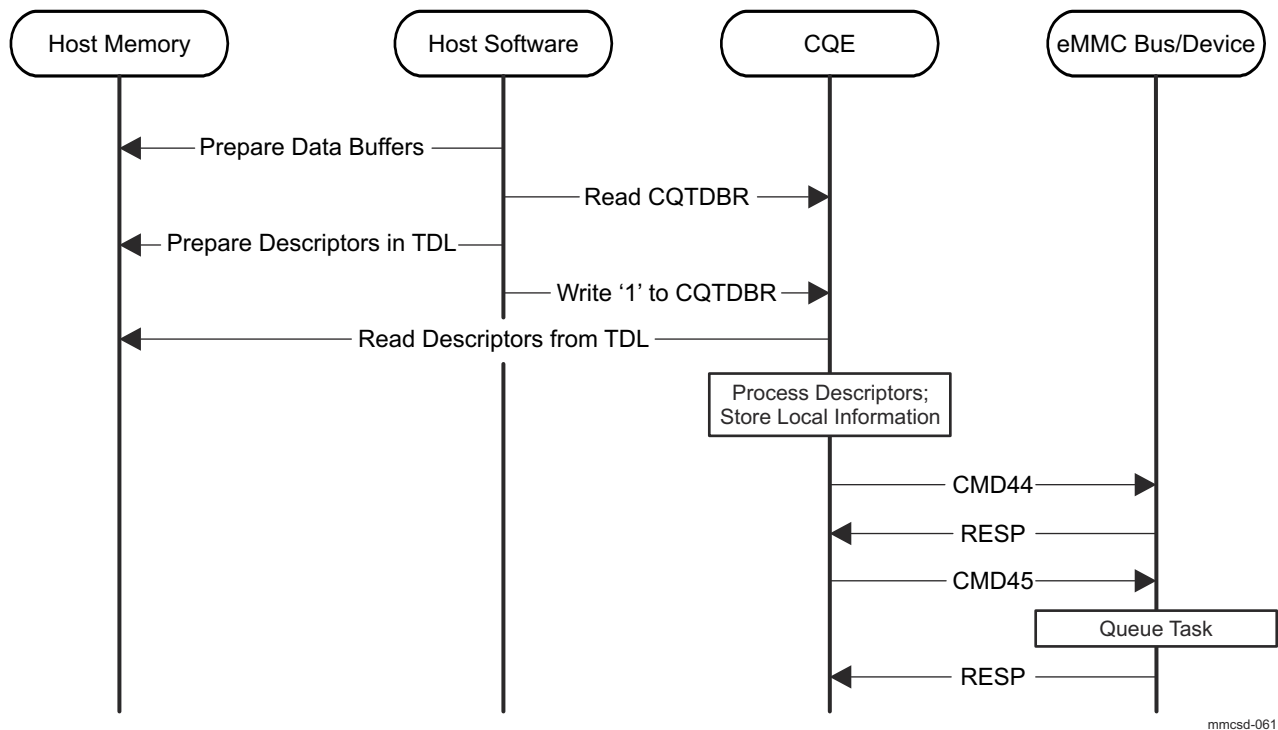

**Figure 12-253. Command Queuing Initialization Sequence**

**Table 12-233. Command Queuing Initialization Sequence**

Step	Description
1	Initialize and enable Command Queueing in the device.
2	Configure Task Descriptor size in MMCSD0_CQ_CONFIG register.
3	Configure MMCSD0_CQ_TDL_BASE_ADDR and MMCSD0_CQ_TDL_BASE_ADDR_UPBITS registers to point to the memory location allocated to the TDL in host memory.
4	Configure CQSST and CQSSBC to control when SEND_QUEUE_STATUS commands are sent to the device by CQE.
5	Configure MMCSD0_CQ_INTR_COALESCING register to control the interrupt coalescing feature: enable/disable, set interrupt count and timer protection.
6	Configure MMCSD0_CQ_RESP_ERR_MASK register to control which errors may trigger a RED interrupt (if different from reset values).
7	Write '1' to MMCSD0_CQ_CONFIG register to enable CQE activity.

#### 12.3.5.5.2.4.2 Task Issuance Sequence

Figure 12-254 and Table 12-234 show a task issuance sequence.

mmcsd-061

**Figure 12-254. Task Issuance Sequence**
**Table 12-234. Task Issuance Sequence**

Step	Description
1	Find an empty transfer request slot by reading the MMCSD0_CQ_TASK_DOOR_BELL register. An empty transfer request slot has its respective bit cleared to '0' in the MMCSD0_CQ_TASK_DOOR_BELL register.

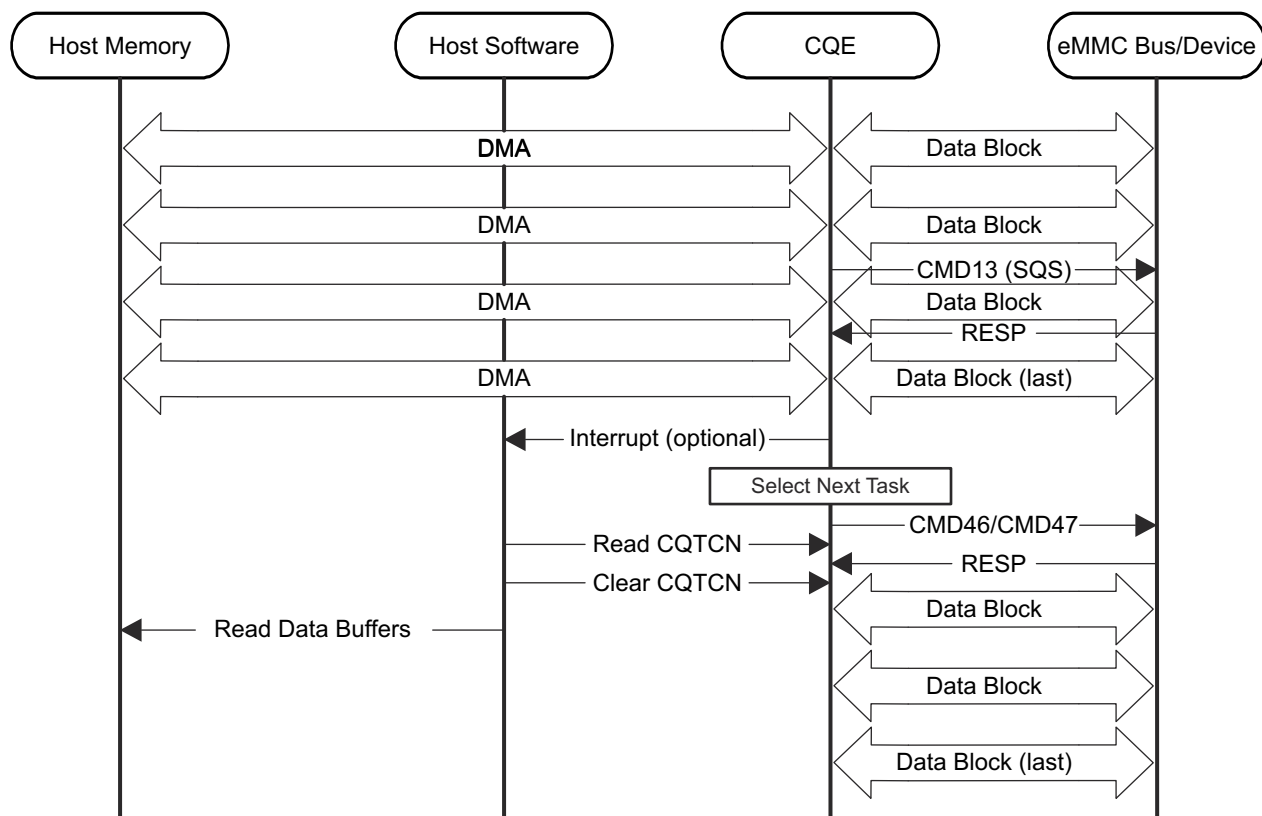

**Table 12-234. Task Issuance Sequence (continued)**

Step	Description
2	Build a Task Descriptor at the 1st entry of the empty slot. Task Descriptor field values: <ul style="list-style-type: none"> <li>1. Valid = 1, to indicate the descriptor is effective.</li> <li>2. End = 1, as required for Task Descriptors.</li> <li>3. Int = 1, if an interrupt on completion is required. Otherwise, Int = 0.</li> <li>4. Act = b101, to indicate a Task Descriptor .</li> <li>5. Data Direction = 1 for read commands, and 0 for write commands.</li> <li>6. Priority = 1 for high priority, and 0 for simple requests.</li> <li>7. QBR = 1 if Queue Barrier functionality is required. 0 otherwise.</li> <li>8. Forced Programming, Context ID, Tag Request, Reliable Write, Block Count, and Block Address programmed according to application requirements.</li> </ul>
3	Build a Transfer Descriptor at the 2nd entry of the empty slot. Transfer Descriptor field values: <ul style="list-style-type: none"> <li>1. Valid = 1, to indicate the descriptor is effective.</li> <li>2. End = 1, if a TRAN descriptor is used, to indicate the task only has one data buffer. End = 0 if LINK descriptor is used.</li> <li>3. Int = 0. Ignore in Command queueing.</li> <li>4. Act = b100, for TRAN descriptors, pointing directly to the task's single data buffer. Act = 401 b110, for LINK descriptors, point to a scatter/gather list (indirect).</li> <li>5. Address and Length programmed according to the data buffer supplied by the application.</li> </ul>
4	If more than one transfer is requested, repeat step 1-3 for all needed transfers.
5	Set MMCSD0_CQ_TASK_DOOR_BELL register to indicate to the CQE that one or more transfer requests are ready to be sent to the attached device. Host software shall only write a '1' to the bit position that corresponds to new tasks; all other bit positions within MMCSD0_CQ_TASK_DOOR_BELL register should be written with a '0', which indicates no change to their current values.

#### 12.3.5.5.2.4.3 Task Execution and Completion Sequence

The CQE is responsible for task execution, communication with the device and moving the data to the buffers in the host memory.

Figure 12-255 and Table 12-235 show a task execution and completion sequence.

mmcsd-062

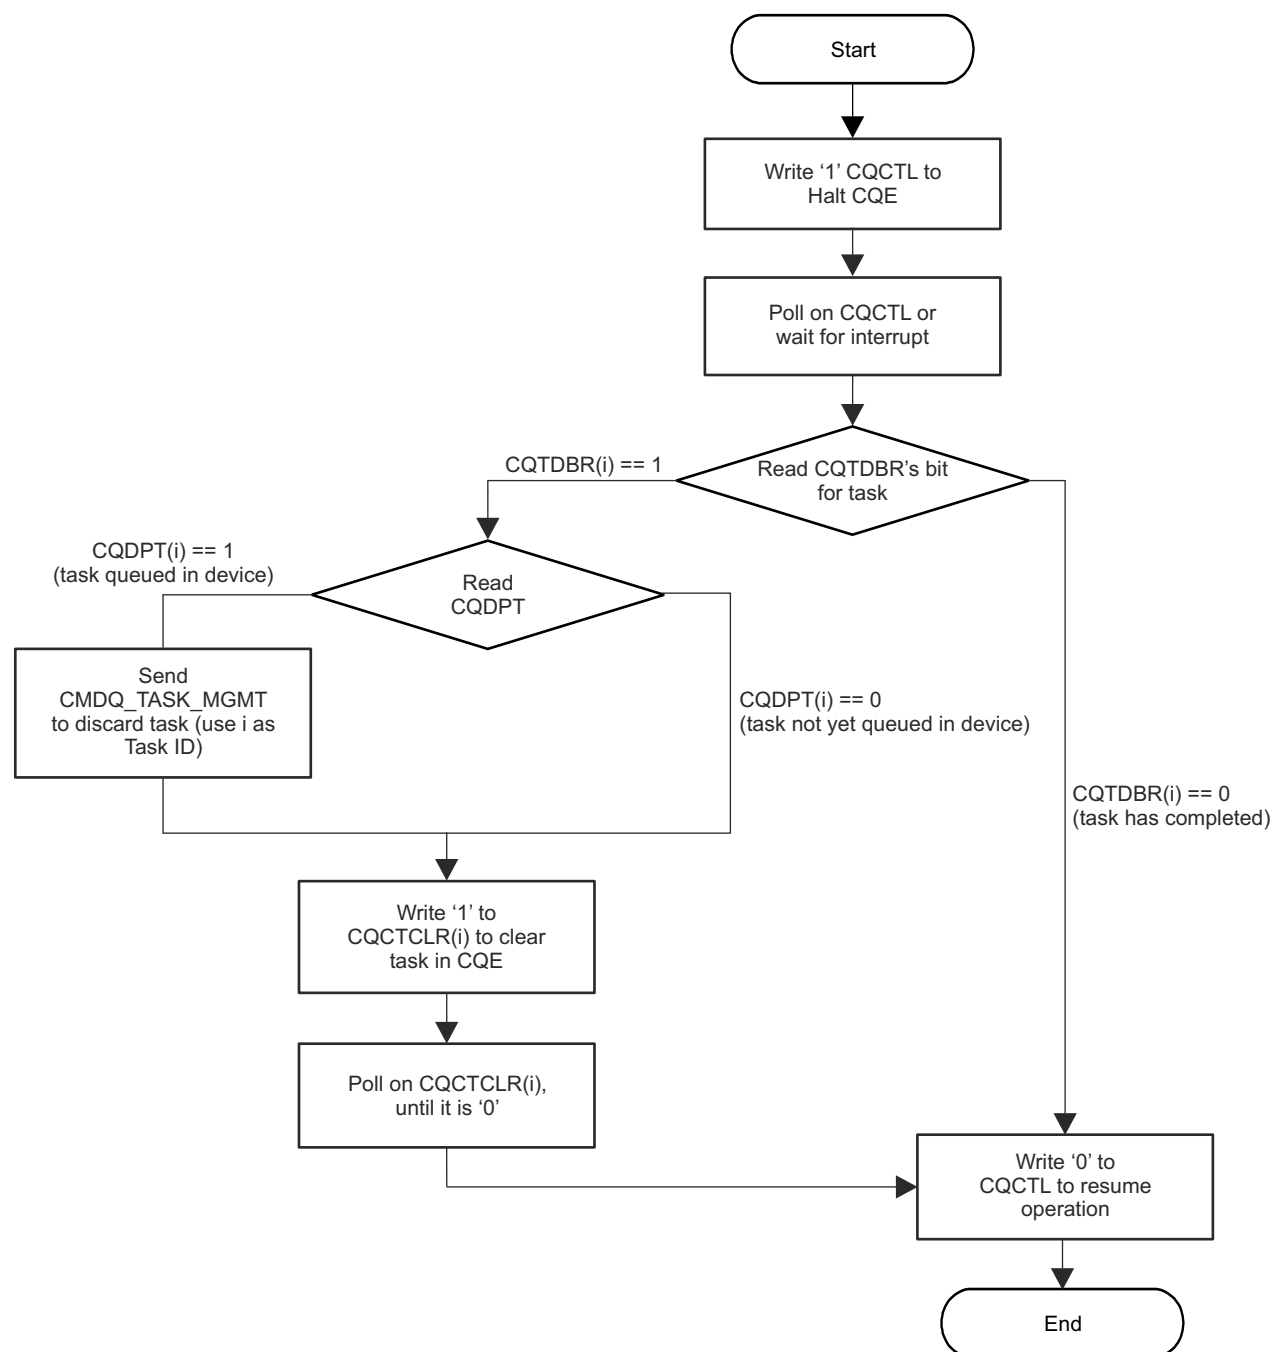

**Figure 12-255. Task Execution and Completion Sequence**

**Table 12-235. Task Execution and Completion Sequence**

Step	Description
1	Once the tasks are queued on the device side CQE sends CMD13 to determine the queue status. The queue status lets the CQE know which tasks are ready for execution.
2	The response to CMD13 may indicate no task is ready in which case the CQE is required to send CMD13 again at a later time as controlled CQSST register.
3	If a task is ready for execution then the host sends EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47) to the device with the task id ordering it to execute a task.
4	When the task execution is completed, an interrupt may be generated, if requested, or as determined by Interrupt Coalescing mechanism.
5	The host software reads MMCSD0_CQ_TASK_COMP_NOTIF register to determine which task(s) has(have) been completed. Each bit set in MMCSD0_CQ_TASK_COMP_NOTIF register represents by index which task has completed but hasn't yet been served by software.
6	For every task completed clear the appropriate MMCSD0_CQ_TASK_COMP_NOTIF register bit.
7	Repeat steps 1-6 for the pending tasks.

#### 12.3.5.5.2.4.4 Task Discard and Clear Sequence

Figure 12-256 and Table 12-236 show a task discard and clear sequence.

mmscd-063

**Figure 12-256. Task Discard and Clear Sequence**
**Table 12-236. Task Discard and Clear Sequence**

Step	Description
1	While CQE is enabled write '1' to MMCS0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
2	Poll on MMCS0_CQ_INTR_STS[0] HALT_COMPLETE bit.
3	Read MMCS0_CQ_TASK_DOOR_BELL register to determine if the task to be discarded is set to 1.
4	Read MMCS0_CQ_DEV_PENDING_TASKS register to check if the task is queued in the device.
5	Send CMDQ_TASK_MGMT(CMD48) to discard task using the task id as the argument.
6	Write '1' to CQCTCLR[i] to clear task in CQE.

**Table 12-236. Task Discard and Clear Sequence (continued)**

Step	Description
7	Poll on CQCTCLR[i] until it is '0'.
8	Write '0' to MMCSD0_CQ_CONTROL register to resume CQE.

#### 12.3.5.5.2.4.5 Error Detect and Recovery when CQ is enabled

Figure 12-257 and Table 12-237 show an error detect and recovery sequence.

**Figure 12-257. Error Detect and Recovery Sequence**
**Table 12-237. Error Detect and Recovery Sequence**

Step	Description
1	Read eMMC host controller MMCSD0_ERROR_INTR_STS register and determine error is related to CQE.
2	Write '1' to MMCSD0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
3	Wait for MMCSD0_CQ_CONTROL[0] HALT_BIT bit to read '1'. In some error cases, this may not happen, so software should proceed to the next step after a sufficient time-out.

**Table 12-237. Error Detect and Recovery Sequence (continued)**

Step	Description
4	Read MMCSD0_CQ_CMD_RESP_INDEX and MMCSD0_CQ_CMD_RESP_ARG registers to determine last response's index and argument.
5	Read MMCSD0_CQ_TASK_ERR_INFO register to determine the transmitted command's index and the index of the task to which it is related.
6	Perform error-specific recovery procedure.
7	Write '0' to MMCSD0_CQ_CONTROL register to resume operation.

## 12.4 Industrial and Communication Interfaces

### 12.4.1 Modular Controller Area Network (MCAN)

This section describes the Modular Controller Area Network (MCAN) modules in the device.

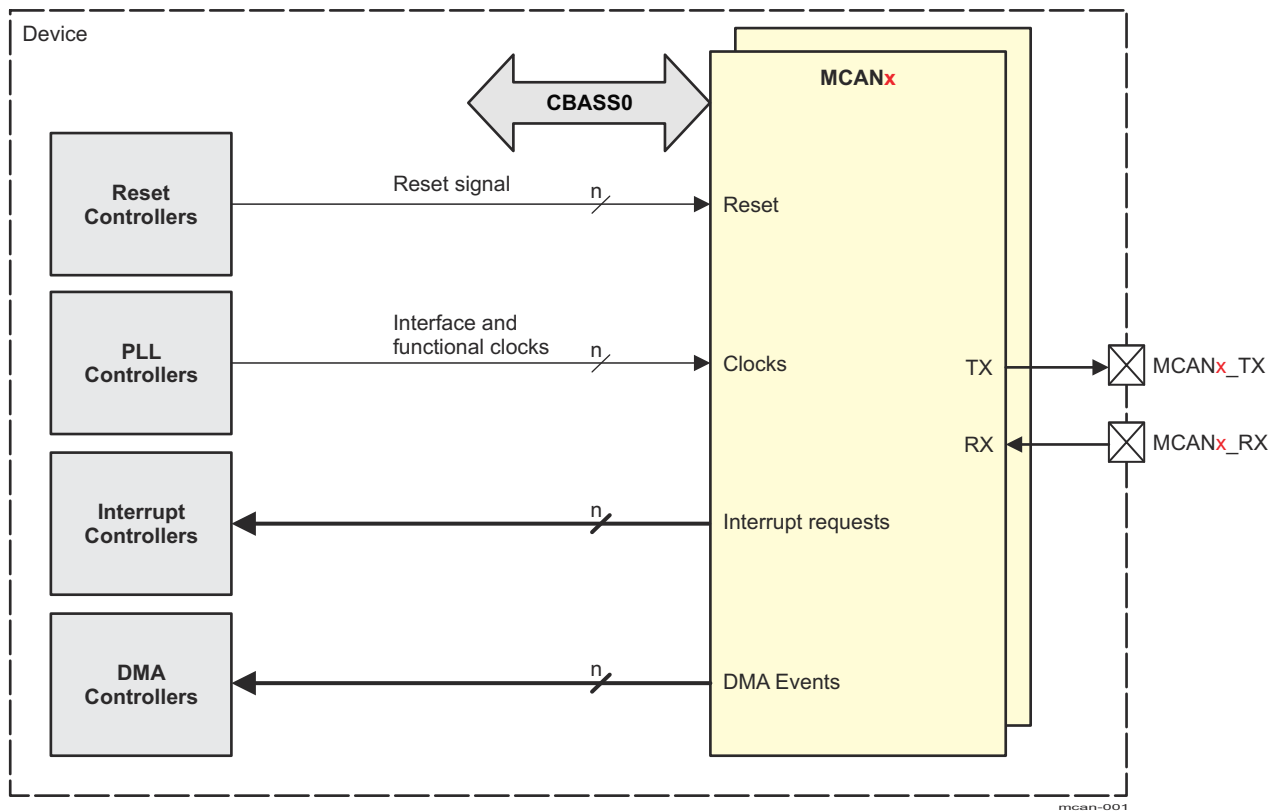

#### 12.4.1.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control. CAN has high immunity to electrical interference. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

They connect to the physical layer of the CAN network through external (for the device) transceivers. Each MCAN module supports flexible bit rates greater than 1 Mbps and is compliant to ISO 11898-1:2015.

Figure 12-258 shows the MCAN modules overview.

A.  $x = 0$  to number of MCAN in a domain -1

**Figure 12-258. MCAN Modules Overview**

#### 12.4.1.1.1 MCAN Features

Each MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements

- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

#### **12.4.1.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

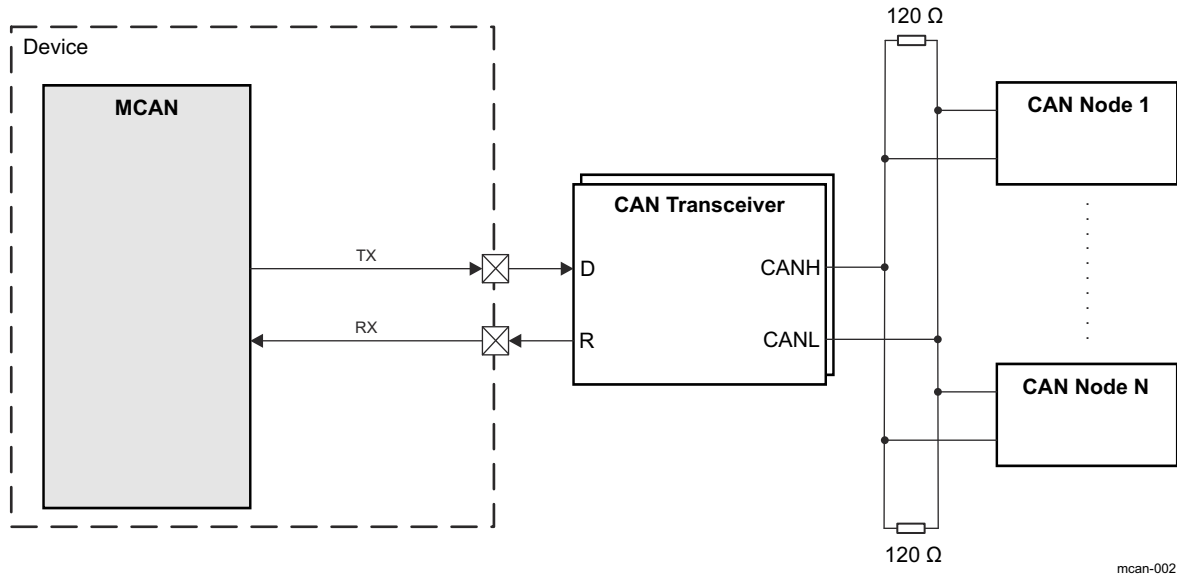

---

### 12.4.1.2 MCAN Environment

This section describes the MCAN external connections (environment).

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the MCAN.

Figure 12-259 shows the MCAN typical application.

**Figure 12-259. MCAN Typical Application**

Table 12-238 describes the MCAN I/O signals.

**Table 12-238. MCAN I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(1)</sup>
<b>MCANi<sup>(2)</sup></b>				
RX	MCANi <sup>(2)</sup> _RX	I	Serial data input from external CAN transceiver	HiZ
TX	MCANi <sup>(2)</sup> _TX	O	Serial data output to external CAN transceiver	1

(1) I = Input; O = Output; HiZ = High Impedance

(2) i represents an MCAN instance. See the device datasheet for available domains and MCAN instances.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

#### 12.4.1.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using Non-Return-to-Zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- The network is multicontroller. When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier based, not address based.
- Content of message is labeled by the identifier that is unique throughout the network (for example: rpm, temperature, position, pressure, and so forth).
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for Classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

#### 12.4.1.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.4.1.4 MCAN Functional Description

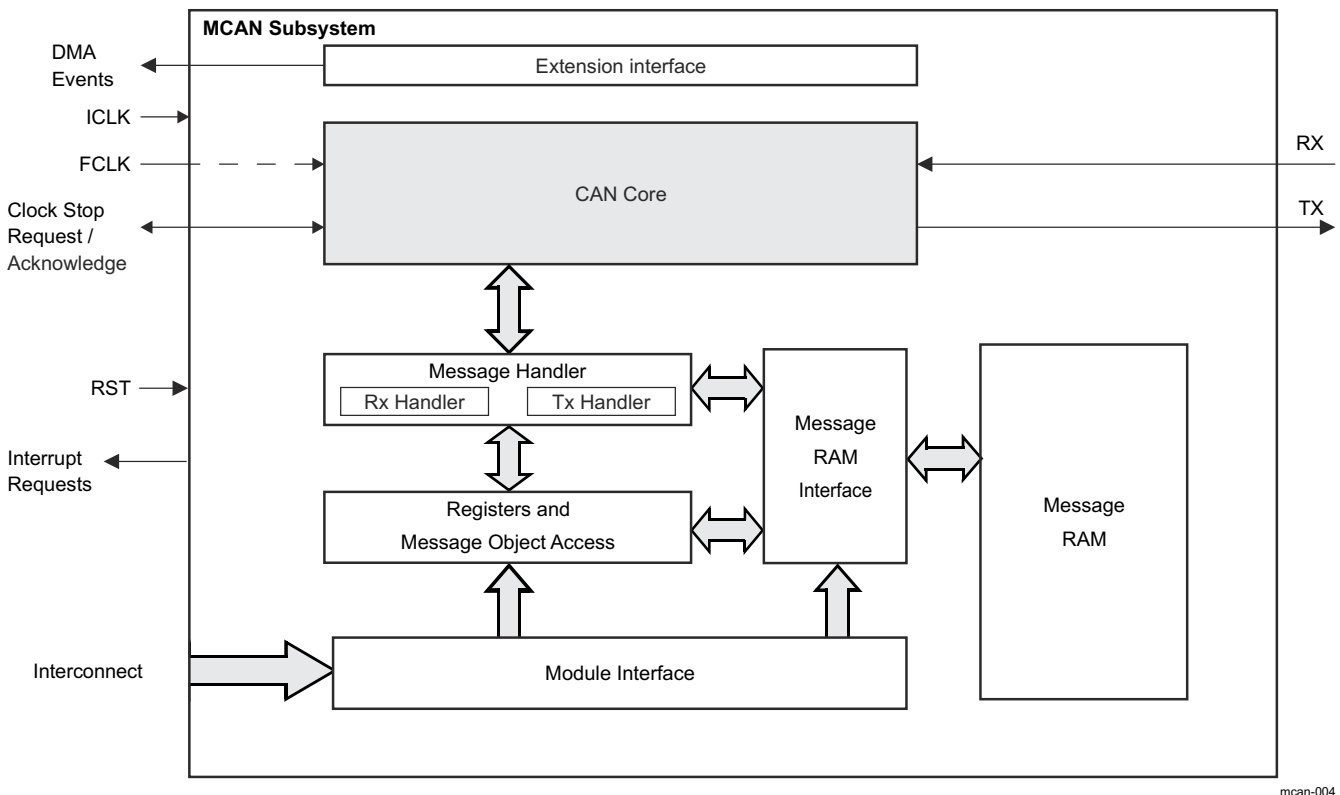

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values greater than 1 Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 12-260 shows the MCAN module block diagram.

**Figure 12-260. MCAN Block Diagram**

The MCAN module blocks description:

- **CAN Core:** the CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see [Section 12.4.1.4.10, Message RAM](#)).
- **Message RAM Interface:** enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** data consistency is ensured by indirect accesses to the message objects. The interface registers have the same word-length as the Message RAM.

- **Module Interface:** provides connection to the Registers and Message Object Access block and Message RAM Interface block
- **Clocking:** two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock ICLK) and the peripheral asynchronous clock (functional clock - FCLK). For more information, see *Module Integration*.
- **Extension Interface:** this interface is used for DMA requests signaling (see [Section 12.4.1.4.2.2](#)).

#### 12.4.1.4.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal to the Host clock domain and to the CAN clock domain.

#### Note

ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated ICLK has to be considered:

$$f_{0,ICLK} \pm \Delta f_{FM,ICLK} \geq f_{FCLK}$$

For more information on how to configure the relevant clock source registers, see *Clocking* and the device-specific Datasheet.

#### 12.4.1.4.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode is requesting or forcing (based on MCANSS\_CTRL[3] DBGSUSP\_FREE bit) the MCAN module to go into initialization mode (see MCAN\_CCCR[0] INIT bit) in which new interrupts and DMA requests will not be issued, that is to prevent the interrupt and DMA requests from propagating to the Host CPU (for more information, see [Section 12.4.1.4.3.8.2, Suspend Mode](#)).

##### 12.4.1.4.2.1 Interrupt Requests

The MCAN module has two interrupt lines. There are 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are 'level high' interrupts.

The MCAN core provides two interrupt requests (for Line 0 and Line 1).

For more information, see the following registers:

- Interrupt Register (MCAN\_IR)
- Interrupt Enable (MCAN\_IE)
- Interrupt Line Select (MCAN\_ILS)
- Interrupt Line Enable (MCAN\_ILE)

The MCAN module is capable of issuing ECC interrupts. After clearing the ECC interrupt source, the application software must also write 1 to EOI register (MCANSS\_ECC\_SEC\_EOI\_REG/MCANSS\_ECC\_DED\_EOI\_REG). For more information, see *ECC Aggregator*.

The MCAN module supports External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see [Section 12.4.1.4.4.1, External Timestamp Counter](#)).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS\_ICS)
- Interrupt Raw Status Register (MCANSS\_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS\_IECS)

- Interrupt Enable Register (MCANSS\_IE)
- Interrupt Enable Status Register (MCANSS\_IES)
- End Of Interrupt Register (MCANSS\_EOI)
- External Timestamp Prescaler Register (MCANSS\_EXT\_TS\_PRESCALER)
- External Timestamp Unserved Interrupts Counter Register (MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR)

For more information about available Interrupt Requests, see *MCAN Hardware Requests*.

#### 12.4.1.4.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extension Interface. The DMA signaling uses a simple DMA request active high pulse.

The active high pulse indicates a pending message is transmitted (see MCAN\_TXBRP). This pulse can be used to transfer another message to the Tx Buffer, which would need to be followed by writing 1 to the corresponding MCAN\_TXBAR[0] AR bit to mark a new Tx message pending transmission.

The Parity on Tx DMA Events is available using an EDC Controller which can be accessed through the ECC Aggregator.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle pulses (ICLK).

#### 12.4.1.4.3 Operating Modes

##### 12.4.1.4.3.1 Software Initialization

Setting the MCAN\_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus\_Off state. While the MCAN\_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN\_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN\_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus\_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN\_CCCR[0] INIT and MCAN\_CCCR[1] CCE bits are set (write protection).

The MCAN\_CCCR[1] CCE bit can only be set/reset while the MCAN\_CCCR[0] INIT = 1. The MCAN\_CCCR[1] CCE bit is automatically reset when the MCAN\_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN\_CCCR[1] CCE bit is set:

- MCAN\_HPMS - High Priority Message Status
- MCAN\_RXF0S - Rx FIFO 0 Status
- MCAN\_RXF1S - Rx FIFO 1 Status
- MCAN\_TXFQS - Tx FIFO/Queue Status
- MCAN\_TXBRP - Tx Buffer Request Pending
- MCAN\_TXBTO - Tx Buffer Transmission Occurred
- MCAN\_TXBCF - Tx Buffer Cancellation Finished
- MCAN\_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN\_TOCV[15-0] TOC field is preset to the value configured by the MCAN\_TOCC[31-16] TOP field when the MCAN\_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN\_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN\_CCCR[1] CCE = 0

- MCAN\_TXBAR - Tx Buffer Add Request
- MCAN\_TXBCR - Tx Buffer Cancellation Request

MCAN\_CCCR[7] TEST and MCAN\_CCCR[5] MON bits can only be set by the Host CPU while MCAN\_CCCR[0] INIT = 1 and MCAN\_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN\_CCCR[6] DAR bit can only be set/reset while MCAN\_CCCR[0] INIT = 1 and MCAN\_CCCR[1] CCE = 1.

Table 12-239 shows the steps to configure the MCAN module.

**Table 12-239. Steps to Configure MCAN Module**

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR[0] INIT bit and check that it has been set	INIT = 1; If INIT $\neq$ 1, wait until it is
2	Unlock protected registers	Set MCAN_CCCR[1] CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR[8] FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR[9] BRSE bit	BRSE = 1 with bit rate switching BRSE = 0 without bit rate switching
5	Set bit timing	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR[1] CCE bit	CCE = 0;
7	Return MCAN module to normal operation	Clear MCAN_CCCR[0] INIT bit and check it has been cleared	INIT = 0; If INIT $\neq$ 0, wait until it is

#### 12.4.1.4.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN\_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

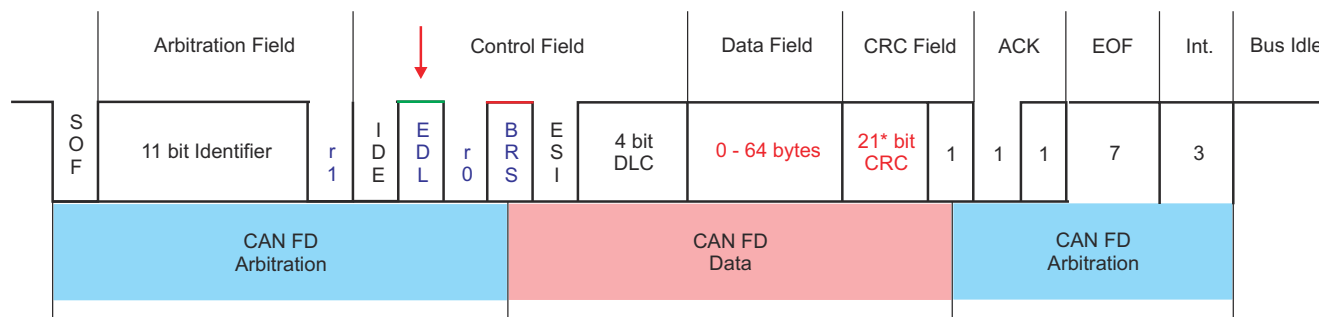

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

#### Note

Automated transmission on reception of remote frames is not supported.

#### 12.4.1.4.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 8 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 12-261, sets a data length of up to 8 or up to 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate to the arbitration phase) are enabled.

\* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

**Figure 12-261. CAN FD Frame**

### Note

Figure 12-261 presents CAN FD frame according to the Non-ISO CAN FD (legacy) protocol. In the new ISO CAN FD protocol the CRC Field includes additional 5 bits (three stuff bit counter (SBC) bits and two parity bits). With these additional bits, a weakness identified in the error detection scheme chosen by the original protocol is removed. By setting MCAN\_CCCR[15] NISO bit, the ISO or Non-ISO CAN FD format can be chosen. In CAN network ISO CAN FD and non-ISO CAN FD devices should never mix.

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN\_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN\_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN\_PSR[4-3] ACT = 10) to Integrating (MCAN\_PSR[4-3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN\_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN\_CCCR[8] FDOE bit. In case MCAN\_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN\_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN\_CCCR[8] FDOE and MCAN\_CCCR[9] BRSE bits can only be changed while the MCAN\_CCCR[0] INIT and MCAN\_CCCR[1] CCE bits are both set. With MCAN\_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN\_CCCR[8] FDOE = 1 and MCAN\_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN\_CCCR[8] FDOE = 1 and MCAN\_CCCR[9] BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

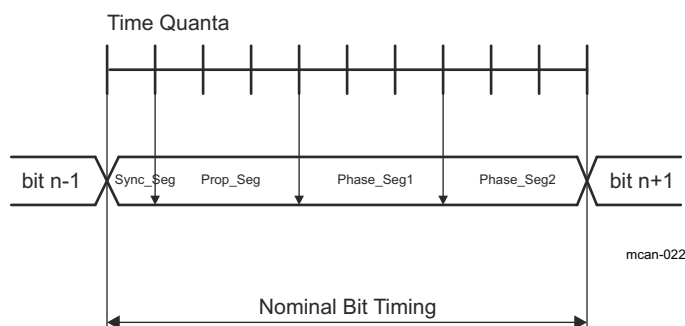

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the DLC coding differs from the standard CAN format (see [Table 12-240](#)).

**Table 12-240. DLC Coding**

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 12-262](#)) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN\_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN\_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

**Figure 12-262. CAN Bit Timing**

The maximum configurable data phase bit timing depends on the CAN clock frequency (FCLK). Example: with FCLK = 20 MHz and the shortest configurable bit time of 4  $t_q$  (time quanta), the bit rate in the data phase is 5 Mbps.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN\_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

#### 12.4.1.4.3.4 Transmitter Delay Compensation

##### 12.4.1.4.3.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase

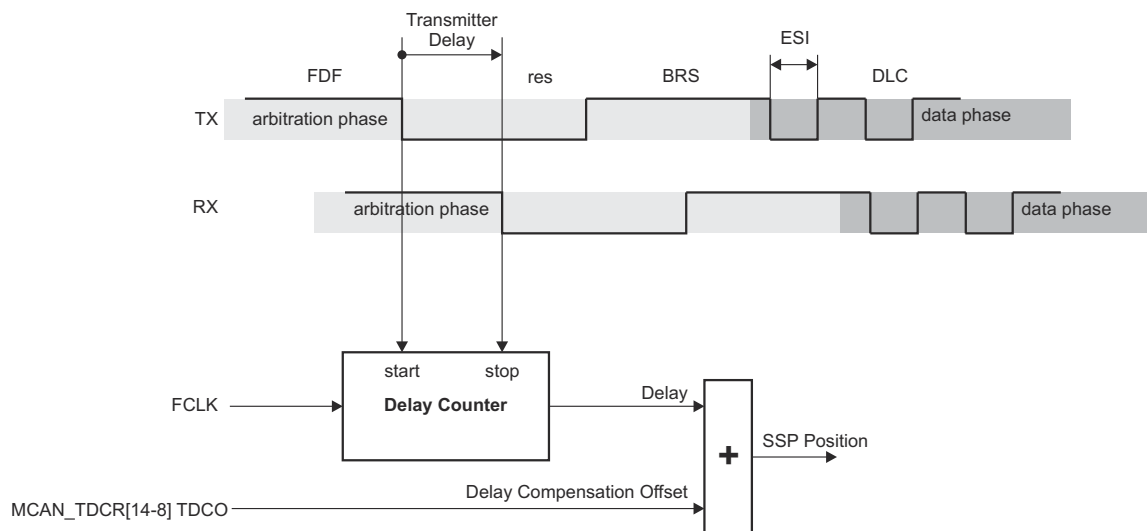

independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN\_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN\_TDCR[14-8] TDCO field (see Figure 12-263). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN\_PSR[22-16] TDCV field. This field is cleared when the MCAN\_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN\_DBTP[23] TDC bit is set.

mcan-005

**Figure 12-263. Transmitter Delay Measurement**

#### 12.4.1.4.3.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN\_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 12-263). The mtq (minimum time quantum) dimension is equal to the CAN clock period (FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN\_TDCR[6-0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN\_TDCR[6-0] TDCF field and the RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN\_TDCR[14-8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN\_TDCR[14-8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

#### 12.4.1.4.3.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (MCAN\_ECR[14-8] REC and MCAN\_ECR[7-0] TEC) are frozen while CAN error logging (MCAN\_ECR[23-16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN\_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN\_CCCR[2] CCE and MCAN\_CCCR[0] INIT bits are set to 1.

The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN\_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

#### Note

The Restricted Operation Mode must not be combined with the Internal Loopback Mode .

#### 12.4.1.4.3.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN\_CCCR[5] MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN\_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 12-264 shows the connection of the TX and RX signals to the MCAN module in Bus Monitoring Mode.

**Figure 12-264. Connection of Signals in Bus Monitoring Mode**

#### 12.4.1.4.3.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN\_CCCR[6] DAR bit).

##### 12.4.1.4.3.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN\_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

##### 12.4.1.4.3.8 Power Down (Sleep Mode)

The entering in Power Down mode is controlled via two sources:

- PSC (via clock stop request signal)
- Software (by writing to the MCAN\_CCCR[4] CSR bit)

As long as the clock stop request signal is active, the MCAN\_CCCR[4] CSR bit is read as 1.

When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN\_CCCR[0] INIT bit to 1 to prevent any further CAN transfers.

The MCAN module acknowledges that it is ready for power down:

- By asserting clock stop acknowledge signal to the PSC (in case of PSC source).
- By setting the MCAN\_CCCR[3] CSA flag bit to 1 (in case of Software source).

In this state, before the clocks are switched off, further register accesses can be made. Now the module clock inputs ICLK and FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN\_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN\_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN\_CCCR[0] INIT bit.

Restoring the clocks from clock stop mode, needs to be done according to how the clock stop was initiated:

- If Software asserts the MCAN\_CCCR[3] CSA flag bit, once the MCAN module goes idle, the MCAN\_CCCR[0] INIT bit is set. To get it started again, Software needs to write 0 to the MCAN\_CCCR[0] INIT bit.
- If PSC is issuing a clock stop request, than there are two options for waking up:
  - After removing clock stop request signal, Software would need to write 0 to the MCAN\_CCCR[0] INIT bit, or
  - If the MCANSS\_CTRL[5] AUTOWAKEUP bit is set, than after removing clock stop request signal, an FSM inside the MCAN module will reset the MCAN\_CCCR[0] INIT bit (without Software).

#### 12.4.1.4.3.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN\_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.1.4.3.8.3, Wakeup request](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN\_CCCR[0] INIT bit is performed to clear it.

#### 12.4.1.4.3.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS\_CTRL[3] DBGSUSP\_FREE bit), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN\_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN\_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.1.4.3.8.3, Wakeup request](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN\_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN\_ECR[23-16] CEL
- MCAN\_PSR[2-0] LEC
- MCAN\_PSR[10-8] DLEC
- MCAN\_PSR[11] RESI
- MCAN\_PSR[12] RBRS
- MCAN\_PSR[13] RFDF
- MCAN\_PSR[14] PXE

#### 12.4.1.4.3.8.3 Wakeup request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN\_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS\_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is de-asserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is de-asserted
- A reset is applied to the MCAN module

#### 12.4.1.4.3.9 Test Modes

The MCAN\_TEST register write access is enabled by setting the test mode enable MCAN\_CCCR[7] TEST bit to 1. The MCAN\_TEST register allows the configuration of the test modes and test functions.

The CAN transmit TX pin has four output functions. One of those functions can be selected by programming the MCAN\_TEST[6-5] TX field. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive RX pin can be monitored from MCAN\_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (FCLK) and Host clock (ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN\_TEST[6-5] TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin via the MCAN\_TEST[7] RX bit.

#### Note

Test modes should be used for self test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

#### 12.4.1.4.3.9.1 Internal Loopback Mode

The MCAN module can be set into Internal Loopback Mode by programming MCAN\_TEST[4] LBCK and MCAN\_CCCR[5] MON bits to 1. The Internal Loopback Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode RX pin is disconnected from the MCAN module and TX pin is held recessive. Figure 12-265 shows the connection of the TX and RX pins to the MCAN module in case of Internal Loopback Mode.

Figure 12-265. Internal Loopback Mode

#### 12.4.1.4.4 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN\_TSCC[19-16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN\_TSCV[15-0] TSC field. A write access to the MCAN\_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN\_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15-0]) or Tx Event FIFO (TXTS[15-0]) element. For more information, see Section 12.4.1.4.10, Message RAM.

#### 12.4.1.4.4.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive

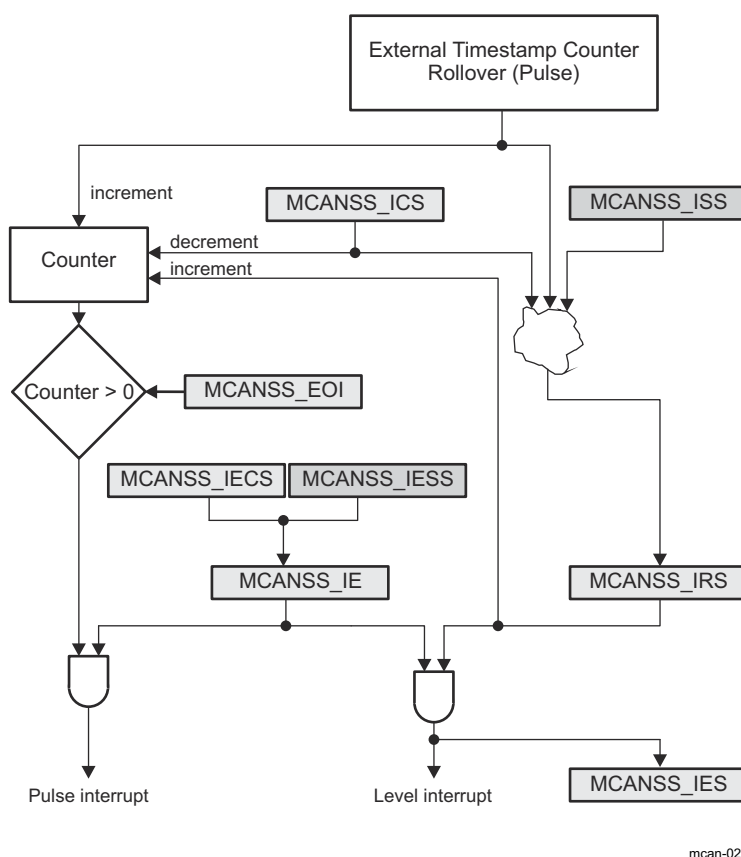

and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN\_TSCC[1-0] TSS field.

The External Timestamp Counter uses the interface clock (ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS\_EXT\_TS\_PRESCALER[23-0] PRESCALER bit field). The External Timestamp Counter counter can be enabled or disabled through the MCANSS\_CTRL[6] EXT\_TS\_CNTR\_EN bit. When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN timestamp interrupt is generated.

When the timestamp rolls over the MCANSS\_IRS register is set (see Figure 12-266). The MCANSS\_IE register can be affected by writing to the MCANSS\_IESS register to set or to the MCANSS\_IECS register to clear. The MCANSS\_IESS register is a shadow register mapped to the same address as the MCANSS\_IE register. The level interrupt is a reflection of both MCANSS\_IRS and MCANSS\_IE being set. The MCANSS\_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS\_ICS register to clear the MCANSS\_IRS register will also decrement the interrupt counter. Writing to the MCANSS\_EOI register will issue another pulse if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS\_ISS). The MCANSS\_ISS register is a shadow register mapped to the same address as the MCANSS\_IRS register.

**Figure 12-266. External Timestamp Counter Interrupt**

#### 12.4.1.4.5 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN\_TOCC register. It is enabled via the MCAN\_TOCC[0] ETOC bit. The Timeout Counter operates

as down-counter and uses the same prescaler programmed by the MCAN\_TSCC[19-16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN\_TOCV[15-0] TOC field. The Timeout Counter can be started only when MCAN\_CCCR[0] INIT = 0 and stopped when MCAN\_CCCR[0] INIT = 1 (example: when the MCAN enters Bus\_Off state). The operation mode is selected by the MCAN\_TOCC[2-1] TOS field. When Continuous Mode is selected, the counter starts when MCAN\_CCCR[0] INIT = 0, a write to the MCAN\_TOCV register presets the counter to the value configured by the MCAN\_TOCC[31-16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN\_TOCC[31-16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN\_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN\_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN\_TOCC[31-16] TOP field.

#### 12.4.1.4.6 ECC Support

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC Aggregator.

##### 12.4.1.4.6.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

##### 12.4.1.4.6.2 ECC Aggregator

---

#### Note

For more information about ECC Aggregator, refer to *ECC Aggregator*.

---

#### 12.4.1.4.7 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

##### 12.4.1.4.7.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register
- Extended ID AND Mask (MCAN\_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 12.4.1.4.10, Message RAM](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single ICLK pulse. For more information, see [Section 12.4.1.4.2.1, DMA Requests](#).
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN\_IR[8] HPM
- Set High Priority Message interrupt flag MCAN\_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:  
New Data flag (MCAN\_NDAT1/MCAN\_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN\_PSR[2-0] LEC respectively MCAN\_PSR[10-8] DLEC fields).
- Rx FIFO:  
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN\_PSR[2-0] LEC respectively MCAN\_PSR[10-8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 12.4.1.4.7.2.2](#) have to be considered.

#### 12.4.1.4.7.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 12.4.1.4.10.5, Standard Message ID Filter Element](#) and [Section 12.4.1.4.10.6, Extended Message ID Filter Element](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN\_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN\_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN\_XIDAM) is not used for Range Filtering.

#### 12.4.1.4.7.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see [Section 12.4.1.4.10.5, Standard Message ID Filter Element](#) and [Section 12.4.1.4.10.6, Extended Message ID Filter Element](#).

