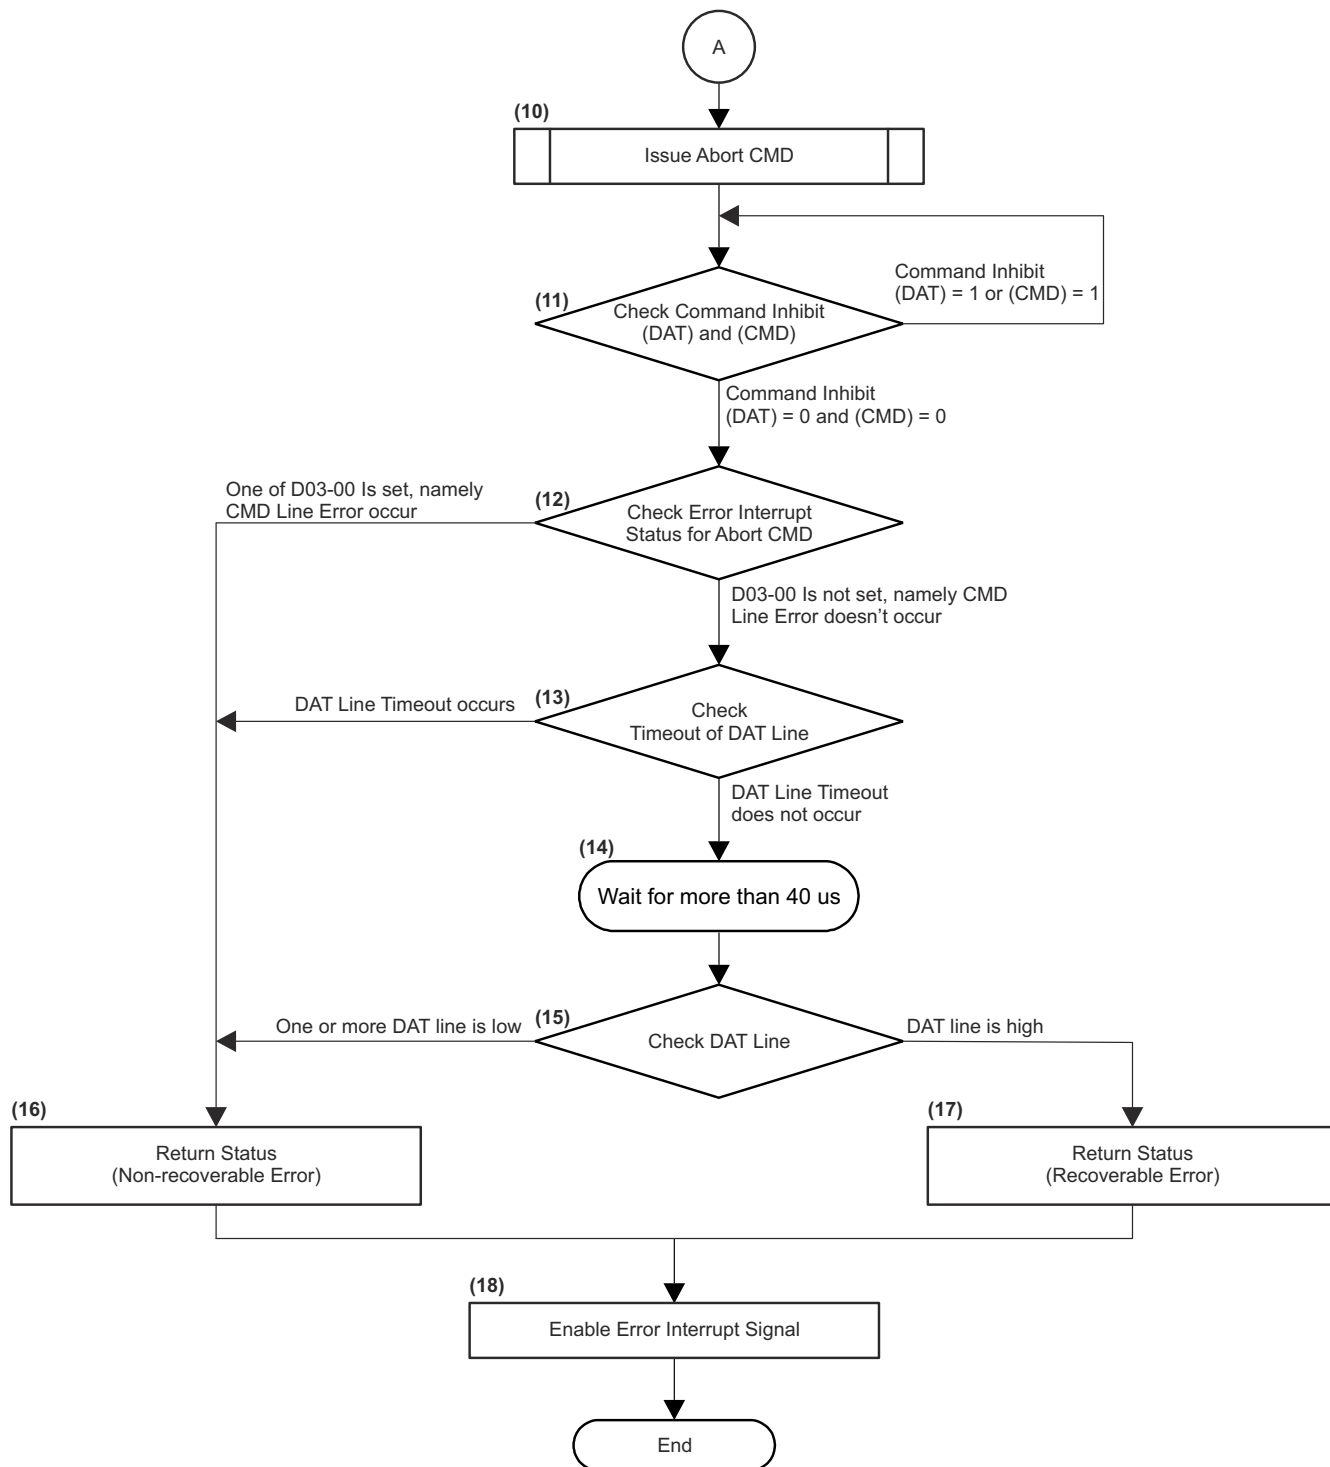

### 12.3.5.5.1.10.1 Error Interrupt Recovery

mmcsd-040

**Figure 12-233. Error Interrupt Recovery Sequence (1)**

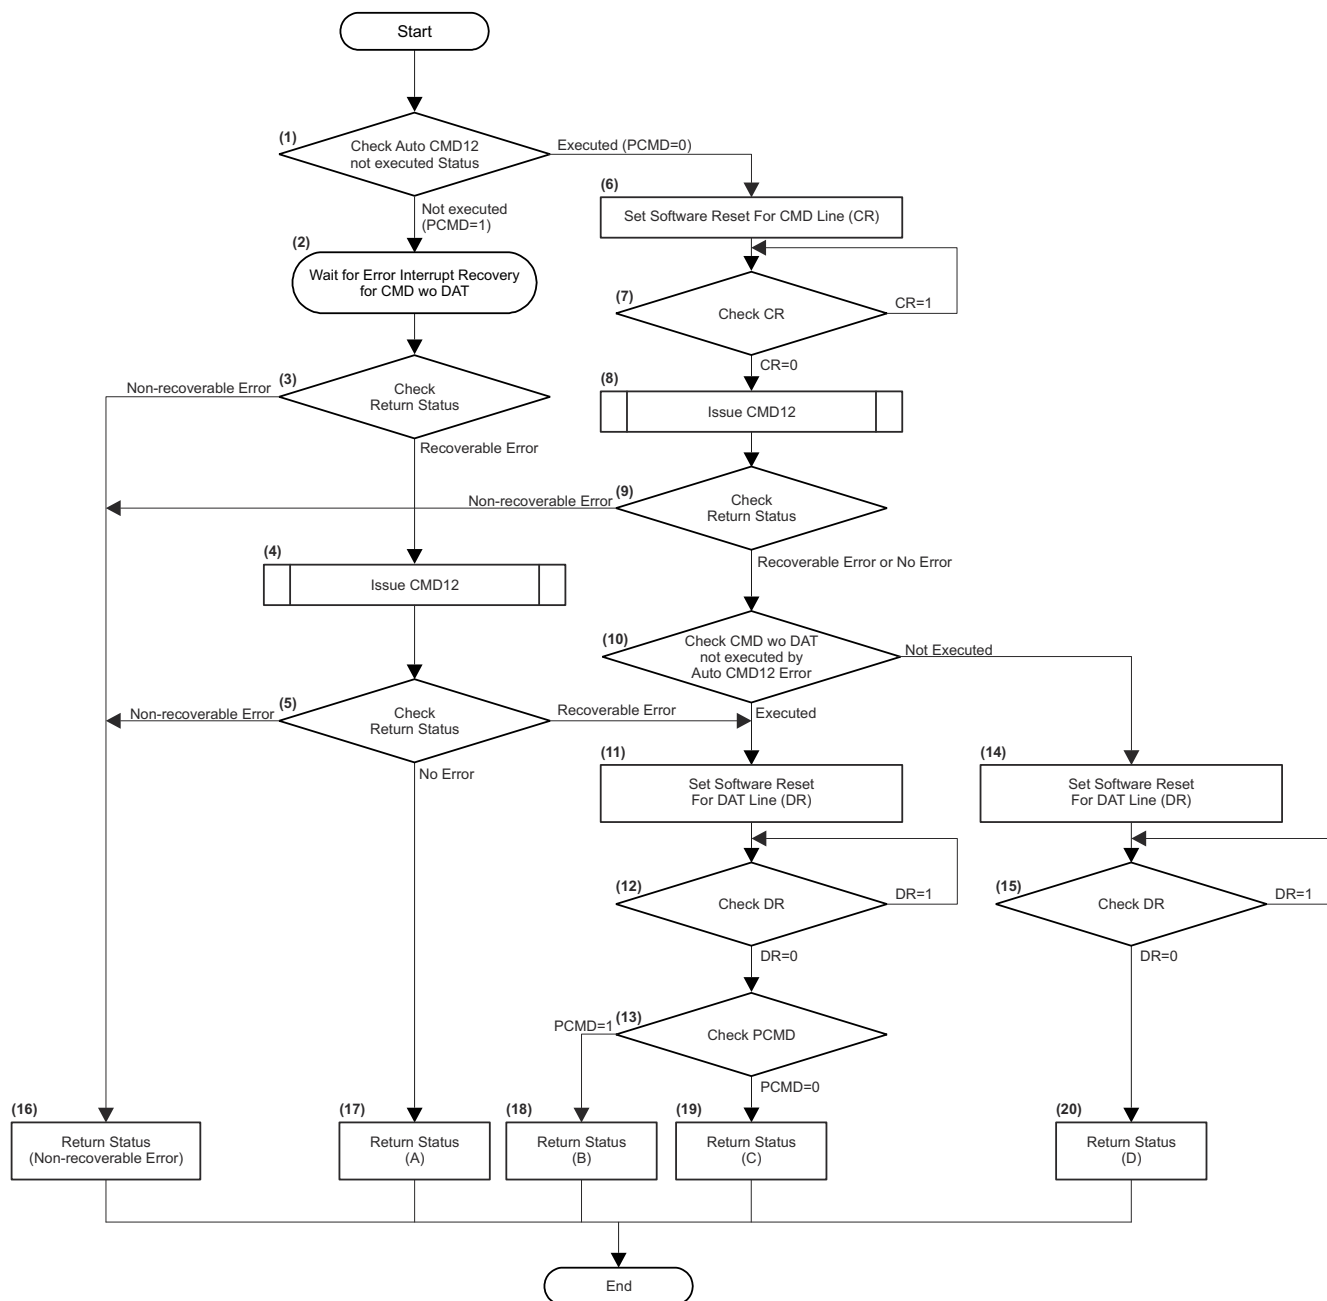

mmcscd-041

**Figure 12-234. Error Interrupt Recovery Sequence (2)**

- (1) Disable the Error Interrupt Signal (MMCSD0\_ERROR\_INTR\_SIG\_ENA).
- (2) Check bits D03-00 in the MMCSD0\_ERROR\_INTR\_STS register. If one of these bits (D03-00) is set to 1, go to step (3). If none are set to 1 (all are 0), go to step (5).
- (3) Set MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1.

- (4) Check MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 0, go to step (5). If it is 1, go to step (4).
- (5) Check bits D06-04 in the MMCSD0\_ERROR\_INTR\_STS register. If one of these bits (D06-04) is set to 1, go to step (6). If none are set to 1 (all are 0), go to step (8).
- (6) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (7) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Save previous error status.
- (9) Clear previous error status with setting them to 1.
- (10) Issue Abort Command.
- (11) MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit and MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit. Repeat this step until both MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit and MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit are set to 0.
- (12) Check bits D03-00 in the MMCSD0\_ERROR\_INTR\_STS register for Abort Command. If one of these bits is set to 1, go to step (16). If none of these bits are set to 1 (all are 0), go to step (13).
- (13) Check MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT bit. If this bit is set to 1, go to step (16). If it is 0, go to step (14).
- (14) Wait for more than 40 us.
- (15) By monitoring the DAT [3:0] Line Signal Level in the MMCSD0\_PRESENTSTATE register, judge whether the level of the DAT line is low or not. If one or more DAT lines are low, go to step (16). If the DAT lines are high, go to step (17).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status of "Recoverable Error".
- (18) Enable the Error Interrupt Signal (MMCSD0\_ERROR\_INTR\_SIG\_ENA).

### 12.3.5.5.1.10.2 Auto CMD12 Error Recovery

mmcsd-042

**Figure 12-235. Auto CMD12 Error Recovery**

The sequence for Auto CMD12 Error Recovery is shown in [Figure 12-235](#). Following four cases A-D shall be covered.

A: An error occurred in CMD\_wo\_DAT, but not in the SD memory transfer.

B: An error occurred in CMD\_wo\_DAT, and also occurred in the SD memory transfer.

C: An error did not occur in CMD\_wo\_DAT, but an error occurred in the SD memory transfer.

D: CMD\_wo\_DAT was not issued, and an error occurred in the SD memory transfer.

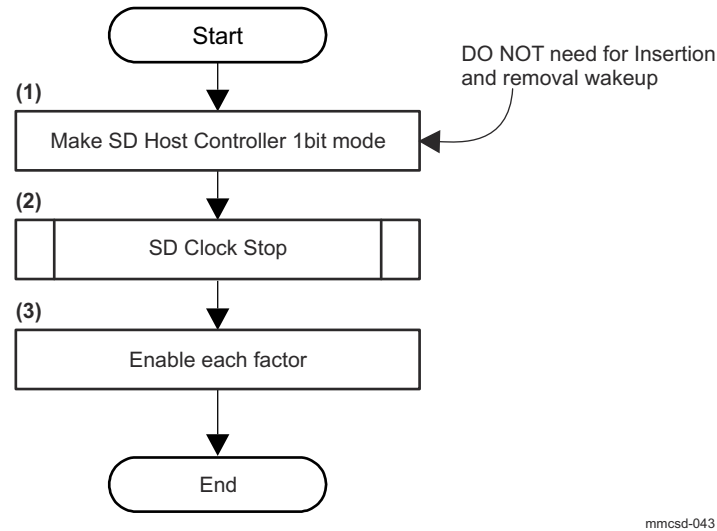

- (1) Check MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit. If this bit is set to 1, go to step (2). If this bit is set to 0, go to step (6). In addition, the Host Driver shall define PCMD flag, which changes to 1 if MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit is set to 1.