#### **12.4.1.4.7.1.3 Classic Bit Mask Filter**

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

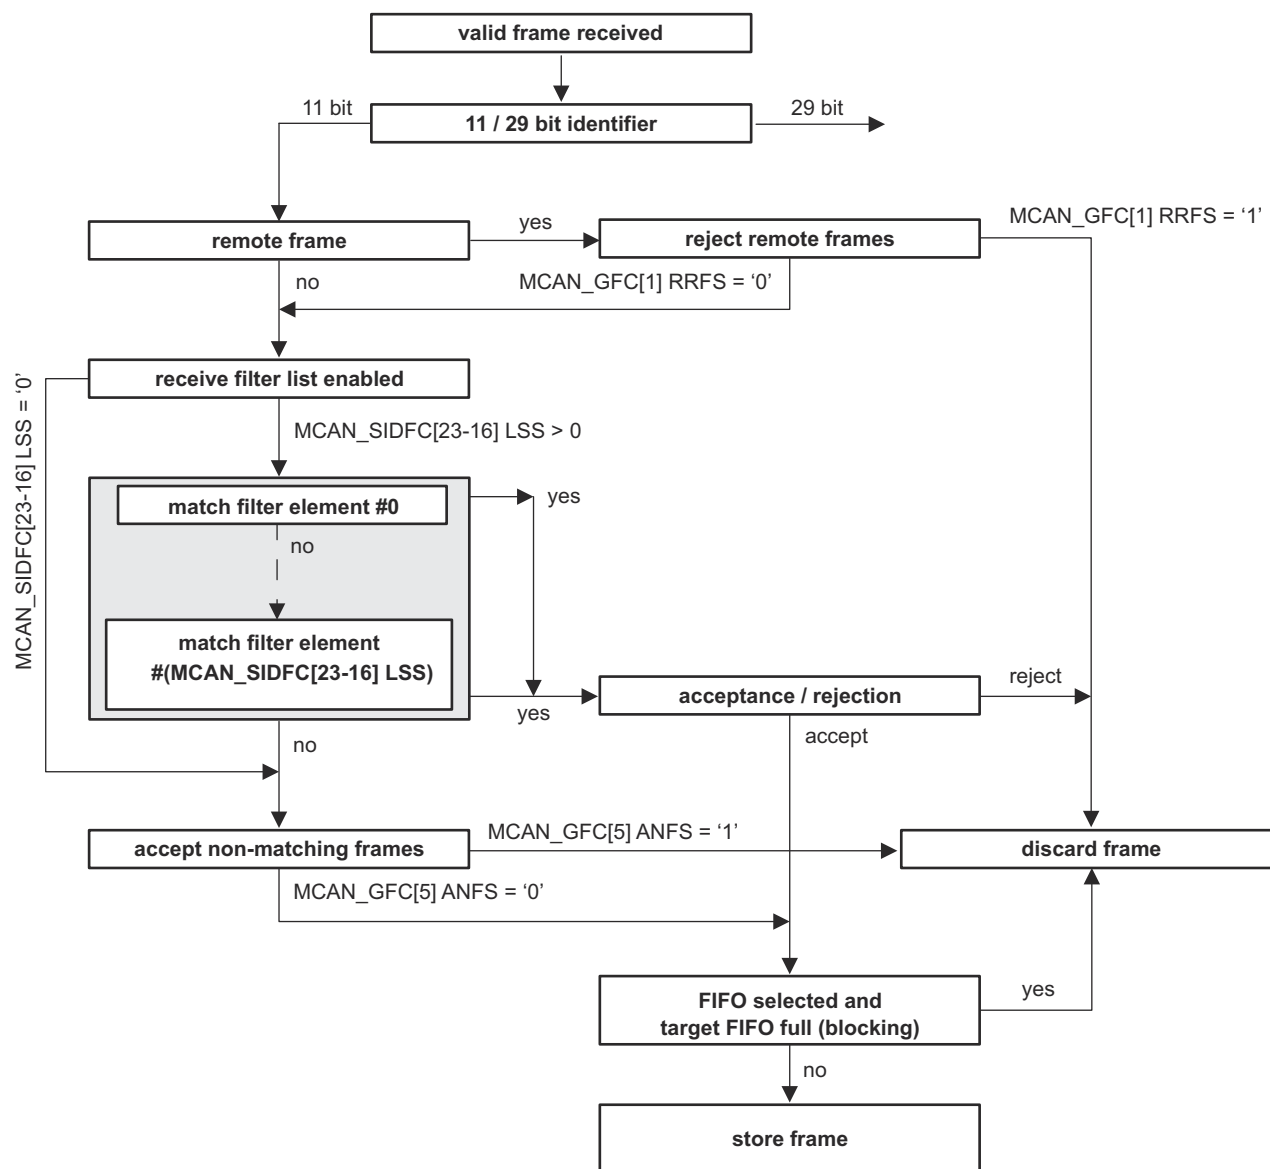

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

#### **12.4.1.4.7.1.4 Standard Message ID Filtering**

The standard Message ID (11-bit ID) filtering flow is shown in [Figure 12-267](#). [Section 12.4.1.4.10.5](#), *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register

mcan-009

**Figure 12-267. Standard Message ID Filter Path**

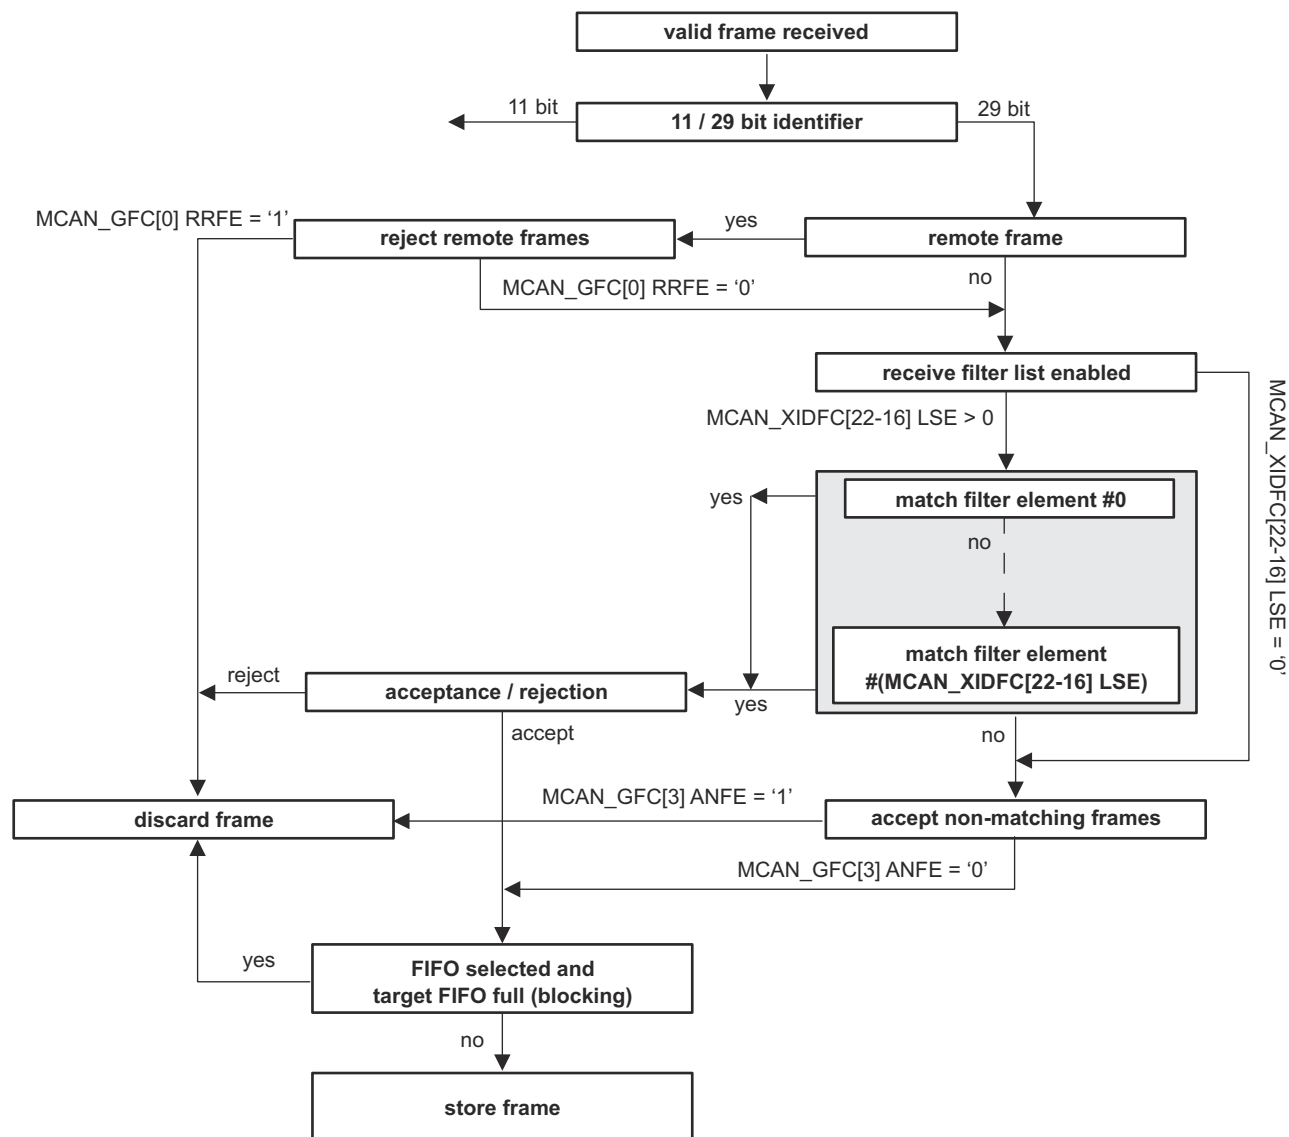

#### 12.4.1.4.7.1.5 Extended Message ID Filtering

The extended Message ID (29-bit ID) filtering flow is shown in [Figure 12-268](#). [Section 12.4.1.4.10.6](#), *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN\_XIDAM).

mcan-010

Figure 12-268. Extended Message ID Filter Path

#### 12.4.1.4.7.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN\_RXF0C and MCAN\_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in [Section 12.4.1.4.7.1, Acceptance Filtering](#). [Section 12.4.1.4.10.2, Rx Buffer and FIFO Element](#) describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN\_RXFnC[30-24] FnWM field (where: n = 0 or 1) an interrupt flag MCAN\_IR[1] RF0W/MCAN\_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI) an Rx FIFO Full condition is signalled by the MCAN\_RXFnS[24] FnF status bit and interrupt flag MCAN\_IR[2] RF0F/MCAN\_IR[6] RF1F is set. [Figure 12-269](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN\_RXFnS[6-0] FnFL field (the number of elements stored in Rx FIFO).

**Figure 12-269. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN\_RXFnC[15-2] FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN\_RXFnS[13-8] FnGI). [Table 12-241](#) presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer/Rx FIFO Data Field Size which is configured via the MCAN\_RXESC register.

**Table 12-241. Rx Buffer/Rx FIFO Element Size**

MCAN_RXESC[10-8] RBDS MCAN_RXESC[2-0] F0DS/ MCAN_RXESC[6-4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

#### 12.4.1.4.7.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN\_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN\_RXFnS[24] FnF = 1 and interrupt flag MCAN\_IR[2] RF0F/MCAN\_IR[6] RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN\_RXFnS[25] RFnL = 1 and interrupt flag MCAN\_IR[3] RFnL/MCAN\_IR[25] RFnL is set.

#### 12.4.1.4.7.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN\_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI) signalled by MCAN\_RXFnS[24] FnF = 1, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. [Figure 12-270](#) shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

**Figure 12-270. Rx FIFO Overflow Handling**

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN\_RXFnA[5-0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN\_RXFnS[24] FnF = 0).

#### 12.4.1.4.7.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN\_RXBC[15-2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10-9] = 00 has to be configured (see [Section 12.4.1.4.10.5, Standard Message ID Filter Element](#) and [Section 12.4.1.4.10.6, Extended Message ID Filter Element](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN\_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

[Table 12-242](#) shows Example Filter Configuration for Rx Buffers.

**Table 12-242. Example Filter Configuration for Rx Buffers**

Filter Element	SFID1[10-0] EFID1[28-0]	SFID2[10-9] EFID2[10-9]	SFID2[5-0] EFID2[5-0]
0	ID message 1	00	00 0000

**Table 12-242. Example Filter Configuration for Rx Buffers (continued)**

Filter Element	SFID1[10-0] EFID1[28-0]	SFID2[10-9] EFID2[10-9]	SFID2[5-0] EFID2[5-0]
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN\_NDAT1/MCAN\_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

#### 12.4.1.4.7.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN\_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

#### 12.4.1.4.7.4 Debug on CAN Support

Debug DMA is not supported feature. Debug messages can be traced through the RX FIFO (see [Section 12.4.1.4.7.2](#)).

#### 12.4.1.4.8 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 12.4.1.4.10.3](#) describes the Tx Buffer Element. [Table 12-243](#) shows the possible configurations for message transmission.

**Table 12-243. Possible Configurations for Message Transmission**

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN\_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

### Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

#### 12.4.1.4.8.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN\_CCCR[14] TXP bit. By default this bit is disabled (MCAN\_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

#### 12.4.1.4.8.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN\_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 12-244 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN\_TXFQS[20-16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

**Table 12-244. Tx Buffer/Tx FIFO/Tx Queue Element Size**

MCAN_TXESC[2-0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

#### 12.4.1.4.8.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN\_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN\_TXFQS[12-8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS[20-16] TFQPI field. After each Add Request (MCAN\_TXBAR[x] ARn = 1) the

Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN\_TXFQS[20-16] TFQPI = MCAN\_TXFQS[12-8] TFGI), Tx FIFO Full condition is signalled by bit MCAN\_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see [Table 12-244](#)). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS[20-16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

#### 12.4.1.4.8.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN\_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS[20-16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN\_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN\_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see [Table 12-244](#)). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS[20-16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

#### 12.4.1.4.8.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

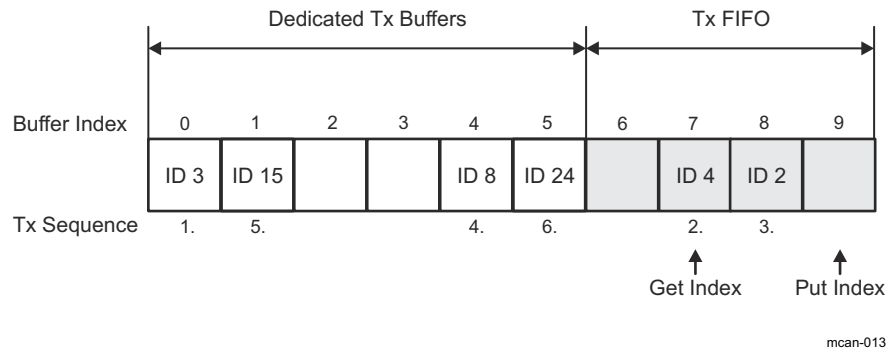

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN\_TXBC[21-16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN\_TXBC[29-24] TFQS field

If the MCAN\_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN\_TXFQS[12-8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

[Figure 12-271](#) shows Mixed Dedicated Tx Buffers/Tx FIFO example.

**Figure 12-271. Mixed Dedicated Tx Buffers/Tx FIFO (example)**

#### 12.4.1.4.8.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

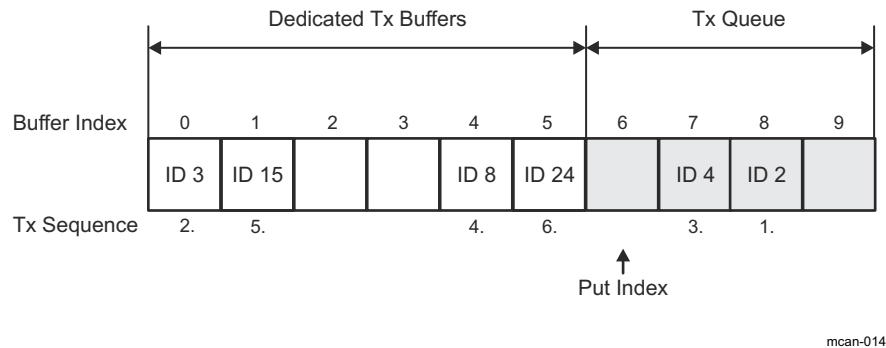

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN\_TXBC[21-16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN\_TXBC[29-24] TFQS field

If MCAN\_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-272 shows Mixed Dedicated Tx Buffers/Tx Queue example.

**Figure 12-272. Mixed Dedicated Tx Buffers/Tx Queue (example)**

#### 12.4.1.4.8.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN\_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN\_TXBCF register (MCAN\_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN\_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN\_TXBTO[n] TOn and MCAN\_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN\_TXBCF[n] CFn = 1.

---

**Note**

If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

---

**12.4.1.4.8.8 Tx Event Handling**

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. [Section 12.4.1.4.10.4](#) describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN\_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN\_TXEFS[12-8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN\_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN\_TXEFC[29-24] EFWM field, interrupt flag MCAN\_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN\_TXEFS[12-8] EFGI field has to be added to the Tx Event FIFO start address MCAN\_TXEFC[15-2] EFSA field.

**12.4.1.4.9 FIFO Acknowledge Handling**

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN\_RXF0A, MCAN\_RXF1A, and MCAN\_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

---

**Note**

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

---

#### 12.4.1.4.10 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

##### 12.4.1.4.10.1 Message RAM Configuration

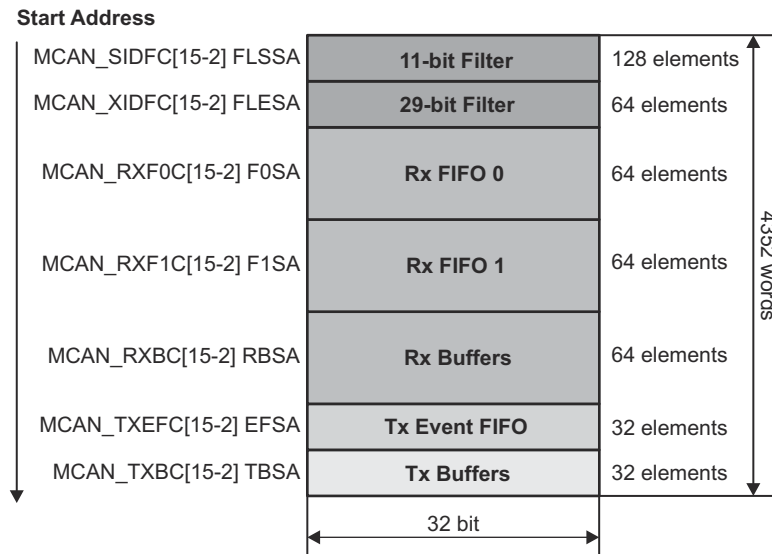

The MCAN module is configured to allocate 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

The Message RAM is capable to include each of the sections listed in [Figure 12-273](#). It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN\_RXESC[2-0] F0DS field
- Rx FIFO 1 via the MCAN\_RXESC[6-4] F1DS field
- Rx Buffers via the MCAN\_RXESC[10-8] RBDS field
- Tx Buffers via the MCAN\_TXESC[2-0] TBDS field

mcan-015

**Figure 12-273. Message RAM Configuration**

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

### Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

#### 12.4.1.4.10.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN\_RXESC register.

Figure 12-274 shows Rx Buffer/Rx FIFO element structure.

**Figure 12-274. Rx Buffer/Rx FIFO Element Structure**

Table 12-245 shows Rx Buffer/Rx FIFO element field descriptions.

**Table 12-245. Rx Buffer/Rx FIFO Element Field Descriptions**

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator <ul style="list-style-type: none"> <li>0h = Transmitting node is error active</li> <li>1h = Transmitting node is error passive</li> </ul>
	30	XTD	Extended Identifier <p>Signals to the Host CPU whether the received frame has a standard or extended identifier.</p> <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>
	29	RTR	Remote Transmission Request <p>Signals to the Host CPU whether the received frame is a data frame or a remote frame.</p> <ul style="list-style-type: none"> <li>0h = Received frame is a data frame</li> <li>1h = Received frame is a remote frame</li> </ul> <p><b>Note:</b> There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]).</p>
	28-0	ID[28-0]	Identifier <p>Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28-18].</p>

**Table 12-245. Rx Buffer/Rx FIFO Element Field Descriptions (continued)**

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5-4] ANFS and MCAN_GFC[3-2] ANFE fields. <ul style="list-style-type: none"> <li>0h = Received frame matching filter index FIDX field</li> <li>1h = Received frame did not match any Rx filter element</li> </ul>
	30-24	FIDX[6-0]	Filter Index 0h-7Fh (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC[23-16] LSS - 1 respectively MCAN_XIDFC[22-16] LSE - 1.
	23-22	RES	Reserved
	21	FDF	FD Format <ul style="list-style-type: none"> <li>0h = Standard frame format</li> <li>1h = CAN FD frame format (new DLC-coding and CRC)</li> </ul>
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> <li>0h = Frame received without bit rate switching</li> <li>1h = Frame received with bit rate switching</li> </ul>
	19-16	DLC[3-0]	Data Length Code <ul style="list-style-type: none"> <li>0h-8h (0-8) = CAN + CAN FD: received frame has 0-8 data bytes</li> <li>9h-Fh (9-15) = CAN: received frame has 8 data bytes</li> <li>9h-Fh (9-15) = CAN FD: received frame has 12/16/20/24/32/48/64 data bytes</li> </ul>
R2	15-0	RXTS[15-0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19-16] TCP.

	...	...	...
	31-24	DBm[7-0]	Data Byte m
	23-16	DBm-1[7-0]	Data Byte m-1
Rn	15-8	DBm-2[7-0]	Data Byte m-2
	7-0	DBm-3[7-0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

### 12.4.1.4.10.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN\_TXBC[29-24] TFQS and MCAN\_TXBC[21-16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN\_TXESC register.

Figure 12-275 shows Tx Buffer element structure.

mcan-018

**Figure 12-275. Tx Buffer Element Structure**

	15-8	DBm-2[7-0]	Data Byte m-2
	7-0	DBm-3[7-0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

#### 12.4.1.4.10.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN\_TXEFS register.

Figure 12-276 shows Tx Event FIFO element structure.

mcan-018

**Figure 12-276. Tx Event FIFO Element Structure**

Table 12-247 shows Tx Event FIFO element field descriptions.

**Table 12-247. Tx Event FIFO Element Field Descriptions**

Word	Bits	Field Name	Description

	23-22	ET[1-0]	Event Type <ul style="list-style-type: none"> <li>0h = Reserved</li> <li>1h = Tx event</li> <li>2h = Transmission in spite of cancellation (always set for transmissions in DAR mode)</li> <li>3h = Reserved</li> </ul>
	21	FDF	FD Format <ul style="list-style-type: none"> <li>0h = Standard frame format</li> <li>1h = CAN FD frame format (new DLC-coding and CRC)</li> </ul>
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> <li>0h = Frame transmitted without bit rate switching</li> <li>1h = Frame transmitted with bit rate switching</li> </ul>
	19-16	DLC[3-0]	Data Length Code <ul style="list-style-type: none"> <li>0h-8h (0-8) = CAN + CAN FD: frame with 0-8 data bytes transmitted</li> <li>9h-Fh (9-15) = CAN: frame with 8 data bytes transmitted</li> <li>9h-Fh (9-15) = CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted</li> </ul>
	15-0	TXTS[15-0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19-16] TCP field.

#### 12.4.1.4.10.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN\_SIDFC[15-2] FLSSA field plus the index of the filter element (0-127).

[Figure 12-277](#) shows Standard Message ID Filter element structure.

**Figure 12-277. Standard Message ID Filter Element Structure**

[Table 12-248](#) shows Standard Message ID Filter element field descriptions.

**Table 12-248. Standard Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
S0	31-30	SFT[1-0]	<p>Standard Filter Type</p> <ul style="list-style-type: none"> <li>0h = Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1)</li> <li>1h = Dual ID filter for SFID1 or SFID2</li> <li>2h = Classic filter: SFID1 = filter; SFID2 = mask</li> <li>3h = Filter element disabled</li> </ul> <p><b>Note:</b> With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = 000)</p>
	29-27	SFEC[2-0]	<p>Standard Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0h = Disable filter element</li> <li>1h = Store in Rx FIFO 0 if filter matches</li> <li>2h = Store in Rx FIFO 1 if filter matches</li> <li>3h = Reject ID if filter matches</li> <li>4h = Set priority if filter matches</li> <li>5h = Set priority and store in FIFO 0 if filter matches</li> <li>6h = Set priority and store in FIFO 1 if filter matches</li> <li>7h = Store into Rx Buffer , configuration of SFT[1-0] ignored</li> </ul>
	26-16	SFID1[10-0]	<p>Standard Filter ID 1</p> <p>When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.</p>
	15-11	RES	Reserved
		SFID2[10-0]	<p>Standard Filter ID 2</p> <p>This bit field has a different meaning depending on the configuration of SFEC:</p> <ul style="list-style-type: none"> <li>1) SFEC = 001 - 110 Second ID of standard ID filter element</li> <li>2) SFEC = 111 Filter for Rx Buffers</li> </ul>
	10-0	SFID2[10-9]	<p>This field is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence.</p> <ul style="list-style-type: none"> <li>0h = Store message into an Rx Buffer</li> <li>1h = Debug Message A</li> <li>2h = Debug Message B</li> <li>3h = Debug Message C</li> </ul> <p><b>Note:</b> Debug feature is not supported.</p>
		SFID2[8-6]	<p>This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches.</p> <p><b>Note:</b> Only three filter event pins are supported.</p>
		SFID2[5-0]	<p>This field defines the offset to the Rx Buffer Start Address</p>

#### 12.4.1.4.10.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN\_XIDFC[15-2] FLESA field plus two times the index of the filter element (0-63).

Figure 12-278 shows Extended Message ID Filter element structure.

**Figure 12-278. Extended Message ID Filter Element Structure**

Table 12-249 shows Extended Message ID Filter element field descriptions.

**Table 12-249. Extended Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
F0	31-29	EFEC[2-0]	<p>Extended Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0h = Disable filter element</li> <li>1h = Store in Rx FIFO 0 if filter matches</li> <li>2h = Store in Rx FIFO 1 if filter matches</li> <li>3h = Reject ID if filter matches</li> <li>4h = Set priority if filter matches</li> <li>5h = Set priority and store in FIFO 0 if filter matches</li> <li>6h = Set priority and store in FIFO 1 if filter matches</li> <li>7h = Store into Rx Buffer or as debug message, configuration of EFT[1-0] ignored</li> </ul>

## 12.4.2 Enhanced Capture (ECAP) Module

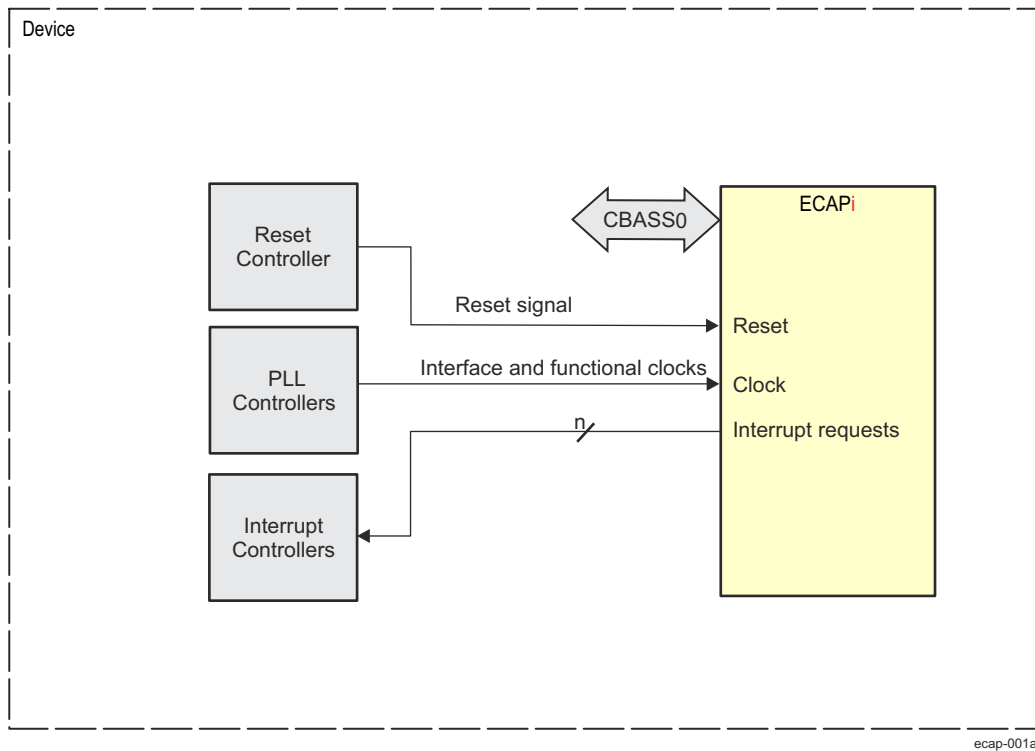

This section describes the Enhanced Capture (ECAP) module in the device.

### 12.4.2.1 ECAP Overview

The Enhanced Capture (ECAP) module can be used for:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

Figure 12-279 shows the ECAP modules overview.

A.  $i = 0$  to number of instances - 1.

**Figure 12-279. ECAP Overview**

#### 12.4.2.1.1 ECAP Features

The ECAP module includes the following features:

- 32-bit time base counter
- 4 × 32 bits event time-stamp capture registers (ECAP0\_CAP1 through ECAP0\_CAP4)
- 4-stage sequencer (Mod4 counter), synchronized to external events (ECAPx pin edges)
- Independent edge polarity (rising / falling edge) selection for all 4 sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Interrupt capabilities on any of the 4 capture events
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

#### 12.4.2.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

## 12.4.2.2 ECAP Environment

### 12.4.2.2.1 ECAP I/O Interface

This section describes the ECAP external connections (environment).

Figure 12-280 shows the ECAP interface signals.

#### Note

i represents an ECAP instance. See the device datasheet for available domains and ECAP instances

**Figure 12-280. ECAP External Interface I/Os**

Table 12-250 describes the ECAP I/O signals.

**Table 12-250. ECAP I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>ECAPi<sup>(3)</sup></b>				
ECAPi <sup>(3)</sup> _CAPIN_APWMOUT	ECAPi <sup>(3)</sup> _IN_APWM_OUT	I/O	ECAPi <sup>(3)</sup> Capture input / PWM output	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) i represents an ECAP instance. See the device datasheet for available domains and ECAP instances

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

## 12.4.2.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.4.2.4 ECAP Functional Description

The ECAP module represents one complete capture channel, which has the following independent key resources:

- Dedicated input capture pin
- 32 events selection mapping capability to the input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (ECAP0\_CAP1 through ECAP0\_CAP4)
- 4-stage sequencer (Mod4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (ECAP0\_CAP1 through ECAP0\_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

Multiple identical ECAP modules can be contained in a system as shown in [Figure 12-281](#). For actual number of the ECAP modules integrated in the device, refer to *ECAP Integration*. The letter x within a signal or module name is used to indicate a generic ECAP instance on a device. For example, output interrupt request, ECAP1INT belongs to ECAP1, ECAP2INT belongs to ECAP2, and so forth.

**Figure 12-281. Multiple ECAP Modules**

##### 12.4.2.4.1 Capture and APWM Operating Modes

The ECAP module resources can be used to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The ECAP0\_CAP1 and ECAP0\_CAP2 registers become the active period and compare registers, respectively, while the ECAP0\_CAP3 and ECAP0\_CAP4 registers become the period and capture shadow registers, respectively. [Figure 12-282](#) is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

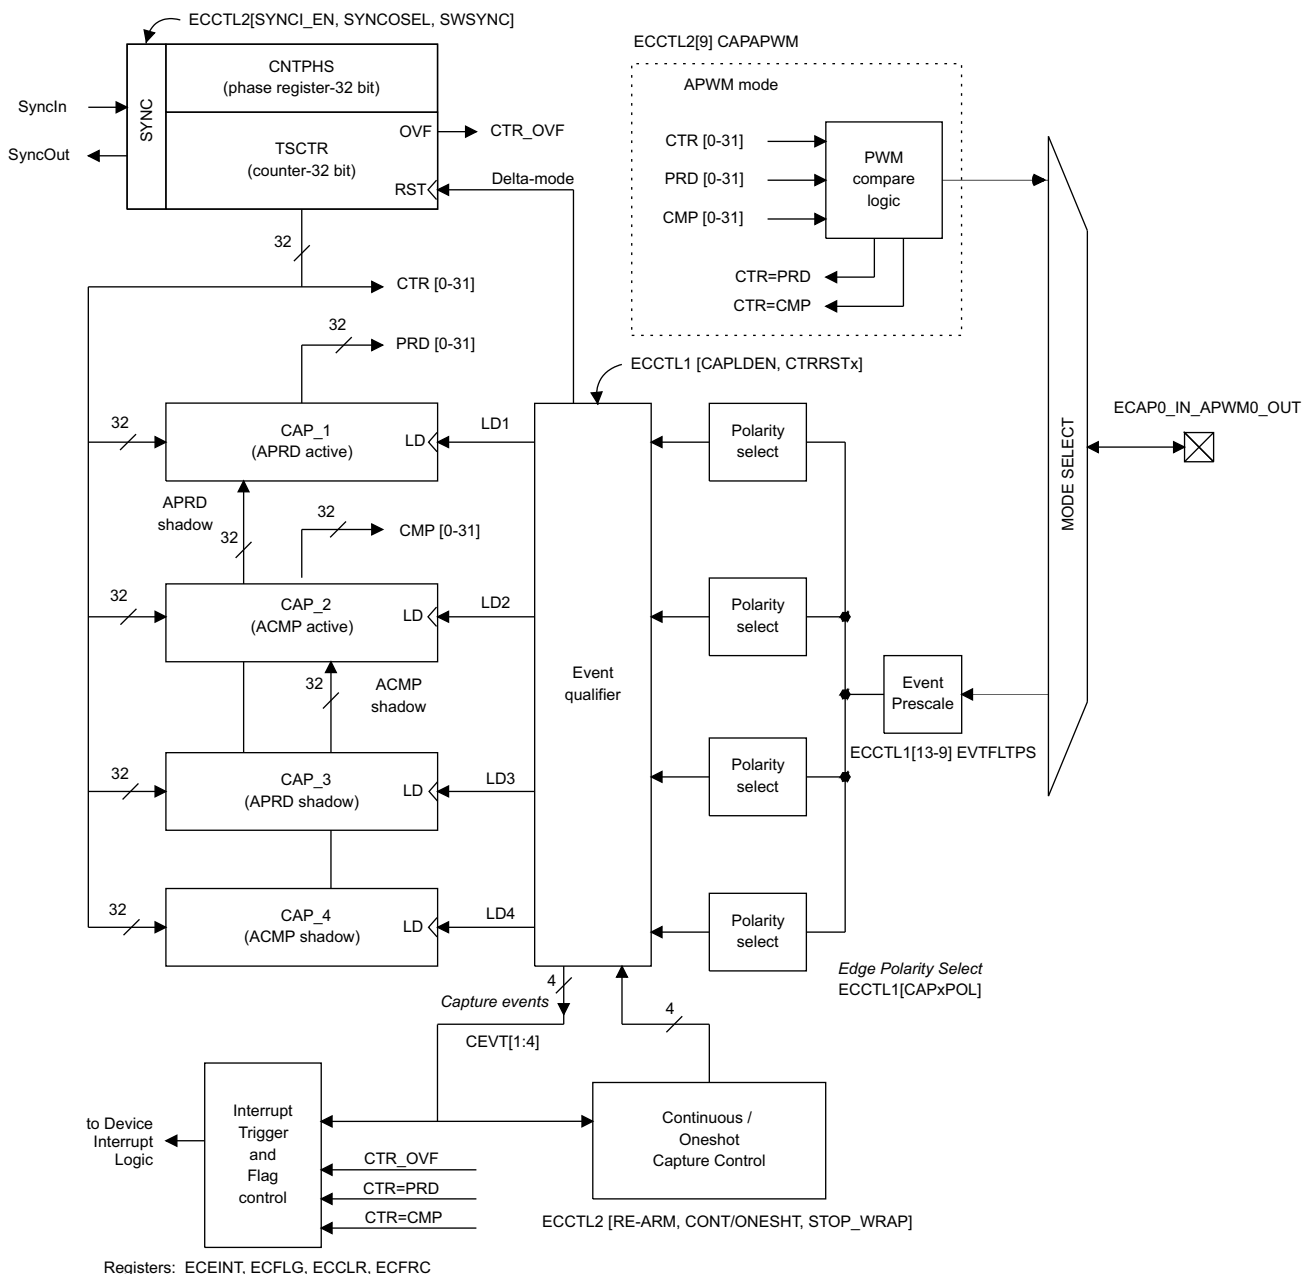

ecap-004

- A single pin is shared between CAP and APWM functions. In capture mode, it is an input. In APWM mode, it is an output.
- In APWM mode, writing any value to the ECAP0\_CAP1/ECAP0\_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP0\_CAP3/ECAP0\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP0\_CAP3/ECAP0\_CAP4) invokes the shadow mode.

**Figure 12-282. Capture and APWM Modes of Operation**

#### 12.4.2.4.1.1 ECAP Capture Mode Description

Figure 12-283 shows the various components that implement the capture function.

ecap-005

Figure 12-283. Capture Function Diagram

#### 12.4.2.4.1.1.1 ECAP Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 12-284 shows a functional diagram and Figure 12-285 shows the operation of the prescale function.

ecap-006

- A. When a prescale value of 1 is chosen (ECAP0\_ECCTL[13-9] EVTFLTPTS = 0b0000) the input capture signal by-passes the prescale logic completely.

**Figure 12-284. Event Prescale Control**

ecap-007

**Figure 12-285. Prescale Function Waveforms**

#### 12.4.2.4.1.1.2 ECAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Mod4 sequencer.
- The edge event is gated to its respective CAP $n$  register by the Mod4 counter. The CAP $n$  register is loaded on the falling edge.

#### 12.4.2.4.1.1.3 ECAP Continuous/One-Shot Control

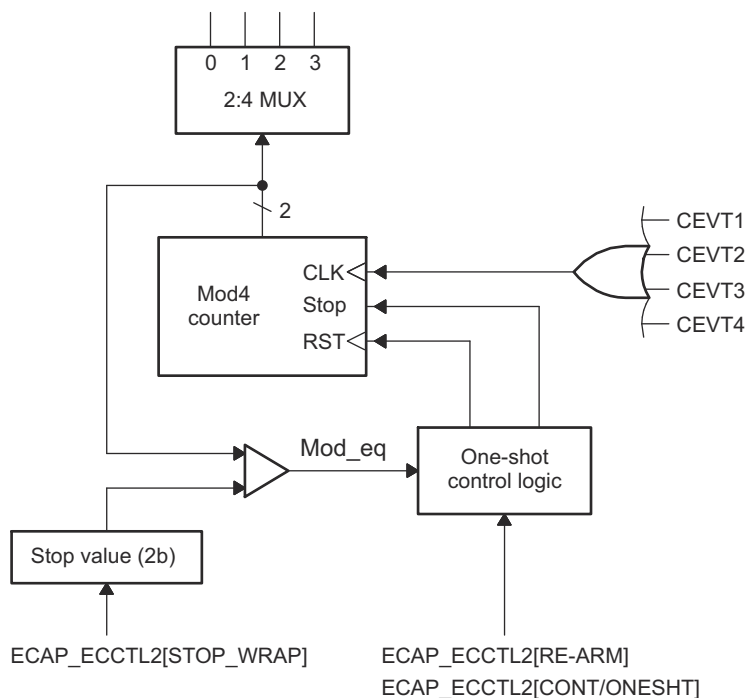

- The Mod4 (2-bit) counter is incremented via edge qualified events CEVT1 through CEVT4 (see the ECAP0\_ECINT\_EN\_FLG register).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output; when equal the Mod4 counter stops and inhibits further loads of the ECAP0\_CAP1 through ECAP0\_CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 12-286) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the ECAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of the ECAP0\_CAP1 through ECAP0\_CAP4 registers (time-stamps).

Re-arming prepares the ECAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of the ECAP0\_CAP1 through ECAP0\_CAP4 registers again, providing the ECAP0\_ECCTL[8] CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0), the one-shot action is ignored, and capture values continue to be written to the ECAP0\_CAP1 through ECAP0\_CAP4 registers in a circular buffer sequence.

ecap-008

**Figure 12-286. ECAP Continuous/One-shot Block Diagram**

#### 12.4.2.4.1.1.4 ECAP 32-Bit Counter and Phase Control

This counter (Figure 12-287) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1 through LD4 signals.

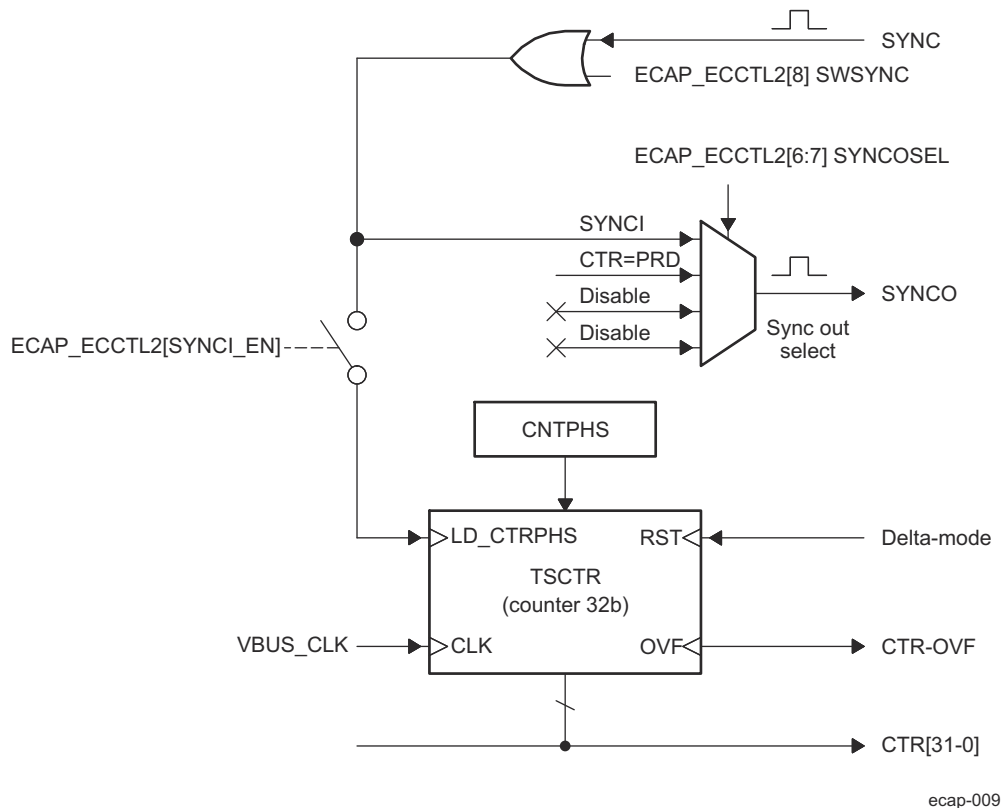

Figure 12-287. ECAP Counter and Synchronization Block Diagram

#### 12.4.2.4.1.1.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via the control ECAP0\_ECCTL[8] CAPLDEN bit. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

The ECAP0\_CAP1 and ECAP0\_CAP2 registers become the active period and compare registers, respectively, in APWM mode.

The ECAP0\_CAP3 and ECAP0\_CAP4 registers become the respective shadow registers (APRD and ACMP) for the ECAP0\_CAP1 and ECAP0\_CAP2 registers during APWM operation.

#### 12.4.2.4.1.1.6 ECAP Interrupt Control

An interrupt can be generated on capture events CEVT1 through CEVT4, CNTOVF (see the ECAP0\_ECINT\_EN\_FLG[21] CNTOVF\_FLG bit) or APWM events (TSCNT = PRD, TSCNT = CMP). See [Figure 12-288](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the ECAP<sub>n</sub> module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register (ECAP0\_ECINT\_EN\_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECAP0\_ECINT\_EN\_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag ECAP0\_ECINT\_EN\_FLG[16] INT\_FLG bit. An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1h, and the INT\_FLG flag bit is 0h. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECAP0\_ECINT\_CLR\_FRC) before any other interrupt pulses are generated. The interrupt force register (ECAP0\_ECINT\_CLR\_FRC) can force an interrupt event. This is useful for test purposes.

#### 12.4.2.4.1.1.7 ECAP Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of the ECAP0\_CAP1 or ECAP0\_CAP2 registers from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to the ECAP0\_CAP1 or ECAP0\_CAP2 register immediately upon writing a new value.
- On period equal, CTR[31-0] = PRD[31-0]

#### Note

The CEVT1\_FLG, CEVT2\_FLG, CEVT3\_FLG, CEVT4\_FLG flags are only active in capture mode (ECAP0\_ECCTL[25] CAP\_APWM == 0h). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode (ECAP0\_ECCTL[25] CAP\_APWM == 1h). CNTOVF\_FLG flag is valid in both modes.

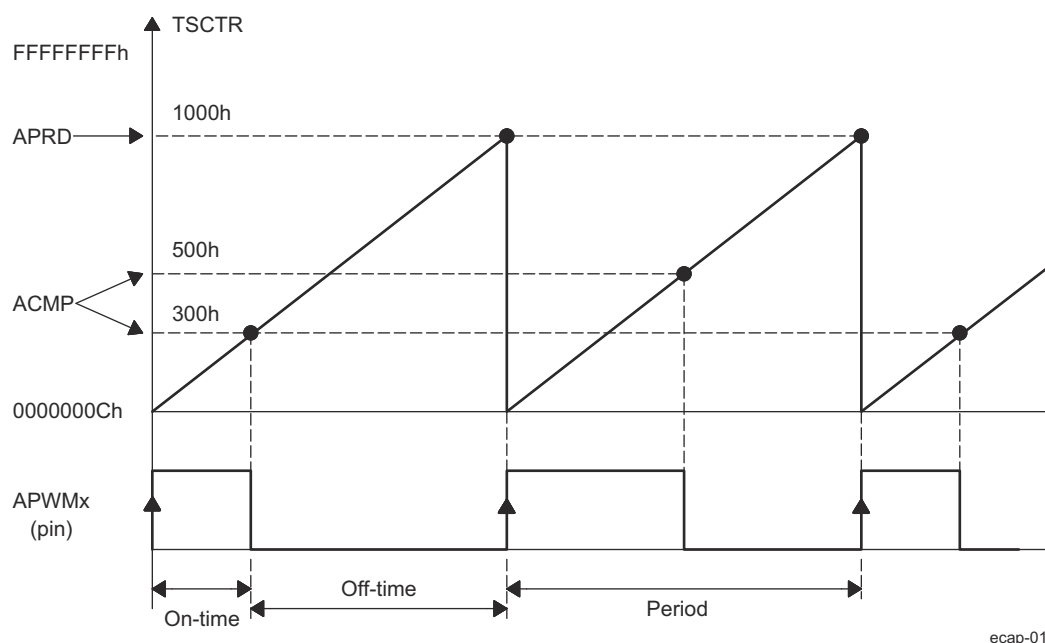

**Figure 12-288. Interrupts in ECAP Module**

#### 12.4.2.4.1.2 ECAP APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When the ECAP0\_CAP1/ECAP0\_CAP2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via the shadow registers - APRD and ACMP (ECAP0\_CAP3/ECAP0\_CAP4). The shadow register contents are transferred over to ECAP0\_CAP1/ECAP0\_CAP2 registers either immediately upon a write, or on a TSCNT = PRD trigger.
- In APWM mode, writing to the ECAP0\_CAP1/ECAP0\_CAP2 active registers will also write the same value to the corresponding shadow registers (ECAP0\_CAP3/ECAP0\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP0\_CAP3/ECAP0\_CAP4) will invoke the shadow mode.
- During initialization, software must write the PRD and CMP values to the active registers. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, software should use only shadow registers.

**Figure 12-289. PWM Waveform Details of ECAP APWM Mode Operation**

The behavior of APWM active-high mode (APWMPOL == 0) is:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active-low mode (APWMPOL == 1) is:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

#### 12.4.2.4.2 Summary of ECAP Functional Registers

[Table 12-251](#) shows the ECAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode.

#### Note

In APWM mode, writing to the ECAP0\_CAP1/ECAP0\_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP0\_CAP3/ECAP0\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP0\_CAP3/ECAP0\_CAP4) invokes the shadow mode.

**Table 12-251. ECAP Control and Status Functional Registers**

Offset	Register Name	Description	Size (×16)
0h	ECAP0_TSCNT	Time-Stamp Counter Register	2
4h	ECAP0_CNTPHS	Counter Phase Offset Value Register	2
8h	ECAP0_CAP1	Capture 1 Register	2
Ch	ECAP0_CAP2	Capture 2 Register	2
10h	ECAP0_CAP3	Capture 3 Register	2
14h	ECAP0_CAP4	Capture 4 Register	2
28h	ECAP0_ECCTL	Capture Control Register	2
2Ch	ECAP0_ECINT_EN_FLG	Capture Interrupt Enable and Flag Register	2
30h	ECAP0_ECINT_CLR_FRC	Capture Interrupt Clear and Forcing Register	2
5Ch	ECAP0_PID	Revision ID Register	2

#### Note

For more information on the ECAP registers, see *ECAP Registers*.

### 12.4.2.5 ECAP Use Cases

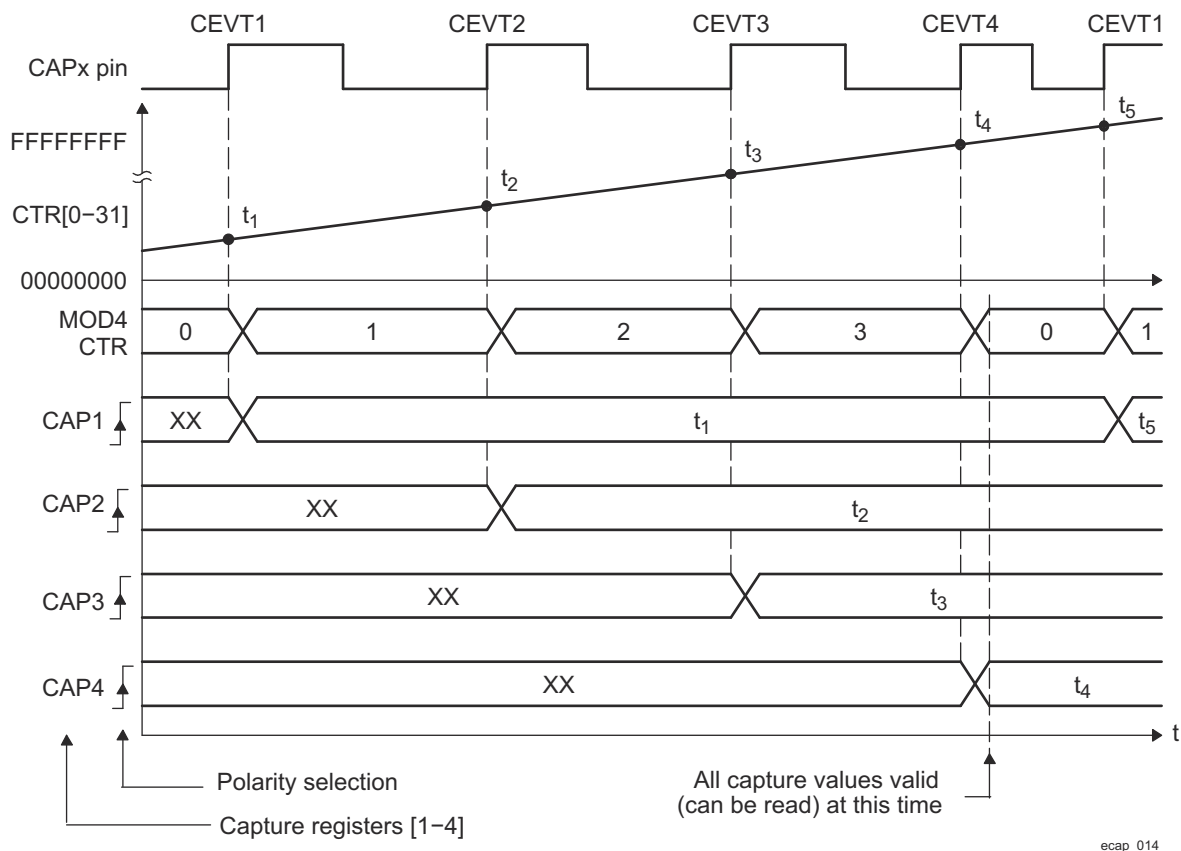

The following sections will provide applications examples and code snippets to show how to configure and operate the ECAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPXPOL bits
#defineEC_RISING      0x0
#defineEC_FALLING     0x1
// CTRRSTx bits
#defineEC_ABS_MODE    0x0
#defineEC_DELTA_MODE  0x1
// PRESCALE bits

#defineEC_ENABLE       0x1
#defineEC_FORCE        0x1
```

#### 12.4.2.5.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 12-290 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 12-290), if this occurs, the CNTOVF\_FLG (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4-th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAP $n$  registers.

**Figure 12-290. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect**

**Table 12-252. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger**

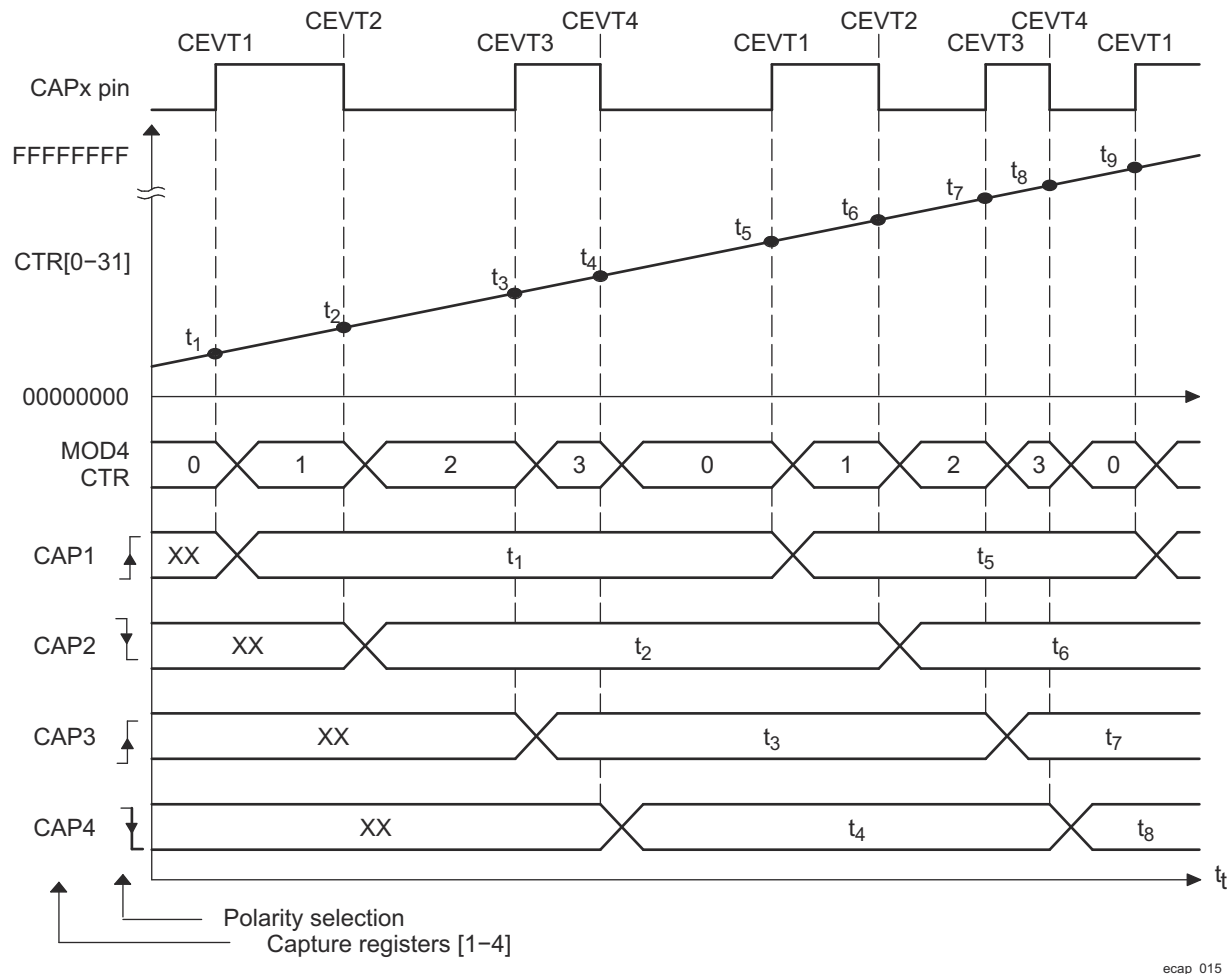

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING

ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-1. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;// Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;// Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;// Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;// Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1;// Calculate 1st period
Period2 = TSt3-TSt2;// Calculate 2nd period
Period3 = TSt4-TSt3;// Calculate 3rd period
```

#### 12.4.2.5.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 12-291 the ECAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...etc. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , etc. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , etc.

**Figure 12-291. Capture Sequence for Absolute Time-Stamp, Rising and Falling Edge Detect**

**Example 12-2. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;// Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;// Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;// Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;// Fetch Time-Stamp captured at t4
Period1 = TSt3-TSt1;// Calculate 1st period
DutyOnTime1 = TSt2-TSt1;// Calculate On time
DutyOffTime1 = TSt3-TSt2;// Calculate off time
```

### 12.4.2.5.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 12-292 shows how the ECAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CNTOVF\_FLG (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAP<sub>n</sub> contents directly give timing data without the need for CPU calculations: Period1 = T<sub>1</sub>, Period2 = T<sub>2</sub>,...etc. As shown in Figure 12-292, the CEVT1 event is a good trigger point to read the timing data, T<sub>1</sub>, T<sub>2</sub>, T<sub>3</sub>, T<sub>4</sub> are all valid here.

**Figure 12-292. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect**

**Table 12-254. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING

ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-3. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECAPxRegs.CAP1;// Fetch Time-Stamp captured at T1
Period1 = ECAPxRegs.CAP2;// Fetch Time-Stamp captured at T2
Period2 = ECAPxRegs.CAP3;// Fetch Time-Stamp captured at T3
Period3 = ECAPxRegs.CAP4;// Fetch Time-Stamp captured at T4
```

#### 12.4.2.5.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example

In Figure 12-293 the ECAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information: Period1 =  $T_1 + T_2$ , Period2 =  $T_3 + T_4$ , ...etc Duty Cycle1 (on-time %) =  $T_1 / \text{Period1} \times 100\%$ , etc Duty Cycle1 (off-time %) =  $T_2 / \text{Period1} \times 100\%$ , etc.

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

**Figure 12-293. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect**

**Table 12-255. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers**

Register	Bit	Value

**Example 12-4. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers**

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECAPxRegs.CAP2;// Fetch Time-Stamp captured at T2
DutyOffTime1 = ECAPxRegs.CAP3;// Fetch Time-Stamp captured at T3
DutyOnTime2 = ECAPxRegs.CAP4;// Fetch Time-Stamp captured at T4
DutyOffTime2 = ECAPxRegs.CAP1;// Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

### 12.4.2.5.5 Application of the APWM Mode

#### 12.4.2.5.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the ECAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM $n$ . The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

**Figure 12-294. PWM Waveform Details of APWM Mode Operation**

**Table 12-256. ECAP Initialization for APWM Mode**

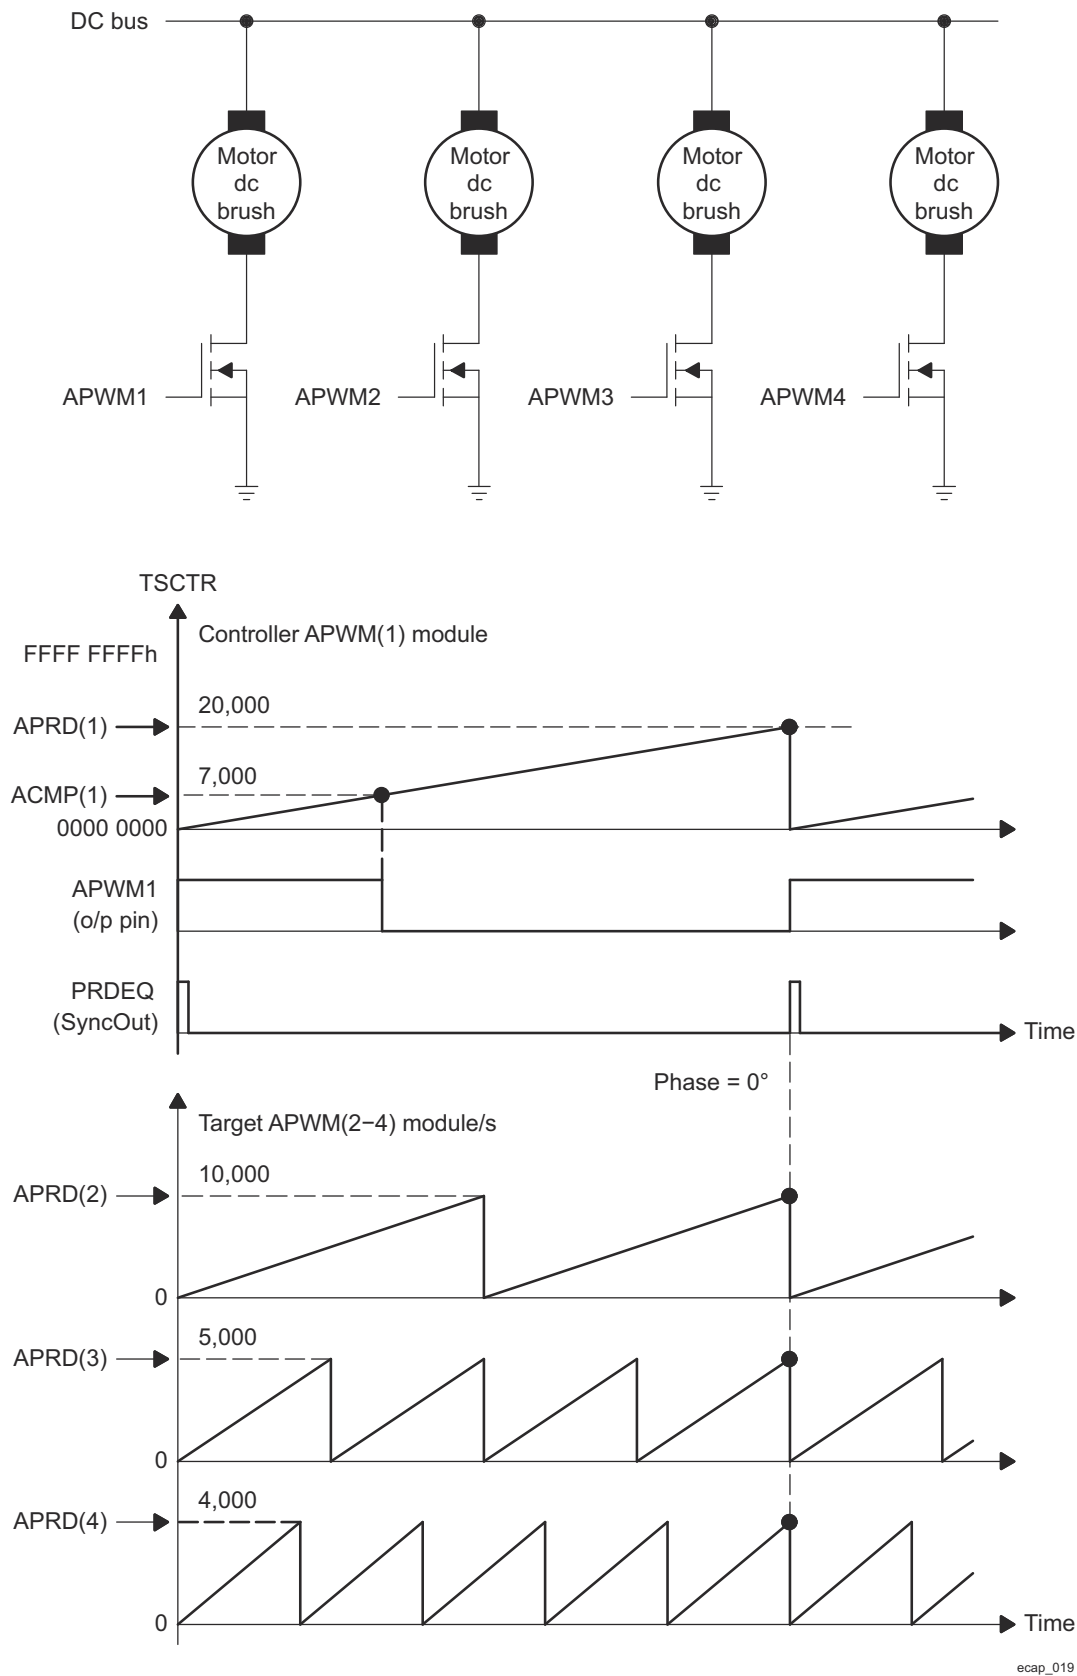

Register	Bit	Value
CAP1	CAP1	0x1000
CTRPHS	CTRPHS	0x0
ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-5. Code Snippet for APWM Mode**

```
// Code snippet for APWM mode Example 1
// Run Time (Instant 1, e.g. ISR call)
//=====
ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
```

**12.4.2.5.5.2 Multichannel PWM Generation with Synchronization Example**

Figure 12-295 takes advantage of the synchronization feature between the ECAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one ECAP module is configured as the Controller and the remaining 3 are Targets all receiving their synch pulse (CTR = PRD) from the controller. Note the Controller is chosen to have the lower frequency ( $F_1 = 1/20,000$ ) requirement. Here Target2 Freq =  $2 \times F_1$ , Target3 Freq =  $4 \times F_1$  and Target4 Freq =  $5 \times F_1$ . Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

**Figure 12-295. Multichannel PWM Example Using 4 ECAP Modules**

ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-6. Code Snippet for Multichannel PWM Generation with Synchronization**

```
// Code snippet for APWM mode Example 2
// Run Time (Note: Example execution of one run-time instant)
//=====
ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

#### 12.4.2.5.5.3 Multichannel PWM Generation with Phase Control Example

In [Figure 12-296](#), the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by  $120^\circ$  from each other. Hence if "Leg" 1 (controlled by APWM1) is the reference Leg (or phase), that is,  $0^\circ$ , then Leg 2 need  $120^\circ$  off-set and Leg 3 needs  $240^\circ$  off-set. The waveforms in [Figure 12-296](#) show the timing relationship between each of the phases (Legs). Note ECAP1 module is the Controller and issues a SyncOut pulse to the targets (modules 2, 3) whenever TSCTR = Period value.

**Figure 12-296. Multiphase (channel) Interleaved PWM Example Using 3 ECAP Modules**

**Example 12-7. Code Snippet for Multichannel PWM Generation with Phase Control**

```
// Code snippet for APWM mode Example 3
// Run Time (Note: Example execution of one run-time instant)
//=====
// All phases are set to the same duty cycle
ECAP1Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP2Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP3Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
```

**12.4.3 Enhanced Pulse Width Modulation (EPWM) Module**

This chapter describes the Enhanced Pulse Width Modulation (EPWM) module in the device.

**12.4.3.1 EPWM Overview**

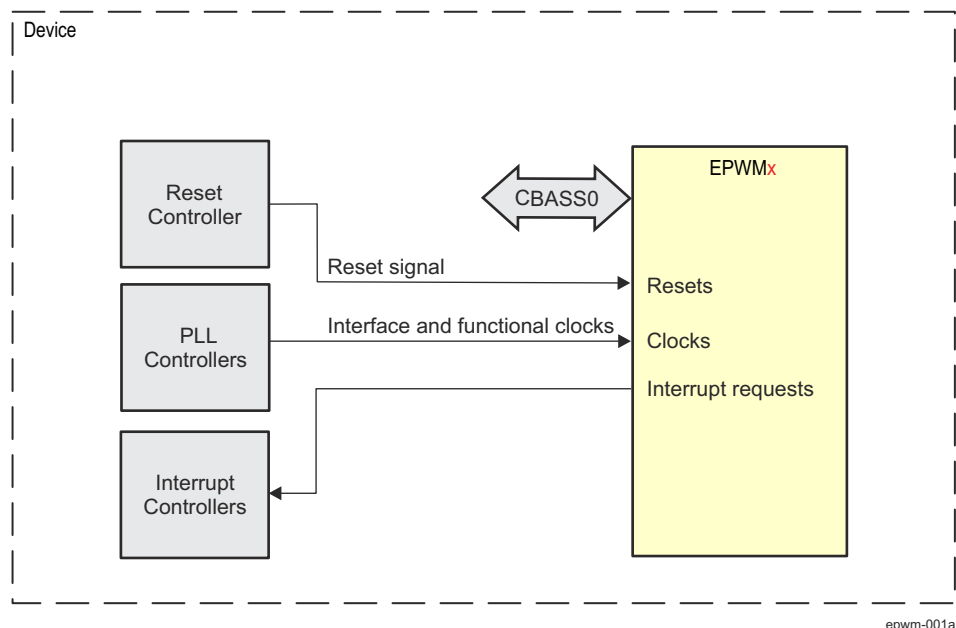

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The EPWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross-coupling or sharing of resources has been avoided; instead, the EPWM is built up from smaller single-channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In the further description, the letter x within a signal or module name is used to indicate a generic EPWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the EPWMx instance. Thus, EPWM1A and EPWM1B belong to EPWM1, EPWM2A and EPWM2B belong to EPWM2, and so forth.

The EPWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB.

As also described in *Daisy-Chain Connectivity between EPWM Modules*, the EPWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the Enhanced Capture (ECAP) peripheral module. The EPWM modules can also operate stand-alone.

Figure 12-297 shows the EPWM module overview.

A. <sub>x</sub> = 0 to number of instances

**Figure 12-297. EPWM Overview**

#### 12.4.3.1.1 EPWM Features

Each EPWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs
- Allows events to trigger both CPU interrupts and ADC start of conversions
- Programmable event prescaling minimizes CPU overhead on interrupts
- PWM chopping by a high-frequency carrier signal, useful for pulse transformer gate drives

#### 12.4.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

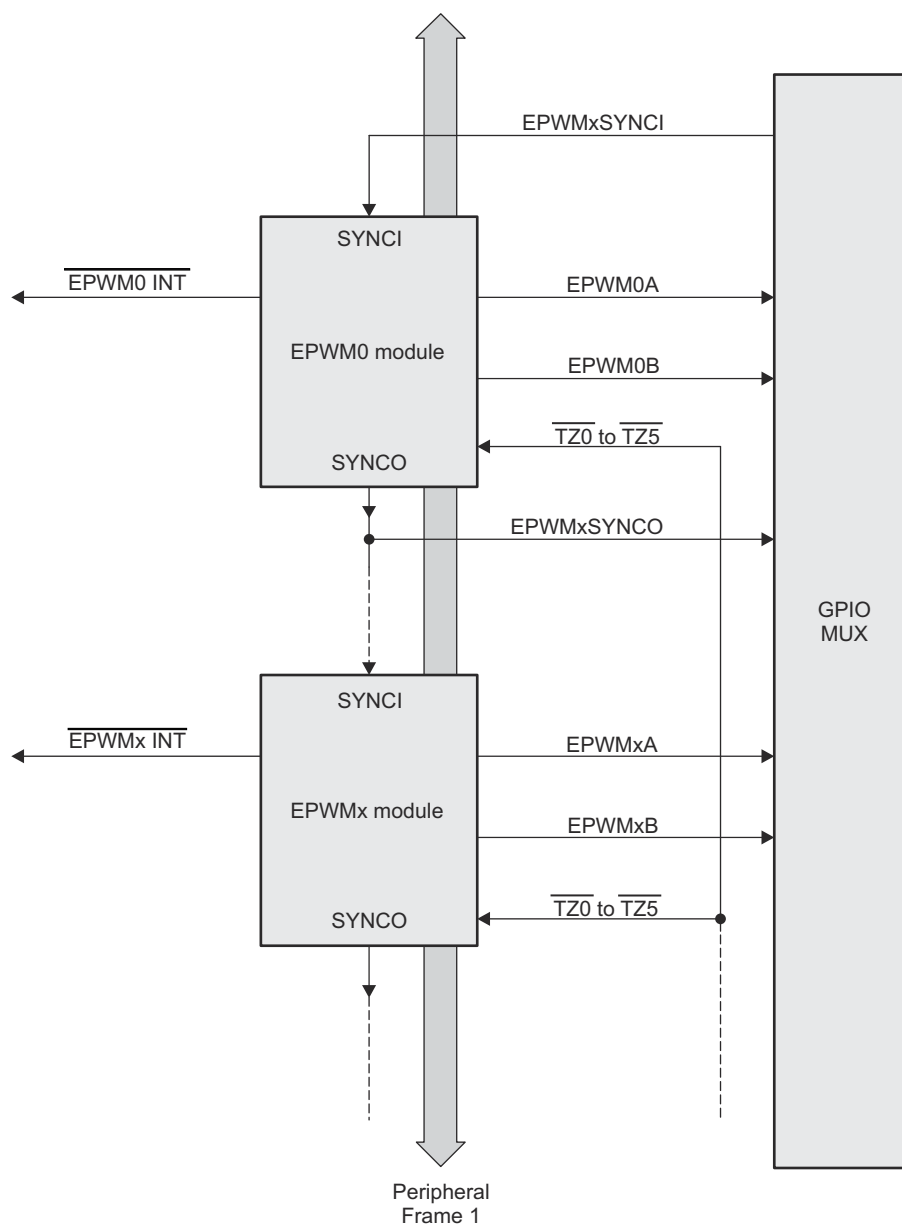

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 12.4.3.1.3 Multiple EPWM Module Details

Each EPWM module is connected to the input/output signals shown in [Figure 12-298](#).

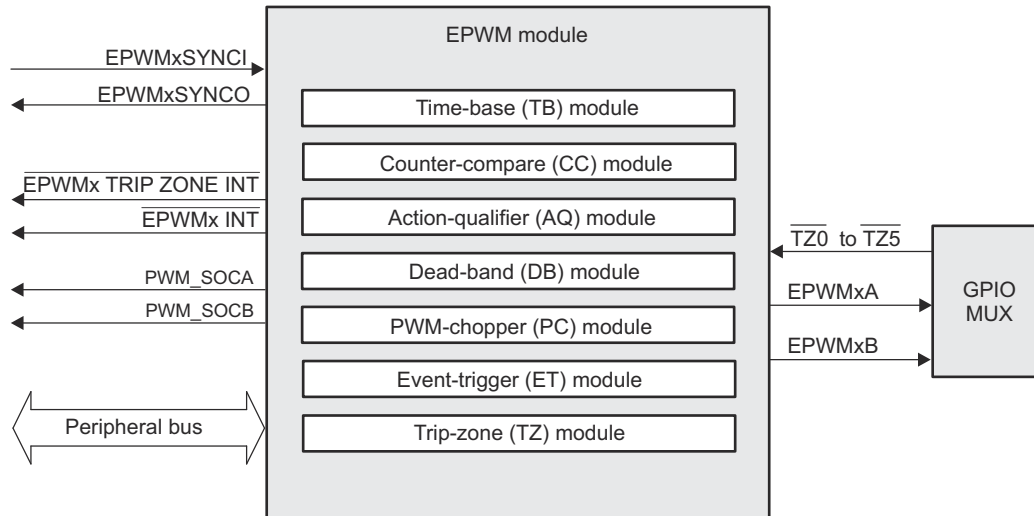

The order in which the EPWM modules are connected may differ from what is shown in [Figure 12-298](#). See *Daisy-Chain Connectivity between EPWM Modules* for the actual synchronization scheme implemented in the device. Each EPWM module consists of seven submodules and is connected within a system via the signals shown in [Figure 12-299](#).

epwm-001

A. x = 0 to number of instances

**Figure 12-298. Multiple EPWM Modules**

epwm-002

A. x = 0 to number of instances

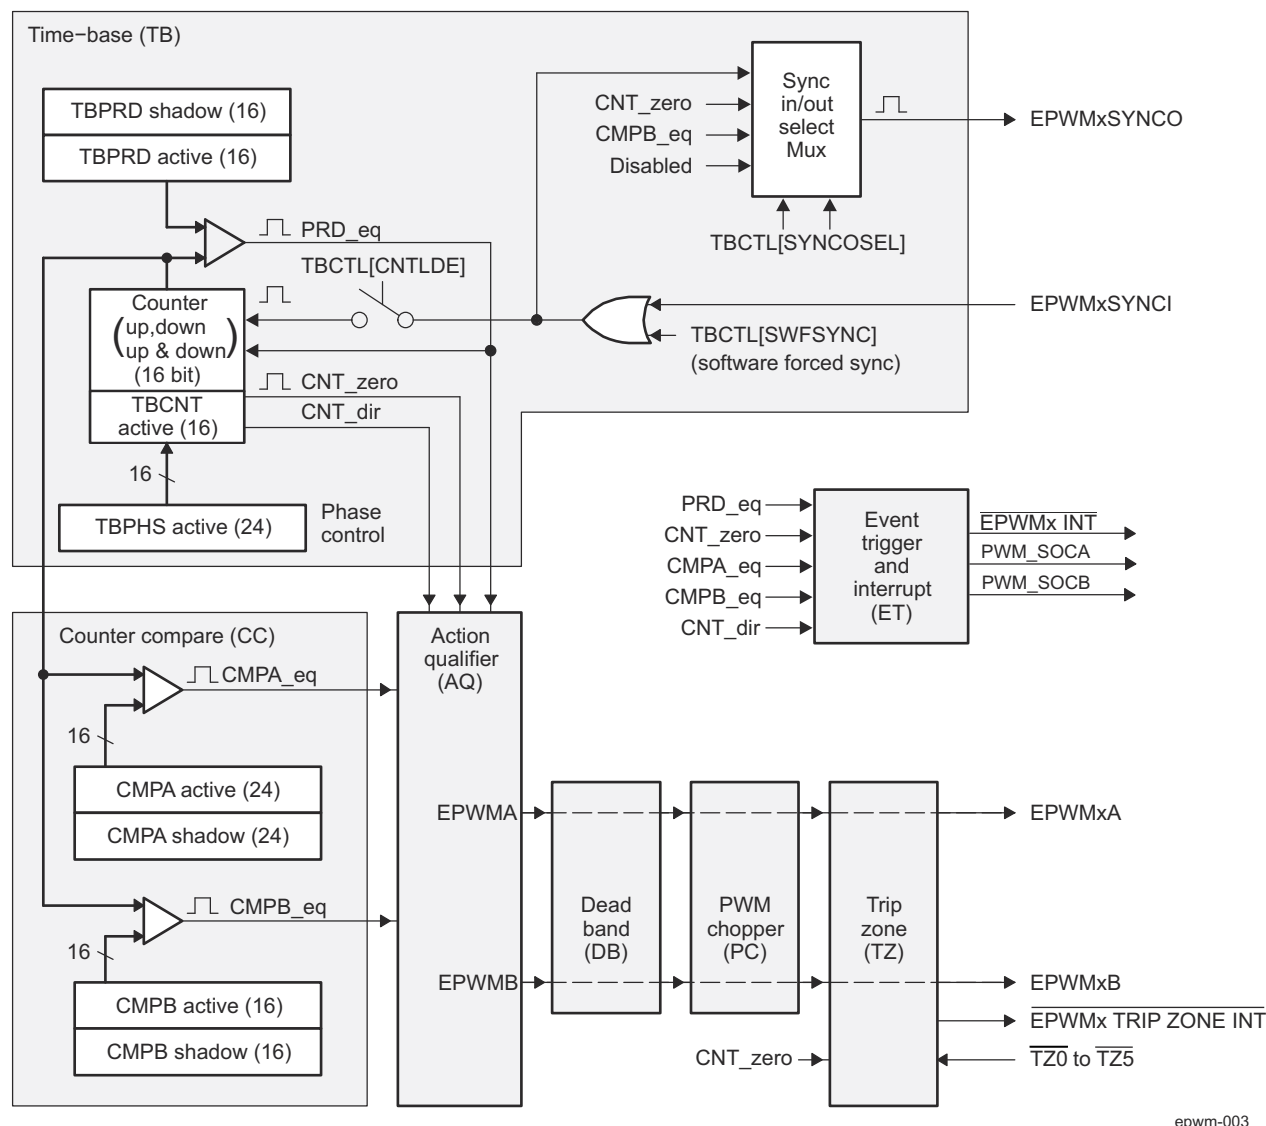

**Figure 12-299. Submodules and Signal Connections for an EPWM Module**

Figure 12-300 shows more internal details of a single EPWM module.

The main signals used by the EPWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**  
The PWM output signals are available external to the device through the GPIO peripheral.
- **Trip-zone signals (TZ0 to TZ5)**  
These input signals alert the EPWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals**  
The synchronization signals daisy chain the EPWM modules together. Each module can be configured to either use or ignore its synchronization input. For more information see *Daisy-Chain Connectivity between EPWM Modules*.
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**  
Each EPWM module has two ADC start of conversion signals (one for each sequencer). Any EPWM module can trigger a start of conversion for either sequencer. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the EPWM module.
- **Peripheral Bus**  
The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the EPWM registers.

Figure 12-300 also shows the key internal submodule interconnect signals. Each submodule is described in *EPWM Functional Description*.

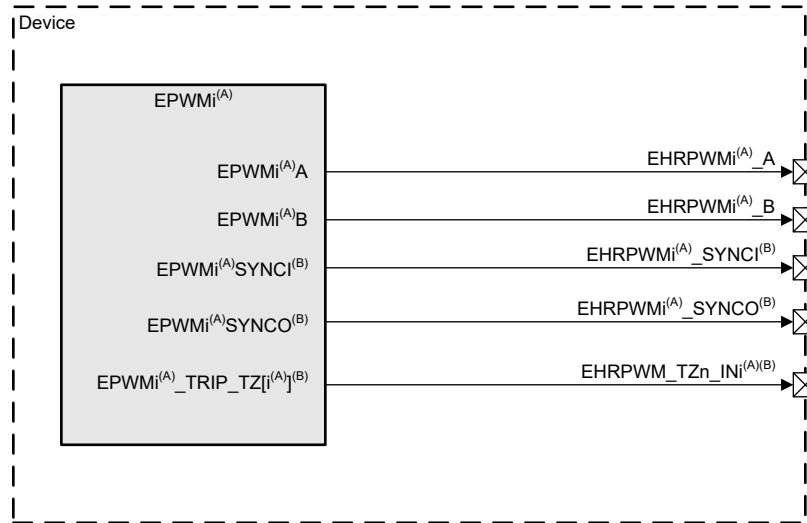

**Figure 12-300. EPWM Submodule Interconnect Signals**

### 12.4.3.2 EPWM Environment

The EPWMx (where x = 0 to number of instances) module is hereinafter referred to as EPWM module.

This section describes the EPWM external connections (environment).

Figure 12-301 shows the EPWM I/O interface signals.

**Figure 12-301. EPWM I/O Interface Signals**

A. i represents a valid instance of EPWM in a domain. See the device datasheet for specifics.

B. Pin only available on specific instances. See the device datasheet for specifics.

Table 12-264 describes the EPWM I/O signals.

**Table 12-264. EPWM I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) i represents a valid instance of EPWM in a domain. See the device datasheet for specifics.

(4) Pin only available on specific instances. See the device datasheet for specifics.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

### 12.4.3.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.4.3.4 EPWM Functional Description

Seven submodules are included in each EPWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

#### 12.4.3.4.1 EPWM Submodule Features

[Table 12-265](#) lists the seven key submodules together with a list of their main configuration parameters.

**Table 12-265. Submodule Configuration Parameters**

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> <li>Scale the time-base clock (TBCLK) relative to the system clock (FICLK).</li> <li>Configure the PWM time-base counter (TBCNT) frequency or period.</li> <li>Time-base counter mode selection: <ul style="list-style-type: none"> <li>count-up mode: used for asymmetric PWM</li> <li>count-down mode: used for asymmetric PWM</li> <li>count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>Configure the time-base phase relative to another EPWM module.</li> <li>Synchronize the time-base counter between modules through hardware or software.</li> <li>Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>Configure how the time-base counter will behave when the device is halted by an emulator.</li> <li>Specify the source for the synchronization output of the EPWM module: <ul style="list-style-type: none"> <li>Synchronization input signal</li> <li>Time-base counter equal to zero</li> <li>Time-base counter equal to counter-compare B (CMPB)</li> <li>No output synchronization signal generated</li> </ul> </li> </ul>
Counter-compare (CC)	<ul style="list-style-type: none"> <li>Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB</li> <li>Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> </ul>
Action-qualifier (AQ)	<ul style="list-style-type: none"> <li>Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> <li>No action taken</li> <li>Output EPWMxA and/or EPWMxB switched high</li> <li>Output EPWMxA and/or EPWMxB switched low</li> <li>Output EPWMxA and/or EPWMxB toggled</li> </ul> </li> <li>Force the PWM output state through software control</li> <li>Configure and control the PWM dead-band through software</li> </ul>
Dead-band (DB)	<ul style="list-style-type: none"> <li>Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>Specify the output rising-edge-delay value</li> <li>Specify the output falling-edge delay value</li> <li>Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification</li> </ul>
PWM-chopper (PC)	<ul style="list-style-type: none"> <li>Create a chopping (carrier) frequency</li> <li>Pulse width of the first pulse in the chopped pulse train</li> <li>Duty cycle of the second and subsequent pulses</li> <li>Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.</li> </ul>

**Table 12-265. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	<ul style="list-style-type: none"> <li>Configure the EPWM module to react to one, all, or none of the trip-zone pins</li> <li>Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> <li>Force EPWMxA and/or EPWMxB high</li> <li>Force EPWMxA and/or EPWMxB low</li> <li>Force EPWMxA and/or EPWMxB to a high-impedance state</li> <li>Configure EPWMxA and/or EPWMxB to ignore any trip condition</li> </ul> </li> <li>Configure how often the EPWM will react to the trip-zone pin: <ul style="list-style-type: none"> <li>One-shot</li> <li>Cycle-by-cycle</li> </ul> </li> <li>Enable the trip-zone to initiate an interrupt</li> <li>Bypass the trip-zone module entirely</li> </ul>
Event-trigger (ET)	<ul style="list-style-type: none"> <li>Enable the EPWM events that will trigger an interrupt.</li> <li>Specify the rate at which events cause triggers (every occurrence or every second or third occurrence)</li> <li>Poll, set, or clear event flags</li> </ul>

Some examples on various EPWM module configurations are shown below. These examples use the constant definitions shown in [Example 12-8](#).

## Constant Definitions Used in the EPWM Code Examples

```
// TBCTL (Time-Base Control)

#### 12.4.3.4.2 EPWM Time-Base (TB) Submodule

This section describes the Time-Base (TB) submodule in the PWM module.

##### 12.4.3.4.2.1 Overview

Each EPWM module has its own time-base submodule that determines all of the timing events. Built-in synchronization logic allows the time-base of multiple EPWM modules (EPWMx) to work together as a single system. [Figure 12-302](#) illustrates the time-base module's place within the EPWM.

**Figure 12-302. EPWM Time-Base Submodule**

##### 12.4.3.4.2.2 Controlling and Monitoring the EPWM Time-Base Submodule

[Table 12-266](#) lists the registers used to control and monitor the time-base submodule.

**Table 12-266. EPWM Time-Base Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

[Figure 12-303](#) shows the critical signals and registers of the time-base submodule. [Table 12-267](#) provides descriptions of the key signals associated with the time-base submodule.

**Table 12-267. EPWM Time-Base Submodule Key Signals (continued)**

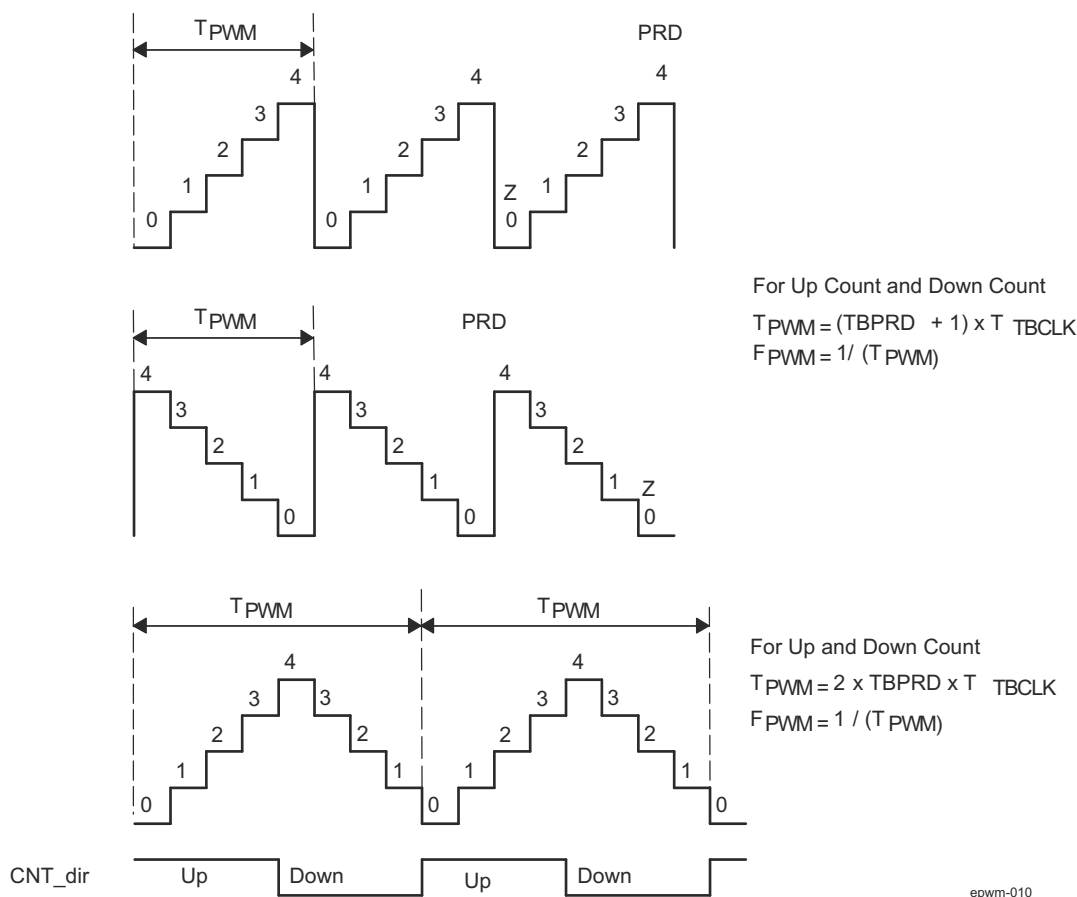

Signal	Description
CNT_dir	Time-base counter direction.  Indicates the current direction of the EPWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CNT_max	Time-base counter equal max value (TBCNT = FFFFh).  Generated event when the EPWM_TBCNT register value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock.  This is a prescaled version of the system clock — FICLK and is used by all submodules within the EPWMn. This clock determines the rate at which time-base counter increments or decrements.

#### 12.4.3.4.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period register (EPWM\_TBPRD) and the mode of the time-base counter. [Figure 12-304](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (EPWM\_TBPRD[15:0] TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (FICLK).

The time-base counter has three modes of operation selected by the time-base control register (EPWM\_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset back to the period value and it repeats this pattern.

**Figure 12-304. EPWM Time-Base Frequency and Period**

#### 12.4.3.4.2.3.1 EPWM Time-Base Period Shadow Register

The time-base period register (EPWM\_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the EPWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM\_TBCTL[3] PRDL bit. This bit enables and disables the EPWM\_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM\_TBPRD shadow register is enabled when EPWM\_TBCTL[3] PRDL = 0h. Reads from and writes to the EPWM\_TBPRD register memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM\_TBPRD (Active) ← EPWM\_TBPRD (shadow)) when the time-base counter register (EPWM\_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM\_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM\_TBCTL[3] PRDL = 1h), then a read from or a write to the TBPRD memory address goes directly to the active register.

#### 12.4.3.4.2.3.2 EPWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the EPWM modules on a device. Each EPWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (EPWM0) comes from an external pin. For the device EPWM environment sync pin details refer to the [Section 12.4.3.2](#). The possible synchronization connections for the remaining EPWM modules is shown in [Figure 12-305](#).

**Figure 12-305. EPWM Time-Base Counter Synchronization Scheme 1**

Each EPWM module can be configured to use or ignore the synchronization input. If the EPWM\_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the EPWM module (EPWM\_TBCNT register) will be automatically loaded with the phase register (EPWM\_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM\_TBPHS → EPWM\_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1h to the EPWM\_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

This feature enables the EPWM module to be automatically synchronized to the time base of another EPWM module. Lead or lag phase control can be added to the waveforms generated by different EPWM modules to synchronize them. In up-down-count mode, the EPWM\_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See [Figure 12-306](#) through [Figure 12-309](#) for examples.

Clearing the EPWM\_TBCTL[2] PHSEN bit configures the EPWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other EPWM modules. In this way, a controller time-base (for example: EPWM1) and downstream modules (EPWM2–EPWMx) can be set and they may select to run in synchronization with the controller.

#### 12.4.3.4.2.4 Phase Locking the Time-Base Clocks of Multiple EPWM Modules

As already described in the *EPWM Modules Time-Base Clock Gating*, TB\_CLKEN bit in the CTRLMMR\_EPWMn\_CTRL (where n = 0 to 8) register of the device CTRL\_MMR0 can be used to individually control or globally synchronize the time-base clocks of all enabled EPWM modules on a device. When all

TB\_CLKEN bits are set to 0h, the time-base clocks of all EPWMx (where x = 0 to 8) modules are stopped (default). When all TB\_CLKEN bits are simultaneously set in software to 1h, all EPWMx modules time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM\_TBCTL register of each EPWM module must be set identically. The proper procedure for enabling the EPWM clocks is as follows:

1. Enable the EPWM module clocks.
2. Set TB\_CLKEN = 0. This will stop the time-base clock within any enabled EPWMx module.
3. Configure the prescaler values and desired EPWM modes per each involved EPWMx.
4. Simultaneously set TB\_CLKEN bits to 1h.

#### 12.4.3.4.2.5 EPWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, [Figure 12-306](#) to [Figure 12-309](#) show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

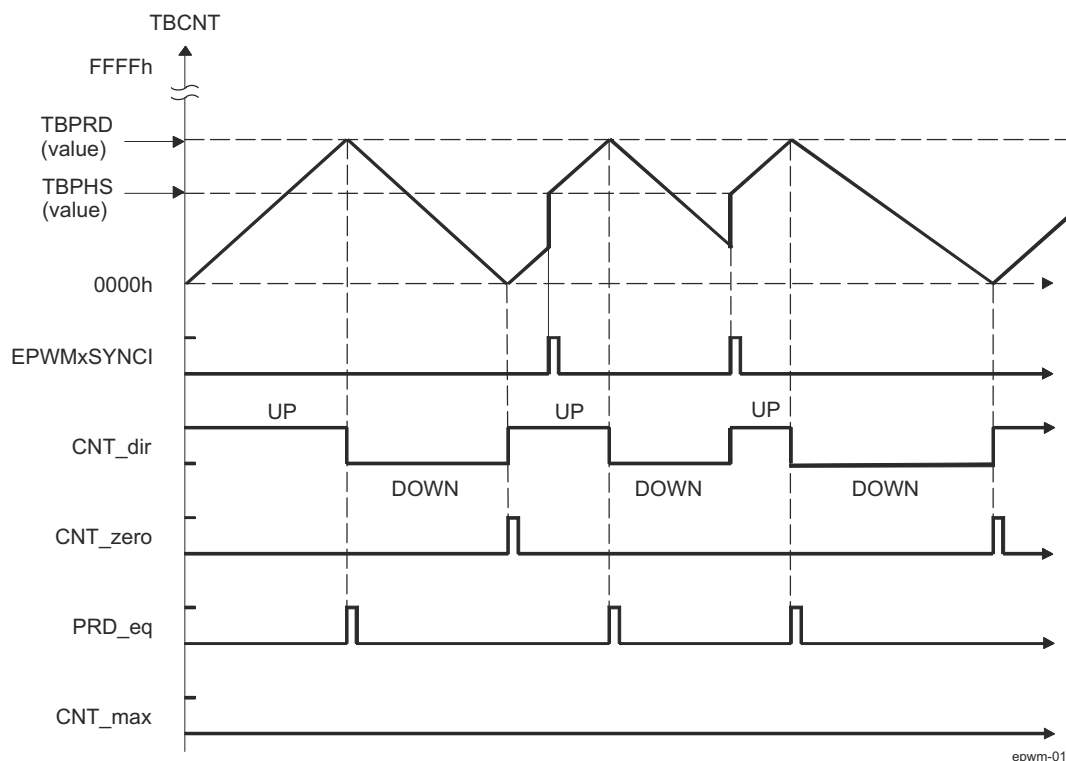

**Figure 12-306. EPWM Time-Base Up-Count Mode Waveforms**

**Figure 12-307. EPWM Time-Base Down-Count Mode Waveforms**

**Figure 12-308. EPWM Time-Base Up-Down-Count Waveforms, EPWM\_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event**

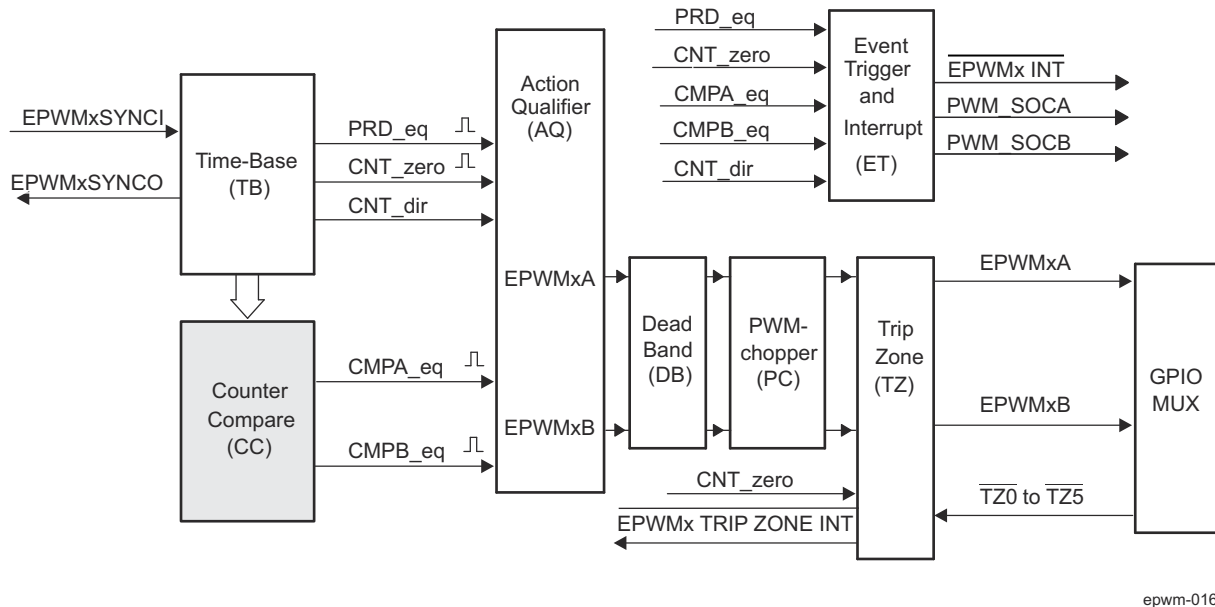

**Figure 12-309. EPWM Time-Base Up-Down Count Waveforms, EPWM\_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event**

#### 12.4.3.4.3 EPWM Counter-Compare (CC) Submodule

This section describes the Counter-Compare (CC) submodule in the PWM module.

##### 12.4.3.4.3.1 Overview

Figure 12-310 illustrates the counter-compare submodule within the EPWM. Figure 12-311 shows the basic structure of the counter-compare submodule.

**Figure 12-310. EPWM Counter-Compare Submodule**

CC module features:

- Generates events based on programmable time stamps using the EPWM\_CMPA and EPWM\_CMPB registers
  - CMPA\_eq (Time-base counter equals counter-compare A register (TBCNT = CMPA)).
  - CMPB\_eq (Time-base counter equals counter-compare B register (TBCNT = CMPB)).
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle.

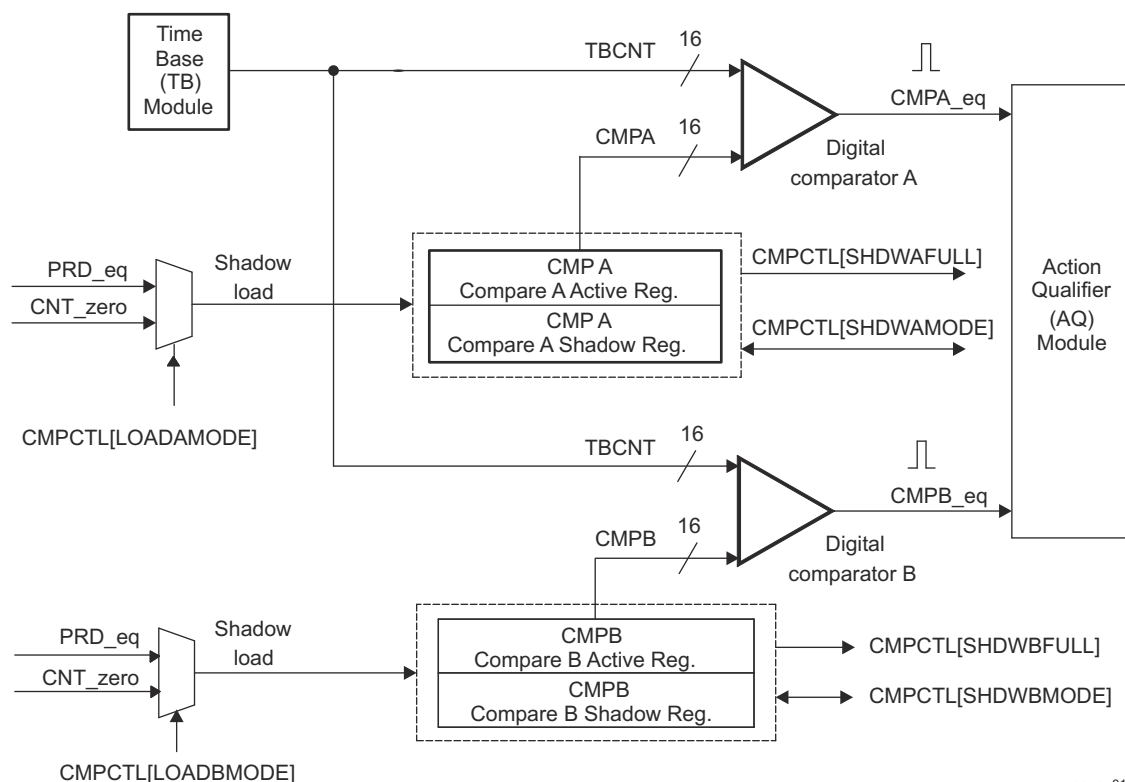

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (EPWM\_CMPA) and counter-compare B (EPWM\_CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

##### 12.4.3.4.3.2 Controlling and Monitoring the EPWM Counter-Compare Submodule

Table 12-268 lists the registers used to control and monitor the counter-compare submodule. Table 12-269 lists the key signals associated with the counter-compare submodule.

**Table 12-268. EPWM Counter-Compare Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

**Figure 12-311. EPWM Counter-Compare Submodule Signals and Registers**

**Table 12-269. EPWM Counter-Compare Submodule Key Signals**

Signal	Description of Event	Register Bitfields Compared
CMPA_eq	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
PRD_eq	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

#### 12.4.3.4.3.3 Operational Highlights for the EPWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CMPA: Time-base counter equal to counter-compare A register (EPWM\_TBCNT = EPWM\_CMPA).
2. CMPB: Time-base counter equal to counter-compare B register (EPWM\_TBCNT = EPWM\_CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 12.4.3.4.4](#) for more details.

The counter-compare EPWM\_CMPA and EPWM\_CMPB registers each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the EPWM\_CMPCTL[4] SHDWAMODE and EPWM\_CMPCTL[6] SHDWBMODE bits. These bits enable and disable the EPWM\_CMPA shadow register and EPWM\_CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Load Mode:**

The shadow mode for the EPWM\_CMPA register is enabled by clearing the EPWM\_CMPCTL[4] SHDWAMODE bit and the shadow register for EPWM\_CMPB register is enabled by clearing the EPWM\_CMPCTL[6] SHDWBMODE bit. Shadow mode is enabled by default for both EPWM\_CMPA and EPWM\_CMPB register.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

- PRD\_eq: Time-base counter equal to the period (TBCNT = TBPRD).
- CNT\_zero: Time-base counter equal to zero (TBCNT = 0000h)
- Both PRD\_eq and CNT\_zero events occurrence

Which of these three events will drive the counter compare module is specified by the EPWM\_CMPCTL[1-0] LOADAMODE and EPWM\_CMPCTL[3-2] LOADBMODE register bit fields. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

- **Immediate Load Mode:**

If immediate load mode is selected (EPWM\_CMPCTL[4] SHDWAMODE = 1h or EPWM\_CMPCTL[6] SHDWBMODE = 1h), then a read from or a write to the register will go directly to the active register.

[Figure 12-312](#) and [Figure 12-313](#) show Compare A and B Dual Shadow registers.