- (2) Wait for Error Interrupt Recovery for CMD\_wo\_DAT.
- (3) Check "Return Status". In the case of "Non-recoverable Error", go to step (16). In the case of "Recoverable Error", go to step (4).
- (4) Issue CMD12 .
- (5) If the CMD line errors occur for the CMD12 (one of D03-00 is set in the MMCSD0\_ERROR\_INTR\_STS register), "Return Status" is "Non-recoverable Error" and go to step (16). If not CMD line error and busy timeout error occur (D04 is set in the MMCSD0\_ERROR\_INTR\_STS register), "Return Status" is "Recoverable Error" and go to step (11). Otherwise, "Return Status" is "No error" and go to step (17).
- (6) Set MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 for software reset of the CMD line.
- (7) Check MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Issue CMD12 . Acceptance of CMD12 depends on the state of the card. CMD12 may make the card to return to tran state. If the card is already in tran state, the card does not response to CMD12.
- (9) Check "Return Status" for CMD12. If "Return Status" returns "Non-recoverable Error", go to step (16). In the case of "Recoverable Error" or "No error", go to step (10).
- (10) Check the MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit. If this bit is 0, go to step (11). If it is 1, go to step (14).
- (11) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (12) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (13). If it is 1, go to step (12).
- (13) Check the PCMD flag. If PCMD is 1, go to step (18). If it is 0, go to step (19).
- (14) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (15) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (20). If it is 1, go to step (15).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status that an error has occurred in CMD\_wo\_DAT, but not in the SD memory transfer.
- (18) Return Status that an error has occurred in both CMD\_wo\_DAT, and the SD memory transfer.
- (19) Return Status that an error has not occurred in CMD\_wo\_DAT, but has occurred in the SD memory transfer.
- (20) Return Status that CMD\_wo\_DAT has not been issued, and an error has occurred in the SD memory transfer.

#### 12.3.5.5.1.11 Wakeup Control (Optional)

After the Host System goes into standby mode, the Host System can resume from standby via a wakeup event initiated by one of the following three events:

- (1) Interrupt from a SD card: If an SD card interrupt occurs, the Host System can resume from standby mode. If the Host System uses this wakeup factor, SD Bus power shall be kept on.
- (2) Insertion of SD card: If a SD card is inserted, the Host System can resume from standby mode.
- (3) Removal of SD card: If a SD card is removed, the Host System can resume from standby mode.

The sequence for preparing wakeup before the Host System goes into standby mode is shown in [Figure 12-236](#).