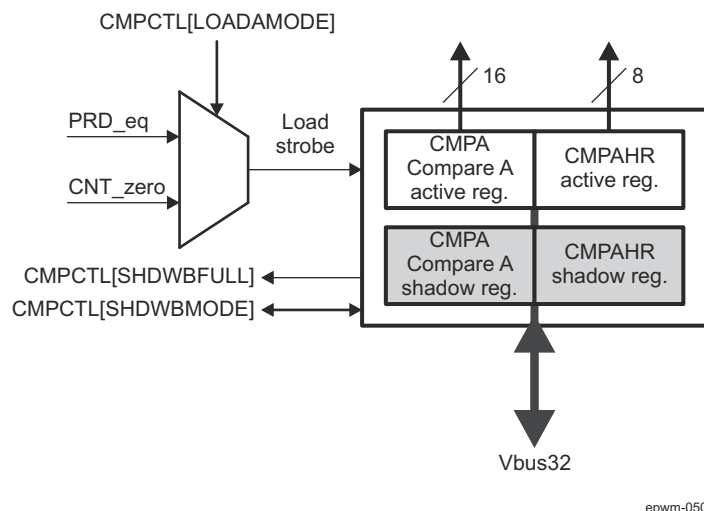

Figure 12-312. Compare A Dual Shadow register

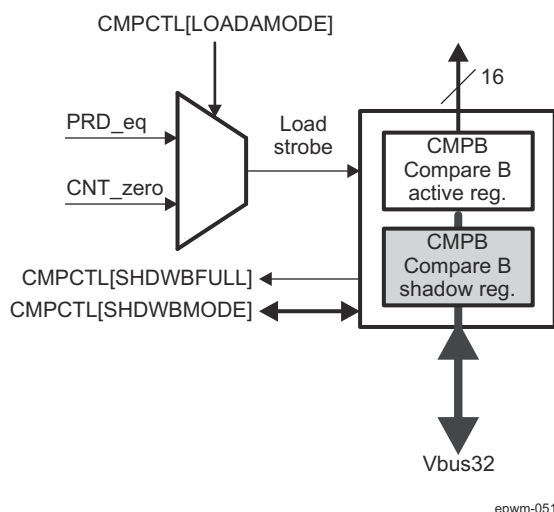

Figure 12-313. Compare B Dual Shadow register

#### 12.4.3.4.3.4 EPWM Counter-Compare Submodule Timing Waveforms

As described in [Section 12.4.3.4.2](#), the Time Base (TB) module can be configured to operate in 3 distinct count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

The timing diagrams in [Figure 12-314](#) to [Figure 12-317](#) show how CMPA and CMPB events are generated in each of the 3 count modes and how the EPWMxSYNCI signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 12-314. EPWM Counter-Compare Event Waveforms in Up-Count Mode**

**Figure 12-315. EPWM Counter-Compare Events in Down-Count Mode**

**Figure 12-316. EPWM Counter-Compare Events in Up-Down-Count Mode, EPWM\_TBCTL[13] PHSDIR = 0  
Count Down on Synchronization Event**

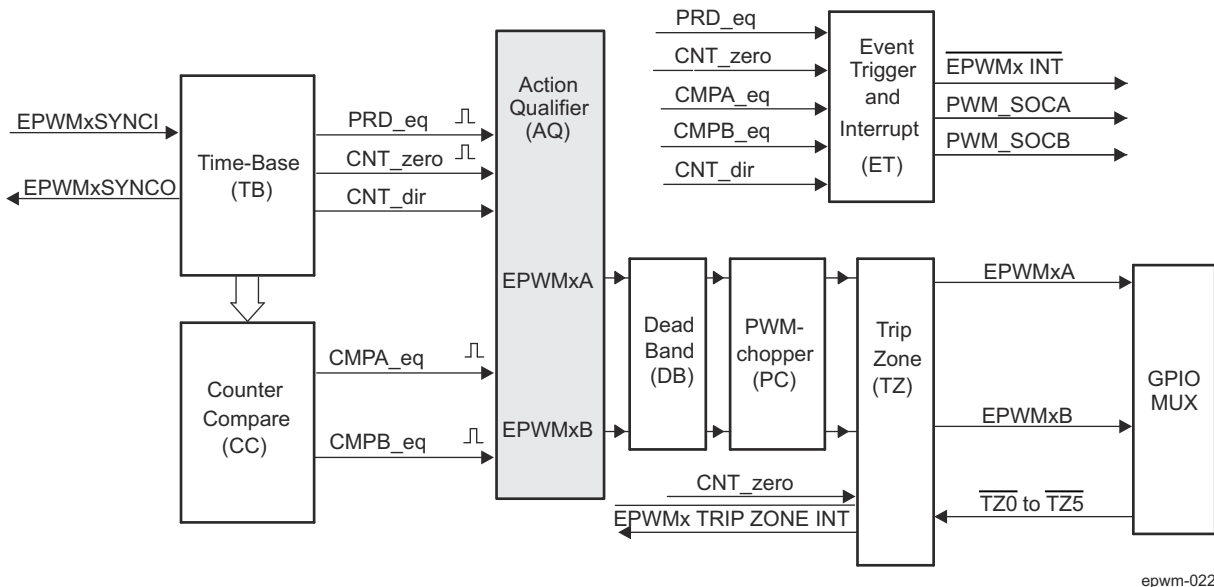

**Figure 12-317. EPWM Counter-Compare Events in Up-Down-Count Mode, EPWM\_TBCTL[13] PHSDIR = 1  
Count Up on Synchronization Event**

#### 12.4.3.4.4 EPWM Action-Qualifier (AQ) Submodule

This section describes the Action-Qualifier (AQ) submodule in the PWM module.

##### 12.4.3.4.4.1 Overview

Figure 12-318 shows the action-qualifier (AQ) submodule in the EPWM system. This submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

**Figure 12-318. EPWM Action-Qualifier Submodule**

AQ module features:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - PRD\_eq: Time-base counter equal to the period (TBCNT = TBPRD)
  - CNT\_zero: Time-base counter equal to zero (TBCNT = 0000h)
  - CMPA\_eq: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CMPB\_eq: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

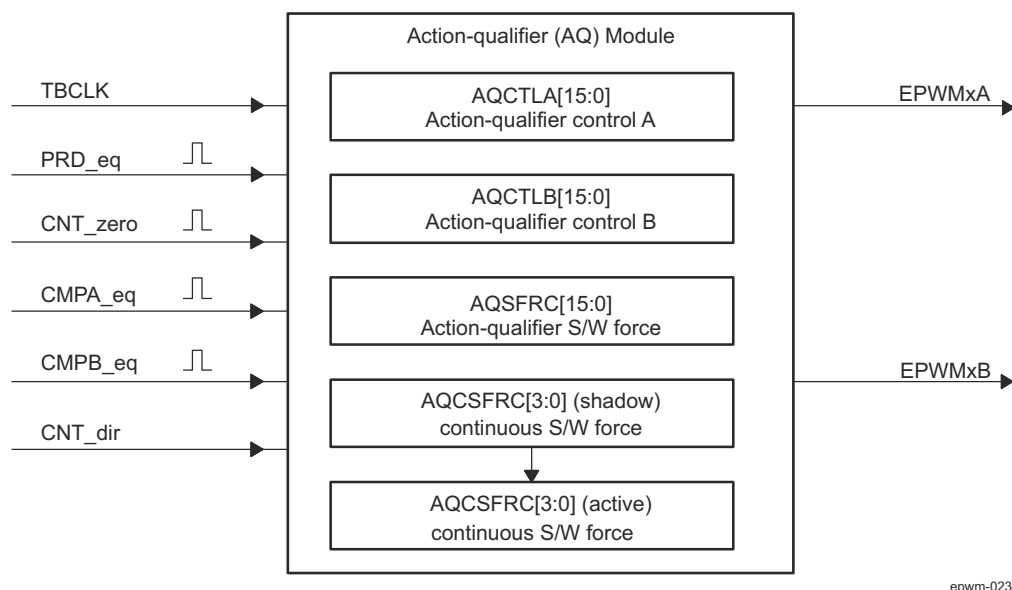

##### 12.4.3.4.4.2 Controlling and Monitoring the EPWM Action-Qualifier Submodule

Table 12-270 lists the registers used to control and monitor the action-qualifier submodule.

**Table 12-270. EPWM Action-Qualifier Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
EPWM_AQSFRC	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers as shown in Figure 12-319. The possible input events are summarized again in Table 12-271.

**Figure 12-319. EPWM Action-Qualifier Submodule Inputs and Outputs**
**Table 12-271. EPWM Action-Qualifier Submodule Possible Input Events**

Signal	Description	Register Bitfield Compared
PRD_eq	Time-base counter equal to the period value	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero	TBCNT = 0000h
CMPA_eq	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by EPWM\_AQSFRC and EPWM\_AQCSFRC registers.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the Event\_Trigger (ET) submodule description in [Section 12.4.3.4.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 12-320](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
<div>SW ×</div>	<div>Z ×</div>	<div>CA ×</div>	<div>CB ×</div>	<div>P ×</div>	Do Nothing
<div>SW ↓</div>	<div>Z ↓</div>	<div>CA ↓</div>	<div>CB ↓</div>	<div>P ↓</div>	Clear Low
<div>SW ↑</div>	<div>Z ↑</div>	<div>CA ↑</div>	<div>CB ↑</div>	<div>P ↑</div>	Set High
<div>SW T</div>	<div>Z T</div>	<div>CA T</div>	<div>CB T</div>	<div>P T</div>	Toggle

epwm-024

**Figure 12-320. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

#### 12.4.3.4.3 EPWM Action-Qualifier Event Priority

It is possible for the EPWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is: events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 12-272](#). A priority level 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

**Table 12-272. EPWM Action-Qualifier Event Priority for Up-Down-Count Mode**

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) <sup>(1)</sup>	Counter equals CMPB on up-count (CBU) <sup>(1)</sup>
6 (Lowest)	Counter equals CMPA on down-count (CAD) <sup>(1)</sup>	Counter equals CMPA on up-count (CBU) <sup>(1)</sup>

(1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 12-273](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

**Table 12-273. EPWM Action-Qualifier Event Priority for Up-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 12-274](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 12-274. EPWM Action-Qualifier Event Priority for Down-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 12-275](#).

**Table 12-275. Behavior if CMPA/CMPB is Greater than the Period**

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB $\leq$ TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $>$ TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB $<$ TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB $<$ TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB $<$ TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event occurs on a period match (TBCNT = TBPRD).

#### 12.4.3.4.4 Waveforms for Common EPWM Configurations

##### Note

The waveforms in this chapter show the EPWMs behavior for a static compare register value. In a running system, the active compare registers (EPWM\_CMPA and EPWM\_CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place — either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

##### Use up-down-count mode to generate a symmetric PWM:

- If EPWM\_CMPA / EPWM\_CMPB is loaded on zero, then use EPWM\_CMPA / EPWM\_CMPB values greater than or equal to 1.
- If EPWM\_CMPA / EPWM\_CMPB is loaded on period, then use EPWM\_CMPA / EPWM\_CMPB values less than or equal to TBPRD - 1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

##### Use up-down-count mode to generate an asymmetric PWM:

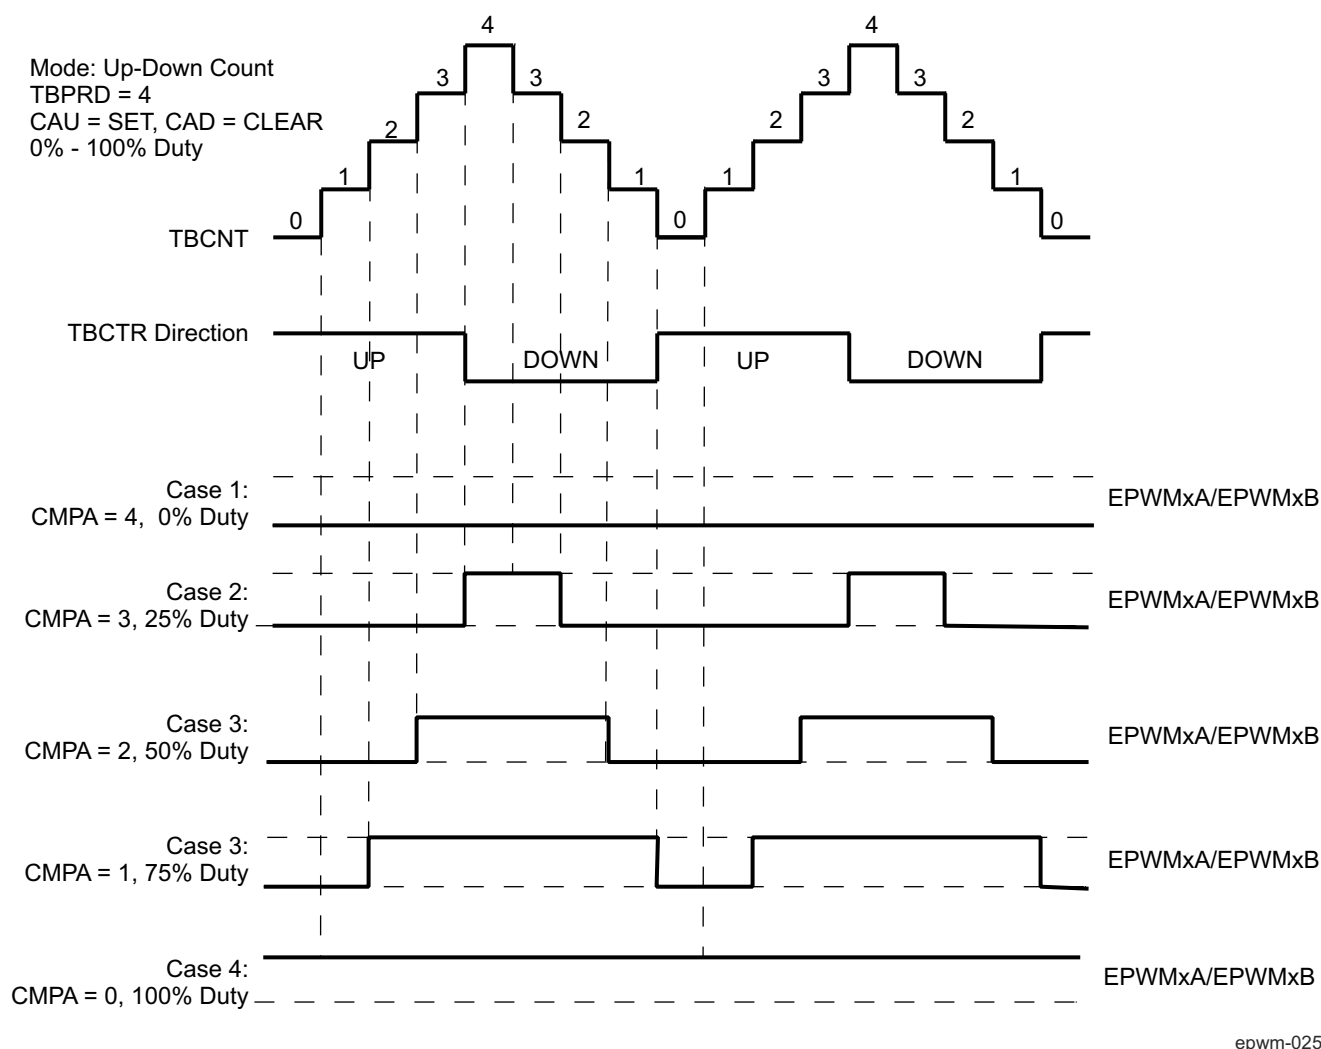

- To achieve 50-0% asymmetric PWM use the following configuration: Load EPWM\_CMPA / EPWM\_CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50-0% PWM duty.

##### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load EPWM\_CMPA / EPWM\_CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 12-321 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When  $CMPA = 0$ , the PWM signal is low for the entire period giving the 0% duty waveform. When  $EPWM\_CMPA = EPWM\_TBPRD$ , the PWM signal is high achieving 100% duty.

When using this configuration in practice, if  $CMPA/CMPB$  is loaded on zero, then use  $CMPA/CMPB$  values greater than or equal to 1. If  $CMPA/CMPB$  is loaded on period, then use  $CMPA/CMPB$  values less than or equal to  $TBPRD - 1$ . This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

#### 12.4.3.4.5 EPWM Dead-Band Generator (DB) Submodule

This section describes the Dead-Band Generator (DB) submodule in the PWM module.

##### 12.4.3.4.5.1 Overview

Figure 12-328 illustrates the dead-band generator submodule within the EPWM module.

**Figure 12-328. Dead-Band Generator Submodule**

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the EPWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in Figure 12-328)

##### 12.4.3.4.5.2 Controlling and Monitoring the EPWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

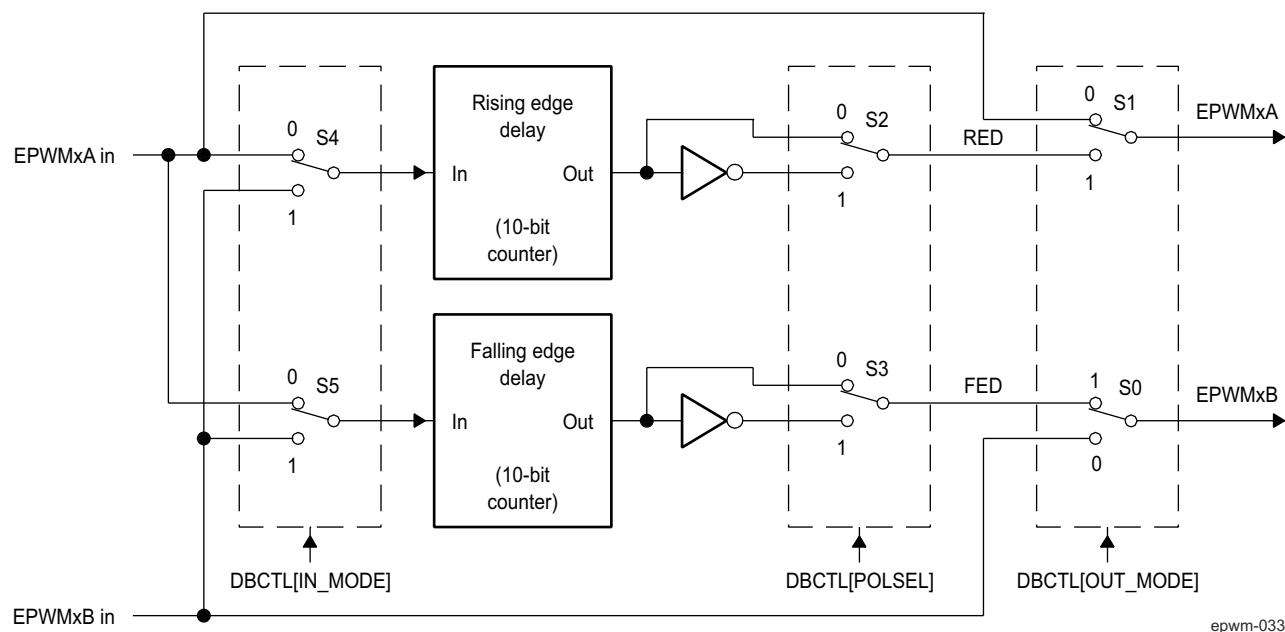

**Table 12-288. Dead-Band Generator Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

### 12.4.3.4.5.3 Operational Highlights for the EPWM Dead-Band Generator Submodule

The dead-band submodule has two groups of independent selection options as shown in Figure 12-329.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the EPWM\_DBCTL[5-4] IN\_MODE control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the EPWM\_DBCTL[1-0] OUT\_MODE bit fields. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (EPWM\_DBCTL[3-2] POLSEL) allows to be specified whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

**Figure 12-329. Configuration Options for the EPWM Dead-Band Generator Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 12-289](#) lists some classical dead-band configurations. These modes assume that the EPWM\_DBCTL[5-4] IN\_MODE is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 12-289](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows to be fully disabled the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 12-330](#). Note that to generate equivalent waveforms to [Figure 12-330](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 12-289](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 12-289. Classical Dead-Band Operating Modes**

Mode	Mode Description <sup>(1)</sup>	EPWM_DBCTL[3-2] POLSEL		EPWM_DBCTL[1-0] OUT_MODE	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

(1) These are classical dead-band modes and assume that EPWM\_DBCTL[5-4] IN\_MODE = 0h0. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN\_MODE configuration.

[Figure 12-330](#) shows waveforms for typical cases where 0% < duty < 100%.

**Figure 12-330. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the EPWM\_DBRED and EPWM\_DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formulas to calculate falling-edge-delay and rising-edge-delay are:

$$FED = EPWM\_DBFED \times T_{TBCLK}$$

$$RED = EPWM\_DBRED \times T_{TBCLK}$$

Where  $T_{TBCLK}$  is the period of TBCLK, the prescaled version of FICLK.

#### 12.4.3.4.6 EPWM-Chopper (PC) Submodule

This section describes the PWM-Chopper (PC) submodule in the PWM module.

##### 12.4.3.4.6.1 Overview

Figure 12-331 illustrates the PWM-chopper (PC) submodule within the EPWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if a pulse transformer-based gate drivers to control the power switching elements is needed.

Figure 12-331. PWM-Chopper Submodule

##### 12.4.3.4.6.2

PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

##### 12.4.3.4.6.3 Controlling the EPWM-Chopper Submodule

The EPWM-chopper submodule operation is controlled via the register in Table 12-290.

Table 12-290. EPWM-Chopper Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

#### 12.4.3.4.6.4 Operational Highlights for the EPWM-Chopper Submodule

Figure 12-332 shows the operational details of the EPWM-chopper submodule. The carrier clock is derived from FICLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM\_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 12-332. PWM-Chopper Submodule Signals and Registers

#### 12.4.3.4.6.5 EPWM-Chopper Waveforms

Figure 12-333 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 12-333. Simple EPWM-Chopper Submodule Waveforms Showing Chopping Action Only**

#### 12.4.3.4.6.5.1 EPWM-Chopper One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{FICLK} \times 8 \times OSHTWTH$$

Where  $T_{FICLK}$  is the period of the system clock (FICLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 12-334 shows the first and subsequent sustaining pulses.

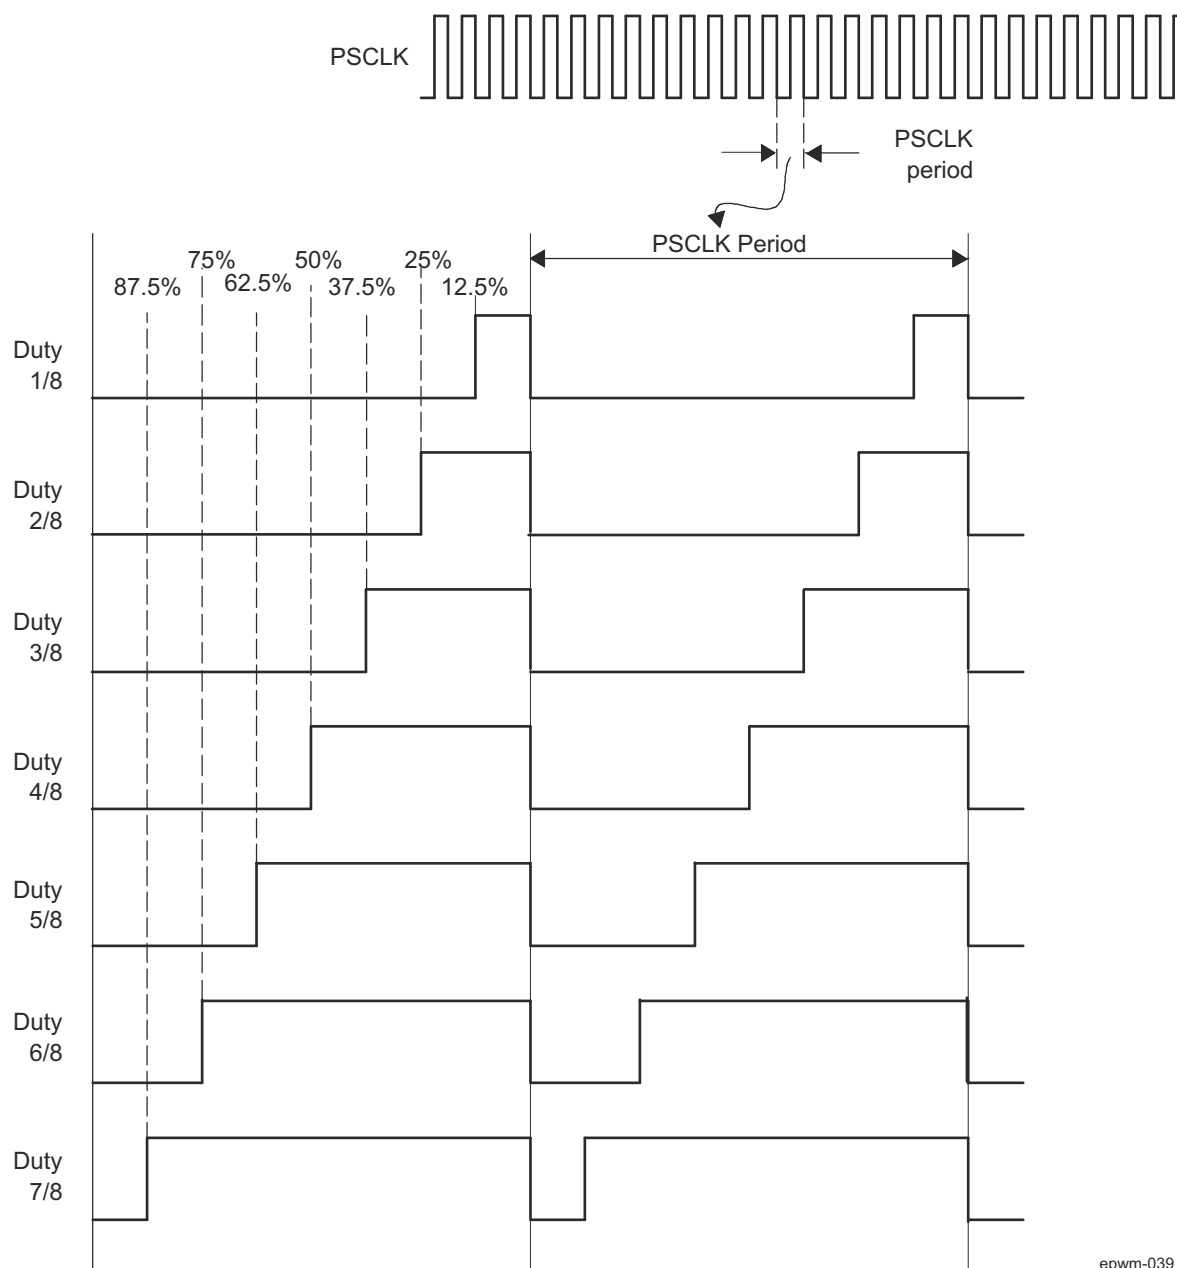

**Figure 12-334. EPWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

### 12.4.3.4.6.5.2 EPWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 12-335 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5 to 87.5%.

epwm-039

**Figure 12-335. EPWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

#### 12.4.3.4.7 EPWM Trip-Zone (TZ) Submodule

This section describes the Trip-Zone (TZ) submodule in the PWM module.

##### 12.4.3.4.7.1 Overview

Figure 12-336 shows how the trip-zone (TZ) submodule fits within the EPWM module. Each EPWM module is connected to six  $\overline{TZ}$  signals ( $\overline{TZ0}$  to  $\overline{TZ5}$ ) that are sourced from the GPIO MUX. These signals indicate external fault or trip conditions, and the EPWM outputs can be programmed to respond accordingly when faults occur. See *EPWM Integration* to determine the number of trip-zone pins available for the device.

**Figure 12-336. EPWM Trip-Zone Submodule**

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ0}$  to  $\overline{TZ5}$  can be flexibly mapped to any EPWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

#### Note

For each EPWMx module, 6 tripzone input events are supported ( $\overline{EPWMx\_TRIP\_TZ[5:0]}$ ). Each tripzone input for all EPWMx modules are tied to a common tripzone input pin, so that any EPWMx can be triggered by any of the six tripzone inputs.

### 12.4.3.4.7.2 Controlling and Monitoring the EPWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

**Table 12-291. EPWM Trip-Zone Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register <sup>(1)</sup>	24h	No
EPWM_TZCTL	Trip-Zone Control Register <sup>(1)</sup>	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register <sup>(1)</sup>	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register <sup>(1)</sup>	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register <sup>(1)</sup>	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register <sup>(1)</sup>	30h	No

(1) All trip-zone registers are EALLOW protected and can be modified only after executing the EALLOW instruction.

### 12.4.3.4.7.3 Operational Highlights for the EPWM Trip-Zone Submodule

The trip-zone signals at pin  $\overline{TZ0}$  to  $\overline{TZ5}$  is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each EPWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular EPWM module is determined by the EPWM\_TZSEL register for that specific EPWM module. The trip-zone signal may or may not be synchronized to the system clock (FICLK). A minimum of 1 FICLK low pulse on the  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs is sufficient to trigger a fault condition in the EPWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs.

The  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a EPWM module. The configuration is determined by the EPWM\_TZSEL[5-0] CBCK and EPWM\_TZSEL[13-8] OSHTk bit field (where k = 0 to 5 corresponds to the trip pin), respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM\_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 12-292](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM\_TZFLG[1] CBC) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM\_TZEINT register.

The specified condition on the pins is automatically cleared when the EPWM time-base counter reaches zero (EPWM\_TBCNT[15-0] TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM\_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM\_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM\_TZFLG[1] CBC bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM\_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 12-292](#) lists the possible actions. In addition, the one-shot trip event flag (EPWM\_TZFLG[2] OST) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM\_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM\_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the EPWM output pins by way of the EPWM\_TZCTL[1-0] TZA and EPWM\_TZCTL[3-2] TZB register bit field. One of four possible actions, shown in [Table 12-292](#), can be taken on a trip event.

**Table 12-292. Possible Actions On an EPWM Trip Event**

EPWM_TZCTL[1-0] TZA and/or EPWM_TZCTL[3-2] TZB	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

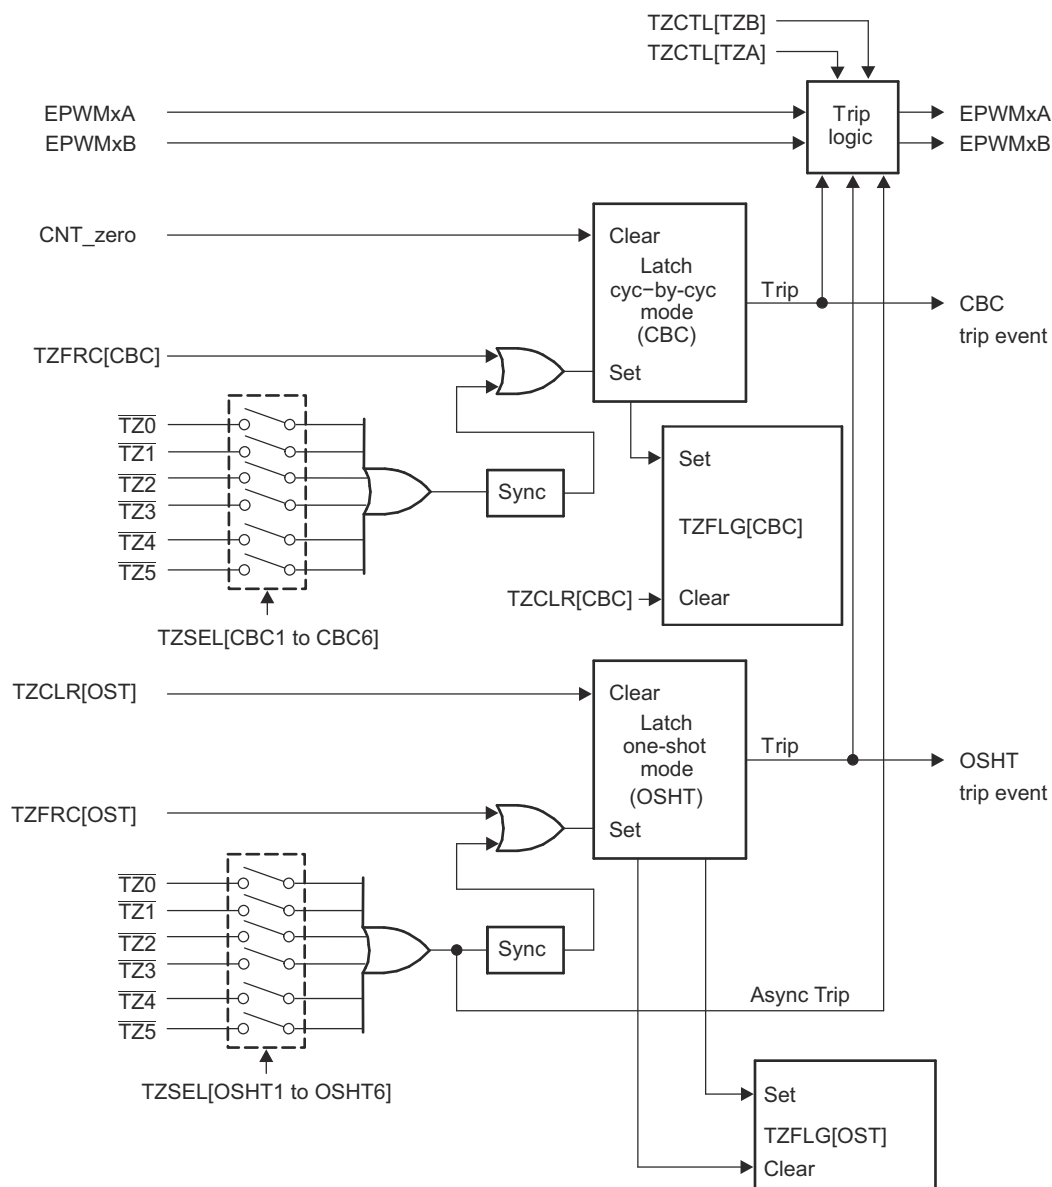

### Example of EPWM Trip-Zone Configurations

A one-shot trip event on  $\overline{TZ0}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the EPWM1 registers as follows:
  - EPWM\_TZSEL[8] OSHT1 = 1: enables  $\overline{TZ}$  as a one-shot event source for EPWM1
  - EPWM\_TZCTL[1-0] TZA = 2: EPWM1A will be forced low on a trip event
  - EPWM\_TZCTL[3-2] TZB = 2: EPWM1B will be forced low on a trip event
- Configure the EPWM2 registers as follows:
  - EPWM\_TZSEL[8] OSHT1 = 1: enables  $\overline{TZ}$  as a one-shot event source for EPWM2
  - EPWM\_TZCTL[1-0] TZA = 1: EPWM2A will be forced high on a trip event
  - EPWM\_TZCTL[3-2] TZB = 1: EPWM2B will be forced high on a trip event

#### 12.4.3.4.7.4 Generating EPWM Trip-Event Interrupts

Figure 12-337 and Figure 12-338 illustrate the trip-zone submodule control and interrupt logic, respectively.

epwm-041

**Figure 12-337. EPWM Trip-Zone Submodule Mode Control Logic**

**Figure 12-338. EPWM Trip-Zone Submodule Interrupt Logic**

#### 12.4.3.4.8 EPWM Event-Trigger (ET) Submodule

This section describes the Event-Trigger (ET) submodule in the PWM module.

##### 12.4.3.4.8.1 Overview

Figure 12-339 shows the event-trigger (ET) submodule in the EPWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an aggregated interrupt request.

**Figure 12-339. EPWM Event-Trigger Submodule**

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags

#### 12.4.3.4.8.2 Controlling and Monitoring the EPWM Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in [Table 12-293](#):

**Table 12-293. EPWM Event-Trigger Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM_ETFRC	Event-Trigger Force Register	3Ah	No

#### 12.4.3.4.8.3 Operational Overview of the EPWM Event-Trigger Submodule

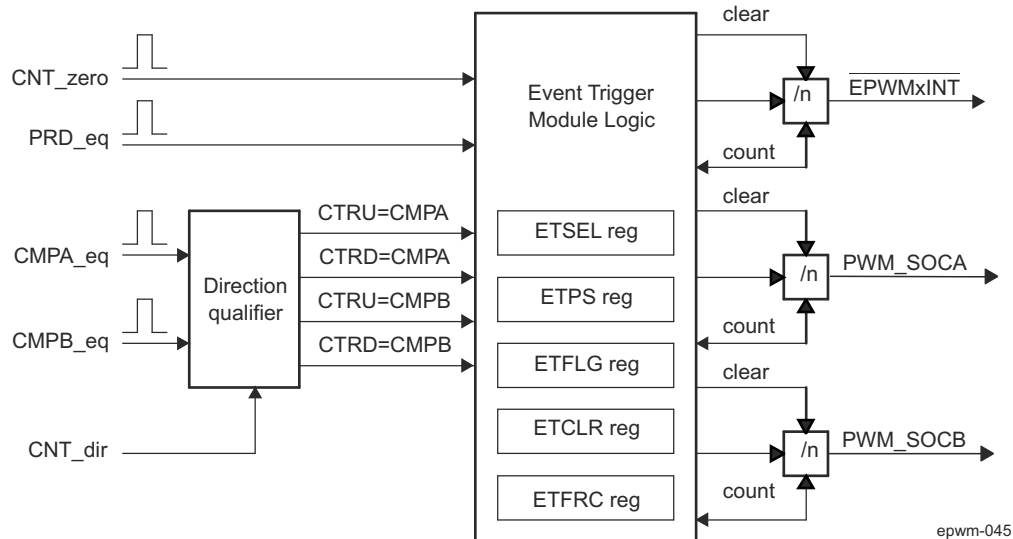

Each EPWM module has one interrupt request line as shown in [Figure 12-340](#). Mapping interrupt lines to device host interrupt controllers is device specific and is covered in *EPWM Integration*.

**Figure 12-340. EPWM Event-Trigger Submodule Inter-Connectivity to Interrupt Controller**

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in [Figure 12-341](#)) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

**Figure 12-341. EPWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- **ETSEL** — This selects which of the possible events will trigger an interrupt.
- **ETPS** — This programs the event prescaling options previously mentioned.
- **ETFLG** — These are flag bits indicating status of the selected and prescaled events.
- **ETCLR** — These bits allow to clear the flag bits in the EPWM\_ETFLG register via software.
- **ETFRC** — These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 12-342](#).

[Figure 12-342](#) shows the event-trigger's interrupt generation logic. The interrupt-period (EPWM\_ETPS[1-0] INTPRD) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (EPWM\_ETSEL[2-0] INTSEL) bits. The event can be one of the following:

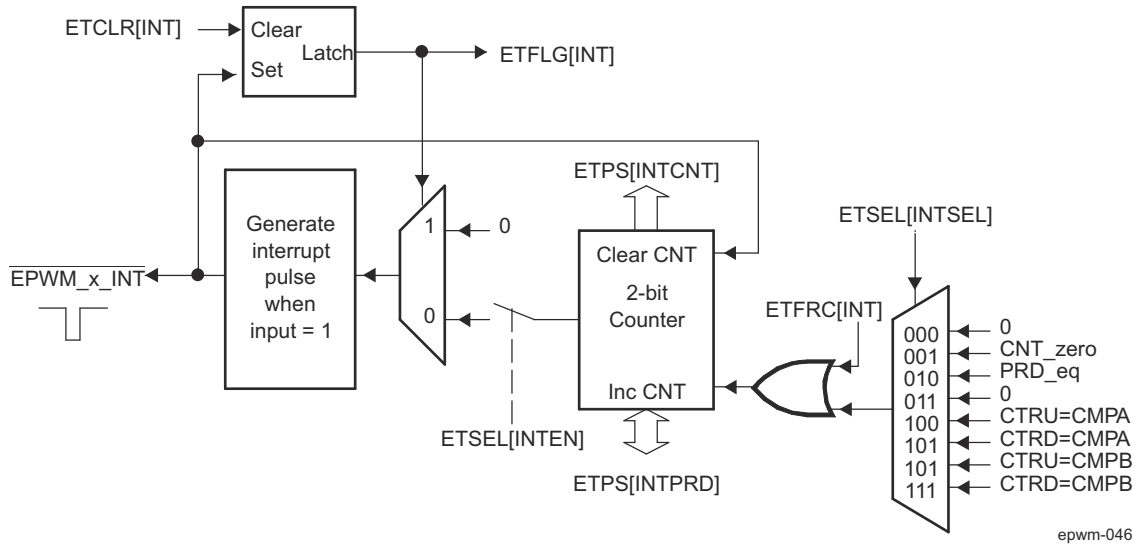

- Time-base counter equal to zero (EPWM\_TBCNT[15-0] TBCNT = 0000h).
- Time-base counter equal to period (EPWM\_TBCNT[15-0] TBCNT = EPWM\_TBPRD[15-0] TBPRD).
- Time-base counter equal to the compare A register (EPWM\_CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (EPWM\_CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (EPWM\_CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (EPWM\_CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (EPWM\_ETPS[3-2] INTCNT) register bits. That is, when the specified event occurs the EPWM\_ETPS[3-2] INTCNT bits are incremented until they reach the value specified by the EPWM\_ETPS[1-0] INTPRD bit field. When EPWM\_ETPS[3-2] INTCNT = EPWM\_ETPS[1-0] INTPRD the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When EPWM\_ETPS[3-2] INTCNT reaches EPWM\_ETPS[1-0] INTPRD, one of the following behaviors will occur:

- If interrupts are enabled, EPWM\_ETSEL[3] INTEN = 1h and the interrupt flag is clear, EPWM\_ETFLG[0] INT = 0h, then an interrupt pulse is generated and the interrupt flag is set, EPWM\_ETFLG[0] INT = 1h, and the event counter is cleared EPWM\_ETPS[3-2] INTCNT = 0h. The counter will begin counting events again.
- If interrupts are disabled, EPWM\_ETSEL[3] INTEN = 0h, or the interrupt flag is set, EPWM\_ETFLG[0] INT = 1h, the counter stops counting events when it reaches the period value EPWM\_ETPS[3-2] INTCNT = EPWM\_ETPS[1-0] INTPRD.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[0] INT flag is cleared. This allows for one interrupt to be pending while one is serviced.

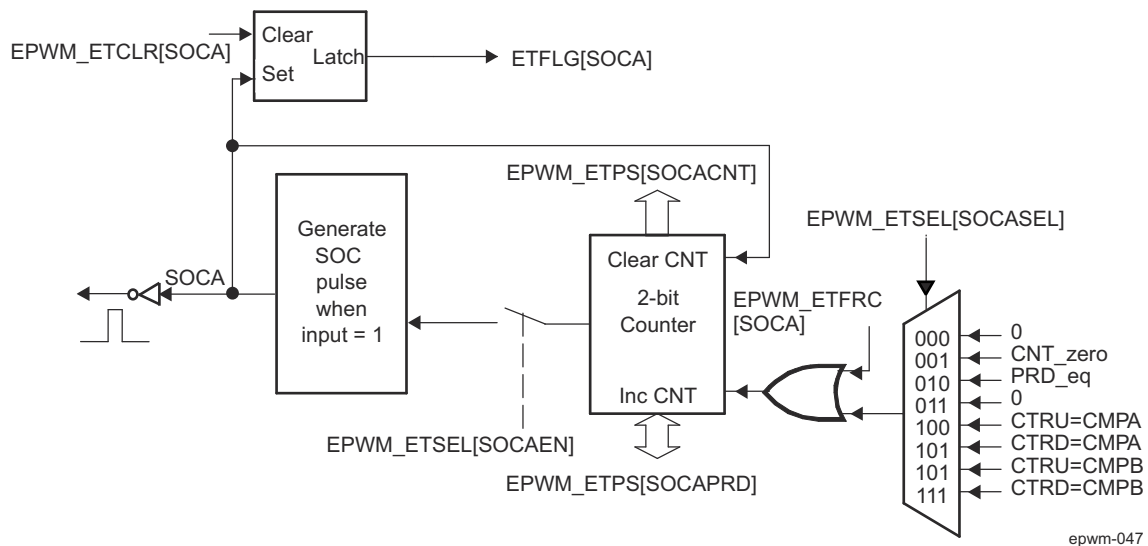

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1h to the EPWM ETFRC[0] INT bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0h, the counter is disabled and hence no events will be detected and the EPWM ETFRC[0] INT bit is also ignored.

**Figure 12-342. EPWM Event-Trigger Interrupt Generator**

#### 12.4.3.4.8.4 Operation Overview of the EPWM SOCx Pulse Generator

Figure 12-343 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The EPWM\_ETPS[11-10] SOCACNT counter and EPWM\_ETPS[9-8] SOCAPRD period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag EPWM\_ETFLG[2] SOCA is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable EPWM\_ETSEL[11] SOCAEN bit stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the EPWM\_ETSEL[10-8] SOCASEL and EPWM\_ETSEL[14-12] SOCBSEL bit field. The possible events are the same events that can be specified for the interrupt generation logic.

**Figure 12-343. EPWM Event-Trigger SOCA Pulse Generator**

Figure 12-344 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

**Figure 12-344. EPWM Event-Trigger SOCB Pulse Generator**

#### 12.4.3.4.9 EPWM Functional Register Groups

The [Table 12-294](#) lists the groups of EPWM module registers according to their functionalities.

**Table 12-294. EPWM Module Control and Status Registers Grouped by Submodule**

Register Name	Offset	Size (×16)	Shadow	Register Description
<b>Time-Base (TB) Submodule Registers</b>				
EPWM_TBCTL	0h	1	No	Time-Base Control Register
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register
<b>Counter-Compare (CC) Submodule Registers</b>				
EPWM_CMPCTL	Eh	1	No	Counter-Compare Control Register
EPWM_CMPA	12h	1	Yes	Counter-Compare A Register
EPWM_CMPB	14h	1	Yes	Counter-Compare B Register
<b>Action-Qualifier (AQ) Submodule Registers</b>				
EPWM_AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
EPWM_AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
EPWM_AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
EPWM_AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
<b>Dead-Band (DB) Generator Submodule Registers</b>				
EPWM_DBCTL	1Eh	1	No	Dead-Band Generator Control Register
EPWM_DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
EPWM_DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
<b>Trip-Zone (TZ) Submodule Registers</b>				
EPWM_TZSEL	24h	1	No	Trip-Zone Select Register <sup>(1)</sup>
EPWM_TZCTL	28h	1	No	Trip-Zone Control Register <sup>(1)</sup>
EPWM_TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register <sup>(1)</sup>

**Table 12-294. EPWM Module Control and Status Registers Grouped by Submodule (continued)**

Register Name	Offset	Size (×16)	Shadow	Register Description
EPWM_TZFLG	2Ch	1	No	Trip-Zone Flag Register <sup>(1)</sup>
EPWM_TZCLR	2Eh	1	No	Trip-Zone Clear Register <sup>(1)</sup>
EPWM_TZFRC	30h	1	No	Trip-Zone Force Register <sup>(1)</sup>
<b>Event-Trigger (ET) Submodule Registers</b>				
EPWM_ETSEL	32h	1	No	Event-Trigger Selection Register
EPWM_ETPS	34h	1	No	Event-Trigger Pre-Scale Register
EPWM_ETFLG	36h	1	No	Event-Trigger Flag Register
EPWM_ETCLR	38h	1	No	Event-Trigger Clear Register
EPWM_ETFRC	3Ah	1	No	Event-Trigger Force Register
<b>PWM-Chopper Submodule Registers</b>				
EPWM_PCCTL	3Ch	1	No	PWM-Chopper Control Register

(1) EALLOW protected registers.

#### 12.4.3.4.10 Proper EPWM Interrupt Initialization Procedure

When the EPWM peripheral clock is enabled it is possible that interrupt flags may be set due to spurious events as the EPWM registers not being properly initialized. The proper procedure for initializing the EPWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable EPWM interrupts
3. Initialize peripheral registers
4. Clear any spurious EPWM flags
5. Enable EPWM interrupts
6. Enable global interrupts

## 12.4.4 Enhanced Quadrature Encoder Pulse (EQEP) Module

This section describes the Enhanced Quadrature Encoder Pulse (EQEP) module in the device.

### 12.4.4.1 EQEP Overview

The Enhanced Quadrature Encoder Pulse (EQEP) peripheral is used for direct interface with a linear or rotary incremental encoder to get position, direction and speed information from a rotating machine for use in high performance motion and position control system. The disk of an incremental encoder is patterned with a single track of slots patterns, as shown in [Figure 12-345](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position and zero reference.

**Figure 12-345. Optical Encoder Disk**

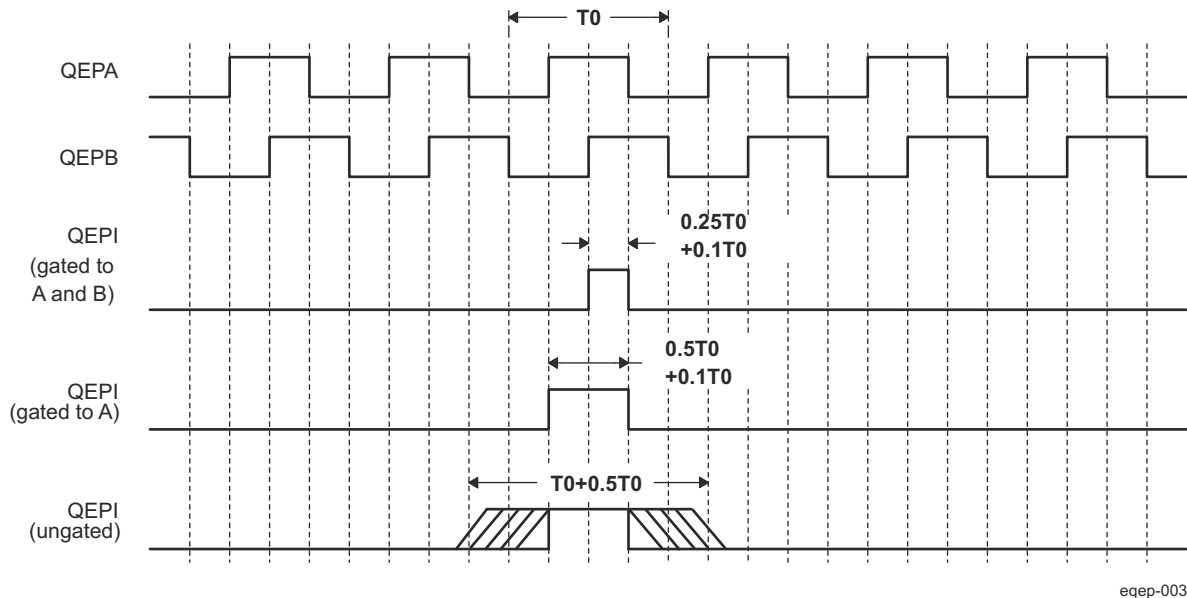

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 12-346](#).

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

**Figure 12-346. QEP Encoder Output Signal for Forward/Reverse Movement**

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in [Figure 12-347](#). A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 12-347. Index Pulse Example**

Some typical applications for rotary encoders range from fax machines to motor controllers, and even robot localization. Rotary sensors are fundamental to the robotics and motion control systems found today. The optical shaft encoder can be used to improve a robot in various ways. The encoder can measure rotational distance traveled and speed, which can be used to monitor, for example, the angular position of a robot gripper arm or the speed of a robot.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (17)$$

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (18)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

X: Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement.

[Equation 17](#) is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is the inverse of the velocity calculation rate.

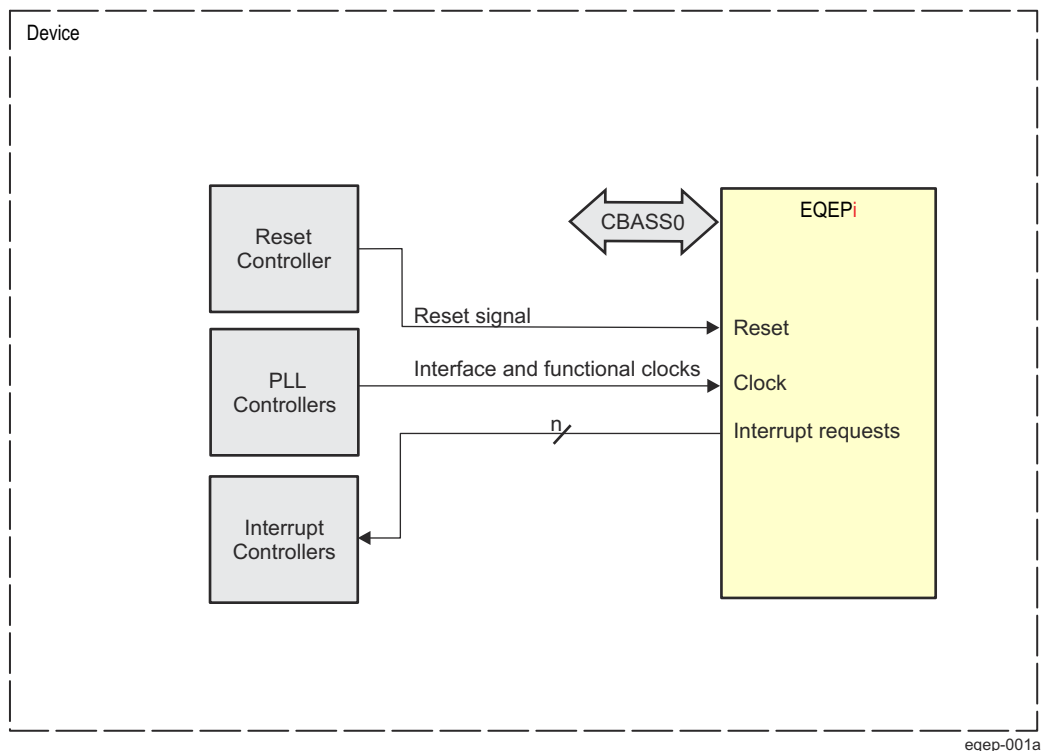

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where T is the constant time between unit time events and is known in advance).

Estimation based on [Equation 17](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 18](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 18](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation of [Equation 17](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 18](#) at low speed and have the software switch over to [Equation 17](#) when the motor speed rises above some specified threshold.

[Figure 12-348](#) shows the EQEP module overview.

A.  $i = 0$  to number of instances - 1.

**Figure 12-348. EQEP Overview**

#### 12.4.4.1.1 EQEP Features

The EQEP module includes the following features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit
- Position counter and control unit for position measurement
- Quadrature edge capture unit for low-speed measurement
- Unit time base for speed and frequency measurement
- Watchdog timer for detecting stalls
- EQEP inputs (A/B/INDEX and STROBE) are available at chip level
- EQEP phase error output is also available. The status of the phase error can be observed by software through the CTRLMMR\_EQEP\_STATCTRLMMR\_EQEP\_STAT register in the CTRL\_MMR0 module.

- Counting modes:
  - Quadrature
  - Clockwise / Counter Clockwise
  - Count / Direction
- Start of Convert input for on-chip Strobe
- EQEP internal strobe (EQEP Strobe input is logically ORed with EQEP A and B inputs) may be used to:
  - Initialize the Position Counter with a non-zero value (for example, due to a limit switch input becoming active)
  - Snapshot the Position Counter into the EQEP\_QPOSSLAT register
  - Gate the EQEP Index input preventing it from resetting the Position Counter

#### **12.4.4.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

---

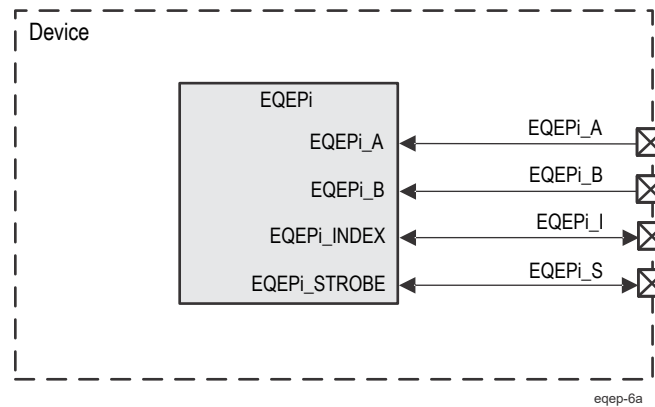

### 12.4.4.2 EQEP Environment

#### 12.4.4.2.1 EQEP I/O Interface

The EQEP<sub>i</sub> (where  $i = 0$  to 2) module is hereinafter referred to as EQEP module.

This section describes the EQEP external connections (environment).

Figure 12-349 shows the EQEP interface signals.

**Figure 12-349. EQEP External Interface I/Os**

Table 12-295 describes the EQEP I/O signals.

**Table 12-295. EQEP I/O Signals**

Module Pin	Device Level Signal Name	I/O Type <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>EQEP<sub>i</sub><sup>(4)</sup></b>				
EQEP <sub>i</sub> <sup>(4)</sup> _A	EQEP <sub>i</sub> <sup>(4)</sup> _A	I	EQEP <sub>i</sub> <sup>(4)</sup> Quadrature input A	HiZ
EQEP <sub>i</sub> <sup>(4)</sup> _B	EQEP <sub>i</sub> <sup>(4)</sup> _B	I	EQEP <sub>i</sub> <sup>(4)</sup> Quadrature input B	HiZ
EQEP <sub>i</sub> <sup>(4)</sup> _INDEX	EQEP <sub>i</sub> <sup>(4)</sup> _I	I/O <sup>(3)</sup>	EQEP <sub>i</sub> <sup>(4)</sup> Index input/output	HiZ
EQEP <sub>i</sub> <sup>(4)</sup> _STROBE	EQEP <sub>i</sub> <sup>(4)</sup> _S	I/O <sup>(3)</sup>	EQEP <sub>i</sub> <sup>(4)</sup> Strobe input/output	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) Output functionality is not supported. Only inputs are pinned out. For more information see *Device Specific EQEP Features*.

(4)  $i$  represents an EQEP instance. See the device datasheet for available domains and EQEP instances

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

### 12.4.4.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.4.4.4 EQEP Functional Description

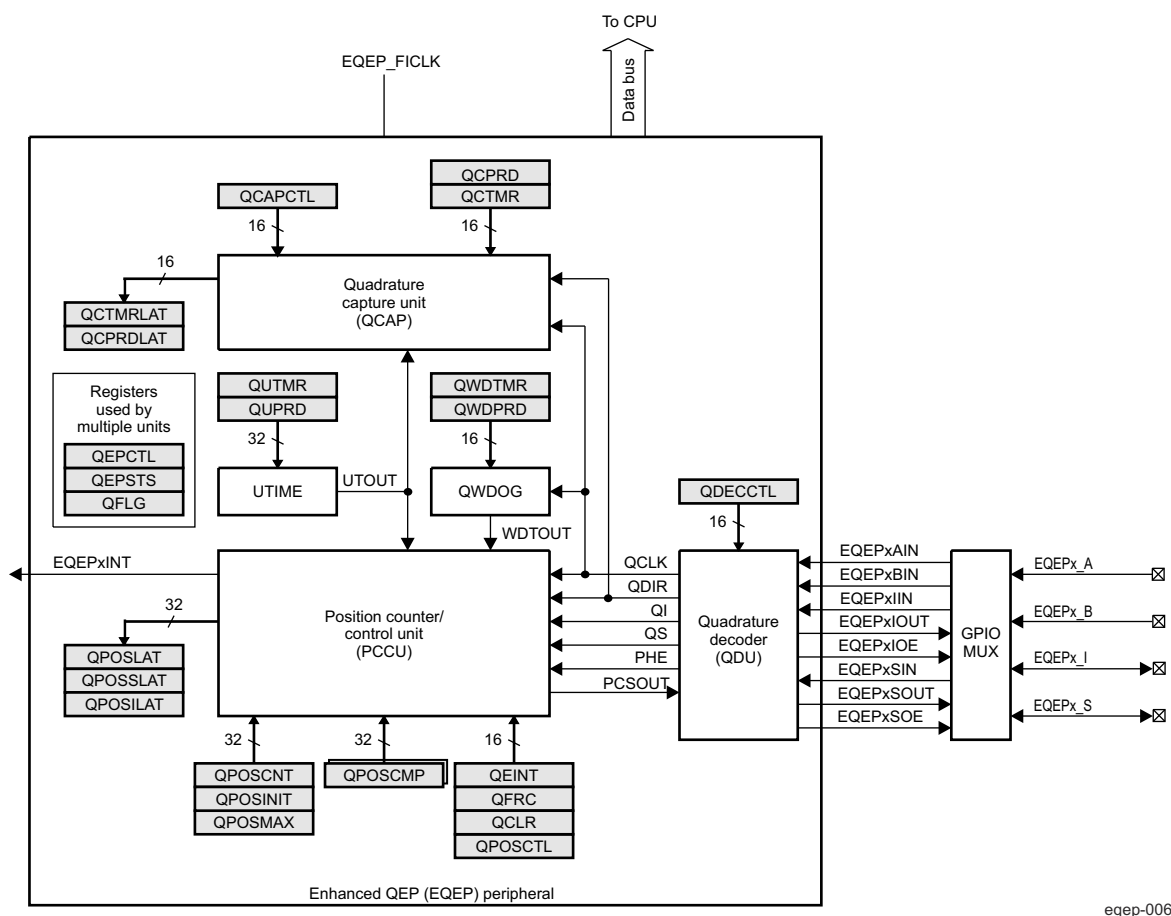

This section provides the EQEP functional description and corresponding functional details about EQEPx inputs.

#### Note

Multiple identical EQEP modules can be contained in a system. For actual number of EQEP modules integrated in the device, refer to *EQEP Integration*. The letter x within a signal or module name is used to indicate a generic EQEP instance on a device. For example, output interrupt request, EQEP0\_EQEP\_INT\_0 belongs to EQEP0, EQEP1\_EQEP\_INT\_0 belongs to EQEP1, and so forth.

The EQEP peripheral contains the following major functional units (as shown in Figure 12-350):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Three stage/six stage digital noise filter
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG).

**Figure 12-350. Functional Block Diagram of the EQEP Peripheral**

#### 12.4.4.4.1 EQEP Inputs

The EQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- EQEPx\_A and EQEPx\_B: These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock mode: The EQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of EQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPa signal leads QEPb signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The EQEPx\_A pin provides the clock input and the EQEPx\_B pin provides the direction input.
- EQEPx\_I: Index or Zero Marker: The EQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the EQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- EQEPx\_S: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

Figure 12-351 shows a functional block diagram of the QDU.

**Figure 12-351. Functional Block Diagram of Decoder Unit**

#### 12.4.4.4.2.1 EQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode.

##### 12.4.4.4.2.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

#### Direction Decoding

The direction decoding logic of the EQEP circuit determines which one of the sequences (EQEPA, EQEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the EQEP status register (EQEP\_QEP\_STS\_CT). [Table 12-296](#) and [Figure 12-352](#) show the direction decoding logic in truth table and state machine form. Both edges of the EQEPA and EQEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the EQEP logic is four times that of each input sequence. [Figure 12-353](#) shows the direction decoding and clock generation from the EQEP input signals.

#### Phase Error Flag

In normal operating conditions, quadrature inputs EQEPA and EQEPB will be 90 degrees out of phase. The phase error flag (QPEI\_FLG) is set in the EQEP\_QINT\_EN\_FLG register when edge transition is detected simultaneously on the EQEPA and EQEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 12-352](#) are invalid transitions that generate a phase error.

#### Count Multiplication

The EQEP position counter provides 4× times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both EQEP input clocks (EQEPA and EQEPB) as shown in [Figure 12-353](#).

#### Reverse Count

In normal quadrature count operation, EQEPA input is fed to the QA input of the quadrature decoder and the EQEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

**Table 12-296. Quadrature Decoder Truth Table**

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment (+1)
	QB↓	DOWN	Decrement (-1)
	QA↓	TOGGLE	Increment (+1) or Decrement (-1)
QA↓	QB↓	UP	Increment (+1)
	QB↑	DOWN	Decrement(-1)
	QA↑	TOGGLE	Increment (+1) or Decrement (-1)
QB↑	QA↑	DOWN	Increment (+1)
	QA↓	UP	Decrement (-1)
	QB↓	TOGGLE	Increment (+1) or Decrement (-1)
QB↓	QA↓	DOWN	Increment (+1)
	QA↑	UP	Decrement (-1)
	QB↑	TOGGLE	Increment (+1) or Decrement (-1)

**Figure 12-352. Quadrature Decoder State Machine**

**Figure 12-353. Quadrature-clock and Direction Decoding**

#### 12.4.4.4.2.1.2 EQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. EQEPA input will provide the clock for position counter and the EQEPB input will have the direction information. The position counter is incremented on every rising edge of a EQEPA input when the direction input is high and decremented when the direction input is low.

#### 12.4.4.4.2.1.3 EQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

#### 12.4.4.4.2.1.4 EQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables clock generation to the position counter on both edges of a EQEPA input, thereby increasing the measurement resolution by 2× factor.

#### 12.4.4.4.2.2 EQEP Input Polarity Selection

Each EQEP input can be inverted using the in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL[8-5]) control bits. As an example, setting of the QIP bit in EQEP\_QDEC\_QEP\_CTL inverts the index input.

#### 12.4.4.4.2.3 EQEP Position-Compare Sync Output

The EQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (EQEP\_QPOSCNT) and the position-compare register (EQEP\_QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables the position-compare sync output and the SPSEL bit in EQEP\_QDEC\_QEP\_CTL selects either an EQEP index pin or an EQEP strobe pin.

#### 12.4.4.4.3 EQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (EQEP\_QDEC\_QEP\_CTL and EQEP\_QCAP\_QPOS\_CTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

##### 12.4.4.4.3.1 EQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement).

In all the above operating modes, position counter is reset to 0 on overflow and to QPOS MAX bifield value in EQEP\_QPOS MAX register on underflow. Overflow occurs when the position counter counts up after QPOS MAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in EQEP\_QINT\_EN\_FLG register.

#### 12.4.4.4.3.1.1 EQEP Position Counter Reset on Index Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM] = 0b00)

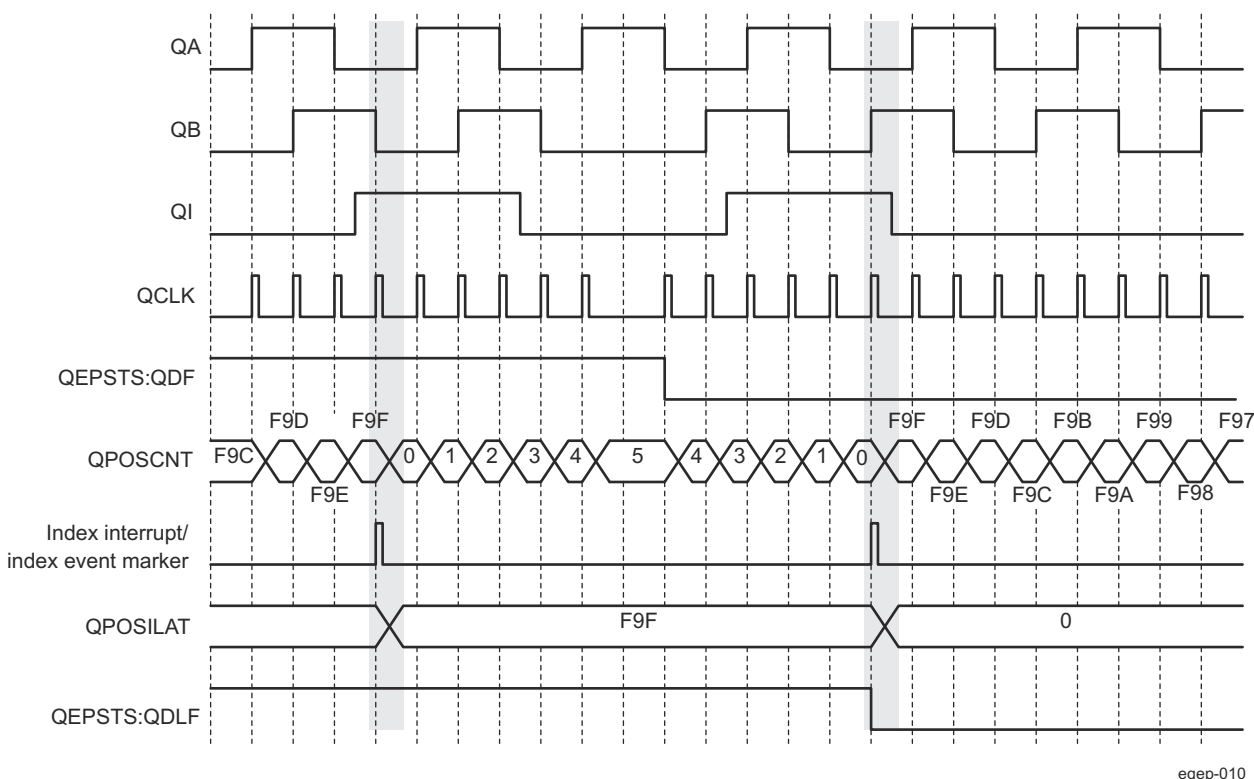

If the index event occurs during the forward movement, then position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP\_QPOS MAX register on the next EQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in EQEP\_QEP\_STS\_CT registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of EQEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of EQEPB for the forward rotation and on the rising edge of EQEPB for the reverse rotation as shown in Figure 12-354.

The position-counter value is latched to the EQEP\_QPOSILAT register and direction information is recorded in the EQEP\_QEP\_STS\_CT[4] QDLF bit on every index event marker. The position-counter error flag (EQEP\_QEP\_STS\_CT[0] PCEF) and error interrupt flag (EQEP\_QINT\_EN\_FLG[17] PCEI\_FLG) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (EQEP\_QEP\_STS\_CT[0] PCEF) is updated on every index event marker and an interrupt flag (EQEP\_QINT\_EN\_FLG[17] PCEI\_FLG) will be set on error that can be cleared only through software.

The index event latch configuration EQEP\_QDEC\_QEP\_CTL[21-20] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

eqep-010

**Figure 12-354. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or F9Fh)**

#### 12.4.4.4.3.1.2 EQEP Position Counter Reset on Maximum Position (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b01)

If the position counter is equal to QPOSMAX (in EQEP\_QPOSMAX register), then the position counter is reset to 0 on the next EQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to 0, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 12-355 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF); it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL= 0b11).

**Figure 12-355. Position Counter Underflow/Overflow (QPOSMAX = 4)**

eqep-011

#### 12.4.4.4.3.1.3 Position Counter Reset on the First Index Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP\_QPOSMAX register on the next EQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 12.4.4.4.3.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in EQEP\_QEP\_STS\_CT registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11).

#### 12.4.4.4.3.1.4 Position Counter Reset on Unit Time out Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP\_QPOSILAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP\_QPOSMAX register, depending on the direction mode selected by EQEP\_QDEC\_QEP\_CTL[15-14] QSRC bits on a unit time event). This is useful for frequency measurement.

#### 12.4.4.4.3.2 EQEP Position Counter Latch

The EQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP\_QPOSCNT) into QPOSILAT (EQEP\_QPOSILAT register) and QPOSSLAT (EQEP\_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

##### 12.4.4.4.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b01 and EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b10 modes).

In such cases, the EQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP\_QEP\_STS\_CT[4] QDLF bit on every index event marker.

- Latch on Rising edge (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b01)
- Latch on Falling edge (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b10)
- Latch on Index Event Marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (EQEP\_QINT\_EN\_FLG[26] IELI\_FLG) is set when the position counter is latched to the EQEP\_QPOSILAT register. The index event latch configuration bits are ignored when EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b00.

When Position counter reset on an index event mode is selected through EQEP\_QDEC\_QEP\_CTL[29-28] PCRM bit field (value: 0h), EQEP\_QDEC\_QEP\_CTL[21-20] IEL bit field must be configured to 0h and position counter value is latched into the EQEP\_QPOSILAT[31-0] QPOSILAT register for every index marker.

##### Latch on Rising Edge

(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b01)

The position counter value (QPOSCNT) is latched to the EQEP\_QPOSILAT register on every rising edge of an index input.

##### Latch on Falling Edge

(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b10)

The position counter value (QPOSCNT) is latched to the EQEP\_QPOSILAT register on every falling edge of index input.

##### Latch on Index Event

Marker/Software Index Marker  
(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11)

The first index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and

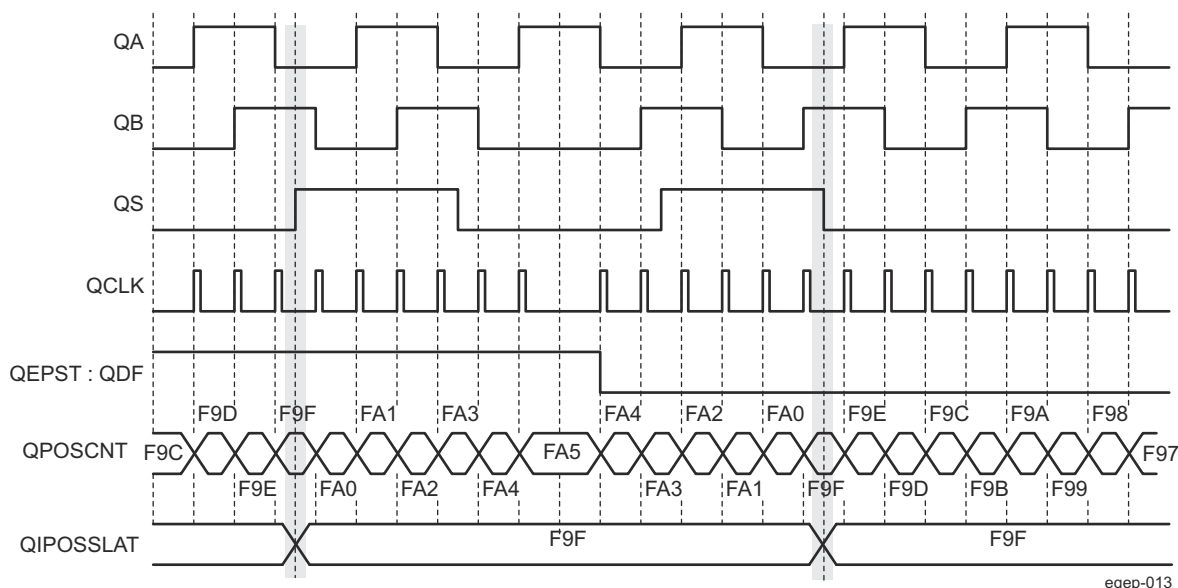

### 12.4.4.4.3.2 EQEP Strobe Event Latch

The position-counter value is latched to the EQEP\_QPOSSLAT register on the rising edge of the strobe input (QCLK) by clearing the EQEP\_QDEC\_QEP\_CTL[22] SEL bit. Latching on the falling edge of the strobe input (QCLK) can be done by inverting the strobe input using the EQEP\_QDEC\_QEP\_CTL[5] QSP bit.

If the EQEP\_QDEC\_QEP\_CTL[22] SEL bit is set, then the position counter value is latched to the EQEP\_QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 12-357](#).

The strobe event latch interrupt flag (EQEP\_QINT\_EN\_FLG[25] SELI\_FLG) is set when the position counter is latched to the EQEP\_QPOSSLAT register.

**Figure 12-357. EQEP Strobe Event Latch (EQEP\_QDEC\_QEP\_CTL[22] SEL = 0b1)**

#### 12.4.4.4.3.3 EQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

#### Note

When all of the above events occur simultaneously, the sequence of priority is as follows: 1) Software Initialization, 2) strobe event initialization, 3) Index Event Initialization.

#### Index Event Initialization (IEI)

The EQEPx\_I index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the EQEP\_QDEC\_QEP\_CTL[25-24] IEI bits are 2h, then the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (EQEP\_QDEC\_QEP\_CTL[25-24] IEI) is set when the position counter is initialized with a value in the EQEP\_QPOSINIT register.

If EQEP\_QDEC\_QEP\_CTL[25-24] IEI bit field is configured with value 0h (default) or 1h, the index event initialization of position counter is disabled.

If EQEP\_QDEC\_QEP\_CTL[25-24] IEI bit field is configured with value 3h, then the the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the falling edge of strobe input signal.

#### Strobe Event Initialization (SEI)

If the EQEP\_QDEC\_QEP\_CTL[27-26] SEI bits are 2h, then the position counter is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input.

If the EQEP\_QDEC\_QEP\_CTL[27-26] SEI bits are 3h, then the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag (EQEP\_QDEC\_QEP\_CTL[27-26] SEI) is set when the position counter is initialized with a value in the EQEP\_QPOSINIT register.

If EQEP\_QDEC\_QEP\_CTL[27-26] SEI bit field is configured with value 0h (default) or 1h, the strobe event initialization of position counter is disabled.

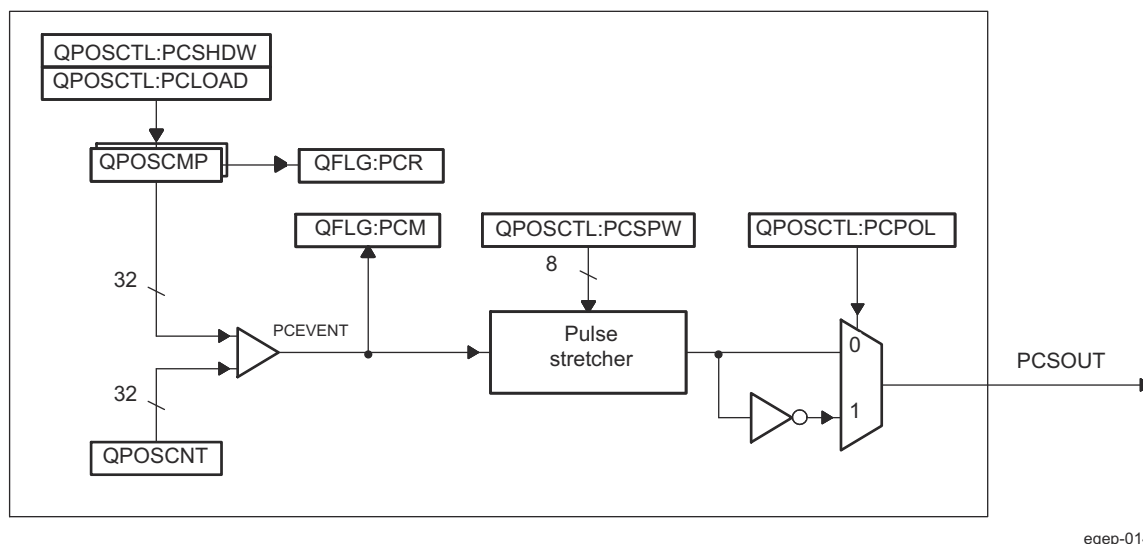

#### Software Initialization (SWI)

The position counter can be initialized in software by writing a 1h to the EQEP\_QDEC\_QEP\_CTL[23] SWI bit, which will automatically be cleared after initialization.

#### 12.4.4.4.3.4 EQEP Position-Compare Unit

The EQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. [Figure 12-358](#) shows a diagram. The position-compare (EQEP\_QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the EQEP\_QCAP\_QPOS\_CTL[31] PCSHDW bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

**Figure 12-358. EQEP Position-compare Unit**

In shadow mode, SW can configure the position-compare unit (EQEP\_QCAP\_QPOS\_CTL[30] PCLOAD) to load the shadow register value into the active register on the following events and to generate the position-compare ready (EQEP\_QINT\_EN\_FLG[23] PCRI\_FLG) interrupt after loading.

- Load on compare match
- Load on position-counter zero event.

The position-compare match (EQEP\_QINT\_EN\_FLG[24] PCMI\_FLG) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (EQEP\_QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if EQEP\_QPOSCMP bitfield POSCMP = 0x2, the position-compare unit generates a position-compare event on the transition from 1 to 2 of the EQEP position counter for forward counting direction and on the transition from 3 to 2 of the EQEP position counter for reverse counting direction (see [Figure 12-359](#)).

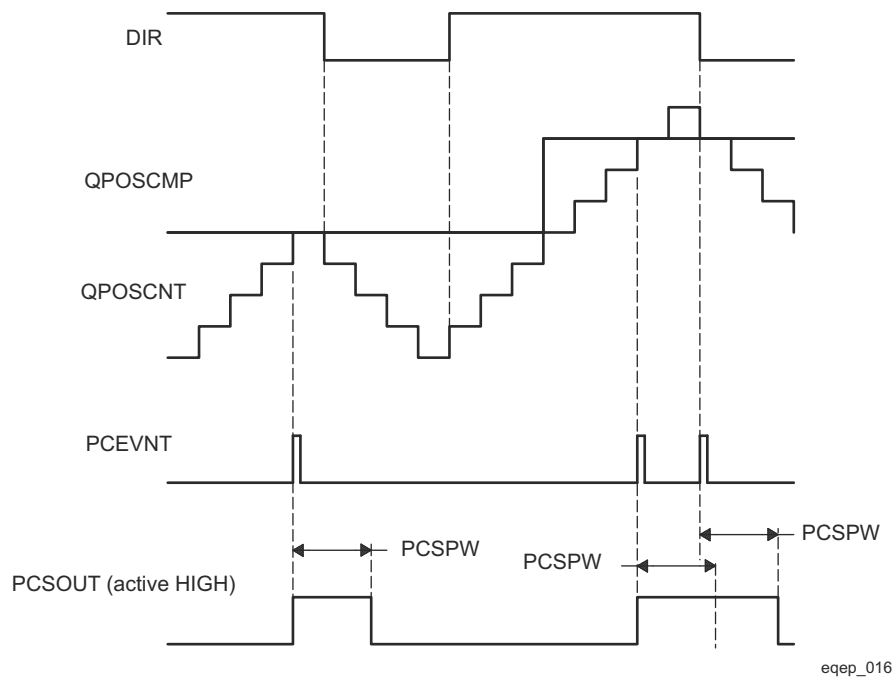

#### Note

When EQEP\_QCAP\_QPOS\_CTL[30] PCLOAD = 0h, the shadow register is loaded into the active register as soon as POSCNT becomes zero, and it should not generate another shadow load if the POSCNT continues to stay at zero

**Figure 12-359. EQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 12-360](#).

**Figure 12-360. EQEP Position-compare Sync Output Pulse Stretcher**

#### 12.4.4.4 EQEP Edge Capture Unit

The EQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 12-361](#). This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (19)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 12-362](#))
- $\Delta T$  - Elapsed time between unit position events
- $v(k)$  - Velocity at time instant "k"

The EQEP capture timer (QCTMR bitfield in EQEP\_QCTMR register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the EQEP\_QCAP\_QPOS\_CTL[6-4] CCPS bits. The capture timer QCTMR value is latched into the capture period register (EQEP\_QC\_PRD\_TLAT) on every unit position event and then the capture timer is reset.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the EQEP overflow error flag (EQEP\_QEP\_STS\_CT[3] COEF) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (EQEP\_QEP\_STS\_CT[2] CDEF).

Capture Timer (EQEP\_QCTMR register) and Capture period register (EQEP\_QC\_PRD\_TLAT) can be configured to latch on following events.

- CPU read of EQEP\_QPOSCNT register
- Unit time-out event

If the EQEP\_QDEC\_QEP\_CTL[18] QCLM bit is cleared, then the capture timer and capture period values are latched into the EQEP\_QC\_PRD\_TLAT and EQEP\_QCPRDLAT registers, respectively, when the CPU reads the position counter in EQEP\_QPOSCNT.

---

#### Note

Capture timer and capture period values are not latched for an emulation read.

---

If the EQEP\_QDEC\_QEP\_CTL[18] QCLM bit is set, then the position counter, capture timer, and capture period values are latched into the EQEP\_QPOSLAT, EQEP\_QC\_PRD\_TLAT and EQEP\_QCPRDLAT registers, respectively, on unit time out.

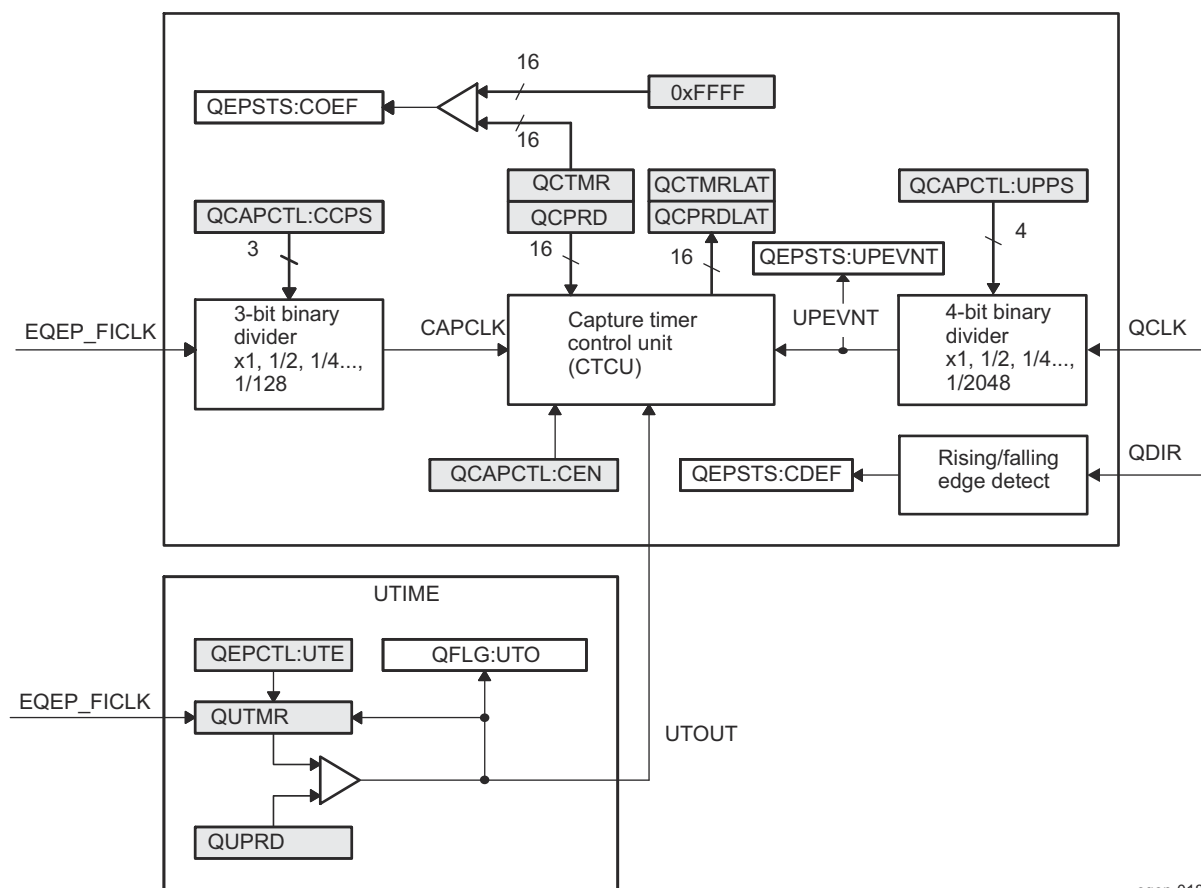

[Figure 12-363](#) shows the capture unit operation along with the position counter.

---

#### Note

The EQEP\_QCAP\_QPOS\_CTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLKOUT/4 to SYSCLKOUT/8, where SYSCLKOUT is equivalent to EQEPx\_FICLK). The capture unit must be disabled before changing the prescaler.

---

**Figure 12-361. EQEP Edge Capture Unit**

N - Number of quadrature periods selected using EQEP QCAP QPOS CTL[3:0] UPPS bits

**Figure 12-362. Unit Position Event for Low Speed Measurement (EQEP\_QCAP\_QPOS\_CTL[UPPS] = 0010)**

**Figure 12-363. EQEP Edge Capture Unit - Timing Details**

Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (20)$$

OR

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (21)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

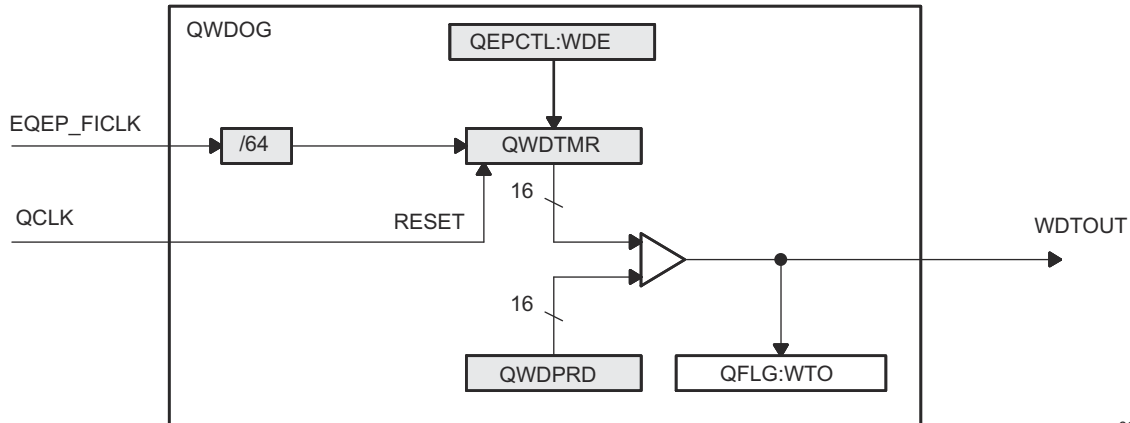

t(k-1): Time instant "k - 1"

Unit time (T) and unit period (X) are configured using the EQEP\_QUPRD and EQEP\_QCAP\_QPOS\_CTL[3-0] UPPS registers. Incremental position output and incremental time output is available in the EQEP\_QOSLAT and EQEP\_QCPRLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
$\Delta X$	Incremental Position = QOSLAT(k) - QOSLAT(k - 1)
X	Fixed unit position defined by sensor resolution and QCAPCTL[3-0] UPPS bits
$\Delta T$	Capture Period Latch (EQEP_QCPRLAT)

#### 12.4.4.4.5 EQEP Watchdog

The EQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The EQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP\_QINT\_EN\_FLG[20] WTOI\_FLG). The time-out value is programmable through the watchdog period bit field (EQEP\_QWD\_TMR\_PRD[31-16] QWDPRD).

eqep-022

**Figure 12-364. EQEP Watchdog Timer**

The EQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event. The latched values are used for velocity calculation as described in Section [Section 12.4.4.4.4](#).

Figure 12-366 shows how the interrupt mechanism works in the EQEP module.

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (EQEP\_QINT\_EN\_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (EQEP\_QINT\_EN\_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is only generated to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (EQEP\_QINT\_CLR\_FRC), before any other interrupt pulses are generated. SW can force an interrupt event by way of the interrupt force register (EQEP\_QINT\_CLR\_FRC), which is useful for test purposes.

#### 12.4.4.4.8 Summary of EQEP Functional Registers

Table 12-297 lists the registers with their memory locations, sizes, and reset values.

**Table 12-297. EQEP Control and Status Functional Registers**

Offset	Acronym	Register Description	Size (×16)/ #shadow
0h	EQEP_QPOSCNT	EQEP Position Counter Register	2/0
4h	EQEP_QPOSINIT	EQEP Position Counter Initialization Register	2/0
8h	EQEP_QPOSMAX	EQEP Maximum Position Count Register	2/0
Ch	EQEP_QPOSCMP	EQEP Position-Compare Register	2/1

## 12.5 Audio Peripherals

## 12.5.1 Audio Tracking Logic (ATL)

This chapter describes the integration of the Audio Tracking Logic (ATL) subsystem in the device.

### 12.5.1.1 ATL Overview

The Audio Tracking Logic (ATL) is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock. This same IP can also be used generically to track errors between two reference signals (such as frame syncs) and generate a modulated clock output (using software-controlled cycle stealing) which averages to some desired frequency. This process can be used as a hardware assist for asynchronous sample rate conversion algorithms.

#### 12.5.1.1.1 ATL Features Overview

The ATL module supports the following features:

- One ATL module, containing four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local audio word select [AWS] and baseband word select [BWS])
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing. The intention is to use these clocks to derive audio output bit clock on MCASP
- Selection between ATL\_VCLK clock or functional ATL\_PCLK to run error counting timers and to derive modulated ATCLK clock outputs.
- Clock and reset management: Receives clock and reset signals from the device PSC module. The ATL module receives hardware reset.
- Power management: The ATL belongs to the PD0 power domain.
- Local software reset

#### 12.5.1.1.2 ATL Ports

**Table 12-298. ATL Clocks and Resets**

Clocks	
Module Clock Input	Description
ATL_VCLK	ATL interface clock
ATL_PCLK	ATL functional clock.

## 12.5.2 Multichannel Audio Serial Port (MCASP)

This section describes the Multichannel Audio Serial Port (MCASP).

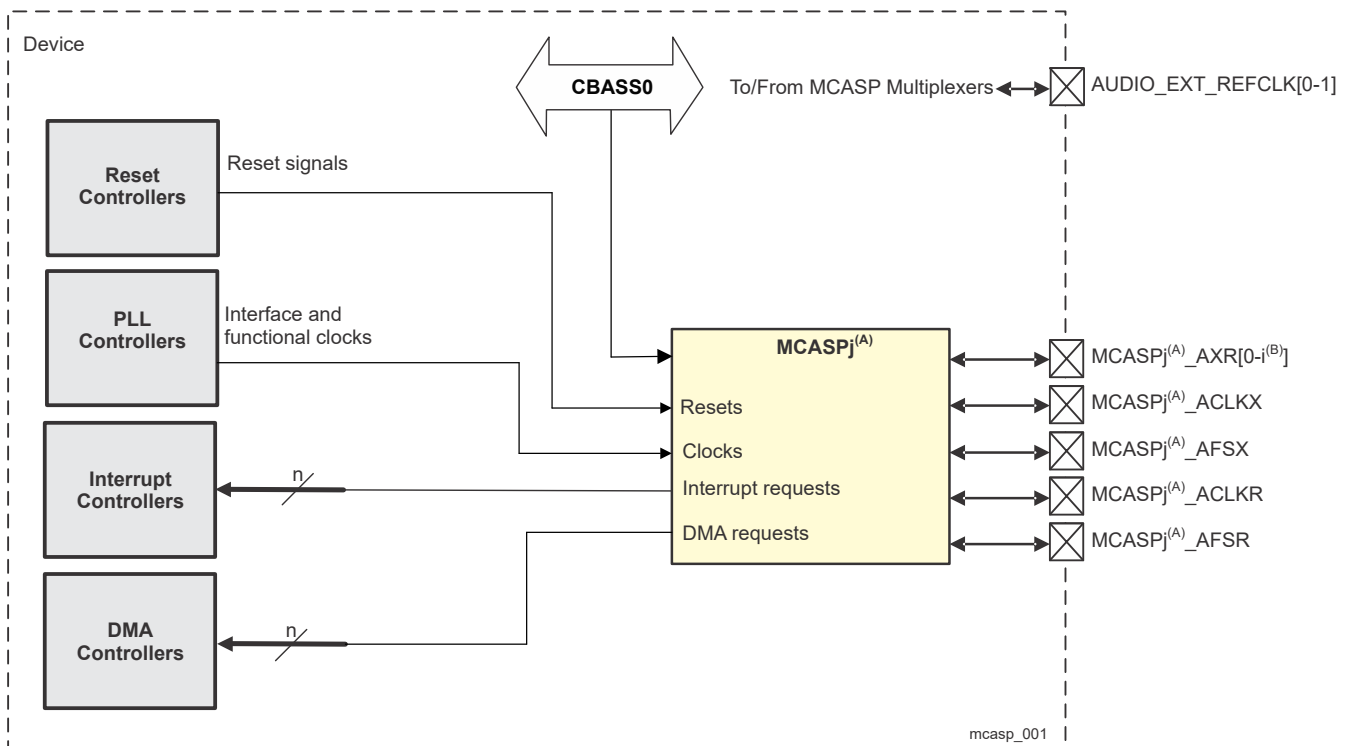

### 12.5.2.1 MCASP Overview

This section introduces the Multichannel Audio Serial Port (MCASP) module and describes its main functions and connections in the device.

The MCASP functions as a general-purpose audio serial port are optimized to the requirements of various audio applications. The MCASP module can operate in both transmit and receive modes. The MCASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an inter-component digital audio interface transmission (DIT). The MCASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although inter-component digital audio interface reception (DIR) mode (this is, S/PDIF stream receiving) is not natively supported by the MCASP module, a specific TDM mode implementation for the MCASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

Figure 12-367 shows the MCASP modules overview.

A. j represents a valid instance of MCASP in a domain

B. i represents the maximum number of MCASPj\_AXR signals - 1.

Figure 12-367. MCASP Modules Overview

#### 12.5.2.1.1 MCASP Features

Each MCASP module includes the following main features:

- Independent serializer for each AXRx channel of each MCASP module
- Clock stop request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- Interconnect interface port for CBASS0

- Two independent clock generator modules for transmit and receive (clocking flexibility allows the MCASP to receive and transmit at different rates. For example, the MCASP can receive data at 48 kHz, but output up-sampled data at 96 kHz or 192 kHz)
- Each MCASP module functional clock can be generated:
  - Internally (controller mode)
  - Supplied over MCASP serial interface (target mode)
  - Has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator
  - TDM streams from 2 to 32, and 384 time slots
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits
  - Data formatter for bit manipulation
- Glueless connection to audio Analog-to-Digital Converters (ADC), Digital-to-Analog Converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components
- Wide variety of I2S and similar bit-stream format
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats
  - Enhanced channel status/user data RAM
- 384-slot TDM with external digital audio interface receiver (DIR) device
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the MCASP receive section
- Support for 2 × DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the MCASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the MCASP serializers
  - All transmit DMA requests are mapped to the device DMA controllers
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupts

---

#### Note

Because a serializer receive and transmit channels data is shared on the same MCASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

---

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

#### 12.5.2.1.2 Unsupported Features

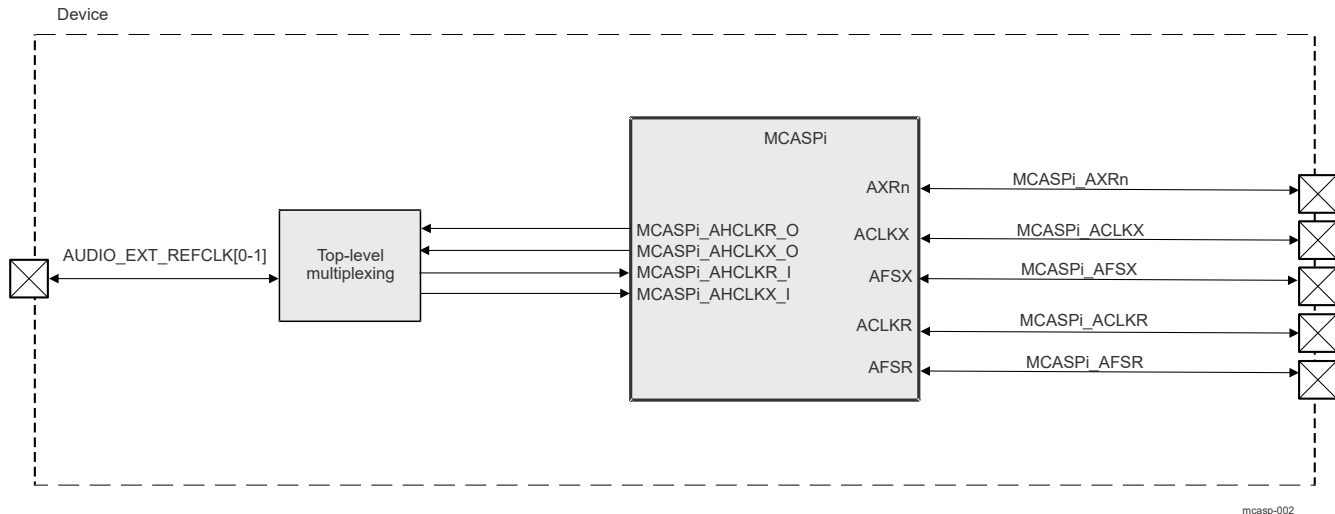

See the *Module Integration* section for information about unsupported features.

### 12.5.2.2 MCASP Environment

This section describes the MCASP application fields from an environment point of view (external connections). This section also lists the possible interfaces and describes the protocol and data format used in each case.

#### 12.5.2.2.1 MCASP Signals

Figure 12-368 shows all of the MCASP interface signals.

#### Note

i represents a MCASP instance. See the device datasheet for available domains and MCASP instances.

n represents a AXR signal from a MCASP instance. See the device datasheet for available domains and MCASP instances.

**Figure 12-368. MCASP Interface Signals**

Table 12-299 describes the MCASP I/O signals.

**Table 12-299. MCASP I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCASPi<sup>(3)</sup> module</b>				
AXR0	MCASPi <sup>(3)</sup> _AXR0	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	MCASPi <sup>(3)</sup> _AXR1	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	MCASPi <sup>(3)</sup> _AXR2	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	MCASPi <sup>(3)</sup> _AXR3	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	MCASPi <sup>(3)</sup> _AXR4	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	MCASPi <sup>(3)</sup> _AXR5	I/O	Audio transmit/receive data - channel 5	HiZ
AXR6	MCASPi <sup>(3)</sup> _AXR6	I/O	Audio transmit/receive data - channel 6	HiZ
AXR7	MCASPi <sup>(3)</sup> _AXR7	I/O	Audio transmit/receive data - channel 7	HiZ
AXR8	MCASPi <sup>(3)</sup> _AXR8	I/O	Audio transmit/receive data - channel 8	HiZ
AXR9	MCASPi <sup>(3)</sup> _AXR9	I/O	Audio transmit/receive data - channel 9	HiZ
AXR10	MCASPi <sup>(3)</sup> _AXR10	I/O	Audio transmit/receive data - channel 10	HiZ
AXR11	MCASPi <sup>(3)</sup> _AXR11	I/O	Audio transmit/receive data - channel 11	HiZ
AXR12	MCASPi <sup>(3)</sup> _AXR12	I/O	Audio transmit/receive data - channel 12	HiZ

**Table 12-299. MCASP I/O Signals (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
AXR13	MCASPi <sup>(3)</sup> _AXR13	I/O	Audio transmit/receive data - channel 13	HiZ
AXR14	MCASPi <sup>(3)</sup> _AXR14	I/O	Audio transmit/receive data - channel 14	HiZ
AXR15	MCASPi <sup>(3)</sup> _AXR15	I/O	Audio transmit/receive data - channel 15	HiZ
ACLKX	MCASPi <sup>(3)</sup> _ACLKX	I/O	Transmit bit clock	HiZ

ACLKR	MCASPi <sup>(3)</sup> _ACLKR	I/O	Receive bit clock	HiZ
AFSR	MCASPi <sup>(3)</sup> _AFSR	I/O	Receive frame synchronization	HiZ
MCASPi <sup>(3)</sup> _AHCLKX_I/O	AUDIO_EXT_REFCLK[0-1]	I/O	Transmit high-frequency controller clock. See <i>Module Integration</i>	HiZ
MCASPi <sup>(3)</sup> _AHCLKR_I/O	AUDIO_EXT_REFCLK[0-1]	I/O	Receive high-frequency controller clock. See <i>Module Integration</i>	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

(2) HiZ = High Impedance

(3) i represents a MCASP instance. See the device datasheet for available domains and MCASP instances.

#### Note

MCASPi\_AHCLKR\_I/O and MCASPi\_AHCLKX\_I/O signals are multiplexed to AUDIO\_EXT\_REFCLK[0-1] device pins.

#### Note

For MCASPi\_ACLKR\_I/O, MCASPi\_ACLKX\_I/O, MCASPi\_AHCLKR\_I/O and MCASPi\_AHCLKX\_I/O signals to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### Note

A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the *MCASP\_PDIR* register and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP\_SRCTLn (n = 0 to 15).

### 12.5.2.2.2 MCASP Protocols and Data Formats

#### 12.5.2.2.2.1 Protocols Supported

The MCASP supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots
  - S/PDIF, IEC60958-1, AES-3 formats
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots

- TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to MCASP using the I2S protocol (one time slot for each DIR subframe)

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AFSR/X and AHCLKR/X\_I/O
- Slot length (number of bits per time slot): 2, 4, 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 2, 4, 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0, 1, 2 bit clocks
- Left/right alignment of word inside slot
- Bit order: MSB first or LSB first
- Bit mask/pad/rotate function
  - Automatically aligns data internally in either Q31 or integer formats
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

---

#### Note

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

---

In DIT mode for MCASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame
- Biphasic encoded 3.3 V Output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Support for consumer and professional applications
- Separate valid bit (V) for subframe A, B
- Stereo Support Only (Mono means send data 2 × via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphasic Mark Encoded Data).