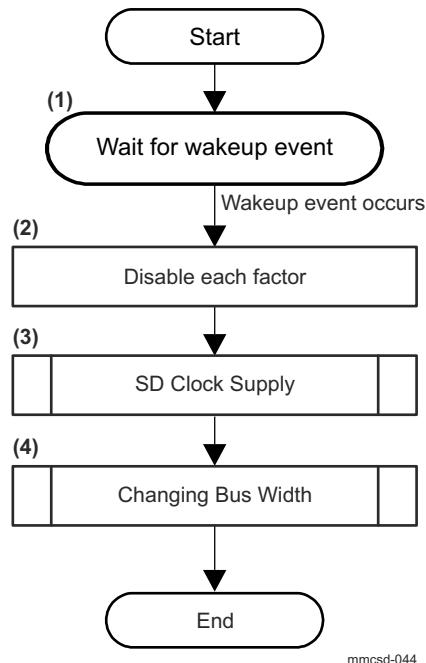

**Figure 12-236. Wakeup Control before Standby Mode**

(1) Set MMCSD0\_HOST\_CONTROL1[1] DATA\_WIDTH bit to 0.

(2) Execute SD Clock Stop Sequence as described in [Section 12.3.5.5.1.2.2](#), *SD Clock Supply and Stop Sequence*.

(3) Clear the MMCSD0\_NORMAL\_INTR\_STS register and the MMCSD0\_NORMAL\_INTR\_SIG\_ENA register, and then set the enable bits of each wakeup event factor to 1 in the MMCSD0\_WAKEUP\_CONTROL register and set the bits of MMCSD0\_ERROR\_INTR\_STS\_ENA register to use wakeup.

The sequence for wakeup once in standby mode is shown in [Figure 12-237](#).

**Figure 12-237. Wakeup from Standby**

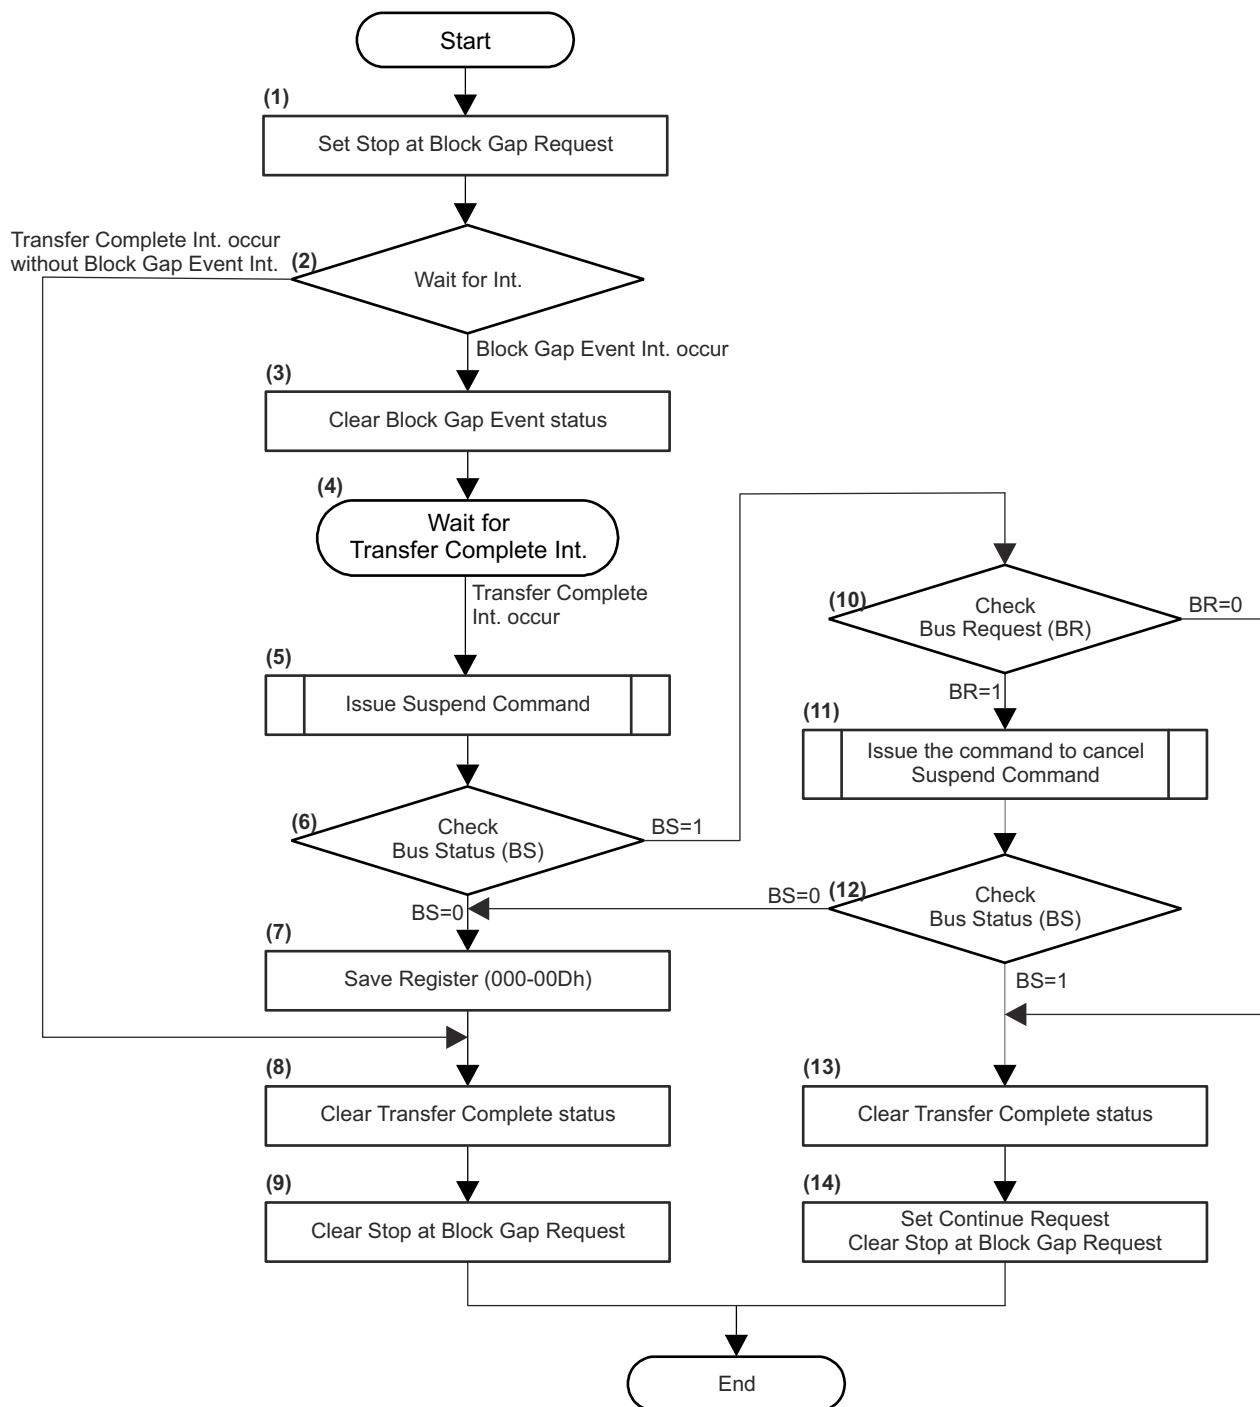

(1) Wait for wakeup event.

- (2) Set the enable bits of each wakeup event factor to 0 in the MMCSD0\_WAKEUP\_CONTROL register and then clear event statuses in the MMCSD0\_NORMAL\_INTR\_STS register. If necessary, set the MMCSD0\_NORMAL\_INTR\_SIG\_ENA register.
- (3) Execute SD Clock Supply Sequence (see [Section 12.3.5.5.1.2.2](#), *SD Clock Supply and Stop Sequence*).
- (4) Set the SD Bus width (see [Section 12.3.5.5.1.4](#), *Changing Bus Width*).

#### **12.3.5.5.1.12 Suspend/Resume (Optional, Not Supported from Version 4.00)**

If a SD card supports suspend and resume functionality, then the Host Controller can initiate suspend and resume. It is necessary for both the Host Controller and the SD card to support the function of "Read Wait". ADMA operation does not support this function.

### 12.3.5.5.1.12.1 Suspend Sequence

mmscd-045

**Figure 12-238. The Sequence for Suspend**

(1) Set MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 1 to stop the SD transaction.

(2) Wait for an Interrupt. If MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is set to 0 and MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit is set to 1, go to step (8). If MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is set to 1, go to step (3).

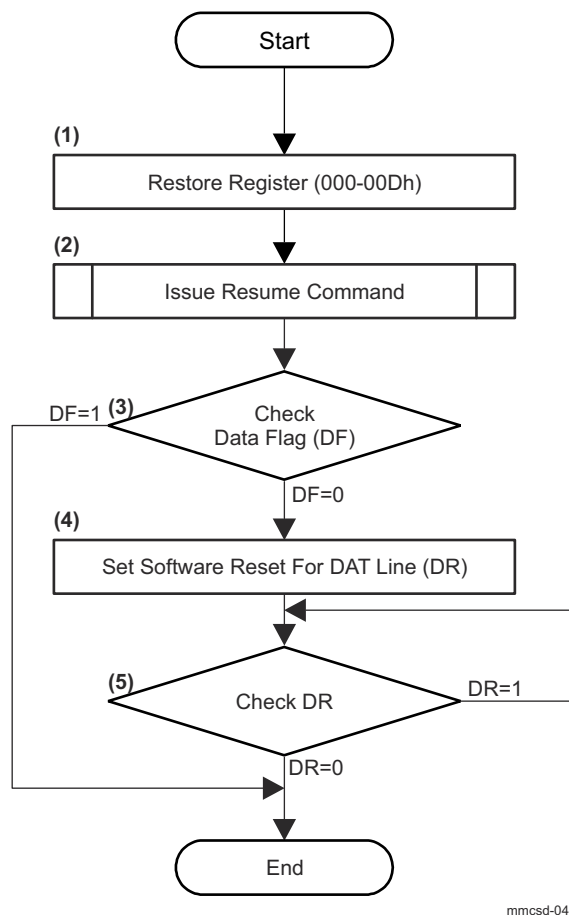

- (3) Set MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit to 1 to clear this bit.
- (4) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (5) Issue the Suspend Command in accordance with [Section 12.3.5.5.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (6) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (10).
- (7) Save the register .
- (8) Set MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (9) Set MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 0 to clear this bit.
- (10) Check the BR value of the response data. If BR is 1, go to step (11). If BR is 0, go to step (13).
- (11) Issues the command to cancel the previous suspend command in accordance with [Section 12.3.5.5.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (12) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (13).
- (13) Set MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (14) Set MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 to continue the transaction. At the same time, write 0 to MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to clear this bit.

Conditions			Suspend/Resume Function	
Host Suspend/Resume Support	Card Suspend/Resume Support	Card Read Wait Support	Write Suspend/Resume	Read Suspend/Resume
Not supported	Don't care	Don't care	Cannot be used	Cannot be used
Supported	Not supported	Don't care	Cannot be used	Cannot be used
Supported	Supported	Not supported	Can be used	Cannot be used
Supported	Supported	Supported	Can be used	Can be used

mmcsd-046

**Figure 12-239. Suspend/Resume Condition**

### 12.3.5.5.1.12.2 Resume Sequence

mmcsd-047

**Figure 12-240. The Sequence for Resume**

- (1) Restore the register .
- (2) Issue the Resume Command .
- (3) Check the DF value of the response data. If DF is 0, go to step (4). If DF is 1, go to "End".
- (4) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (5) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to "End". If it is 1, go to step (5).

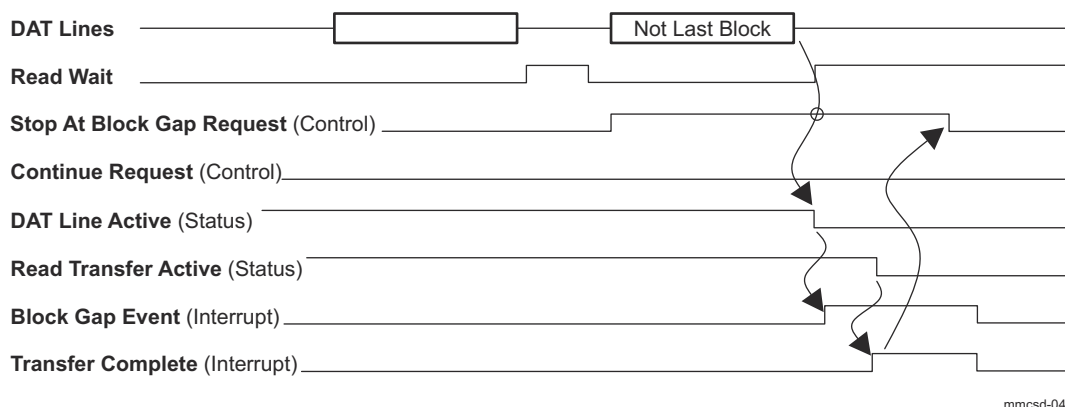

### 12.3.5.5.1.12.3 Stop At Block Gap/Continue Timing for Read Transaction

The timing of Stop At Block Gap Request and Continue Request. The Transfer Complete interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is always generated by setting MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit where data transfer is stopped. However, generation of the Block Gap Event interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is dependent on whether the last data block is sent or not. Block Gap Event is not generated If all data blocks are transferred (the last block is transferred). It is not necessary to enable Block Gap Event interrupt. The status can be checked when transfer complete interrupt is detected. It is not necessary to use Continue Request (MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE) if Block Gap Event status is not set because there is no further data to be transferred. If Read Wait is not supported, Host Controller stops SD Clock at the block gap.

Implementation Note:

The MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL, MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE, MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bits shall be set and cleared by the Host Controller.

The MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set and cleared by the Host Driver. The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit shall be set by the Host Driver and be cleared by the Host Controller. The MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit and MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit shall be set by the Host Controller and be cleared by the Host Driver.

mmcsd-048

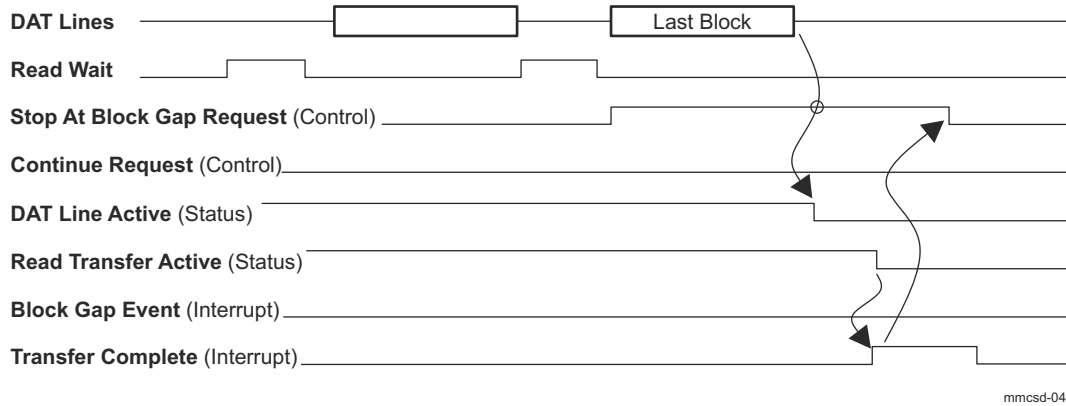

**Figure 12-241. Wait Read Transfer by Stop At Block Gap Request**

The Host Controller can accept a Stop At Block Gap Request (MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP) when all the following conditions are met.

- (1) It is at the block gap.
- (2) The Host Controller can assert read wait or it is already asserted.
- (3) The MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL bit is set to 1.

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit:

- (1) Clear MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT).
- (2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE).
- (3) After accepting MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit, clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-242. Stop At Block Gap Request is Not Accepted at the Last Block of the Read Transfer**

If the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit and stops the transaction normally. The Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is not generated. When the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is generated, and if the MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit status is not set to 1, the driver shall clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-243. Continue Read Transfer by Continue Request**

To restart a stopped data transfer, set the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 (the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set to 0).

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit:

- (1) Release MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL bit (if the data block can accept the next data).
- (2) Set the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit.
- (3) The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit is automatically cleared by (2).

The end of the read transfer is specified by data length.

- (1) Clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and do not generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit).

(2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).

#### 12.3.5.5.1.2.4 Stop At Block Gap/Continue Timing for Write Transaction

mmcsd-051

**Figure 12-244. Wait Write Transfer by Stop At Block Gap Request**

The Host Controller can accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit when matches all following conditions:

- (1) It is at the block gap.
- (2) No valid write data remains in the Host Controller.

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

- (1) Clear the MMCSD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit).
- (2) After the busy signal is released, clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).
- (3) After accepting the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit), clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

mmcsd-052

**Figure 12-245. Stop At Block Gap Request is Not Accepted at the Last Block of the Write Transfer**

If the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit and terminates the transaction normally. The Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is not generated. When the Transfer

Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is generated, and if the MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVEN bit is not set to 1, the driver shall clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-246. Continue Write Transfer by Continue Request**

To restart a stopped data transfer, set the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 (the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set to 0).

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit:

(1) Set the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and MMCSD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit.

(2) The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit is automatically cleared by (1).

The end of transfer is specified by data length.

(1) Clear the MMCSD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit, and do not generate the (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVEN).

(2) After the busy signal is released, clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generates the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).