---

#### Note

The MCASP does NOT natively support DIR-mode reception (this is, receiving in the S/PDIF format). To allow this, the MCASP can use a DIR-input to I2S-output converter implemented by an external device (this is, external DIR component). To facilitate reception in this case, the TDM mode of MCASP receivers logic is extended to support a non-standard 384-slot TDM stream.

---

---

#### Note

An external transceiver must be connected to the MCASP port in the device to translate the electrical signals delivered by the MCASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

---

#### 12.5.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a MCASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 12-369](#) shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn.

Figure 12-369 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the MCASP are configured to operate synchronously.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

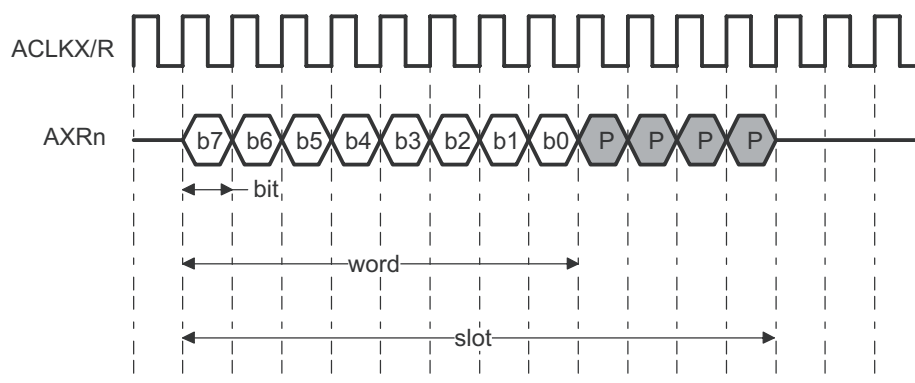

- Word:

A word is a group of bits that make up the data being transferred between the MCASP and the external device. Figure 12-369 shows an 8-bit word.

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the MCASP and the external device. In Figure 12-369, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the MCASP on an AXRn pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, this is, left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 12-370 shows these options.

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.

mccasp-003

**Figure 12-369. Definition of Bit, Word, and Slot**

**Figure 12-370. Bit Order and Word Alignment Within a Slot Examples**

- Frame

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 12-371](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. [Figure 12-371](#) does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the MCASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see [Section 12.5.2.2.2.3, TDM Format](#) and [Section 12.5.2.2.2.5, S/PDIF-Coding Format](#).

### Note

All of the MCASP serializers share the same, device pad accessible, clock and frame signals, as follows:

- AHCLKX\_I/O, ACLKX and AFSX for the transmitting section
- AHCLKR\_I/O, ACLKR and AFSR for the receiving section

**Figure 12-371. Definition of Frame and Frame-Sync Width**

The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See [Section 12.5.2.2.2.3, TDM Format](#) for details on the TDM protocol.
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The MCASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The MCASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The MCASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a MCASP time slot corresponds to a DIT/DIR subframe.

#### 12.5.2.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one MCASP data pin - AXRn is illustrated on [Figure 12-372](#).

(1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported

(2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

**Figure 12-372. TDM Format - 6 channel example**

The TDM format uses three signals in a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also [Section 12.5.2.2.2.2](#)), the latter being also referred to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For MCASP, there is an option to offset the first bit of the first slot with a 0-, 1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

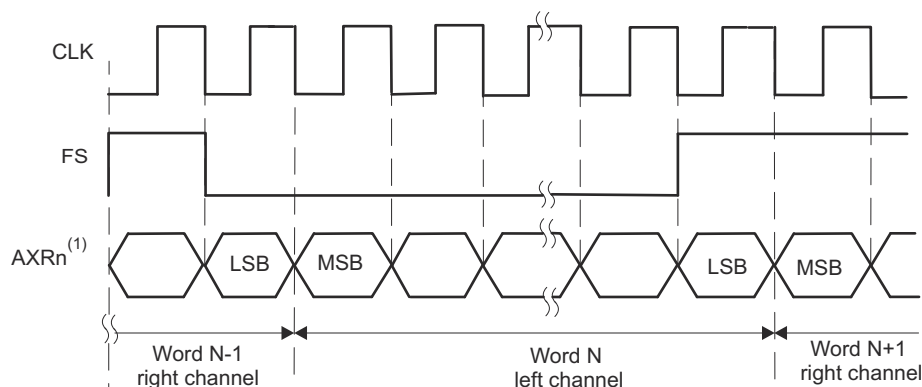

In a typical audio system involving MCASP module, a single TDM data frame is transferred during each sample period  $T_s$  of a data converter. The user has following choices to implement multiple channels:

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available MCASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the MCASP pins AXRn.

#### 12.5.2.2.2.4 I2S Format

The TDM transfer mode of the MCASP supports the I2S format when frame is configured to have 2 slots. The I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. The "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on [Figure 12-373](#).

(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-007

**Figure 12-373. I2S Format Overview**

#### 12.5.2.2.2.5 S/PDIF Coding Format

The MCASP transmitter supports the S/PDIF format with 3.3 V biphasemark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the MCASP. This section briefly discusses the S/PDIF coding format.

#### Note

The DIR- reception of S/PDIF format frames is NOT natively supported from the device MCASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the MCASP TDM-only compatible receiver input.

#### 12.5.2.2.2.5.1 Biphasemark Code

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). For each serializer transmitter  $n$ , the clock, frame, and data are embedded in only one signal - the data signal  $AXR_n$ . In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 12-374](#) and [Table 12-300](#) show how data is encoded to the BMC format.

As shown in [Figure 12-374](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to  $128 \times f_s$ , where  $f_s$  is the sample rate (see [Section 12.5.2.2.2.5.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

**Figure 12-374. Biphas-Mark Code**

**Table 12-300. Biphas-Mark Encoder**

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

#### 12.5.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. [Figure 12-375](#) shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See [Table 12-301](#).
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8–27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in [Table 12-301](#), the preambles (time intervals 0–3) are also defined with even parity.

**Figure 12-375. S/PDIF Subframe Format**

As listed in [Table 12-301](#), the MCASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the MCASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

**Table 12-301. Preamble Codes**

Preamble Code <sup>(1)</sup>	Previous Logical State	Logical States on pin AXRn <sup>(2)</sup>	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

- (1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.
- (2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

#### 12.5.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see [Figure 12-376](#)). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency  $f_s$ . The S/PDIF format clock rate is therefore  $128 \times f_s$  ( $128 = 32$  cells per subframe  $\times 2$  clocks per cell  $\times 2$  subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is  $128 \times 192$  kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

**Figure 12-376. S/PDIF Frame Format**

### 12.5.2.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.5.2.4 MCASP Functional Description

In the text throughout this section a single instance of MCASP is described assuming that all modules are functionally identical. For module availability and integration differences, see [Section 12.5.2.2](#), *MCASP Environment*, and *Module Integration*.

#### 12.5.2.4.1 MCASP Block Diagram

[Figure 12-377](#) shows the major blocks of the MCASP module.

mcasp-012

- A. i represents a valid instance of MCASP in a domain. See the device datasheet for valid instances.
- B. All signals might not be valid for an instance. See the device datasheet for specifics.

**Figure 12-377. MCASP Module Block Diagram**

### Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

#### 12.5.2.4.2 MCASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the MCASP serializers. The first three scenarios are identical between the Tx and Rx part of the MCASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (controller) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for MCASP receivers - RCLK is derived from the bit rate clock of the MCASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the MCASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

##### 12.5.2.4.2.1 MCASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- `MCASP_ACLKXCTL`
- `MCASP_AHCLKXCTL`

In case, the transmit bit clock, ACLKX, is generated internally, the `MCASP_ACLKXCTL[5]` CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the `MCASP_ACLKXCTL[4-0]` CLKXDIV bit field) from the source signal.

If the transmit high-frequency controller clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 12.5.2.4.2](#), the `MCASP_AHCLKXCTL[15]` HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the `MCASP_AHCLKXCTL[11-0]` HCLKXDIV bit field) from the MCASP internal clock source AUXCLK.

Internally, the MCASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 12-378](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If `MCASP_ACLKXCTL[7]` CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the MCASP shifts transmit data at the rising edge of ACLKX. If `MCASP_ACLKXCTL[7]` CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the MCASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 12-378](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between MCASP transmitters and receivers. This is used for example in the MCASP loopback mode.

#### Note

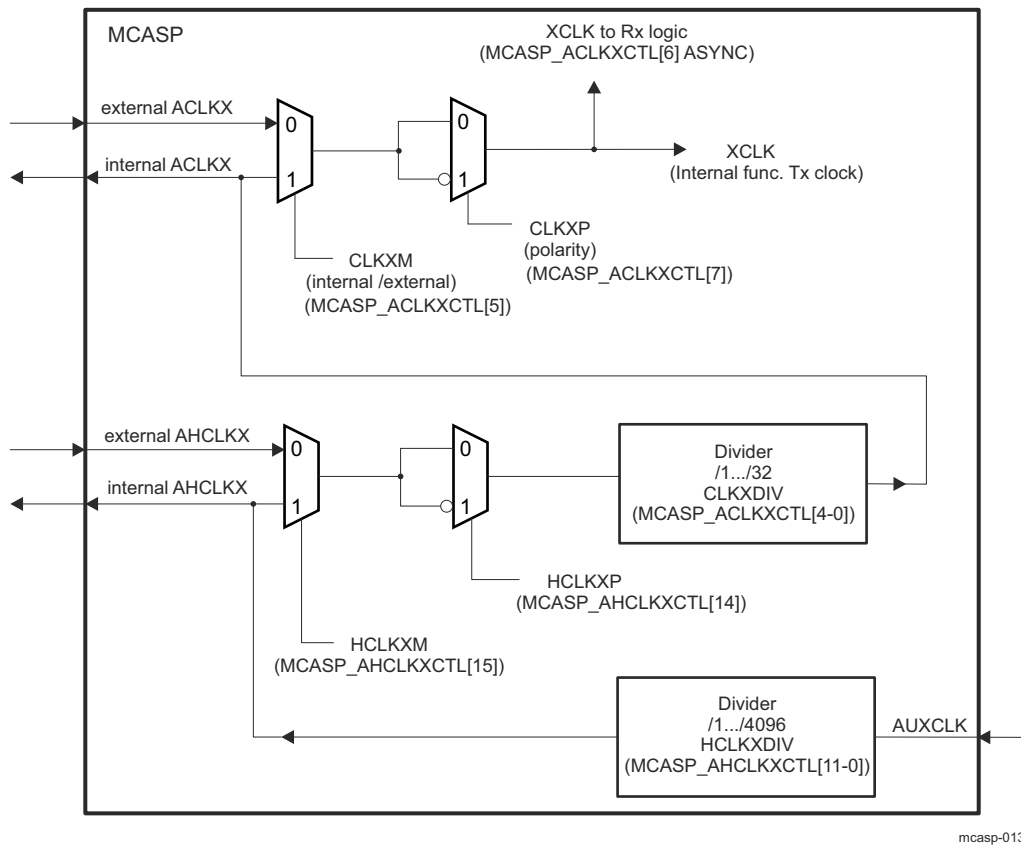

The polarity of ACLKX can be controlled in the *MCASP\_ACLKXCTL*[7] CLKXP bit, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX controller high speed clock via writing the *MCASP\_AHCLKXCTL*[14] HCLKXP bit.

#### Note

In a similar way, the polarity of AHCLKX clock can be controlled in the *MCASP\_AHCLKXCTL*[14] HCLKXP bit, regardless of the AHCLKX signal being internally or externally sourced.

[Figure 12-378](#) presents the block diagram of the transmit clock generator.

**Figure 12-378. Transmit Clock Generator Block Diagram**

### Note

In this device:

- ACLKX is mapped on the device ball ACLKX
- internal AHCLKX is mapped on the device balls AUDIO\_EXT\_REFCLK[0-1]
- external AHCLKX is mapped on MCASPi\_AHCLKX clock from the Device Configuration

For more information about MCASP integration, see [Section 12.5.2.2](#), *MCASP Environment*, and *Module Integration*.

#### 12.5.2.4.2.2 MCASP Receive Clock

The MCASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- *MCASP\_ACLKRCTL*
- *MCASP\_AHCLKRCTL*

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the *MCASP\_ACLKRCTL*[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the *MCASP\_ACLKRCTL*[4-0] CLKRDIV bit field) from the source signal.

If the receive high-frequency controller clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 12.5.2.4.2](#)) and the *MCASP\_AHCLKRCTL*[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the *MCASP\_AHCLKRCTL*[11-0] HCLKRDIV bit field) from the MCASP internal clock source AUXCLK.

### Note

The polarity of ACLKR can be controlled in the *MCASP\_ACLKRCTL*[7] CLKRP bit, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in the *MCASP\_AHCLKRCTL*[14] HCLKRP bit, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the MCASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 12-378](#) and [Figure 12-379](#)) becomes source of the receive clock (RCLK output), when the *MCASP\_ACLKRCTL*[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 12.5.2.4.2.4](#).

[Figure 12-379](#) presents the block diagram of the receive clock generator.

Figure 12-379. Receive Clock Generator Block Diagram

#### Note

In this device:

- ACLKR is mapped on the device ball ACLKR
- internal AHCLKX is mapped on the device balls AUDIO\_EXT\_REFCLK[0-1]
- external AHCLKR is mapped on Device Configuration MCASPi\_AHCLKR from Device Configuration

For more information about MCASP integration, see [Section 12.5.2.2, MCASP Environment](#), and [Module Integration](#).

#### 12.5.2.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The MCASP frame sync generator logic is illustrated in [Figure 12-380](#). The I/O buffers are not part of the MCASP module, and are not shown in the figure.

mcasp-015

**Figure 12-380. Frame Sync Generator Block Diagram**

### Note

For more on MCASP integration, see [Section 12.5.2.2, MCASP Environment](#), and [Module Integration](#).

**For the transmit logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP\_AFSXCTL[1] FSXM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP\_AFSXCTL[0] FSXP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP\_AFSXCTL[4] FXWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP\_AFSXCTL[15-7] XMOD bit field, as follows:
  - For DIT mode (384 slots) - MCASP\_AFSXCTL[15-7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP\_AFSXCTL[15-7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP\_AFSXCTL[15-7] XMOD bit field set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP\_XFMT[17-16] XDATDLY bit field

**For the receive logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP\_AFSRCTL[1] FSRM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP\_AFSRCTL[0] FSRP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP\_AFSRCTL[4] FRWID bit

- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP\_AFSRCTL[15-7] RMOD bit field, as follows:
  - For I2S mode (2 TDM slots) - MCASP\_AFSRCTL[15-7] RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP\_AFSRCTL[15-7] RMOD set in range 0x3 - 0x20
  - For the special 384-slot TDM mode - MCASP\_AFSRCTL[15-7] RMOD = 0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in the MCASP\_RFMT[17-16] RDATA bit field
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP\_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 12.5.2.4.2.4, Synchronous and Asynchronous Transmit and Receive Operations](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

#### Note

Certain restrictions apply to the receive and transmit logic settings, when the MCASP\_ACLKXCTL[6] ASYNC bit is set to 0b0. They are described in [Section 12.5.2.4.2.4](#).

#### 12.5.2.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

##### Synchronous Transmit and Receive Operations -

When the MCASP\_ACLKXCTL[6] ASYNC bit is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 12-379](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When the MCASP\_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP\_DITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ \* RMOD product value must equal XSSZ \* XMOD product value)
- The settings in the MCASP\_ACLKRCTL register are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

##### Asynchronous Transmit and Receive Operations -

When the MCASP\_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

#### Note

Synchronous transmit and receive operations are allowed only in the MCASP TDM (I2S) mode (this is, when MCASP\_DITCTL[0] DITEN = 0b0).

#### 12.5.2.4.3 MCASP Serializers

The MCASP serializers shift serial data in (Rx) and out (Tx) of the MCASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in the MCASP\_XBUFn register) or for receiving (read accessible in the MCASP\_RBUFn register) data. In addition, each serializer has a dedicated control register (MCASP\_SRCTLn) and a serial bidirectional data pin - AXRn. The register MCASP\_SRCTLn allows n-th serializer to be configured as a transmitter, receiver, or as inactive.

There are transmit and receive data formatting units to support data alignment options of the MCASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in the MCASP\_SRCTLn register, shifts in data through MCASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in the MCASP\_SRCTLn register, shifts out data on MCASP corresponding device level bidirectional data pad AXRn (n = 0 to 15).

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for MCASP there are at most a couple of zones, one for transmit and one for receive.

Figure 12-381 shows the serializer block diagram.

**Figure 12-381. Individual Serializer and Connections Within MCASP**

#### Transmission on the n-th serializer is performed as follows:

The MCASP is serviced by writing data into the MCASP\_XBUFFn register, which is an alias of the serializer data buffer - XRBUFFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFFn register in the serializer. The data is then copied from the XRBUFFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

#### Reception from the n-th serializer is performed as follows:

The data is shifted into the MCASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFFn, and can be accessed in the MCASP\_RBUFFn register, which is an alias of the serializer data buffer - XRBUFFn for receive function. When software reads the data from this register, the MCASP passes the data through the receive format unit, hence it returns the formatted data.

#### Serializer controls:

A serializer n is configured as inactive via setting MCASP\_SRCTLn[1-0] SRMOD bit field to 0x0.

For a transmitting serializer, the MCASP\_SRCTLn[3-2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting MCASP\_SRCTLn[1-0] SRMOD bit field to 0x1.

Receive function for the n-th serializer is selected via setting MCASP\_SRCTLn[1-0] SRMOD bit field to 0x2 (n = 0 to 15).

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see [Section 12.5.2.2.2.5, S/PDIF Coding Format](#).

#### 12.5.2.4.4 MCASP Format Units

The MCASP has one transmit data formatting unit and one receive data formatting unit, shared between the device MCASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the MCASP only supports one transmit format at a time. For example, the MCASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the MCASP only supports one data format at a time, and this format applies to all receiving serializers.

#### Note

The MCASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP\_RFMT/MCASP\_XFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the MCASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP\_RFMT/MCASP\_XFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in the MCASP\_RFMT/MCASP\_XFMT register means that the MCASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

##### 12.5.2.4.4.1 Transmit Format Unit

The MCASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

[Figure 12-382](#) shows the transmit formatting unit.

The MCASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - MCASP\_XFMT:

- XRVRs: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

mcasp-017

**Figure 12-382. Transmit Format Unit**

As shown in [Figure 12-382](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP\_XFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.4.10.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP\_XMASK[31-0] XMASK contents. The masked data is then right-rotated to the MCASP\_XFMT[2-0] XROT bit field positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

#### 12.5.2.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

### Note

Note that, TDM word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 12-302](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 12-302](#) assumes that all slot size (SLOT in [Table 12-302](#)) and word size (WORD in [Table 12-302](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter (typically Q31 or integer).

**Table 12-302. MCASP TFU TDM Mode Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_XFMT bits	
			XROT <sup>(1)</sup>	XRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first <sup>(2)</sup>	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

#### 12.5.2.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP\_XFMT[17-16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP\_XFMT[2-0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP\_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP\_XMASK[32] XMASK = 0xFFFFFFFF00 – 0xFFFFFFFF0000
- MCASP\_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP\_XFMT[2-0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)

- MCASP\_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP\_XMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP\_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 12-303](#) should be applied to MCASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the MCASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

**Table 12-303. MCASP TFU DIT-Mode Example Settings**

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFF000	0x3
LEFT	24	8	0xFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x0000FFFF	0x0
RIGHT	24	0	0x0000FFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the MCASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 12-303](#), the user must set XMASK = 0xFFFF000, and to select a right-rotation to 12 positions (XROT = 0x3).

- After applying 0-s (XPAD = 0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the MCASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table MCASP TFU Example Settings, user is supposed to set XMASK = 0x0000FFFF, and to select right-rotation to 0 positions (XROT = 0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

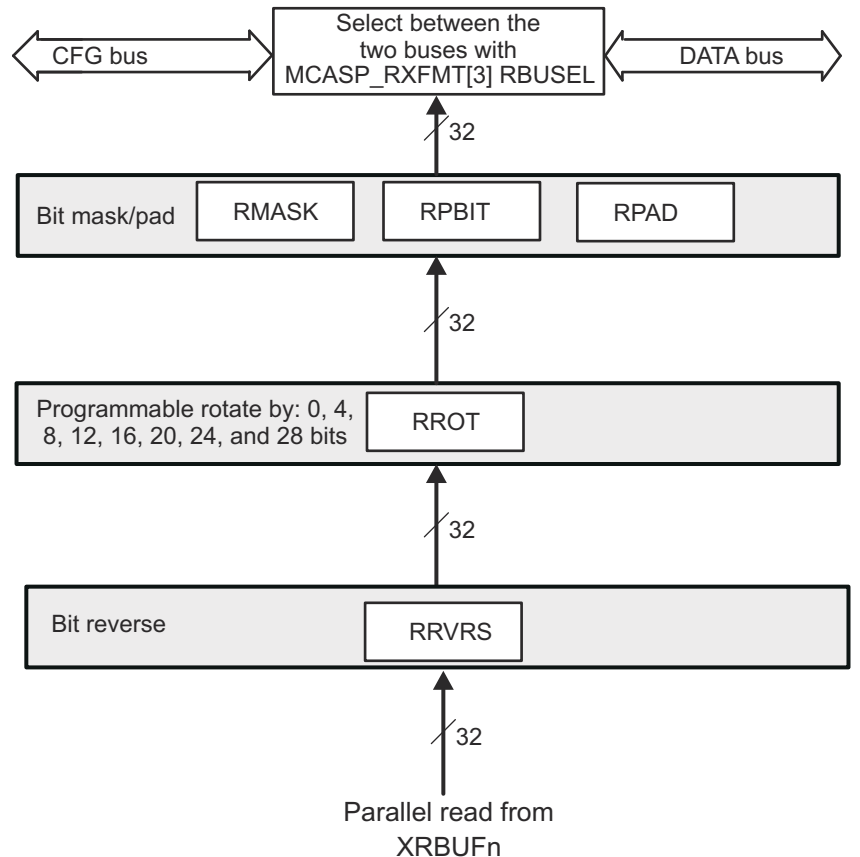

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

#### 12.5.2.4.4.2 Receive Format Unit

The MCASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 12-383](#) shows the receive format unit (RFU).

mcasp-018

**Figure 12-383. Receive Format Unit**

The MCASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP\_RFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 12-383](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP\_RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.4.10.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

#### 12.5.2.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

### Note

Note that the word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the RROT field.

Table 12-304 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

**Table 12-304. MCASP RFU Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RFMT bits	
			RROT <sup>(1)</sup>	RRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	$(32 - (\text{SLOT} - \text{WORD})) \% 32$	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first <sup>(2)</sup>	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 12-304 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 12-383), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

#### 12.5.2.4.5 MCASP State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the MCASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP\_XFMT) and it reports the MCASP status and error conditions in the transmitter status register (MCASP\_XSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP\_RFMT) and it reports the MCASP status and error conditions in the receiver status register (MCASP\_RSTAT).

#### 12.5.2.4.6 MCASP TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of the MCASP\_RTDM/MCASP\_XTDM register and determines if the MCASP should receive/transmit in that time slot.

There are two possibilities for a slot: The MCASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the MCASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUFF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control MCASP\_SRCTLn[3-2] DISMOD register. Refer also to [Section 12.5.2.4.9.2.1, TDM Time Slots Generation and Processing](#), for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

**In case of a DIT-transmission (S/PDIF transfers):** the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP\_XBUFn register during the current time slot (slot 1) is actually shifted out on the next time slot (n = 0 to 15).

The transmit TDM sequencer is controlled by the MCASP\_XTDM register and reports the current transmit slot to the MCASP\_XTDMSLOT[9-0] XSLOT CNT bit field.

#### 12.5.2.4.7 MCASP Software Reset

The MCASP can be put into reset through the global transmit and receive control register (MCASP\_GBLCTL). A valid serial clock must be supplied to the MCASP to assert the software reset bits in the MCASP\_GBLCTL register.

#### 12.5.2.4.8 MCASP Power Management

[Table 12-305](#) describes power-management features available to the MCASP.

**Table 12-305. Local Power-Management Features**

Feature	Registers	Description
Target clock stop modes	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	Force-clock stop, no-clock stop, and smart-clock stop modes are available.

#### CAUTION

No wakeup schema is supported for the MCASP. To ensure a correct behavior after enabling MCASP at device Device Configuration level, the user software is strongly recommended to choose *No Idle* mode, setting MCASP\_PWRIDLESYSCONFIG[1-0] IDLE\_MODE bit field to 0x1. Before disabling MCASP at device Device Configuration level, user software is strongly recommended to choose a *Smart-Idle* mode, setting MCASP\_PWRIDLESYSCONFIG[1-0] IDLE\_MODE bit field to 0x2.

#### 12.5.2.4.9 MCASP Transfer Modes

##### 12.5.2.4.9.1 Burst Transfer Mode

The MCASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

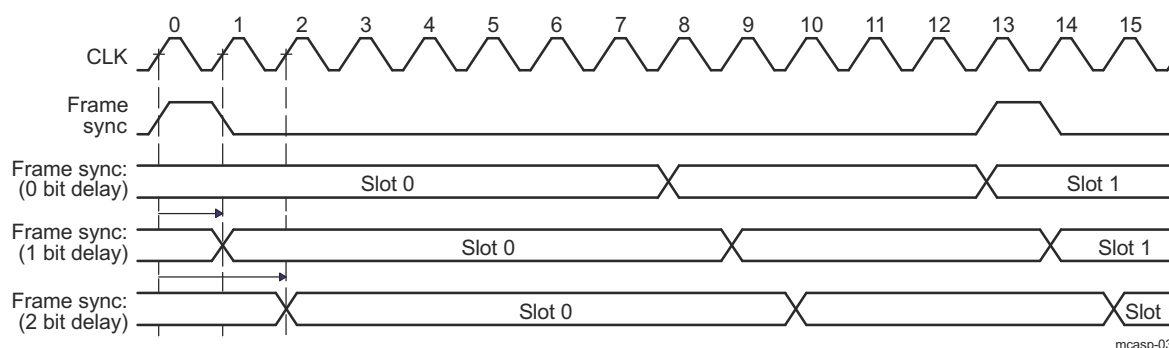

When operating in burst frame sync mode (see [Figure 12-384](#)), as specified for transmit (MCASP\_AFSXCTL[15-7] = 0) and receive (MCASP\_AFSRCTL[15-7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP\_AFSRCTL[4] FRWID = 0, MCASP\_AFSXCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF<sub>n</sub> (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF<sub>n</sub> (for every serializer set to operate as a receiver) has been read.

**Figure 12-384. Burst Frame Sync Mode**

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- **MCASP\_PFUNC**: The clock, frame, data pins must be configured for MCASP function.
- **MCASP\_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP\_PDOUT**, **MCASP\_PDIN**, **MCASP\_PDCLR**: Not applicable. Leave at default.
- **MCASP\_GBLCTL**: Follow the initialization sequence in [Section 12.5.2.5.1.2, MCASP Global Initialization](#), to configure this register.
- **MCASP\_AMUTE**: Not applicable. Leave at default.
- **MCASP\_DLBCTL**: If loopback mode is desired, configure this register according to [Section 12.5.2.4.14, MCASP Loopback Modes](#), otherwise leave this register at default.
- **MCASP\_DITCTL**: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- **MCASP\_RMASK/MCASP\_XMASK**: Mask desired bits according to [Section 12.5.2.4.4, MCASP Format Units](#).
- **MCASP\_RFMT/MCASP\_XFMT**: Program all fields according to data format desired. See [Section 12.5.2.4.4, MCASP Format Units](#).
- **MCASP\_RFMT/MCASP\_XFMT**: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- **MCASP\_ACLKRCTL/MCASP\_ACLKXCTL**: Program all fields according to bit clock desired. See [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- **MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL**: Program all fields according to high-frequency clock desired. See [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- **MCASP\_RTDM/MCASP\_XTDM**: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- **MCASP\_RINTCTL/MCASP\_XINTCTL**: Program all fields according to interrupts desired.
- **MCASP\_RCLKCHK/MCASP\_XCLKCHK**: Not applicable. Leave at default.
- **MCASP\_SRCTL<sub>n</sub>**: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default (n = 0 to 15).
- **MCASP\_DITCSR<sub>Ai</sub>**, **MCASP\_DITCSR<sub>Bi</sub>**, **MCASP\_DITUDR<sub>Ai</sub>**, **MCASP\_DITUDR<sub>Bi</sub>**: Not applicable. Leave at default (i = 0 to 5).

#### 12.5.2.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The MCASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in [Section 12.5.2.2.3, TDM Format](#).

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on MCASP transmitting serializers clock and frame sync options, refer to the [Section 12.5.2.4.2.1, Transmit Clock](#), and [Section 12.5.2.4.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on MCASP receiving serializers clock and frame sync options, refer to [Section 12.5.2.4.2.2, Receive Clock](#), and [Section 12.5.2.4.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- **MCASP\_PFUNC**: The clock, frame, data pins must be configured for MCASP function.
- **MCASP\_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP\_PDOUT**, **MCASP\_PDIN**, **MCASP\_PDCLR**: Not applicable. Leave at default.
- **MCASP\_GBLCTL**: Follow the initialization sequence is described in the [Section 12.5.2.5.2, MCASP Operational Modes Configuration](#).
- **MCASP\_AMUTE**: Leave this register at default state.
- **MCASP\_DLBCTL**: If loopback mode is desired, configure this register according to [Section 12.5.2.4.14](#), otherwise leave this register at default.
- **MCASP\_DITCTL**: DITEN must be left at default 0 to select TDM mode (transmitters only).
- **MCASP\_RMASK/MCASP\_XMASK**: Mask desired bits according to [Section 12.5.2.4.4, MCASP Format Units](#).
- **MCASP\_RFMT/MCASP\_XFMT**: Program all fields according to data format desired. See the [Section 12.5.2.4.4, MCASP Format Units](#).
- **MCASP\_AFSRCTL/MCASP\_AFSXCTL**: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by MCASP. Configure other fields as desired.
- **MCASP\_ACLKRCTL/MCASP\_ACLKXCTL**: Program all fields according to bit clock desired. For more information, refer to [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- **MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL**: Program all fields according to high-frequency clock desired. For more details, refer to [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- **MCASP\_RTDM/MCASP\_XTDM**: Program all fields according to the time slot characteristics desired.
- **MCASP\_XINTCTL**: Program all fields according to transmit interrupts desired.
- **MCASP\_RCLKCHK/MCASP\_XCLKCHK**: Program all fields according to clock checking desired.
- **MCASP\_SRCTLn**: Program all fields according to serializer operation desired (n = 0 to 15).

#### Note

The MCASP\_DITCSRAi, MCASP\_DITCSRBi, MCASP\_DITUDRAi, MCASP\_DITUDRBi (i = 0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

#### 12.5.2.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the MCASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the MCASP may be configured to participate or to be inactive by configuring MCASP\_XTDM and/or MCASP\_RTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP\_XTDM or MCASP\_RTDM register to determine if the MCASP transmits/receives in that time slot.

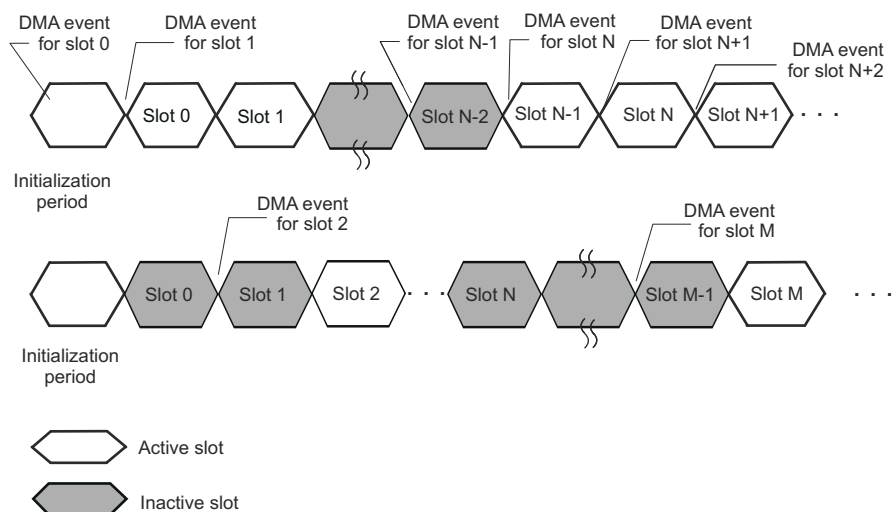

### Note

If a MCASP\_XTDM/MCASP\_RTDM bit defines an active slot (number of slot matches the bit position), the MCASP functions normally during that time slot; otherwise, the MCASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. MCASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP\_SRCTLn[3-2] DISMOD (n = 0 to 15).

Figure 12-385 shows when the transmit DMA event - XINT is generated. See Section 12.5.2.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

mcasp-019

**Figure 12-385. Transmit DMA Event (XINT) Generation in TDM Time Slots**

#### 12.5.2.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The MCASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to MCASP frame) size is 384 samples. The receive TDM time slot register (MCASP\_RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set MCASP\_AFSRCTL[15-7] RMOD bit field to 384 (0x180) to receive 384 time slots

### 12.5.2.4.9.3 DIT Transfer Mode

The DIT transfer mode of the MCASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see [Section 12.5.2.2.2.5, S/PDIF Coding Format](#).

#### 12.5.2.4.9.3.1 Transmit DIT Encoding

When the MCASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the MCASP. The MCASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

#### Note

The transmit TDM time slot register (MCASP\_XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency controller clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 12.5.2.4.4.1.2, DIT Mode Transmission Data Alignment Settings](#).

If the MCASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

#### 12.5.2.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP\_AFSXCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP\_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP\_XFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- **MCASP\_PFUNC**: The data pin - AXRn must be configured for MCASP function. If AHCLKX is used, it must also be configured for MCASP function. Other pins can be configured to function as GPIOs, if desired.
- **MCASP\_PDIR**: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- **MCASP\_GBLCTL**: Global initialization
- **MCASP\_AMUTE**: Leave this register at default state.
- **MCASP\_DITCTL**: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- **MCASP\_XMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.

- MCASP\_XFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 12.5.2.4.4.1.2](#).
- MCASP\_AFSXCTL: Configure the bits according to former discussions.
- MCASP\_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP\_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP\_XTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP\_XINTCTL: Program all fields according to the interrupts desired.
- MCASP\_XCLKCHK: Program all fields according to the clock checking desired.
- MCASP\_SRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins (n = 0 to 15).
- MCASP\_DITCSRAi and MCASP\_DITCSRBi: Program the channel status bits as desired (i = 0 to 5).
- MCASP\_DITUDRAi and MCASP\_DITUDRBi: Program the user data bits as desired (i = 0 to 5).

### Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphasic Mark Encoded Data - see [Section 12.5.2.2.5.1, Biphasic-Mark Code](#)).

#### 12.5.2.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP\_DITCSRAi and MCASP\_DITCSRBi) and user data registers (MCASP\_DITUDRAi and MCASP\_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used (i = 0 to 5).

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 12.5.2.2.5.2, S/PDIF Subframe Format](#). The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP\_DITCSRA0 to MCASP\_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP\_DITCSRB0 to MCASP\_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP\_DITUDRA0 to MCASP\_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP\_DITUDRB0 to MCASP\_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 12-376](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 12-306](#).

**Table 12-306. Channel Status and User Data for Each DIT Block**

#### 12.5.2.4.10 MCASP Data Transmission and Reception

The MCASP is serviced by writing data to the MCASP\_XBUF<sub>n</sub> registers for transmit operations, and by reading data from the MCASP\_RBUF<sub>n</sub> registers for receive operations. The MCASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 12.5.2.4.10.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details (n = 0 to 15).

The MCASP transmit/receive XRBUF<sub>n</sub> buffer can be accessed through one of the two peripheral ports of the device:

- **DATA port:** This port is dedicated to DMA initiated data transfers on the device for MCASP transmit (Tx) purposes.
- **Configuration bus (CFG):** The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 12.5.2.4.10.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.4.10.1.4, Transfers Through the Configuration Bus \(CFG\)](#), discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 12.5.2.4.10.1.5, Using the device CPUs for MCASP Servicing](#), and [Section 12.5.2.4.10.1.6, Using the DMA for MCASP Servicing](#), respectively.

MCASP DATA port allows DMAs to access the MCASP transmit buffer more efficiently on the CBASS0, using burst transfers. The physical addresses to access these registers are listed in *DMA Registers*.

### 12.5.2.4.10.1 Data Ready Status and Event/Interrupt Generation

#### 12.5.2.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP\_XSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUFn to its corresponding XRSRn shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUFn is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP\_SRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP\_XBUFn is written to by the host, the MCASP\_SRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP\_XBUFn register has to be currently written. Once all requested MCASP\_XBUFn are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP\_XSTAT[5] XDATA bit is written to 0b1, or once MCASP\_XBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the XINT event is automatically generated on MCASP[0-2]\_XMIT\_DMA\_EVT line (if enabled in the MCASP\_XEVTCTL register) to notify the DMA of the MCASP\_XBUFn empty status. An interrupt - MCASP[0-2]\_XMIT\_INTR\_PEND can be also generated if the XDATA interrupt is enabled in the MCASP\_XINTCTL register (for details, see [Section 12.5.2.4.12.1, Transmit Data Ready Interrupt](#)).

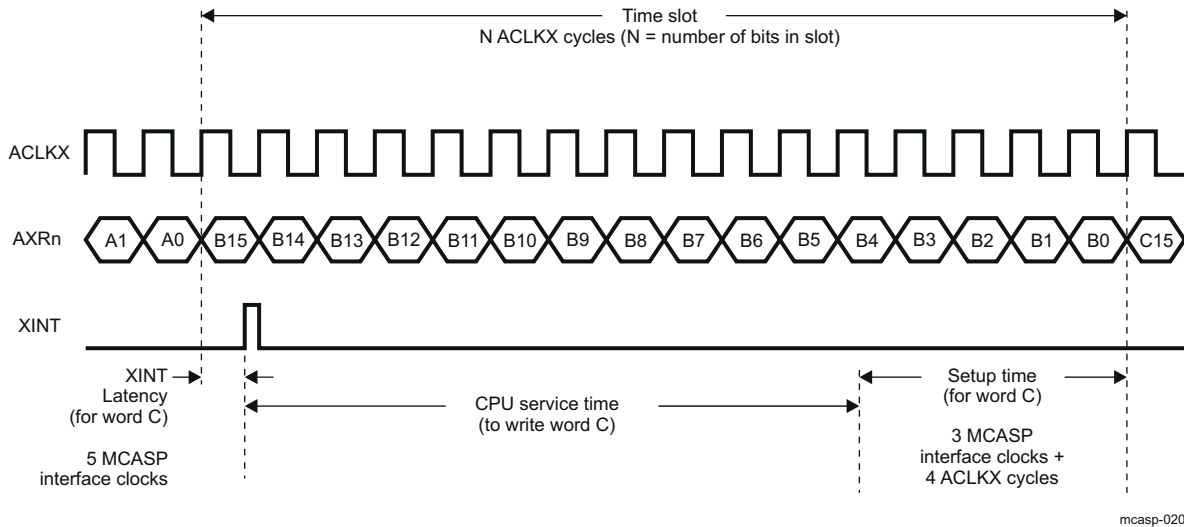

For DMA requests, the MCASP does not require that MCASP\_XSTAT register be read between DMA events. This means that, even if MCASP\_XSTAT register already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 12-386](#) shows the timing details of when XINT is generated at the MCASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the MCASP sets the XDATA flag and generates an XINT event. However, it takes up to five MCASP interface clocks (XINT latency) before XINT is active at the MCASP boundary. Upon XINT, the CPU can begin servicing the MCASP by writing word C into the MCASP\_XBUFn (service time). The CPU must write word C into the MCASP\_XBUFn within the setup time required by the MCASP (setup time) (n = 0 to 15).

The maximum service time (see [Figure 12-386](#)) can be calculated as:

*Service Time = Time Slot – XINT Latency – Setup Time*

**Figure 12-386. Service Time Upon Transmit DMA Event (XINT)**

#### 12.5.2.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP\_RSTAT register reflects the data ready status of XRBUFFn buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUFFn already contains received data (this is, a buffer is full) and is ready to transfer it to the host. The receive data ready event is individually indicated per serializer in its corresponding control register MCASP\_SRCTLn [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP\_RBUFFn register is read from the host, the MCASP\_SRCTLn [5] RRDY bit is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA = 0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP\_RBUFFn register has to be currently read. Once all requested MCASP\_RBUFFn registers are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP\_RSTAT[5] RDATA bit is written to 0b1, or once MCASP\_RBUFFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA flag is set, the RINT event is automatically generated on MCASP[0-2]\_REC\_DMA\_EVT line (if enabled in the MCASP\_PIDTCTL register) to notify the DMA of the MCASP\_RBUFFn full status. An interrupt - MCASP[0-2]\_REC\_INTR\_PEND can be also generated if the RDATA interrupt is enabled in the MCASP\_RINTCTL register (for details, see [Section 12.5.2.4.12.1, Receive Data Ready Interrupt](#)).

[Figure 12-387](#) shows the timing details of when RINT event is generated at the MCASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the MCASP sets the RDATA flag and generates an RINT event. However, it takes up to five MCASP interface clocks (RINT Latency) before RINT is active at the MCASP boundary. Upon RINT, the CPU can begin servicing the MCASP by reading Word A from the MCASP\_RBUFFn (service time). The CPU must read Word A from the MCASP\_RBUFFn register no later than the setup time required by the MCASP (Setup Time) (n = 0 to 15).

The maximum service time (see [Figure 12-387](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{RINT Latency} - \text{Setup Time}$$

**Figure 12-387. CPU Service Time Upon Receive Event (RINT)**

#### 12.5.2.4.10.1.3 Transfers Through the Data Port (DATA)

##### CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP\_XFMT/MCASP\_RFMT register, respectively. Failure to do so may result in software malfunction.

In a typical MCASP transfer scenario, the DMA Controller write accesses the XRBUFn transmit buffer through the MCASP data port (DATA) on CBASS0 Interconnect. CPU hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the MCASP Tx buffer through Interconnect DATA port location. Refer to *DMA Registers*. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 12.5.2.4.11](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in *DMA Registers*, the same physical DATA port address is used regardless of a read or write access is performed. The MCASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

##### Note

DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the MCASP configuration registers addressing their corresponding MCASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See *DMA Registers*).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3

upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

---

#### Note

For write transfers through MCASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

---

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See *DMA Registers*).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the CPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

---

#### Note

To service a serializer for a transmit or receive operation through the MCASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to *DMA Registers*), respectively.

---

---

#### Note

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP\_XTDM) and *transmit* (Tx enabled in MCASP\_SRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 12.5.2.4.15.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP\_RTDM) and *receive* (Rx enabled in MCASP\_SRCTLn) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 12.5.2.4.15.2, Buffer Overrun Error - Receiver](#)) (n = 0 to 15).

---

#### 12.5.2.4.10.1.4 Transfers Through the Configuration Bus (CFG)

#### CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP\_XFMT/MCASP\_RFMT registers, respectively. Failure to do so may result in software malfunction.

---

#### Note

MCASP[0-2] whose data ports are accessible directly via CBASS0 do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

---

In this method, the CPU accesses the XRBUFn transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of MCASP CFG port actual for CBASS0 accesses. The XRBUFn buffer of the n-th serializer configured as a transmitter is aliased

- MCASP\_XBUF<sub>n</sub> in the CFG port address space. For example, the XBUF2 transmit buffer is mapped as the MCASP\_XBUF2 register. Similarly, the XBUF<sub>n</sub> buffer of the n-th serializer configured as a receiver is aliased
- MCASP\_RBUF<sub>n</sub> in the CFG port address space. For example, the XBUF3 receive buffer is mapped as the MCASP\_RBUF3 register.

Accessing the XBUF through the DATA port (see [Section 12.5.2.4.10.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the CPU must provide the exact MCASP\_XBUF<sub>n</sub> or MCASP\_RBUF<sub>n</sub> address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP\_XBUF<sub>n</sub> and MCASP\_RBUF<sub>n</sub> addresses corresponding to MCASP CFG port, see *CFG Registers* (n = 0 to 15).

#### 12.5.2.4.10.1.5 Using a Device CPU for MCASP Servicing

The device CPUs can be used to service the MCASP transmit channels through interrupts (upon MCASP[0-2]\_XMIT\_INTR\_PEND and MCASP[0-2]\_REC\_INTR\_PEND interrupts). Because these interrupt events are connected to device COMPUTE\_CLUSTER0, PRUSS, MAIN2MCU\_LVL\_INTRTR0, R5FSS0/1\_INTRTR0, C66SS0/1\_INTRTR0, R5FSS0/1 modules, they could be software mapped to input interrupt lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP\_XSTAT register and RDATA bit in the MCASP\_RSTAT register can be performed by device CPUs, respectively. As discussed in [Section 12.5.2.4.10.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.4.10.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access MCASP XBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the MCASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP\_XINTCTL/MCASP\_RINTCTL registers, to generate interrupts MCASP[0-2]\_XMIT\_INTR\_PEND/MCASP[0-2]\_REC\_INTR\_PEND to the device CPUs upon data ready

#### 12.5.2.4.10.1.6 Using the DMA for MCASP Servicing

##### Note

The associated static Transfer Request (TR) operations of PDMA0, located in front of MCASP, must be configured to match the MCASP configuration. For more information, refer to chapter *DMA Controllers*.

The typical scenario is to use the DMA to service the MCASP transmit and receive logic through the DATA port. The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 12-377](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the MCASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 12.5.2.4.11, MCASP Audio FIFO \(AFIFO\)](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from MCASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 12.5.2.4.11, MCASP Audio FIFO \(AFIFO\)](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASP[0-2]\_XMIT\_DMA\_EVT and MCASP[0-2]\_REC\_DMA\_EVT outputs. If the AFIFO is disabled (default state) it is transparent for the MCASP module and all request are directly sent to the DMA controller.

**Figure 12-388. DMA Transmit and Receive Event in an Audio Example – One Event**

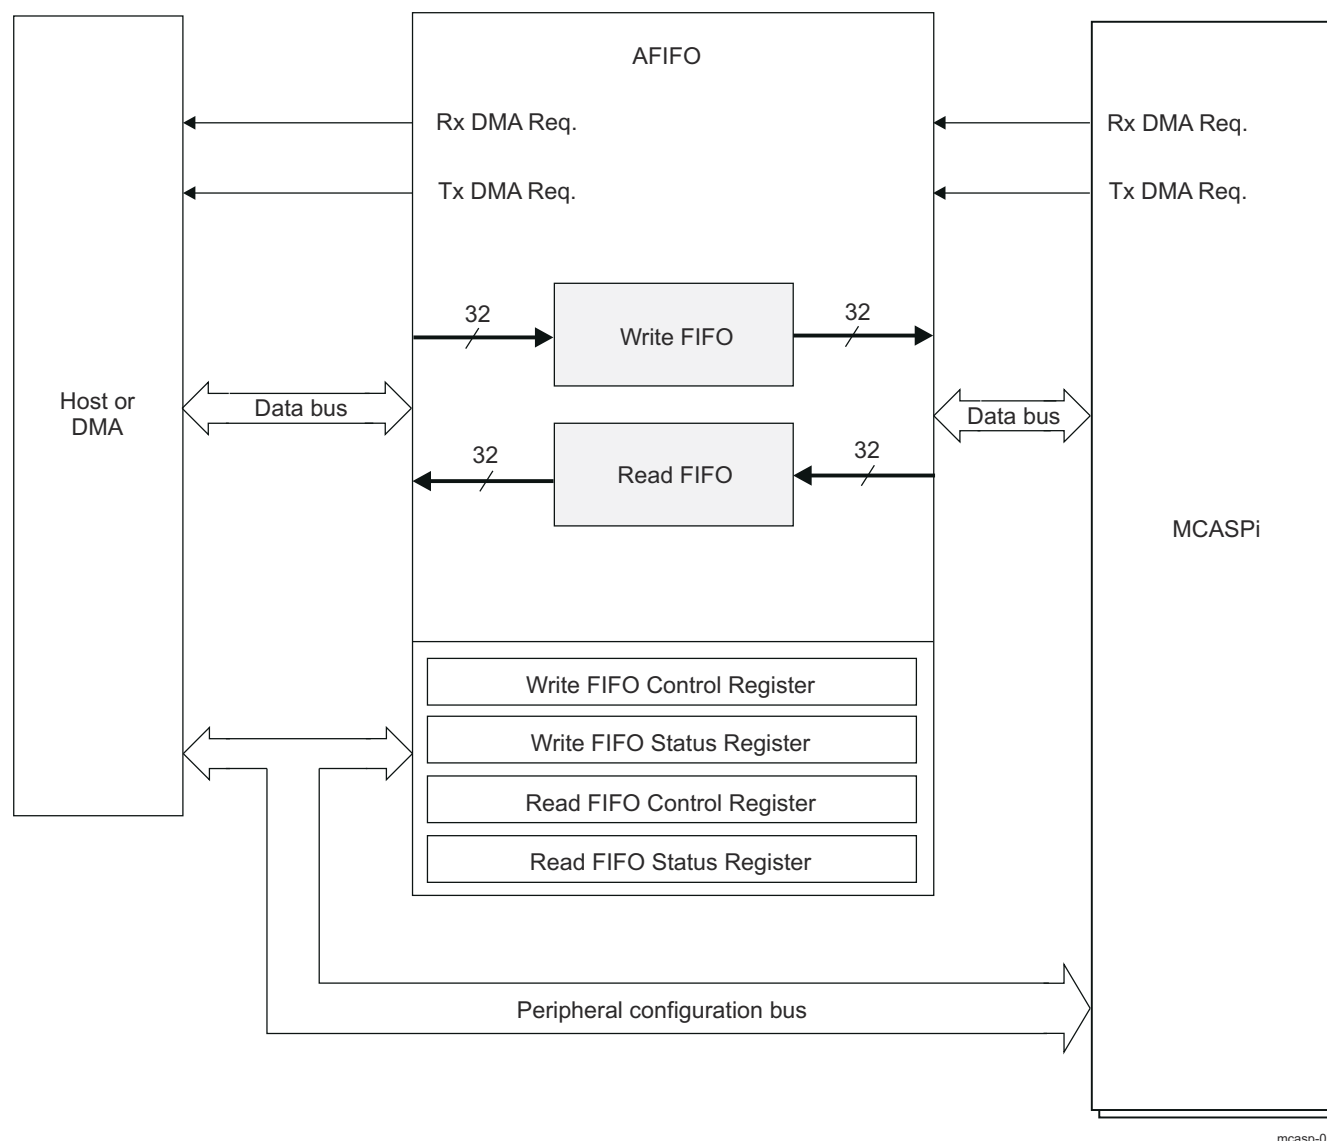

In transmit mode, the DMA event - XINT (MCASP[0-2]\_XMIT\_DMA\_EVT output), which is triggered upon each XDATA transition from 0 to 1, is used to service the MCASP TXBUF<sub>n</sub> transmit buffers. In receive mode, the DMA event RINT (MCASP[0-2]\_REC\_DMA\_EVT output) which is triggered upon each RDATA transition from 0 to 1, is used to service the MCASP RXBUF<sub>n</sub> receive buffers.

Figure 12-388 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the MCASP signals - AXR0, AXR1 and AXR2. It shows the points at which events XINT/RINT are triggered.

In Figure 12-388, a Tx DMA event XINT is triggered on each time slot. In the example, XINT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP\_XEVTCTL register. Similarly, Rx DMA event RINT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP\_PIDTCTL register.

#### 12.5.2.4.11 MCASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 12-389 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the MCASP\_WFIFOCTL and MCASP\_RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the MCASP.

mcasp-034

**Figure 12-389. MCASP Audio FIFO (AFIFO) Block Diagram**

#### 12.5.2.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the MCASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the MCASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Write FIFO is enabled, transmit DMA requests from the MCASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the MCASP, the WFIFO writes WNUMDMA 32-bit words to the MCASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the MCASP (see description for the MCASP\_WFIFOCTL[7-0] WNUMDMA). If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

##### 12.5.2.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the

host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, MCASP\_WFIFOCTL[15-8] WNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP\_WFIFOCTL[7-0] WNUMDMA bit field. If transmit DMA event pacing is not desired, then the value in MCASP\_WFIFOCTL[15-8] WNUMEVT bit field should be set equal to the value in MCASP\_WFIFOCTL[7-0] WNUMDMA bit field.

#### 12.5.2.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from MCASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the MCASP generates receive DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Read FIFO is enabled, receive DMA requests from the MCASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the MCASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the MCASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the MCASP (see description for the MCASP\_RFIFOCTL[7-0] RNUMDMA). If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

#### 12.5.2.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, MCASP\_RFIFOCTL[15-8] RNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP\_RFIFOCTL[7-0] RNUMDMA bit field. If receive DMA event pacing is not desired, then the value in MCASP\_RFIFOCTL[15-8] RNUMEVT bit field should be set equal to the value in MCASP\_RFIFOCTL[7-0] RNUMDMA bit field.

#### 12.5.2.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

#### 12.5.2.4.12 MCASP Events and Interrupt Requests

[Table 12-307](#) lists all the transmit event flags. [Table 12-308](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any MCASP serializer configured as transmitter or receiver respectively.

**Table 12-307. TX Events**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_XINTCTL[0] XUNDRN	MCASP_XSTAT[0] XUNDRN	MCASP[0-2]_XMIT_INTR_PEND	Transmit buffer underrun
MCASP_XINTCTL[1] XSYNCERR	MCASP_XSTAT[1] XSYNCERR	MCASP[0-2]_XMIT_INTR_PEND	Unexpected transmit frame sync
MCASP_XINTCTL[2] XCKFAIL	MCASP_XSTAT[2] XCKFAIL	MCASP[0-2]_XMIT_INTR_PEND	Transmit clock failure

**Table 12-307. TX Events (continued)**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_XINTCTL[3] XDMAERR	MCASP_XSTAT[7] XDMAERR	MCASP[0-2]_XMIT_INTR_PEND	DATA port transmit error
MCASP_XINTCTL[4] XLAST	MCASP_XSTAT[4] XLAST	MCASP[0-2]_XMIT_INTR_PEND	Transmit last slot interrupt
MCASP_XINTCTL[5] XDATA	MCASP_XSTAT[5] XDATA	MCASP[0-2]_XMIT_INTR_PEND	Transmit data-ready interrupt
MCASP_XINTCTL[7] XSTAFRM	MCASP_XSTAT[6] XSTAFRM	MCASP[0-2]_XMIT_INTR_PEND	Transmit start of frame interrupt
n.a.	MCASP_XSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR   XCKFAIL   XUNDRN   XSYNCERR ). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_XSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

**Table 12-308. RX Events**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_RINTCTL[0] ROVRN	MCASP_RSTAT[0] ROVRN	MCASP[0-2]_REC_INTR_PEND	Receive buffer overrun
MCASP_RINTCTL[1] RSYNCERR	MCASP_RSTAT[1] RSYNCERR	MCASP[0-2]_REC_INTR_PEND	Unexpected receive frame sync
MCASP_RINTCTL[2] RCKFAIL	MCASP_RSTAT[2] RCKFAIL	MCASP[0-2]_REC_INTR_PEND	Receive clock failure
MCASP_RINTCTL[3] RDMAERR	MCASP_RSTAT[7] RDMAERR	MCASP[0-2]_REC_INTR_PEND	DATA port receive error
MCASP_RINTCTL[4] RLAST	MCASP_RSTAT[4] RLAST	MCASP[0-2]_REC_INTR_PEND	Receive last slot
MCASP_RINTCTL[5] RDATA	MCASP_RSTAT[5] RDATA	MCASP[0-2]_REC_INTR_PEND	Receive data-ready
MCASP_RINTCTL[7] RSTAFRM	MCASP_RSTAT[6] RSTAFRM	MCASP[0-2]_REC_INTR_PEND	Receive start of frame
n.a.	MCASP_RSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR   RCKFAIL   ROVRN   RSYNCERR ). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RSTAT[3] RTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

Software has to read the MCASP\_XSTAT/MCASP\_RSTAT register to determine which event occurs at a global level for MCASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP\_SRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASP[0-2]\_XMIT\_INTR\_PEND) is asserted (active high) when one of the MCASP\_XSTAT notified events occurs, provided that it is enabled in its corresponding MCASP\_XINTCTL bit. Similarly, a Rx interrupt line (MCASP[0-2]\_REC\_INTR\_PEND) is asserted (active high) when one of MCASP\_RSTAT notified events occurs, provided that it is enabled in its corresponding MCASP\_RINTCTL bit. See also [Section 12.5.2.4.12.4, Multiple Interrupts](#) and the [Section 12.5.2.4.10.1, Data Ready Status and Event/Interrupt Generation](#) (n = 0 to 15).

#### 12.5.2.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if the MCASP\_XSTAT[5] XDATA bit is 1 and MCASP\_XINTCTL[5] XDATA bit is enabled. The [Section 12.5.2.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the MCASP\_XSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

#### 12.5.2.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if the MCASP\_RSTAT[5] RDATA bit is 1 and MCASP\_RINTCTL[5] RDATA bit is enabled. The [Section 12.5.2.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when the MCASP\_RSTAT[5] RDATA bit is set.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

#### 12.5.2.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP\_XSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP\_XINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP\_XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP\_RSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP\_RINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP\_RSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

#### 12.5.2.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP\_XSTAT is set and the interrupt is enabled in MCASP\_XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the MCASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP\_XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP\_XSTAT/MCASP\_RSTAT and the interrupt enabled in MCASP\_XINTCTL/MCASP\_RINTCTL generates a request on the MCASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the MCASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the MCASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP\_XSTAT/MCASP\_RSTAT. If any interrupt requests are active after the write, a new request is generated on the MCASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

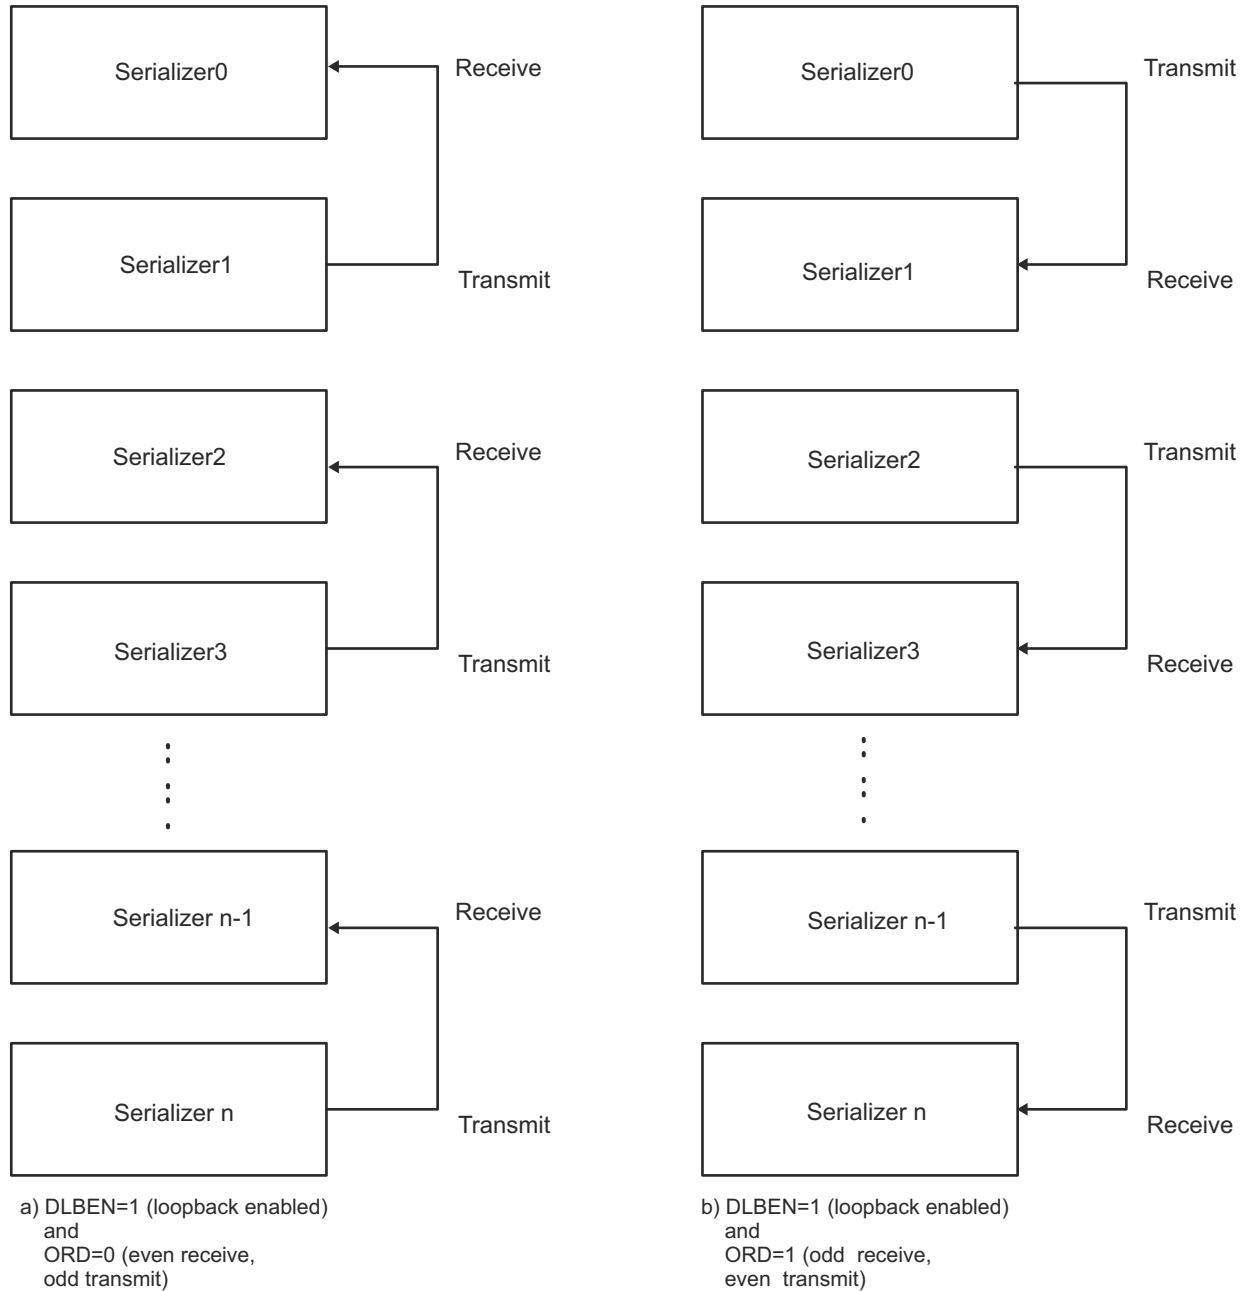

#### **12.5.2.4.13 MCASP DMA Requests**

The MCASP can generate one DMA request to the DMA controller to transmit (MCASP[0-2]\_XMIT\_DMA\_EVT) or receive (MCASP[0-2]\_REC\_DMA\_EVT) data. A DMA request to transmit data is generated if the MCASP\_XEVTCTL[0] XDATDMA bit is cleared. A DMA request to receive data is generated if the MCASP\_PIDTCTL[0] RDATDMA bit is cleared.

#### **12.5.2.4.14 MCASP Loopback Modes**

The MCASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between MCASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the MCASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

[Figure 12-390](#) shows the basic logical connection of the serializers in loopback mode.

mcasp-023

**Figure 12-390. MCASP Serializers Operation in Loopback Mode**

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP\_DLBCCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (the MCASP\_DLBCCTL[4] IOLBEN bit) between a MCASP module internal loopback and a device I/O level loopback.

When a **MCASP internal loopback** is selected (MCASP\_DLBCTL[4] IOLBEN = 0b0 ), it is NOT necessary to configure MCASP\_PFUNC and MCASP\_PDIR registers for MCASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a MCASP output pin by setting the corresponding MCASP\_PFUNC bit to 0 (this is, to function as MCASP, not GPIO) and MCASP\_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP\_DLBCTL[4] IOLBEN = 0b1 ), the MCASP\_PFUNC and MCASP\_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (this is, reaching device I/O buffers ).

When in loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the MCASP. The transmit and receive sections operate synchronously. This is achieved by setting the MCASP\_DLBCTL[3-2] MODE bit field to 0x1 and the MCASP\_ACLKXCTL[6] ASYNC bit to 0b0.

#### 12.5.2.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP\_DLBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal MCASP operation.
- The MCASP\_DLBCTL[4] IOLBEN bit must be set to select between internal (MCASP local) loopback mode or device I/O level loopback mode.
- The MCASP\_DLBCTL[3-2] MODE bit field must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP\_DLBCTL[1] ORD bit must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The MCASP\_ACLKXCTL[6] ASYNC bit must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The MCASP\_AFSRCTL[15-7] RMOD bit field and MCASP\_AFSXCTL[15-7] XMOD bit field must be set within range (0x2 - 0x20) to indicate TDM mode.

#### Note

Loopback mode does not apply to DIT or burst mode, because MCASP receivers do NOT natively support DIR - reception.

#### 12.5.2.4.15 MCASP Error Reporting

The MCASP includes error-checking capability for the serial protocol and data underrun. In addition, the MCASP includes a timer that continually measures the high-frequency controller clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the controller clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

##### 12.5.2.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFFn buffer to XRSRn shift register, but the corresponding (MCASP\_XBUFFn ) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP\_XSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it (n = 0 to 15).

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the MCASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the MCASP and start again with the proper initialization.

#### 12.5.2.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP\_RBUFn register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting (n = 0 to 15).

An overrun is checked only once per time slot. The MCASP\_RSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

#### 12.5.2.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the MCASP\_XSTAT[7] XDMAERR bit, occurs when the DMA or device CPU writes more words to the DATA port of the MCASP than it should.

The MCASP\_XSTAT[7] XDMAERR = 0b1 indicates that the DMA or device CPU wrote too many words to the MCASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting the MCASP\_XSTAT[0] XUNDRN bit.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP transmitter and the DMA must be reinitialized to resynchronize them.

#### 12.5.2.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the MCASP\_RSTAT[7] RDMAERR bit, occurs when the DMA or device CPU reads more words from the DATA port of the MCASP than it should.

The MCASP\_RSTAT[7] RDMAERR bit indicates that the DMA or device CPU read too many words from the MCASP DATA port for a given receive RINT event. Reading too few words results in a receiver overrun error setting the MCASP\_RSTAT[0] ROVRN bit.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP receiver and the DMA must be reinitialized to resynchronize them.

#### 12.5.2.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the MCASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
  - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).

- Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
- 2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
  - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

#### 12.5.2.4.15.6 Clock Failure Detection

##### 12.5.2.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP\_XCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP\_XSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
  - a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP\_XINTCTL)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP\_RCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP\_RSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
  - a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP\_RINTCTL)

##### 12.5.2.4.15.6.2 Transmit Clock Failure Check and Recovery

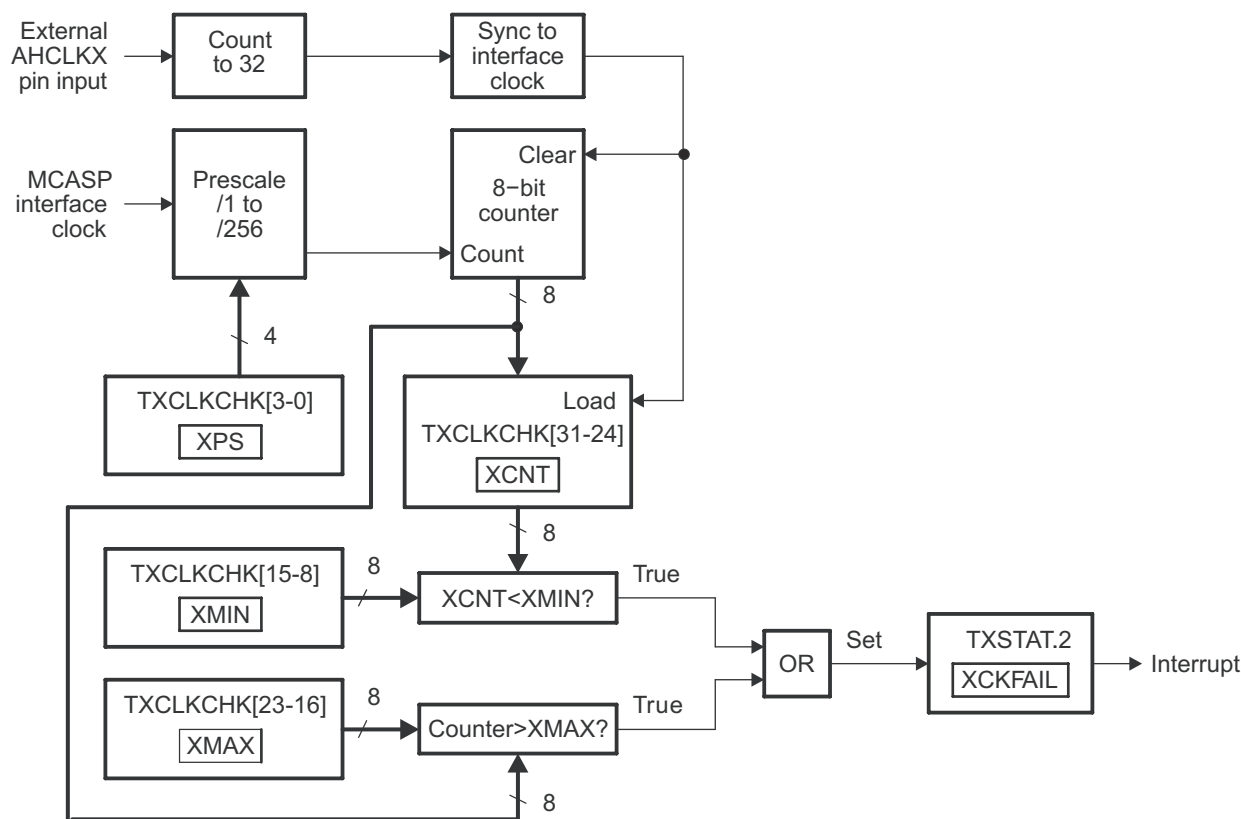

The transmit clock failure check circuit (see [Figure 12-391](#)) works off the internal MCASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP\_XCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (the MCASP\_XSTAT[2] XCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the MCASP\_XSTAT[2] XCKFAIL transmit clock failure flag is set. This causes an interrupt if the MCASP\_XINTCTL[2] XCKFAIL transmit clock failure interrupt enable bit is set.

mcasp-024

**Figure 12-391. Transmit Clock Failure Detection Circuit Block Diagram**

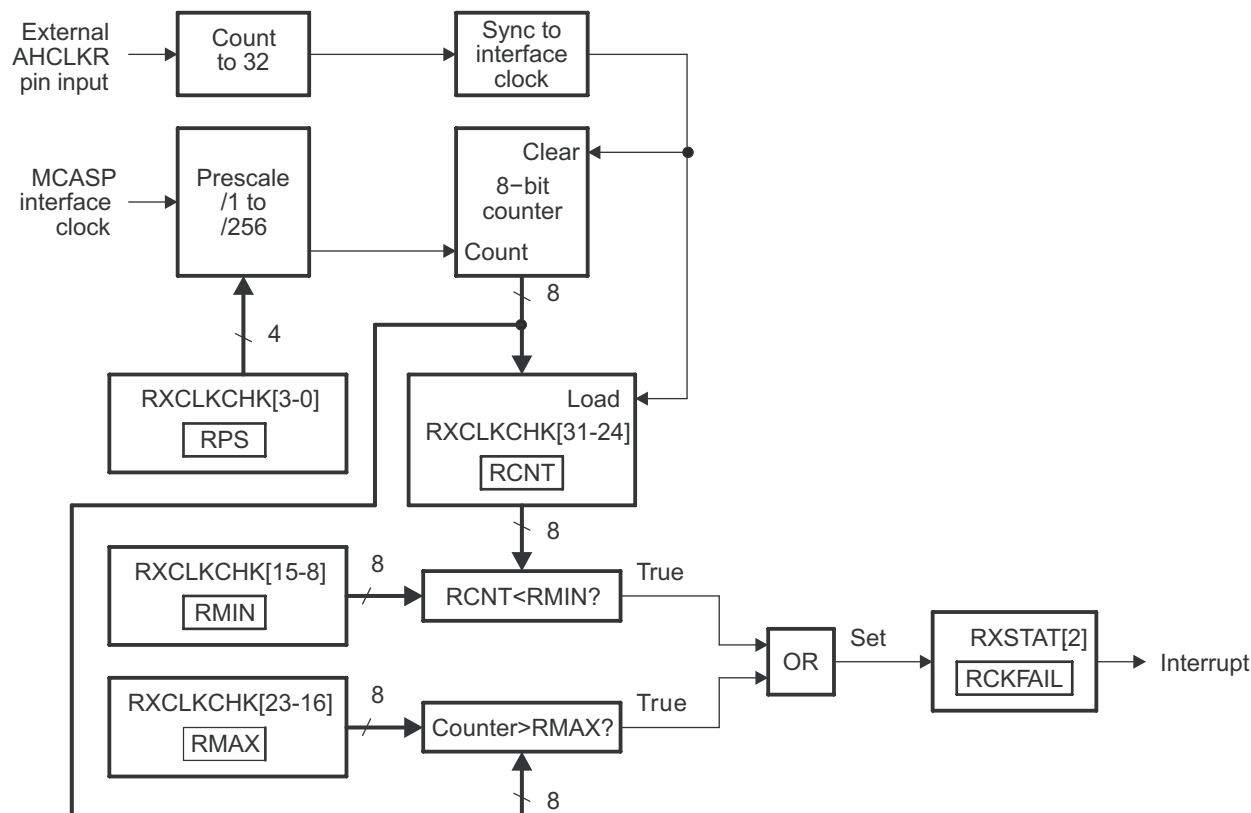

#### 12.5.2.4.15.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see [Figure 12-392](#)) works off both the internal MCASP interface clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP\_RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (the MCASP\_RSTAT[2] RCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

mcasep-025

**Figure 12-392. Receive Clock Failure Detection Circuit Block Diagram**

### 12.5.2.5 MCASP Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCASP module.

#### 12.5.2.5.1 MCASP Global Initialization

##### 12.5.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the MCASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MCASP (for more information, see *Module Integration*, and *MCASP Environment* ).

[Table 12-309](#) describes the global initialization of surrounding modules.

**Table 12-309. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC3	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
PLLCTRL0	PLLCTRL0 configuration must be done to enable the clocks to the MCASP modules, see <i>Clocking</i> .
PLL4	PLL4 configuration must be done to enable the clocks to the MCASP modules, see <i>Clocking</i> .
PLL2	PLL2 configuration must be done to enable the clocks to the MCASP modules, see <i>Clocking</i> .
ATL	ATL configuration must be done to enable the clocks to the MCASP modules, see <i>Audio Tracking Logic (ATL)</i> .
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
MAIN2MCU_LVL_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MAIN2MCU_LVL_INTRTR0 interrupts, see <i>Interrupts</i> .
R5FSS0_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0_CORE0/1 interrupts, see <i>Interrupts</i> .
PDMA0_MCASP_G0	PDMA0_MCASP_G0 controllers configuration must be done to enable the module PDMA0_MCASP_G0 channel request, see <i>PDMA Controller</i> .
Interconnects	For information about the CBASS0 interconnects configuration, see <i>System Interconnect</i> .

#### Note

NAVSS configuration (UMDA channel set-up) must be done in order to move data from/to MCASP via the PDMA Controller. For more information, see *Navigator Subsystem (NAVSS)*.

#### Note

The COMPUTE\_CLUSTER0, MAIN2MCU\_LVL\_INTRTR0, R5FSS0\_CORE0/1, and the PDMA0\_MCASP\_G0 configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected interrupt and DMA controllers of the host CPU must be done for full functionality of the MCASP DMA and interrupt lines.

#### 12.5.2.5.1.2 MCASP Global Initialization

##### 12.5.2.5.1.2.1 Main Sequence – MCASP Global Initialization for DIT-Transmission

The procedure in [Table 12-310](#) initializes the MCASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

#### CAUTION

Before performing MCASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the *MCASP\_GBLCTL* register.

**Table 12-310. MCASP Transmitters Global Initialization for DIT-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP components.	MCASP_GBLCTL[12-8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12-8]	=0x00
3. Configure the local power management.	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See <a href="#">Section 12.5.2.5.1.2.1.1</a> .	
5. Configure the transmit frame sync generator.	See <a href="#">Section 12.5.2.5.1.2.1.2</a> .	
6. Configure the transmit clock generator.	See <a href="#">Section 12.5.2.5.1.2.1.3</a> .	
7. Configure the TDM sequencer—set all slots active.	MCASP_XTDM[31-0] XTDMs	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. <sup>(3)</sup>	MCASP_SRCTLn [1-0] SRMOD; n = 0 to 15	0x1
9. Configure the MCASP pins functionality.	See <a href="#">Section 12.5.2.5.1.2.1.4</a> .	
10. Enable the MCASP DIT - transmission mode.	MCASP_DITCTL[0] DITEN	0x1 <sup>(2)</sup>
11. Configure DIT-specific subframe fields.	See <a href="#">Table 12-315</a> .	
12. Release from reset state the divider that outputs the AHCLKX clock. <sup>(1)</sup>	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. <sup>(1)</sup>	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKXCTL and MCASP\_ACLKXCTL registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

(2) This globally configures all active transmitters to operate in DIT-mode.

(3) For an unused serializer n, write MCASP\_SRCTLn [1-0] SRMOD = 0x0 to disable it (n = 0 to 15).

#### 12.5.2.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in [Table 12-311](#) configures the transmit frame format unit of the MCASP module for a DIT-transmission.

#### Note

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

**Table 12-311. Transmit Format Unit Configuration for DIT-Transmission**

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_XFMT[7-4] XSSZ	0xF
<b>IF:</b> the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_XMASK[31-0] XMASK	0x- <sup>(1)</sup>
Rotate data right by a multiple-of-4- bit positions.	MCASP_XFMT[2-0] XROT	0x- <sup>(1)</sup>
<b>ELSE</b>		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_XMASK[31-0] XMASK	0x- <sup>(1)</sup>
Rotate data right by 0-bit positions.	MCASP_XFMT[2-0] XROT	0x0
<b>ENDIF</b>		

**Table 12-311. Transmit Format Unit Configuration for DIT-Transmission (continued)**

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_XFMT[3] XBUSEL	0x-

(1) Refer to [Section 12.5.2.4.4.1](#), *Transmit Fromat Unit* and [Section 12.5.2.4.4.1.2](#), *DIT-Mode Transmission Data Alignment Settings*.

#### 12.5.2.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in [Table 12-312](#) configures the transmit frame synchronization generator of the MCASP module.

#### Note

The frame synchronization signal is always rising-edge active and always has a single-bit width.

**Table 12-312. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission**

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_AFSXCTL[15-7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_AFSXCTL[1] FSXM	0x1

#### 12.5.2.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

#### Note

By default, the ACLKX and AHCLKX clocks are generated only from the MCASP internal clock source.

The procedure in [Table 12-313](#) configures the transmit clock generator of the MCASP module.

**Table 12-313. Transmit Clock Generator Configuration in DIT-Mode**

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11-0] HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4-0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See <a href="#">Section 12.5.2.4.15.6.1</a> , <i>Clock Failure Check Startup</i> .	

#### 12.5.2.5.1.2.1.4 Subsequence - MCASP Pins Functional Configuration

The procedure in [Table 12-314](#) configures the MCASP pins for MCASP functionality.

**Table 12-314. MCASP Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31-0]	0x0
Configure the MCASP pins as outputs:		
AFSX	MCASP_PDIR[28] AFSX;	0x1
AHCLKX	MCASP_PDIR[27] AHCLKX;	0x1
ACLKX	MCASP_PDIR[26] ACLKX;	0x1
Desired i-th MCASP data pin AXRi is configured as an output for DIT-transmission.	MCASP_PDIR[i] AXRi	0x1

#### 12.5.2.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in [Table 12-315](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

**Table 12-315. DIT-Specific Subframe Fields Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_DITCTL[3] VB	0x-

**Table 12-315. DIT-Specific Subframe Fields Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for even time slots.	MCASP_DITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31-0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31-0] DITUDRBi, where i = 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRai[31-0], where i = 0 to 5 MCASP_DITCSRBi[31-0], where i = 0 to 5	0x- 0x-

**12.5.2.5.1.2.2 Main Sequence – MCASP Global Initialization for TDM-Reception**

The procedure in [Table 12-316](#) initializes a MCASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by MCASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

**CAUTION**

Before performing MCASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the *MCASP\_GBLCTL* register.

**Note**

The MCASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (this is, S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device MCASP receiver input (TDM-only compatible).

**Table 12-316. MCASP Receivers Global Initialization for TDM-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP receive components.	MCASP_GBLCTL[4-0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4-0]	=0x00
3. Configure the local power management.	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	0x1
4. Configure the receive format unit.	See <a href="#">Section 12.5.2.5.1.2.2.1</a> .	
5. Configure the receive frame sync generator.	See <a href="#">Section 12.5.2.5.1.2.2.2</a> .	
6. Configure the receive clock generator.	See <a href="#">Section 12.5.2.5.1.2.2.3</a> .	
7. Program all bits - RTDMSk (where k = 0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RTDM[k] RTDMSk, where k = 0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. <sup>(4)</sup>	MCASP_SRCTLn [1-0] SRMOD; n = 0 to 15	0x2
9. Configure the MCASP pins functionality.	See <a href="#">Section 12.5.2.5.1.2.2.4</a> .	
10. Optional: Configure a MCASP Rx channel for a loopback operation (TDM mode only) in MCASP_DLBCTL [31-0].	See <a href="#">Section 12.5.2.4.14.1</a> , <i>Loopback Mode Configurations</i> .	0x- <sup>(5)</sup>
11. Release from reset state the divider that outputs the AHCLKR clock. <sup>(1)</sup> See also <sup>(2)</sup> .	MCASP_GBLCTL[1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also <sup>(2)</sup> .	MCASP_GBLCTL[1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. <sup>(1)</sup> See also <sup>(3)</sup> .	MCASP_GBLCTL[0] RCLKRST	0x1

**Table 12-316. MCASP Receivers Global Initialization for TDM-Mode Operation (continued)**

Step	Register/Bit Field/Programming Model	Value
14. Poll the bit to ensure that it is successfully latched in the register. See also <sup>(3)</sup> .	MCASP_GBLCTL[0] RCLKRST	=0x1

- (1) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKRCTL and MCASP\_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.
- (2) This step is necessary even if external high-frequency serial clocks are used.
- (3) This step can be skipped if external serial clocks are used and they are running.
- (4) For an unused serializer n, write MCASP\_SRCTLn [1-0] SRMOD = 0x0 to disable it (n = 0 to 15).
- (5) In this case the receiver clock and frame sync are derived from the MCASP transmitter logic, so MCASP\_ACLKXCTL[6] ASYNC must be set to 0b0. Neither MCASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

#### 12.5.2.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in [Table 12-317](#) configures the receive frame format unit of the MCASP module for TDM slots reception.

**Table 12-317. Receive Format Unit Configuration for TDM-Reception**

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RFMT[7-4] RSSZ	0x- <sup>(1)</sup>
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RMASK[31-0] RMASK	0x- <sup>(2)</sup>
Select a padding value for masked-out bits.	MCASP_RFMT[14-13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RBUF <sub>n</sub> which value to be used as a pad value in case MCASP_RFMT[14-13] RPAD = 0x2. (n = 0 to 15)	MCASP_RFMT[12-8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RFMT[2-0] RROT	0x- <sup>(3)</sup>
Received stream bit order (LSB- or MSB-first ). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RFMT[15] RRVRS	0x- <sup>(3)</sup>
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RFMT[17-16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RFMT[3] RBUSEL	0x-

- (1) Refer to [Section 12.5.2.4.4.2, Receive Format Unit](#), regarding options for received TDM-slot sizes.
- (2) For more details on Rx masking value, refer to [Section 12.5.2.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#)
- (3) For more details on rotation and received TDM stream bit order, refer to [Section 12.5.2.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#) and [Table 12-304, MCASP RFU Settings](#).

#### 12.5.2.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 12-318](#) configures the transmit frame synchronization generator of the MCASP module.

#### Note

The same bit - MCASP\_ACLKXCTL[6] ASYNC which is used to determine if MCASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either internally or externally sourced). Hence, the settings in below table [Table 12-318](#) have no effect, if MCASP\_ACLKXCTL[6] ASYNC = 0.

**Table 12-318. Receive Frame-Synchronization Generator Configuration for TDM-Reception**

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[15-7] RMOD	0x- <sup>(1)</sup>

**Table 12-318. Receive Frame-Synchronization Generator Configuration for TDM-Reception (continued)**

Step	Register/Bit Field/Programming Model	Value
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[0] FSRP	0x-
<b>IF</b> receive frame sync - FS is internally generated	Software test condition	
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[1] FSRM	0b1
If MCASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the <a href="#">Table 12-316</a> . This must not be done in current step because the frame control register - MCASP_AFSXCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
<b>ELSE</b>		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: MCASPi_AFSR)	MCASP_PDIR[31] AFSR	0b0
<b>ENDIF</b>		
To generate MCASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

- (1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to *Module Integration*.

#### 12.5.2.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in [Table 12-319](#) configures the receive clock generator of the MCASP module.

#### Note

The settings in below table [Table 12-319](#) have no effect, if *MCASP\_ACLKXCTL[6] ASYNC* = 0 (this is, receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when MCASP loopback mode is used.

**Table 12-319. Receive Clock Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
To use the MCASP receive clock generator, select an asynchronous receiver clock schema (ASYNC = 1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
<b>IF</b> receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKXCTL[11-0] HCLKRDIV	0x-

**Table 12-319. Receive Clock Generator Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Select an internally-generated receive clock.	<i>MCASP_ACLKXCTL</i> [5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	<i>MCASP_ACLKXCTL</i> [7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	<i>MCASP_ACLKXCTL</i> [4-0] CLKRDIV	0x-
Optional: If MCASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the <a href="#">Table 12-316</a> . This must not be done in current step because the clock control register - <i>MCASP_ACLKRCTL</i> must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	<i>MCASP_PDIR</i> [29] ACLKR	0b1
<b>ELSE</b>		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	<i>MCASP_ACLKXCTL</i> [5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	<i>MCASP_ACLKXCTL</i> [7] CLKRP	0x-
Setup an input direction for the ACLKR pin	<i>MCASP_PDIR</i> [29] ACLKR	0b0
<b>ENDIF</b>		
Configure the transmit clock failure detect logic.	See <a href="#">Section 12.5.2.4.15.6.1</a> , <i>Clock Failure Check Startup</i> .	

#### 12.5.2.5.1.2.2.4 Subsequence—MCASP Receiver Pins Functional Configuration

The procedure in [Table 12-320](#) configures the MCASP pins for MCASP functionality.

**Table 12-320. MCASP Receiver Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	<i>MCASP_PFUNC</i> [31-0]	0x0
Configure the MCASP pins direction:	<i>MCASP_PDIR</i> [31] AFSR;	0x-(1)
AFSR	<i>MCASP_PDIR</i> [29] ACLKR;	0x-(2)
ACLRK	<i>MCASP_PDIR</i> [n] AXRn;	0x0
Desired n-th MCASP data pin AXRn is configured as an input for receiving.		

(1) See [Table 12-318](#).

(2) For more details on MCASP clock configurations, refer to [Table 12-319](#).

#### 12.5.2.5.1.2.3 Main Sequence – MCASP Global Initialization for TDM -Transmission

The procedure in [Table 12-321](#) initializes a MCASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

#### CAUTION

Before performing MCASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the *MCASP\_GBLCTL* register.

**Table 12-321. MCASP Transmitters Global Initialization for TDM-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP transmit components.	<i>MCASP_GBLCTL</i> [12-8]	0x00

**Table 12-321. MCASP Transmitters Global Initialization for TDM-Mode Operation (continued)**

Step	Register/Bit Field/Programming Model	Value
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12-8]	=0x00
3. Configure the local power management.	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See <a href="#">Section 12.5.2.5.1.2.3.1</a> .	
5. Configure the transmit frame sync generator.	See <a href="#">Section 12.5.2.5.1.2.3.2</a> .	
6. Configure the transmit clock generator.	See <a href="#">Section 12.5.2.5.1.2.3.3</a> .	
7. Program all bits - XTDMSk, where k = 0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_XTDM[k] XTDMSk, where k = 0 to 31 <sup>(4)</sup>	0x-
8. Configure the desired n-th serializer for transmit mode operation. <sup>(3)</sup>	MCASP_SRCTLn[1-0] SRMOD; n = 0 to 15	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_DITCTL[0] DITEN	0x0 <sup>(2)</sup>
10. Configure the MCASP pins functionality.	See <a href="#">Section 12.5.2.5.1.2.3.4</a> .	
11. Optional: Configure a MCASP Tx channel for loopback operation (TDM mode only) in MCASP_DLBCTL [31-0].	See <a href="#">Section 12.5.2.4.14.1</a> , <i>Loopback Mode Configurations</i> .	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See <sup>(1)</sup>	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See <sup>(1)</sup>	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

- (1) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKXCTL and MCASP\_ACLKXCTL registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
- (2) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.
- (3) For an unused serializer n, write MCASP\_SRCTLn [1-0] SRMOD = 0x0 to disable it (n = 0 to 15).
- (4) Appropriately program in the MCASP\_SRCTLn[3-2] DISMOD bit field, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode) (n = 0 to 15).

#### 12.5.2.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in [Table 12-322](#) configures the transmit frame format unit of the MCASP module for TDM slots transmission.

**Table 12-322. Transmit Format Unit Configuration for TDM-Transmission**

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_XFMT[7-4] XSSZ	0x- <sup>(1)</sup>
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_XMASK[31-0] XMASK	0x- <sup>(2)</sup>
Select a padding value for masked-out bits.	MCASP_XFMT[14-13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_XBUFn which value to be used as a pad value in case MCASP_XFMT[14-13] XPAD = 0x2 (n = 0 to 15).	MCASP_XFMT[12-8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_XFMT[2-0] XROT	0x- <sup>(3)</sup>
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_XFMT[15] XRVRS	0x- <sup>(3)</sup>
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_XFMT[17-16] XDATDLY	0x-

**Table 12-322. Transmit Format Unit Configuration for TDM-Transmission (continued)**

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_XFMT[3] XBUSEL	0x-

- (1) Refer to [Section 12.5.2.4.4.1, Transmit Format Unit](#), regarding options for transmitted TDM-slot sizes.
- (2) For more details on Tx masking value, refer to [Section 12.5.2.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#)
- (3) For more details on rotation and transmitd TDM stream bit order, refer to [Section 12.5.2.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#) and [Table 12-302, MCASP TFU TDM Mode Settings](#).

#### 12.5.2.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 12-323](#) configures the transmit frame synchronization generator of the MCASP module.

**Table 12-323. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission**

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[15-7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[0] FSXP	0x-
<b>IF</b> transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[1] FSXM	0b1
If MCASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the <a href="#">Table 12-321</a> . This must NOT be done in current step because the frame control register - MCASP_AFSXCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
<b>ELSE</b>		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

#### 12.5.2.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in [Table 12-324](#) configures the transmit clock generator of the MCASP module.

**Table 12-324. Transmit Clock Generator Configuration for TDM Cases**

Step	Register/Bit Field/Programming Model	Value
<b>IF</b> transmit clock - XCLK is internally generated	Software test condition	
<b>IF</b> high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11-0] HCLKXDIV	0x-

**Table 12-324. Transmit Clock Generator Configuration for TDM Cases (continued)**

Step	Register/Bit Field/Programming Model	Value
Optional: If MCASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the <a href="#">Table 12-321</a> . This must NOT be done in current step because the clock control register - <i>MCASP_AHCLKXCTL</i> must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	<i>MCASP_PDIR</i> [27] AHCLKX	0b1
<b>ELSE</b>		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	<i>MCASP_AHCLKXCTL</i> [15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	<i>MCASP_AHCLKXCTL</i> [14] HCLKXP	0x-
Setup an input direction for the AHCLKX pin	<i>MCASP_PDIR</i> [27] AHCLKX	0b0
<b>ENDIF</b>		
Select an internally-generated transmit clock.	<i>MCASP_ACLKXCTL</i> [5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	<i>MCASP_ACLKXCTL</i> [7] CLKXP	0x-
Set the divisor for the internally generated transmit clock— <i>ACLKX</i> in range (1 - 32).	<i>MCASP_ACLKXCTL</i> [4-0] CLKXDIV	0x-
Optional: If MCASP transmitter is required to output internally generated clock, <i>ACLKX</i> pin) must be set as an output in step 10 of the sequence documented in the <a href="#">Table 12-321</a> . This must NOT be done in current step because the clock control register - <i>MCASP_ACLKXCTL</i> must be appropriately configured prior to <i>ACLKX</i> pin outputting a transmit clock to an external device.	<i>MCASP_PDIR</i> [26] ACLKX	0b1
<b>ELSE</b>		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	<i>MCASP_ACLKXCTL</i> [5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	<i>MCASP_ACLKXCTL</i> [7] CLKXP	0x-
Setup an input direction for the ACLKX pin	<i>MCASP_PDIR</i> [26] ACLKX	0b0
<b>ENDIF</b>		
Configure the transmit clock failure detect logic.	See <a href="#">Section 12.5.2.4.15.6.1</a> , <i>Clock Failure Check Startup</i> .	

#### 12.5.2.5.1.2.3.4 Subsequence—MCASP Transmit Pins Functional Configuration

The procedure in [Table 12-325](#) configures the MCASP pins for MCASP functionality.

**Table 12-325. MCASP Transmit Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	<i>MCASP_PFUNC</i> [31-0]	0x0
Configure the MCASP pins direction:	<i>MCASP_PDIR</i> [28] AFSR;	0x-(1)
AFSX	<i>MCASP_PDIR</i> [27] AHCLKR;	0x-(2)
AHCLKX	<i>MCASP_PDIR</i> [26] ACLKR;	0x-(2)
ACLKX	<i>MCASP_PDIR</i> [n] AXRn	0x1
Desired n-th MCASP data pin AXRn is configured as an output for transmission.		

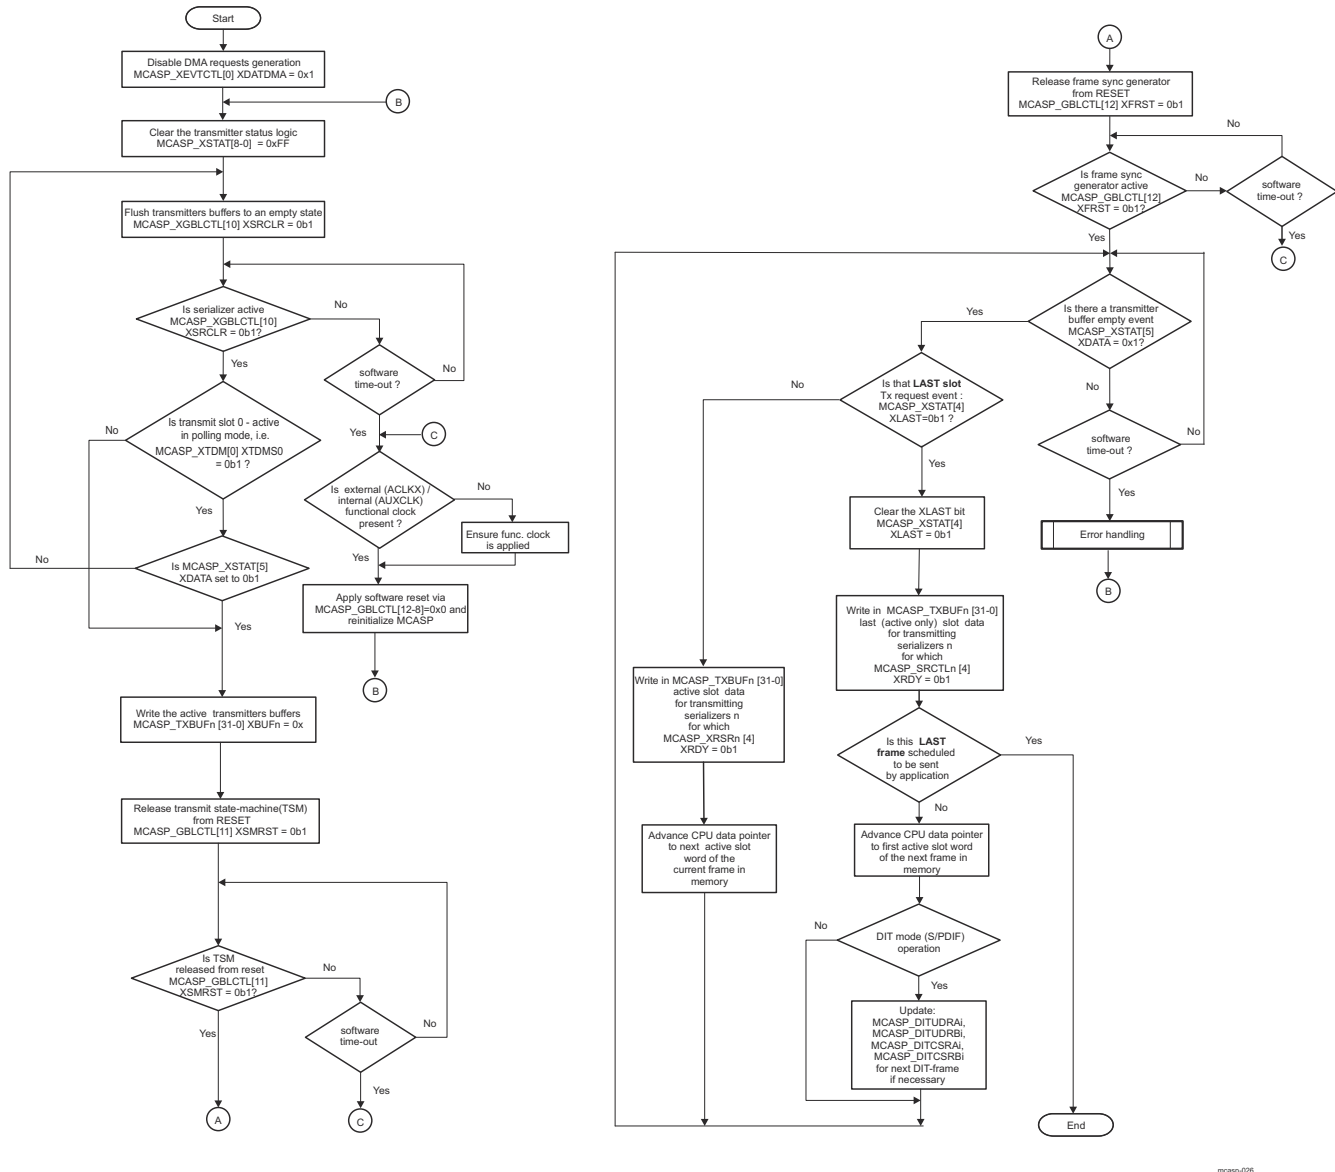

(1) See [Table 12-323](#).

### 12.5.2.5.2 MCASP Operational Modes Configuration

#### 12.5.2.5.2.1 MCASP Transmission Modes

##### 12.5.2.5.2.1.1 Main Sequence – MCASP DIT-/TDM- Polling Transmission Method

Figure 12-393 shows the MCASP DIT-/TDM- polling method.

**Figure 12-393. MCASP DIT-/TDM- Transmission Polling Method**

These registers are for MCASP DIT-/TDM- transmission polling method: *MCASP\_XEVTCTL*, *MCASP\_XSTAT*, *MCASP\_GBLCTL*, *MCASP\_XTDM*, *MCASP\_XBUF<sub>n</sub>*, *MCASP\_SRCTL<sub>n</sub>*, *MCASP\_DITUDRA<sub>i</sub>*, *MCASP\_DITUDRB<sub>i</sub>*, *MCASP\_DITCSRA<sub>i</sub>*, *MCASP\_DITCSRBI* (*n* = 0 to 15 and *i* = 0 to 5).

Table 12-326 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

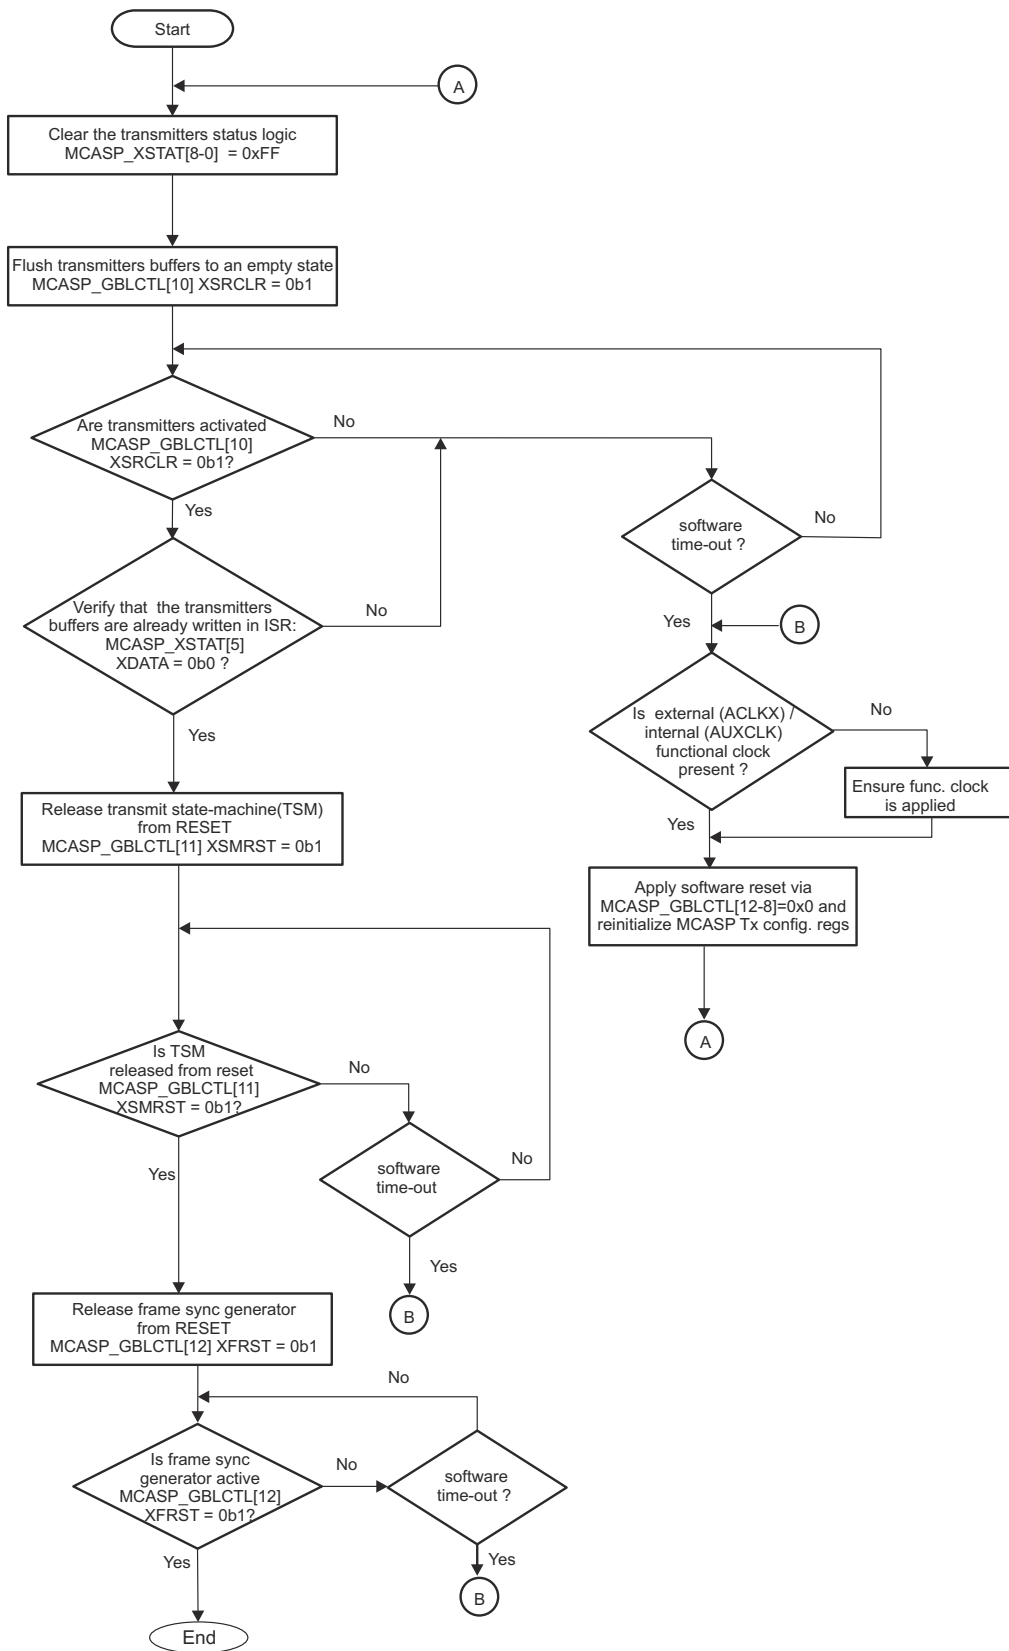

**Table 12-326. Subprocess Call Summary for Main Sequence – MCASP DIT-/TDM- Transmission Polling Method**

Subprocess Name	Cross-Reference
Error handling	Figure 12-399

**12.5.2.5.2.1.2 Main Sequence – MCASP DIT- /TDM - Interrupt Transmission Method**

[Figure 12-394](#) shows the initial setup for interrupt-based transmission.

mcasp-027

**Figure 12-394. Subsequence – DIT-/TDM- Transmission Startup Procedure**

Table 12-327 shows the configuration of the MCASP using an interrupt method for DIT-/TDM- transmission.