### 12.3.5.5.2 Driver Flow Sequence

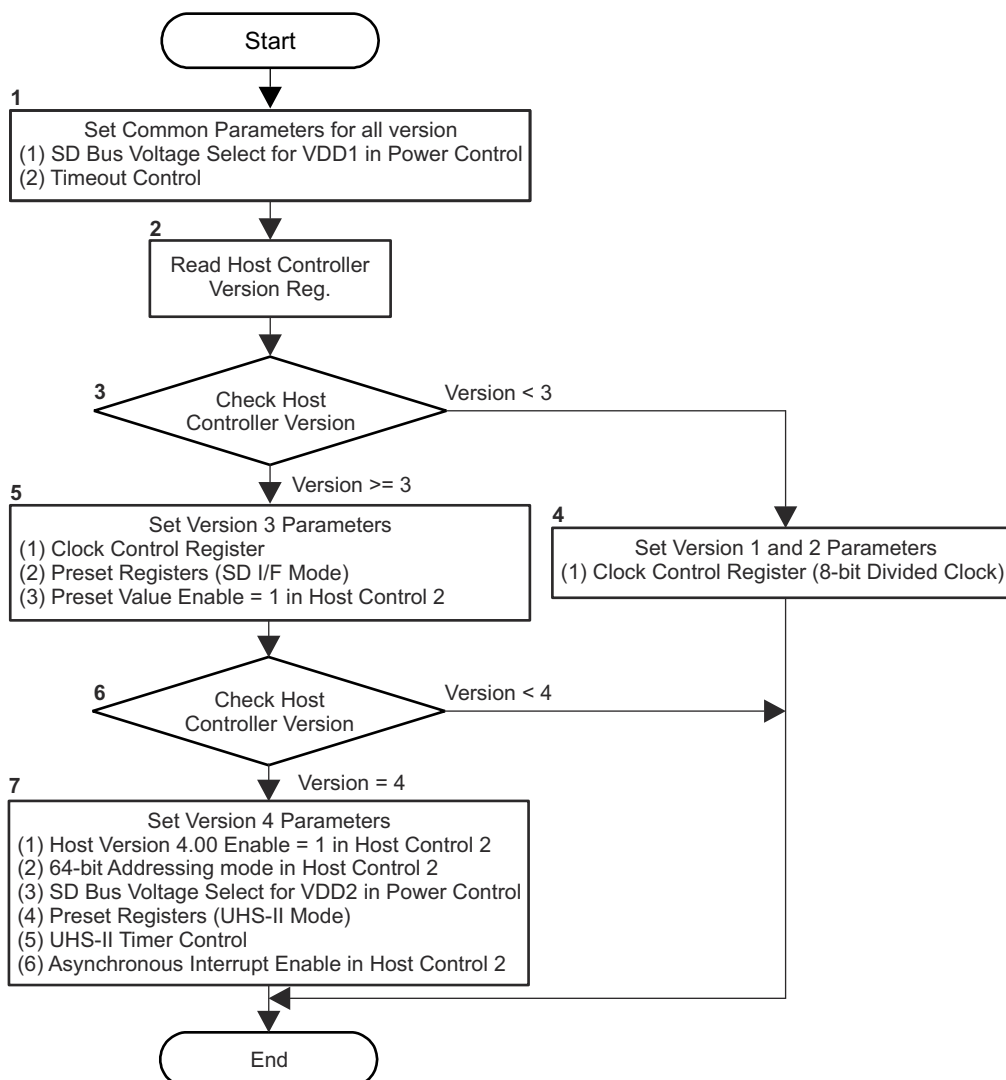

#### Note

UHSII is not supported. For more information, see *Not Supported Features*.

#### 12.3.5.5.2.1 Host Controller Setup and Card Detection

##### 12.3.5.5.2.1.1 Host Controller Setup Sequence

Figure 12-247 and Table 12-231 show a Host Controller setup sequence.

mmcsd-054

**Figure 12-247. Host Controller Setup Sequence**

**Table 12-231. Host Controller Setup Sequence**

Step	Description
1	Set parameters for all Host Controller version. Set the MMCSDB0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE and MMCSDB0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit fields.
2	Read the MMCSDB0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM bit field.
3	If Specification Version number (MMCSDB0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is less than version 3, go to step (4), if it is version 3 or later go to step (5).
4	Set the MMCSDB0_CLOCK_CONTROL register using 8-bit Divided Clock mode.

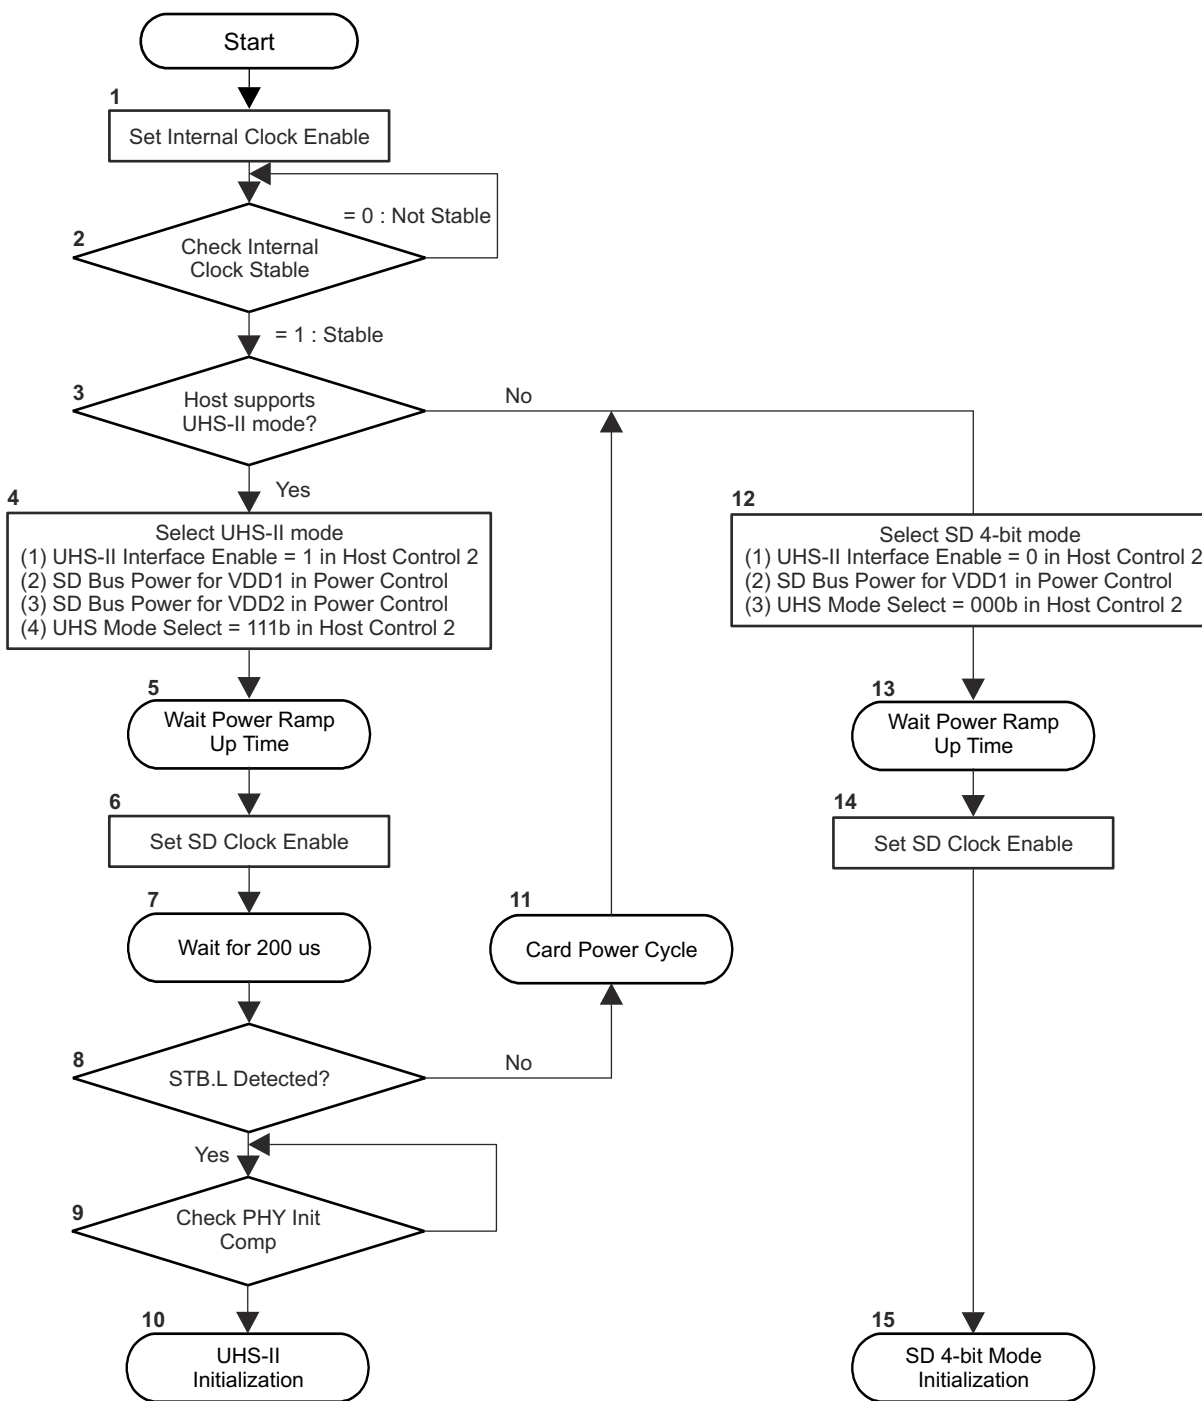

**Table 12-231. Host Controller Setup Sequence (continued)**

Step	Description
5	Set Version 3 parameters. The MMCSD0_CLOCK_CONTROL register is sets in 10-bit Divided Clock Mode or Programmable Clock Mode. If Clock Multiplier in the MMCSD0_CAPABILITIES register is not zero, Programmable Clock Mode should be used. If Preset Value is used, set Preset Values of SD I/F Modes in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set the MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit to 1.
6	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7:0] SPEC_VER_NUM) is version 4, go to step (7), if it is less than version 4, exits.
7	Set Version 4 parameters. Set the MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA bit to 1. If the MMCSD0_CAPABILITIES[27] ADDR_64BIT_SUPPORT_V4 bit is set to 1, set the MMCSD0_HOST_CONTROL2[13] BIT64_ADDRESSING bit to 1. If UHS-II Support is set to 1 and 1.8 V VDD2 Support is set to 1 in the MMCSD0_CAPABILITIES register, set SD Bus Voltage Select for VDD2 to 1.8 V mode in the MMCSD0_POWER_CONTROL register, set preset value for UHS-II Mode to Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set Timeout Counter Value for CMD_RES and Timeout Counter Value for Deadlock in the MMCSD0_UHS2_TIMER_CONTROL register based on Timeout Clock Frequency and Timeout Clock Unit in the MMCSD0_CAPABILITIES register. If Asynchronous Interrupt Support in the MMCSD0_CAPABILITIES register is set to 1, set Asynchronous Interrupt Enable to 1 in the MMCSD0_HOST_CONTROL2 register.

#### 12.3.5.5.2.1.2 Card Interface Detection Sequence

This procedure is invoked by the Card Insertion interrupt. [Figure 12-248](#) and [Table 12-232](#) show a card interface detection sequence.

mmcsd-055

**Figure 12-248. Card Interface Detection Sequence**
**Table 12-232. Card Interface Detection Sequence**

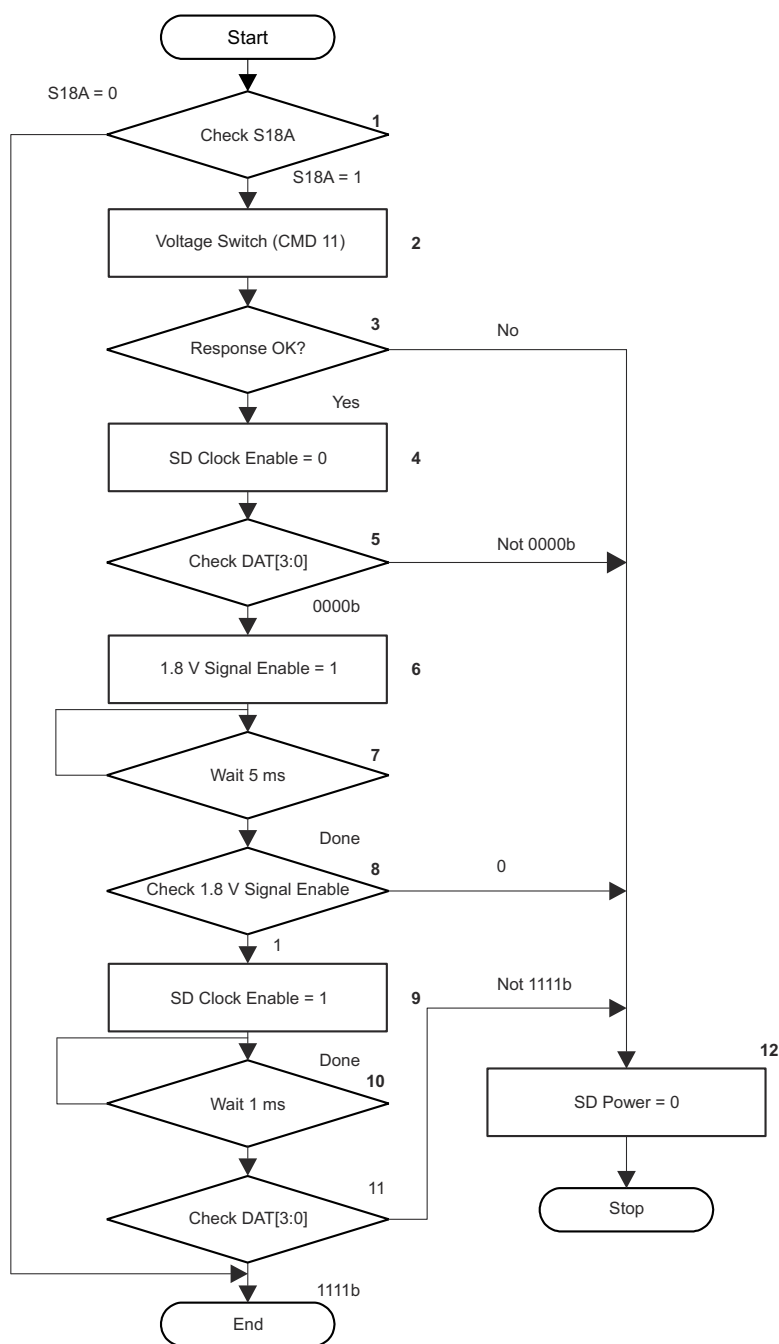

Step	Description
1	Set Internal Clock Enable to 1 in the MMCSDD0_CLOCK_CONTROL register.
2	Wait until Internal Clock Stable is set to 1 in the MMCSDD0_CLOCK_CONTROL register.
3	If Host Supports UHS-II, go to step (4) else go to step (12).
4	Try to initialize a card to UHS-II mode. Set UHS-II Interface Enable to 1 in the MMCSDD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 and SD Bus Power for VDD2 to 1 in the MMCSDD0_POWER_CONTROL register, and set UHS Mode Select to 111b in the MMCSDD0_HOST_CONTROL2 register.

**Table 12-232. Card Interface Detection Sequence (continued)**

Step	Description
5	Wait power ramp up time. It is dependent on a Host System.
6	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
7	Wait 200 $\mu$ s to check a card supports UHS-II mode.
8	Check STB.L Detection in the MMCSD0_PRESENTSTATE register. If UHS-II IF is detected, go to step (9). If UHS-II IF is not detected, go to step (11).
9	Wait until Lane Synchronization in the MMCSD0_PRESENTSTATE register is set to 1 (PHY Initialization is completed).
10	Perform UHS-II initialization.
11	Perform card power cycle.
12	Try to initialize a card to SD 4-bit mode. Set UHS-II Interface Enable to 0 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 000b in the MMCSD0_HOST_CONTROL2 register.
13	Wait power ramp up time. It is dependent on a Host System.
14	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
15	Perform SD 4-bit mode initialization. Refer to <a href="#">Section 12.3.5.5.1.6</a> , <i>Card Initialization and Identification (for SD I/F)</i> .

### 12.3.5.5.2.2 Boot Operation

The boot operation sequence is shown in [Figure 12-249](#).

mmcsd-056

**Figure 12-249. Boot Operation Sequence**

#### 12.3.5.5.2.2.1 Normal Boot Operation: (For Legacy eMMC 5.0)

The Host driver writes the boot timeout value into MMCSD0\_BOOT\_TIMEOUT\_CONTROL register as per the eMMC4.3+ spec.

When the Host driver sets the "BOOT\_ENABLE" to 1 in MMCSD0\_BLOCK\_GAP\_CONTROL register and "DATA\_XFER\_DIR" bit to "1" in MMCSD0\_TRANSFER\_MODE register, the Host controller drives the CMD line to "0" for boot operation.

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV\_BOOT\_ACK" interrupt to the driver

(MMCSD0\_NORMAL\_INTR\_STS[13] RCV\_BOOT\_ACK). If the Host controller doesn't receive the boot acknowledgement from the device within the timeout value, the Host controller will assert the data timeout error interrupt (MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT).

After servicing the boot acknowledge interrupt or data timeout error interrupt, the driver programs the MMCSD0\_BOOT\_TIMEOUT\_CONTROL register with boot data timeout value.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The Host controller terminates the boot operation when the programmed number of blocks is transferred to the System. The Driver can write "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register.

The boot operation can also be terminated in between the boot transfer (the Driver can set the "BOOT\_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, the Host controller asserts soft reset for CMD line and DATA line internally once the driver clears the BOOT\_COMPLETE interrupt (MMCSD0\_NORMAL\_INTR\_STS[14] BOOT\_COMPLETE), to reset all the state machines to idle state.

There is no need to perform error recovery sequence in case data timeout interrupt occurs during boot operation (ignore sending abort command, soft reset and just clear the timeout interrupt and proceed with the boot flow).

If the device sends wrong acknowledgement to the Host, the Host controller will assert Data CRC Error interrupt (MMCSD0\_ERROR\_INTR\_STS[5] DATA\_CRC) on the Driver. In this case, the Host driver has to stop the boot mode operation by setting "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller will assert Data End Bit Error interrupt (MMCSD0\_ERROR\_INTR\_STS[6] DATA\_ENDBIT) on the Driver.

The Host driver stops the boot mode operation by setting "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

**Note:** Enable the MMCSD0\_BLOCK\_GAP\_CONTROL[7] BOOT\_ACK\_ENA bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

#### 12.3.5.5.2.2.2 Alternate Boot Operation (For Legacy eMMC 5.0):

The Host driver writes the boot timeout value as per the eMMC4.3+ spec into MMCSD0\_BOOT\_TIMEOUT\_CONTROL register.

If the "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" is set to 1 in MMCSD0\_BLOCK\_GAP\_CONTROL register and "DATA\_XFER\_DIR" bit is set to 1 in MMCSD0\_TRANSFER\_MODE register, the host controller drives the CMD0 (0xFFFFFFFF) on the CMD line.

The system shall wait for command complete interrupt before "RCV\_BOOT\_ACK" interrupt (MMCSD0\_NORMAL\_INTR\_STS[13] RCV\_BOOT\_ACK).

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV\_BOOT\_ACK" interrupt to the driver.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The System needs to send CMD0 to inform the device about the boot operation complete. The system shall program MMCSD0\_COMMAND register with argument "00000000h" for the CMD0 and waits for command complete.

The Host controller terminates the boot operation when the programmed number of blocks are transferred to the System and the Driver shall send CMD0 to eMMC card and then program "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register.

The boot operation can be terminated at any time (the Driver can send CMD0 and set the "BOOT\_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, all state machines in the Host controller need to move to IDLE state. The Host controller asserts the soft reset for CMD and data line internally when the

driver clears the BOOT\_COMPLETE interrupt (MMCSD0\_NORMAL\_INTR\_STS[14] BOOT\_COMPLETE) and all the state machine goes to the idle state.

If the Host controller doesn't receive the acknowledgement from the device with in timeout value the Host controller will assert the data timeout error interrupt (MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT).

The driver programs the MMCSD0\_BOOT\_TIMEOUT\_CONTROL register with boot data timeout value.

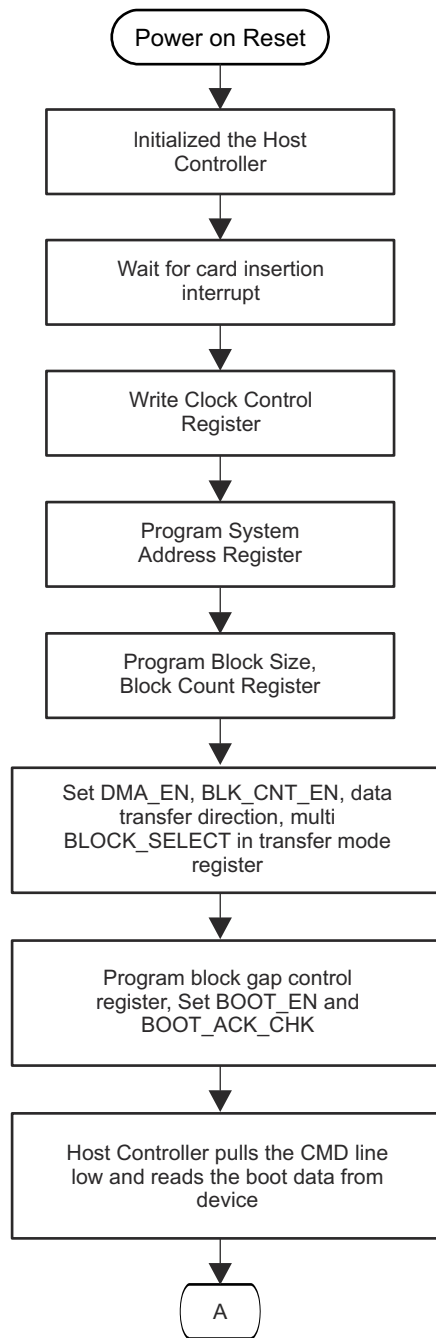

There is no need to perform error recovery sequence in case of data timeout interrupt as mentioned above. If the device sends wrong acknowledgement to the Host, then Host controller will assert Data CRC Error interrupt to the Driver (MMCSD0\_ERROR\_INTR\_STS[5] DATA\_CRC). The Host driver has to stop the boot mode operation by setting "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller asserts Data End Bit Error interrupt (MMCSD0\_ERROR\_INTR\_STS[6] DATA\_ENDBIT) on the Driver. The Host driver stops the boot mode operation by setting "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

**Note:** Enable the MMCSD0\_BLOCK\_GAP\_CONTROL[7] BOOT\_ACK\_ENA bit during boot operation . If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

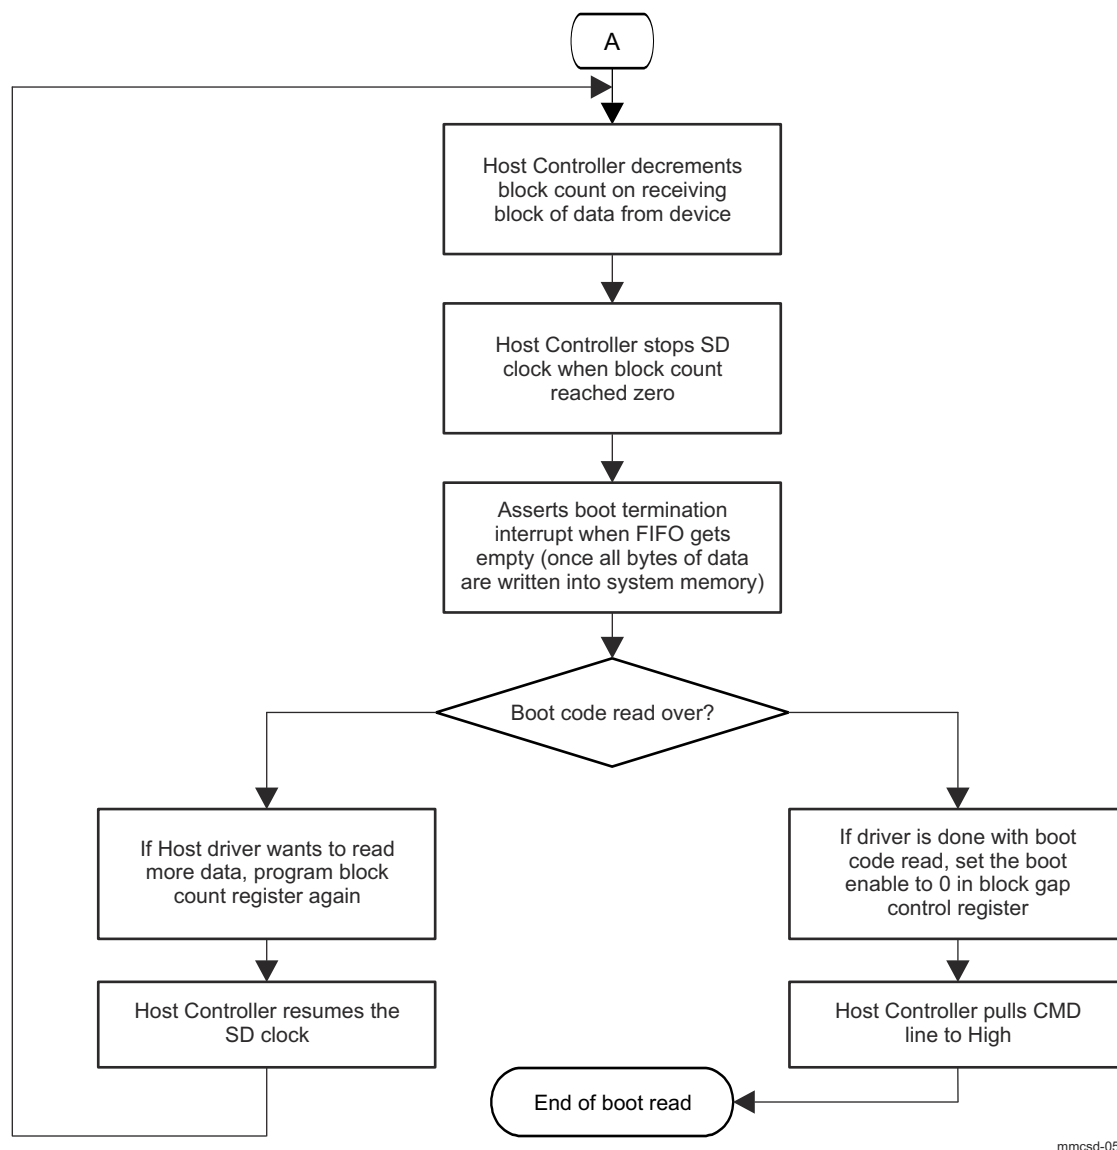

#### **12.3.5.5.2.3 Boot Code Chunk Read Operation (For Legacy eMMC 5.0):**

The following figure explains the boot code read done as chunks of data (the Driver can read the boot data as 2K, 4K, 1K and 8K etc. instead of 128K at a time

mmcsd-057

**Figure 12-250. Boot Code Access Flow Diagram (1)**

**Figure 12-251. Boot Code Access Flow Diagram (2)**

### 12.3.5.5.2.3 Retuning procedure (For Legacy Interface)

#### 12.3.5.5.2.3.1 Sampling Clock Tuning

The SD bus can be operating in high clock frequency mode and then the data window from the card on CMD and DAT[3:0] lines gets smaller. The position of the data window will vary depending on the card and host system implementation. Therefore, the Host Controller shall support a tuning circuit when SDR104 or SDR50.

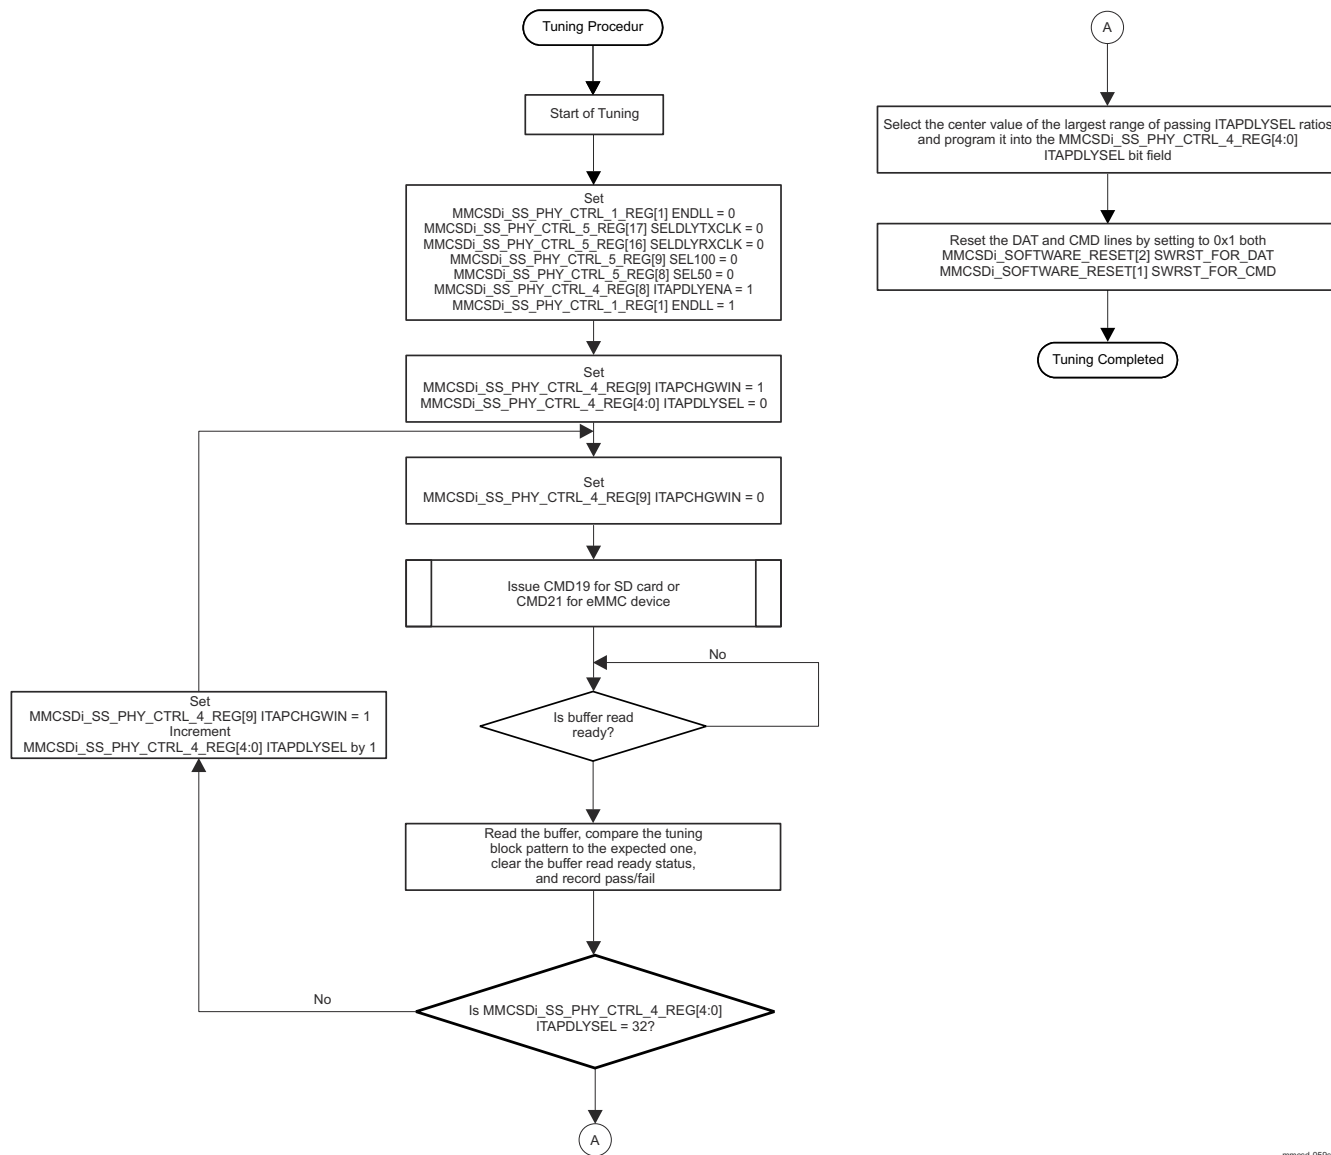

The Host Controller shall support a tuning circuit when SDR104 or SDR50 (if Use Tuning for SDR50 is set to 1 in the MMCSD0\_CAPABILITIES register) is supported by executing the tuning procedure and adjusting the sampling clock. Execute Tuning and Sampling Clock Select in the MMCSD0\_HOST\_CONTROL2 register are used to control the tuning circuit.

See [MMC SW Tuning Algorithm](#) for more information.

#### 12.3.5.5.2.3.2 Tuning Sequence

The [Figure 12-252](#) defines sampling clock tuning procedure supported by Host Controller. In default, for lower frequency operation, fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using

SDR104, sampling clock tuning is required. Start of sampling clock tuning is requested by setting Execute Tuning to 1 and Sampling Clock Select to 0.

**Figure 12-252. MMCSD Clock Tuning**

Host driver issue CMD19 repeatedly until the host controller resets Execute Tuning to 0. Host Controller resets Execute Tuning to 0 when tuning is completed or tuning is not completed within 40 times. Host Driver can abort this loop by 40 times CMD19 issue or 150 ms time-out.

If tuning is completed successfully, Host Controller set Sampling Clock Select to 1 and this means the Host Controller start to use tuned sampling clock. If tuning is failed, Host Controller keeps Sampling Clock Select to 0. By writing Sampling Clock Select to 0, sampling clock is switched from tuned sampling clock to fixed sampling clock. Re-tuning time would be smaller than the first tuning time. CMD19 response errors are not indicated while tuning is performed.

The clock tuning tap delay values are selected using Variable sampling point detection. Fixed tap delay value is used for fixed tuning clock method.

### 12.3.5.5.2.3.3 Re-Tuning Modes

The re-tuning timing is specified by two methods: Re-Tuning Request generated by Host Controller and expiration of a re-tuning timer prepared by Host Driver.

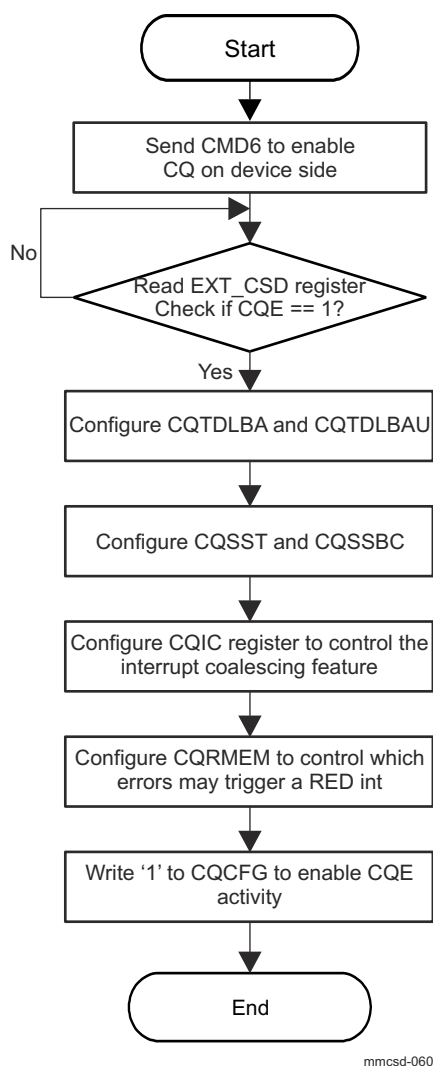

(1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MB.

(2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled.

### 12.3.5.5.2.4 Command Queuing Driver Flow Sequence

#### 12.3.5.5.2.4.1 Command Queuing Initialization Sequence

Figure 12-253 and Table 12-233 show a Command Queuing initialization sequence.