**Table 12-327. MCASP DIT-/TDM- Interrupt Transmission Model**

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_XINTCTL[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update).	MCASP_XINTCTL[4] XLAST	0x1
IF write transfer is through the MCASP DATA port (MCASP_XFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the MCASP Transmitters Global Initialization - see Table 12-310)	
Enable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x0
<b>ENDIF</b>		
DIT/TDM - Transmission Startup Procedure	See Figure 12-394.	

These registers are for MCASP DIT-/TDM- transmission startup procedure: MCASP\_GBLCTL, MCASP\_XSTAT.

#### 12.5.2.5.2.1.3 Main Sequence –MCASP DIT- /TDM - Mode DMA Transmission Method

Table 12-328 shows the configuration of the ↓ using the DMA method for transmission. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

#### Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

**Table 12-328. MCASP DMA Transmission Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_XFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of MCASP DATA port usage.	MCASP_XINTCTL[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_XINTCTL[4] XLAST	0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_XINTCTL[5] XDATA	0x0
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 12-394. The only difference is that DMA automatically services all the XINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 12-397.	See Figure 12-394.	

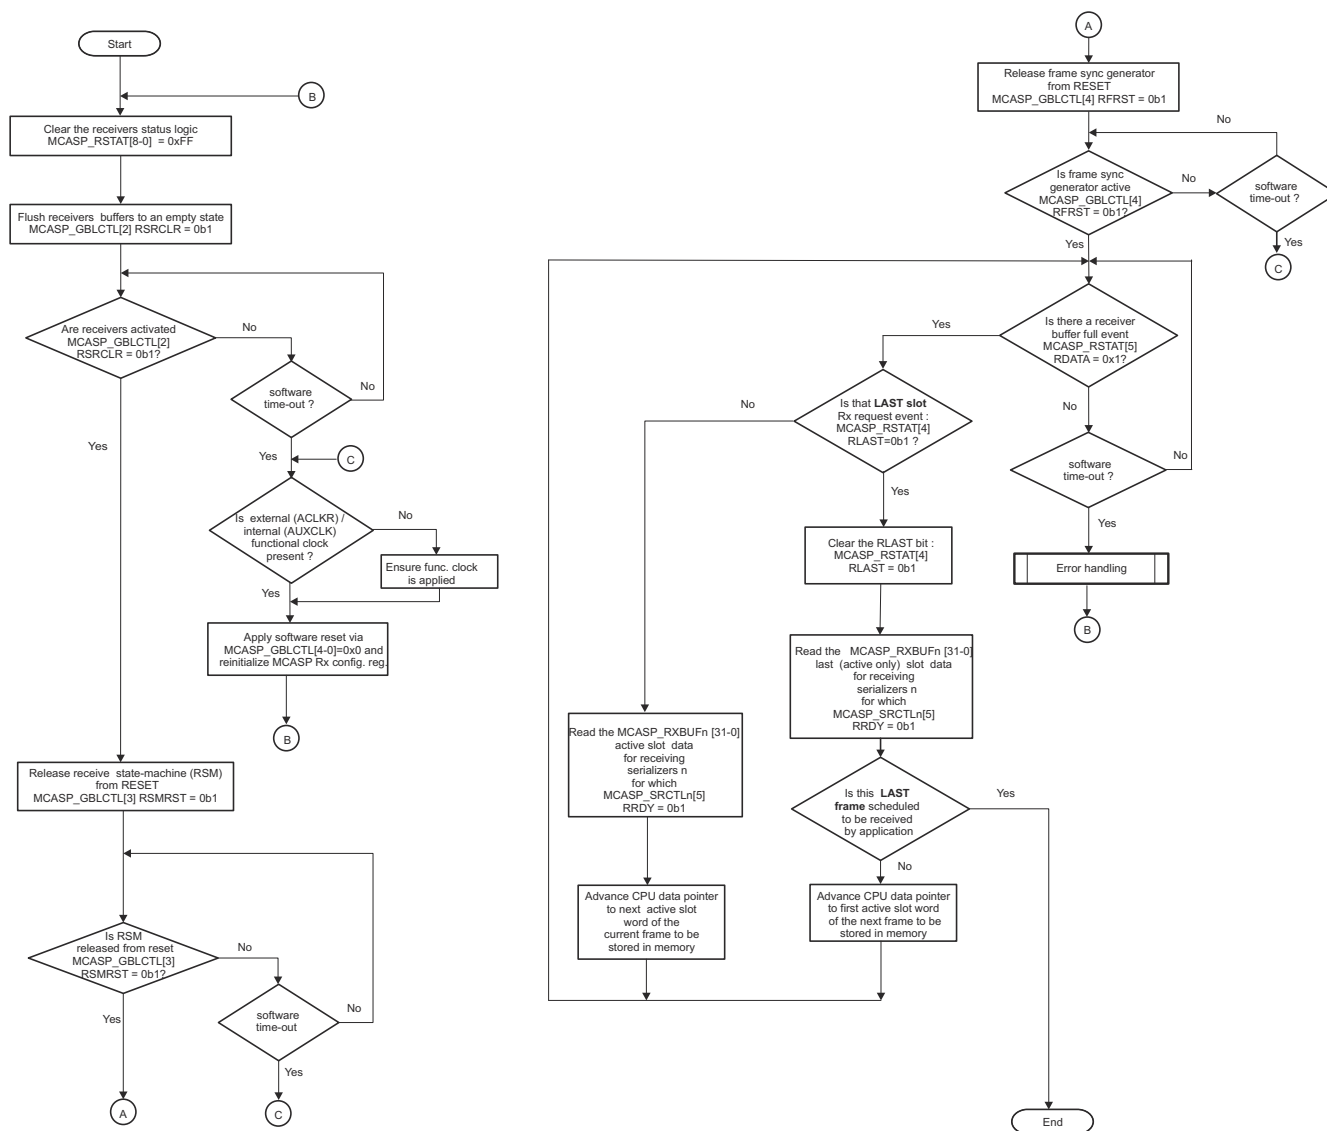

#### 12.5.2.5.2 MCASP Reception Modes

#### 12.5.2.5.2.2.1 Main Sequence – MCASP Polling Reception Method

Figure 12-395 shows the MCASP polling reception method.

### Note

The MCASP polling reception model considers the device CPUs as the accessor of audio data from the MCASP receive buffers.

### Figure 12-395. MCASP Polling Reception Method

These registers are for MCASP reception polling method: MCASP\_RSTAT, MCASP\_XGBLCTL, MCASP\_RBUF<sub>n</sub>, MCASP\_SRCTL<sub>n</sub> (n = 0 to 15).

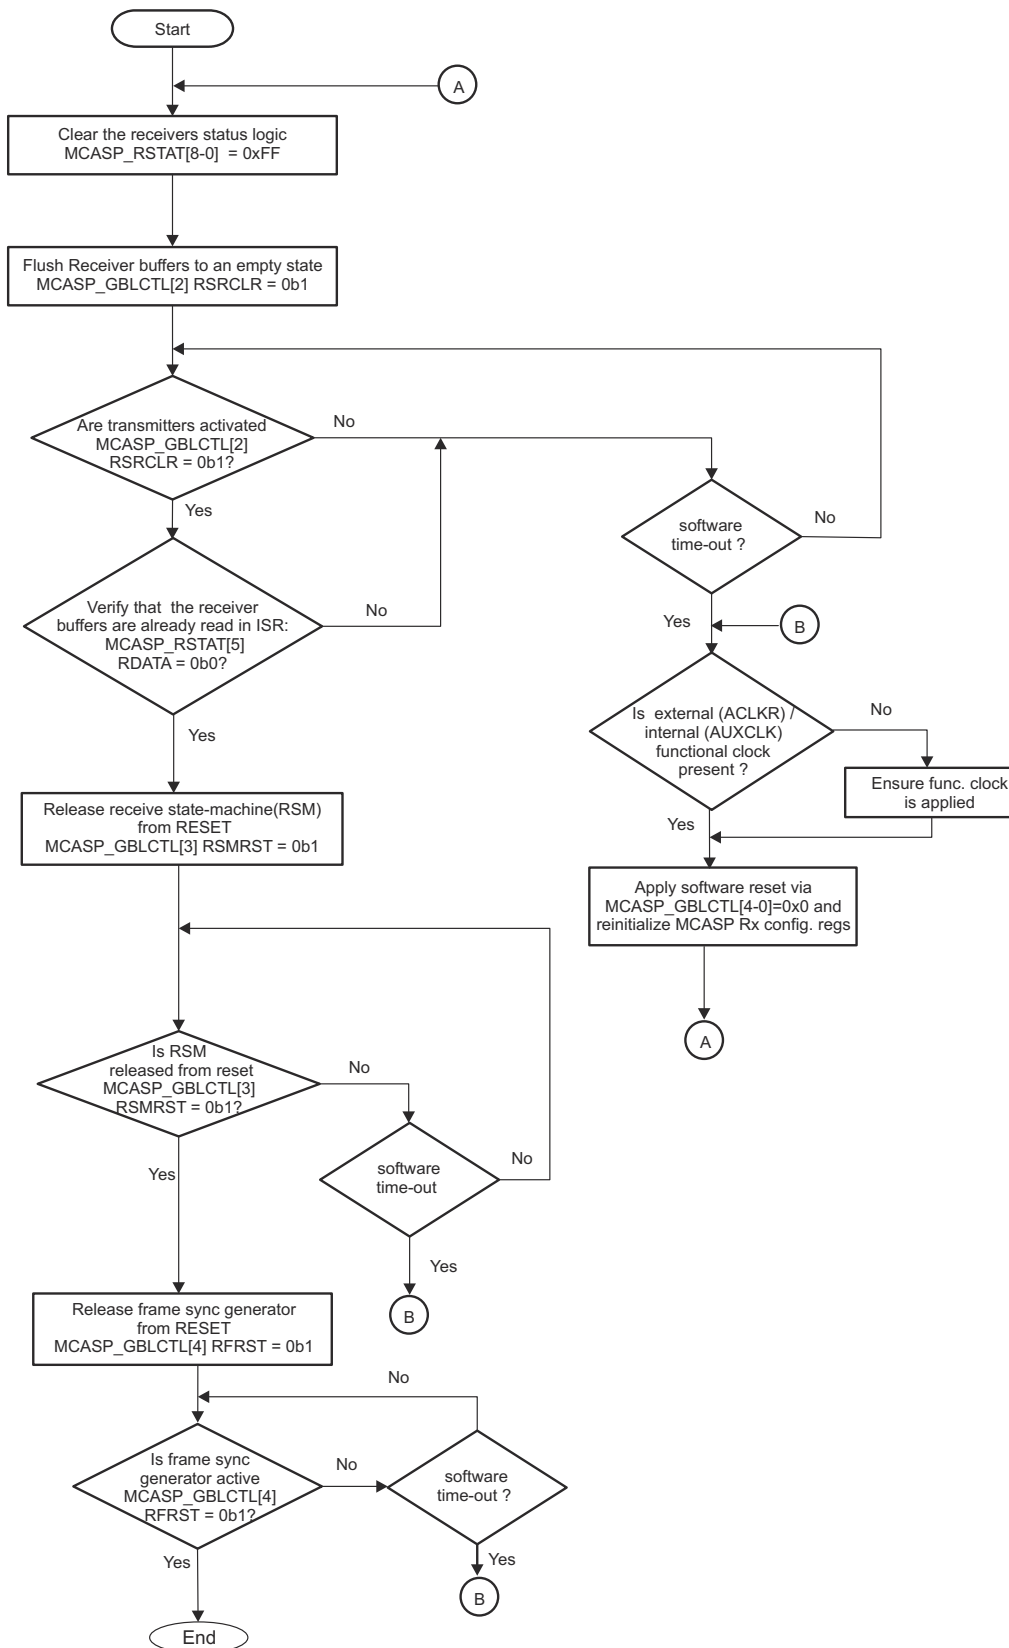

[Table 12-329](#) summarizes the subprocess call for the polling mode.

**Table 12-329. Subprocess Call Summary for Main Sequence – MCASP Reception Polling Method**

Subprocess Name	Cross-Reference
Error handling	<a href="#">Figure 12-400</a>

#### **12.5.2.5.2.2.2 Main Sequence – MCASP TDM - Interrupt Reception Method**

[Figure 12-396](#) shows the initial setup for interrupt-based reception.

mcasp-032

**Figure 12-396. Subsequence – TDM - Reception Startup Procedure**

Table 12-330 shows the configuration of the MCASP using an interrupt method for TDM- reception.

**Table 12-330. MCASP TDM- Interrupt Reception Model**

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_RINTCTL[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt	MCASP_RINTCTL[4] RLAST	0x1
<b>IF</b> read transfer is through the MCASP DATA port (MCASP_RFMT[3] RBUSEL is set to 0b0).		
Software test condition (setting is done in step4 of the <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i> - see <a href="#">Table 12-316</a> )		
Enable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x0
<b>ENDIF</b>		
TDM - Transmission Startup Procedure	See <a href="#">Figure 12-396</a> .	

These registers are for MCASP TDM- interrupt reception model: MCASP\_XGBLCTL, MCASP\_RSTAT.

#### 12.5.2.5.2.2.3 Main Sequence – MCASP TDM - Mode DMA Reception Method

[Table 12-331](#) shows the configuration of the MCASP using the DMA method for reception. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

#### Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

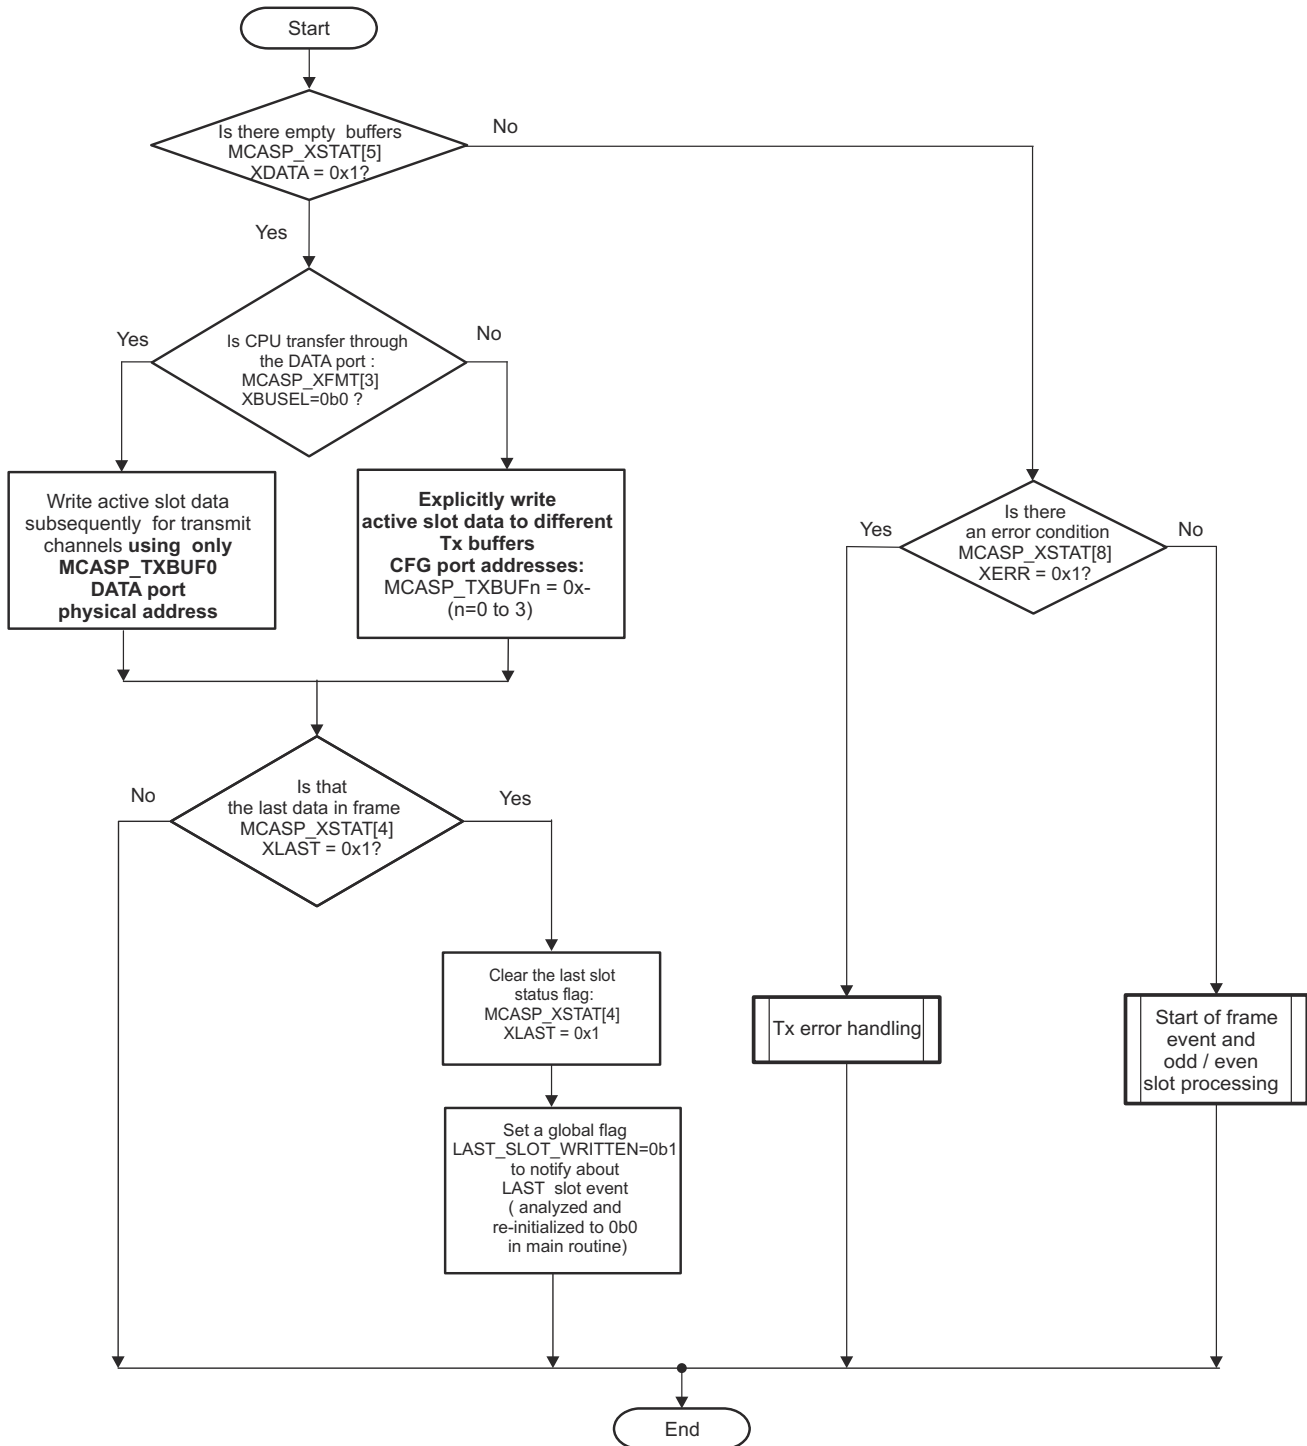

**Table 12-331. MCASP DMA Reception Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_RFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of MCASP DATA port usage.	MCASP_RINTCTL[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_RINTCTL[4] RLAST	0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_RINTCTL[5] RDATA	0x0
DMA startup reception procedure. This procedure is identical than the one shown in <a href="#">Figure 12-396</a> . The only difference is that DMA automatically services all the RINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in <a href="#">Figure 12-398</a> .	See <a href="#">Figure 12-396</a> .	

### 12.5.2.5.2.3 MCASP Event Servicing

#### 12.5.2.5.2.3.1 MCASP DIT-/TDM- Transmit Interrupt Events Servicing

Figure 12-397 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the MCASP module.

## 12.6 Camera Peripherals

## 12.6.1 Camera Serial Interface Receiver (CSI\_RX\_IF)

The following sections describe the Camera Serial Interface Receiver (CSI\_RX\_IF) modules in the device.

### 12.6.1.1 CSI\_RX\_IF Overview

The integration of the CSI\_RX\_IF module allows the device to stream video inputs from multiple cameras to internal memory.

Figure 12-401 shows the CSI\_RX\_IF module overview.

**Figure 12-401. CSI\_RX\_IF Module Overview**

#### 12.6.1.1.1 CSI\_RX\_IF Features

The CSI\_RX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3
- Supports up to 16 virtual channels per input (partial MIPI CSI v2.0 feature)
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_RX
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported)
- One independent (simultaneous) output stream:
  - One (up to 32 Channels) DMA interface through a 128-bit PSI\_L connection to DMSS for transfers to memory:
    - Byte packed (32x4) format, elastic buffer mode
    - Max rate 1 data cycle every 4 main clocks
    - ByteValid per byte in Last Data Phase (LDP)
    - 32 thread ID's supported (virtual channel & data type combinations); Flexible number of threads (32 Max)

- Virtual channels and data types mapped via mmr to PSI\_L thread ID's
- Internal FF based FIFO; RAM based buffer (2kx128)
- Functional and data path error interrupts
- ECC support

#### 12.6.1.1.2 *Unsupported Features*

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

---

#### 12.6.1.2 CSI\_RX\_IF Environment

The CSI\_RX\_IF has no dedicated pins. At the device level, video inputs come from the DPHY\_RX, see [Section 12.6.2](#).

#### 12.6.1.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

## 12.6.1.4 CSI\_RX\_IF Functional Description

### 12.6.1.4.1 CSI\_RX\_IF Block Diagram

Figure 12-402 depicts a simplified internal block diagram of the CSI\_RX\_IF and its surroundings.

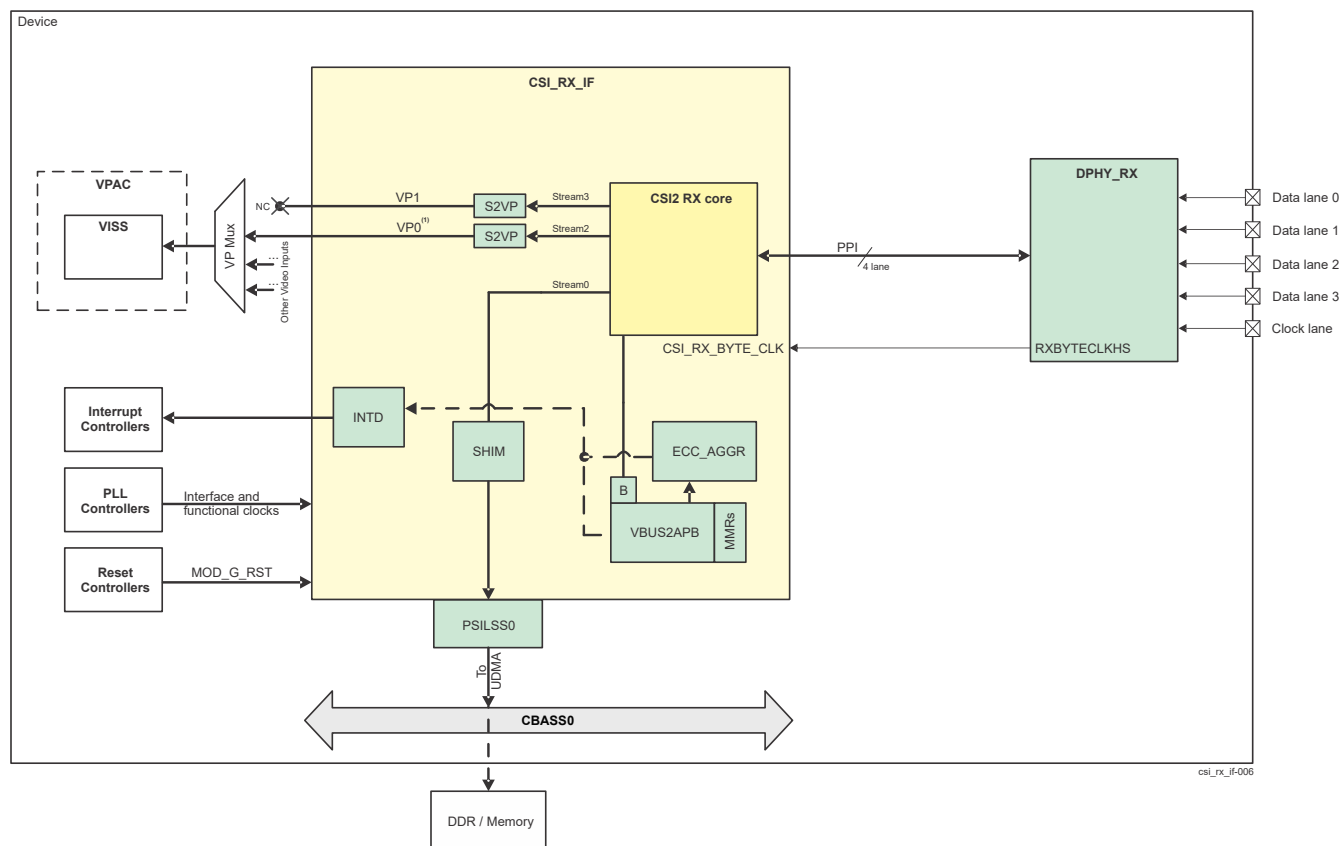

Figure 12-402. CSI\_RX\_IF Block Diagram

The CSI2 core streams 4 channels of data to the export path.

**Stream0** (high BW DMA up to 32 channel contexts) streams 32-bits worth of data, that is re-formatted and sent as pixel format into 128 bits as PSIL data. There are 32 sets of MMRs/Registers that map virtual channels and data type to PSIL threads. Data is sent out PSIL in FIFO order as it is received. There is no priority. Data re-formatting is done to end up with correct data organization in memory so that other ip can use the data. The data type must be configured in MMRs to ensure proper reformatting. See [Section 12.6.1.4.5](#). The large buffer of PSIL data (2048x128) has ECC protection, see [Section 12.6.1.4.7](#)

### 12.6.1.4.2 CSI\_RX\_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI\_RX\_IF by device LPSC. It is internally resynchronized to the functional clock domain.

A software reset is triggered by configuring the CSIRX\_SOFT\_RESET bit-fields for protocol reset and/or module reset.

### 12.6.1.4.3 CSI\_RX\_IF Clock Configuration

There are four clock domain in the CSI\_RX\_IF.

1. The CSI\_RX\_MAIN\_CLK clock runs the CSI2 core PSIL DMA. The minimum clock rate for the CSI\_RX\_MAIN\_CLK is 312.5MHz when DPHY is at max data rate (slower clock permissible when DPHY is at lower data rates). When CSI\_RX\_MAIN\_CLK is operating lower than 312.5MHz, then the clock is

essentially limiting the clock rate of the DPHY\_RX. Said another way, CSI\_RX\_MAIN\_CLK must be at least the CSI\_RX\_BYTE\_CLK rate, else FIFOs will overflow.

The maximum clock rate is 500MHz 16ffc, 650 Max

$f(\text{CSI\_RX\_BYTE\_CLK}) \times \text{nb\_lanes} / 4$ ; where  $f(\text{CSI\_RX\_BYTE\_CLK})$  is the minimum frequency of CSI\_RX\_BYTE\_CLK.

2. The CSI\_RX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_RX\_MAIN\_CLK.
3. The CSI\_RX\_BYTE\_CLK is the clock supplied by the DPHY\_RX PLL and is divided down to byte clock. The DPHY\_RX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_RX is not in HS operation.

Table 12-333 shows the CSI\_RX\_IF and DPHY\_RX inter-clock dependencies.

**Table 12-333. CSI\_RX\_IF Inter-clock Dependencies**

	CSI_RX_MAIN_CLK	CSI_RX_VBUS_CLK	CSI_RX_VP_CLK	CSI_RX_BYTE_CLK
<b>Min freq</b>	CSI_RX_BYTE_CLK freq	CSI_RX_MAIN_CLK / 2 freq	CSI_RX_BYTE_CLK freq	N/A
<b>Max freq</b>	500MHz	CSI_RX_MAIN_CLK / 2 freq	720MHz	312.5MHz

#### 12.6.1.4.4 CSI\_RX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_RX\_IF interrupt signals. For detailed description and mapping of the interrupt of the device interrupt processors see *CSI\_RX\_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI\_RX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-334 lists the event generation and corresponding registers of the CSI\_RX\_IF controller.

**Table 12-334. CSI\_RX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_RX_CSI_ERR_IRQ	CSIRX_ERROR_IRQS_MASK_CFG	CSIRX_ERROR_IRQS	Stream error detected. The CSI_RX_IF0 will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_CSI_ERR_IRQ. Read the status register bitfields to trace the source of the event.
CSI_RX_CSI_IRQ	INTD_CFG_ENABLE_REG_LEVEL_0 CSIRX_ERROR_IRQS_MASK_CFG	INTD_CFG_STATUS_REG_LEVEL_0 CSIRX_ERROR_IRQS	Global functional interrupt that various resynchronized sources converge into interrupt generation.
CSI_RX_CSI_LEVEL	CSIRX_MONITOR_IRQS_MASK_CFG	CSIRX_STREAM0_FIFO_FILL_LVL CSIRX_STREAM1_FIFO_FILL_LVL CSIRX_STREAM2_FIFO_FILL_LVL CSIRX_STREAM3_FIFO_FILL_LVL CSIRX_STREAM0_FIFO_FILL_LVL	PSI_L fifo overflow or VP0/VP1 frame/line mismatch (at the minimum an error interrupt will occur at the end of frame but may be issued within the frame as well). Read the status register bitfields to trace the source of the event.
CSI_RX_CORR_LEVEL	CSIRX_ASF_INT_MASK	CSIRX_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.
CSI_RX_UNCORR_LEVEL	CSIRX_ASF_INT_MASK	CSIRX_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.

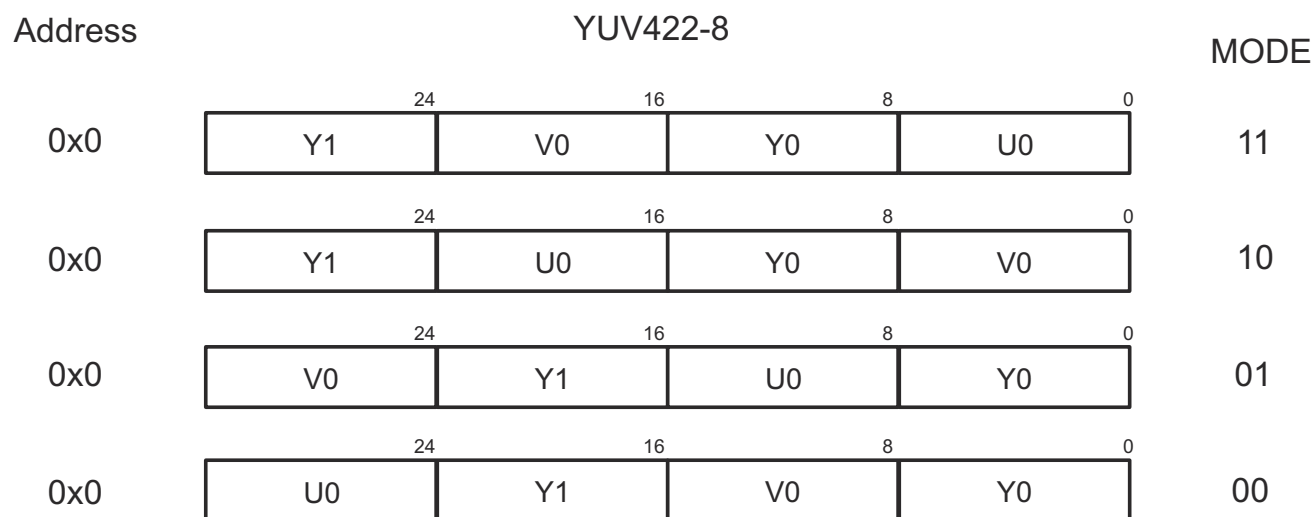

**Table 12-334. CSI\_RX\_IF Interrupt Events Cross Table (continued)**

Event	Mask Register	Status Register	Description
CSI_RX_CSI_FATAL	CSIRX_ASF_INT_MASK	CSIRX_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSIRX_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSIRX_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSIRX_ASF_INT_MASK	CSIRX_ASF_INT_STATUS	ASF port non-fatal interrupt. Level sensitive. Set CSIRX_ASF_FATAL_NONFATAL_SELECT to whether fatal or non-fatal ASF interrupt is triggered. If any of the CSIRX_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

#### 12.6.1.4.5 CSI\_RX\_IF Data Memory Organization Details

#### 12.6.1.4.6 CSI\_RX\_IF PSI\_L (DMA) Interface

##### Note

This section describes CSI\_RX\_IF PSI\_L specific functionality related to the camera interface. The general PSI\_L functional description and registers are described in the PSI\_L specific chapter (see *PSIL Subsystem (PSILSS)*).

##### 12.6.1.4.6.1 PSI\_L DMA framing

The CSI\_RX\_IF stream interface provides the usual VSYNC/HSYNC signals. The signals are per virtual channel where the transition from 1-to-0 or 0-to-1 represents SOF/EOF or SOL/EOL. VSYNC/HSYNC transition is usually not coincident with a valid data phase, though there are use cases where it can be. Because of the nature of CSI protocol, the VSYNC and HSYNC transactions require at least a single clock cycle and can only transition sequentially (important fact in handling of VSYNC events).

There is a rarely used mode of CSI where an entire frame is passed in a single packets without line breaks. In this mode, there are no HSYNC transitions at line starts/ends.

Lastly, there is redundant information provided with each CSI packet where the packet length is supplied in bytes.

To overcome these framing restrictions, the CSI\_RX\_IF PSILSS0 passes metadata through the DMA FIFO. Anytime metadata is inserted into the FIFO, the CSI\_RX\_IF stream is stalled for a clock cycle. The forms of supported meta tags are:

- SOF for a given virtChan
- EOF for a given virtChan
- Packet length in bytes for a given dmaCntx

The PSILSS0 will disregard the HSYNC signal entirely. The long packet beginning is used as SOL and the EOL will be "counted" using the packet length provided. In the special case where packets are of FRAME length, the SOL/EOL handling is identical.

The PSILSS0 solution for VSYNC handling is to create the concept of metadata FIFO entry which is indicated by a metadata bit. The SOF or EOF VSYNC information plus the virtualChan index is fed into the FIFO. On the output of the FIFO, the SOF is saved for each context of that virtualChan type. The very next data phase of that channel context will be marked as SOF. Additionally a state bit per context is maintained indicating the channel is MOP (middle of packet). Once the EOF arrives at the FIFO output, all contexts of that type virtual channel (and currently in MOP state) will receive a PSI\_EOP with zero active bytes of data.

### CAUTION

The line and frame size is not known outside the CSI core (i.e. not passed to the DMA interface). Therefore any mismatches at system level programming will be unknown. If the DMA line/frame size does not match the CSI\_RX\_IF line/frame size, it is assumed the DMA will not result in any adverse side effects as a result of not enough data or too much data.

#### 12.6.1.4.6.2 PSI\_L DMA error handling due to FIFO overflow

The DMA error handling is also called a PSI\_L protocol enforcer. It is intended to prevent hang of the PSILSS0. Unnatural packet size should not cause hang so only SOP/SOL/EOL/EOP framing is enforced. The following list highlights the error handling mechanism:

- For context cleanup the protocol enforcer:
  - cycle through each context index checking if context is in MOL or MOP
  - close out MOP with EOP and MOL&MOP with EOL&EOP
- dropOnFloor SOP if currently in MOPstate
- dropOnFloor EOP if not currently in MOPstate
- dropOnFloor FIFO data
- EOL context if EOP and MOLstate
- After closing out all open contexts the PSILSS0 logic will then wait till end of frame per virtual channel. Once a new frame starts it will then start sending out data from that new frame

#### 12.6.1.4.7 CSI\_RX\_IF ECC Protection Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_RX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregator in the CSI\_RX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the ECC register set, see *CSI\_RX\_IF\_ECC\_AGGR\_0 Registers*. For complete details on the features and functions of the ECC aggregator, see chapter *ECC Aggregator*.

#### 12.6.1.4.8 CSI\_RX\_IF Programming Guide

##### 12.6.1.4.8.1 Overview

This section details specific steps on how to program the CSI\_RX\_IF controller.

##### 12.6.1.4.8.2 Controller Configuration

The CSI\_RX\_IF streams will default to accept all virtual channels and all data types after reset, so the user must program the stream configuration and pixel interface to match the system use case.

### Note

The CSI\_RX\_IF controller can be configured so that the reset values can adopt the users Power\_On state. This can reduce the programming steps required by the system.

The CSI\_RX\_IF controller is designed to operate all the defined streams with all virtual channels and all data types passed to the pixel interface. Also, the connection to the front interface adopts reset values that will allow the connection of the lanes to expect no remapping.

The basic system configuration steps are then programming the number of enabled data lanes and starting the streams.

The system can also decrease the virtual channel and data type processed by the stream by configuring the data config (CSIRX\_STREAM0\_DATA\_CFG - CSIRX\_STREAM3\_DATA\_CFG) registers.

The user must perform a read from the stream config register (CSIRX\_STREAM0\_CFG - CSIRX\_STREAM3\_CFG) at power up to identify the number of streams and pixel interface mode. The stream FIFO depth must be determined from the system configuration information defined at build time to ensure that any programmed [31-16] FIFO\_FILL level is valid for the available FIFO depth.

#### 12.6.1.4.8.3 Power on Configuration

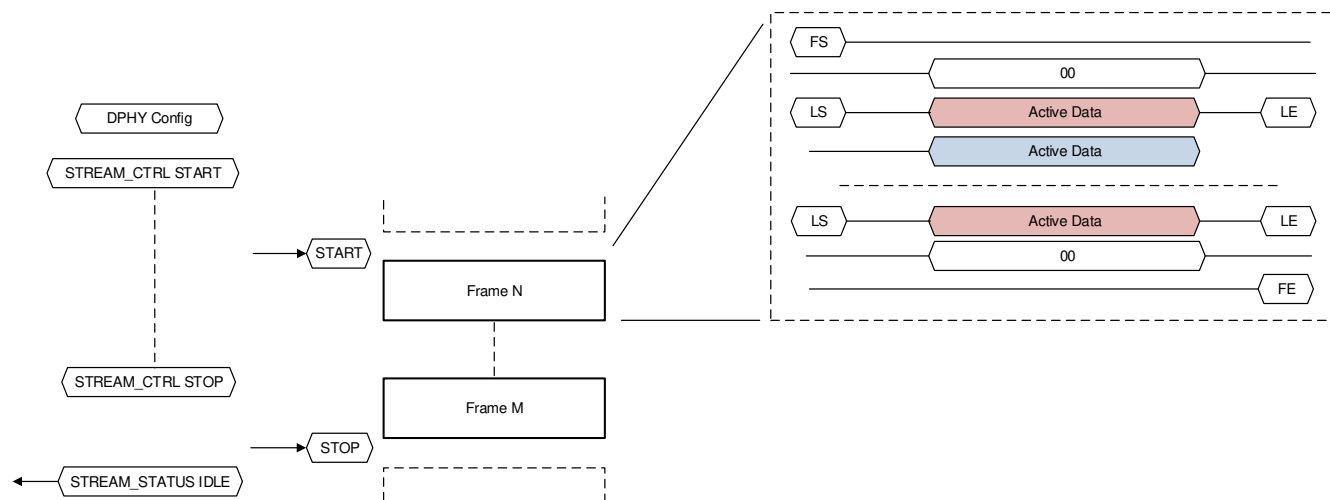

The CSI\_RX\_IF requires the system to perform the configuration of the DPHY\_RX interface before starting the streams of the controller. The default configuration of the controller and each stream can be identified by reading the device ID CSIRX\_DEVICE\_CONFIG register.

The FW must read the CSIRX\_DEVICE\_CONFIG register at power up. This will provide the FW the number of streams that will need to be configured, and all the default system information for the FIFO structures in the available streams.

**Table 12-335. CSIRX\_DEVICE\_CONFIG bitfield details**

STREAMx_NUM_PIXELS	The width of the pixel interface and the bits per pixel for the selected datatype will determine how many pixels can be output in a single cycle. Default will be 1 pixel per clock. 00 -> 1 pixel per clock 01 -> 2 pixels per clock 10 -> 4 pixels per clock
DATAPATH_SIZE	Internal Datapath width 00 - 32 bit, all other values are reserved.
NUM_STREAMS	Number of Stream interfaces (1-4) = (value+1)
MAX_LANE_NB	Max Number of Lanes (1-4) = (value+1)

Figure 12-410 shows the minimal sequence of registers that will configure the DPHY\_RX and then start the stream; this will output all the pixel information for all virtual channels and all data types detected in the link data stream.

**Figure 12-410. Minimal Stream Control - Start and Stop**

#### 12.6.1.4.8.4 Stream Start and Stop

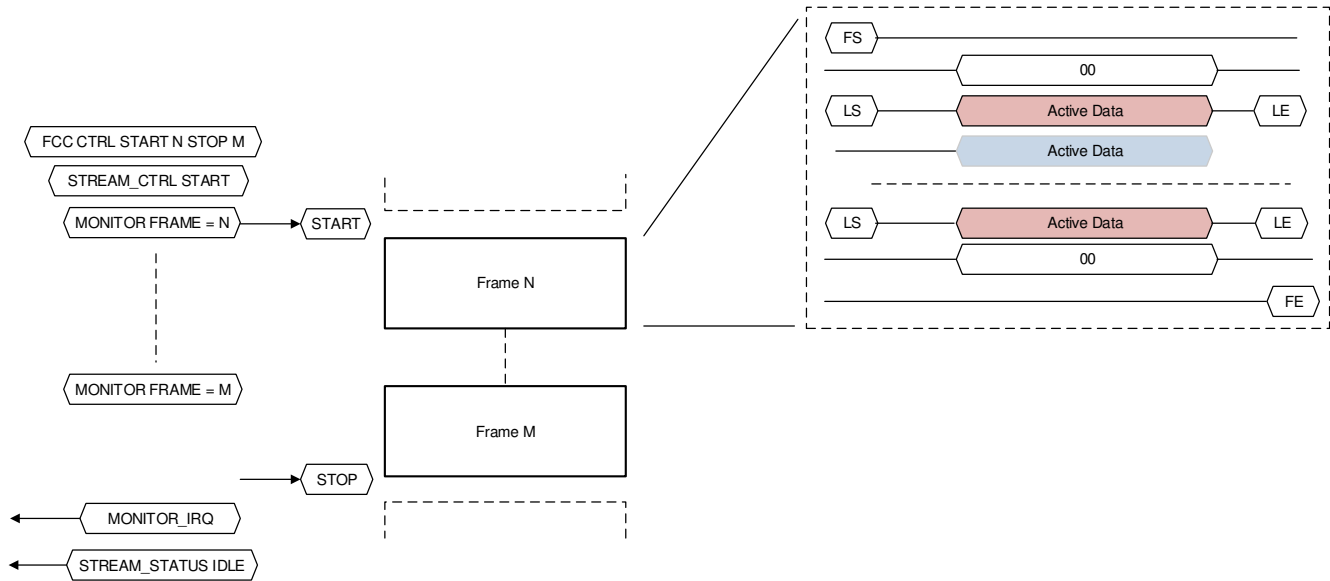

The CSI\_RX\_IF will perform management of the stop and halt control to the pixel stream during functional operation to allow any stream to change the virtual channel or data type information that the stream will process.

- The FW will use the stream control register (CSIRX\_STREAM0\_CTRL - CSIRX\_STREAM3\_CTRL) to perform a stop (set bit 1) and wait for the end of any current frame, and wait for the stream to return its state to IDLE, which can be read from stream status register register (CSIRX\_STREAM0\_STATUS - CSIRX\_STREAM3\_STATUS)[31] RUNNING = 1.
- The FW will use the stream control register to perform an abort and wait for the end of any current line, and wait for the stream to return its state to IDLE, which can be read from register STREAM\_STATUS[31] RUNNING = 1.

**Figure 12-411. Stream Reconfiguration Using Start Stop Start Flow**

The CSI\_RX\_IF will use the monitor control or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

**Figure 12-412. Stream Start and Stop Using Monitor Control**

#### 12.6.1.4.8.5 Error Control With Soft Resets

The CSI\_RX\_IF will perform control of the soft reset either for error event recovery or to clear a stream FIFO or internal state machine.

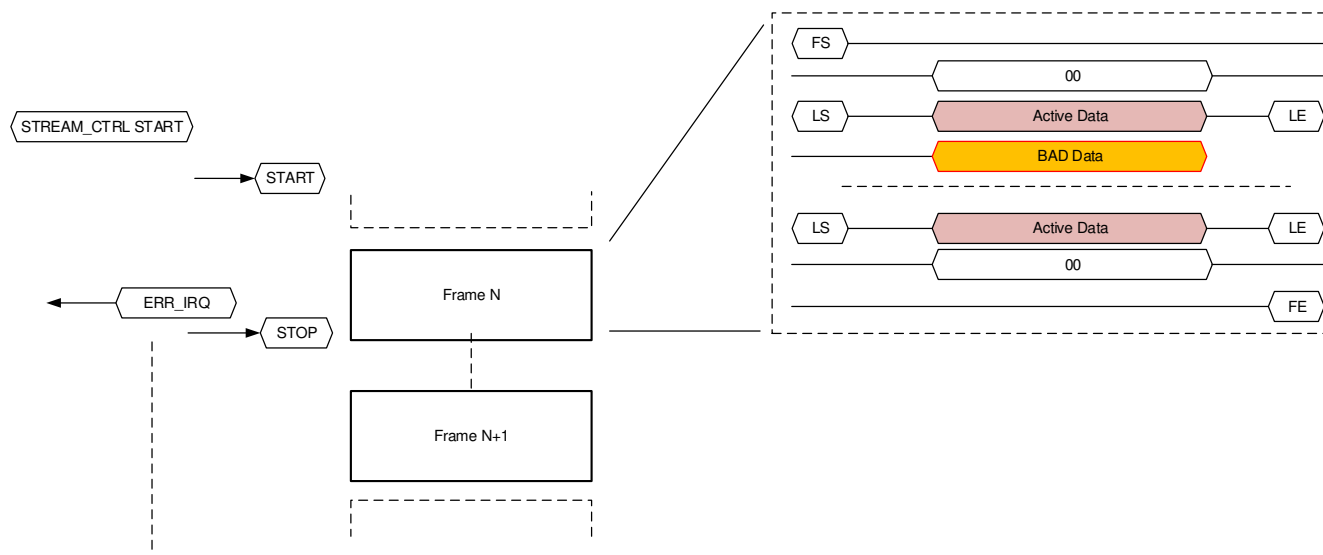

- The FRONT block can be soft reset if the DPHY\_RX becomes unresponsive and the controller wishes to maintain its configuration. In this case the DPHY\_RX resets can be applied and the DPHY\_RX enabled to begin the transfer again.
- The Protocol block can be soft reset if the FRONT soft reset is required, and the protocol is not in the IDLE state.
- The stream soft resets (CSIRX\_STREAM0\_CTRL - CSIRX\_STREAM3\_CTRL)[4] SOFT\_RST can be used to clear the stream to the stop state and reset all the stream state machines and FIFO. If the system has a failure and wishes to clear the stream FIFO and return to a safe state on the pixel interface, the stream soft reset should be asserted.

#### 12.6.1.4.8.6 Stream Error Detected – No Error Bypass Mode

The CSI\_RX\_IF will default to stop processing the frame whenever a header Reserved DT or ECC error is detected, or when a long packet payload CRC is identified.

The CSI\_RX\_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSIRX\_ERROR\_IRQS.

The CSI\_RX\_IF will stop processing the current frame and stop the stream.

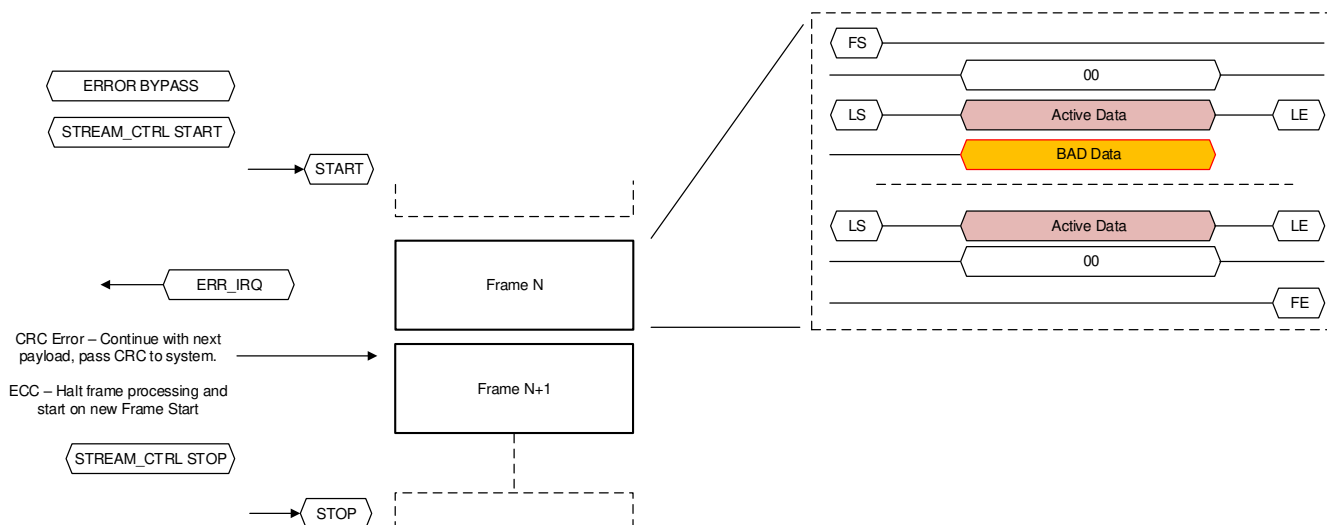

**Figure 12-413. Stream Error Detection Causing Stop**

#### 12.6.1.4.8.7 Stream Error Detected – Error Bypass Mode

The CSI\_RX\_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSIRX\_ERROR\_IRQS.

The CSI\_RX\_IF will continue processing the current frame and continue the stream when a header Reserved DT or a long packet payload CRC error is detected.

The CSI\_RX\_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

**Figure 12-414. Stream Error Bypass - CRC Error During Payload**

#### 12.6.1.4.8.8 Stream Error Detected – Soft Reset Recovery

The CSI\_RX\_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

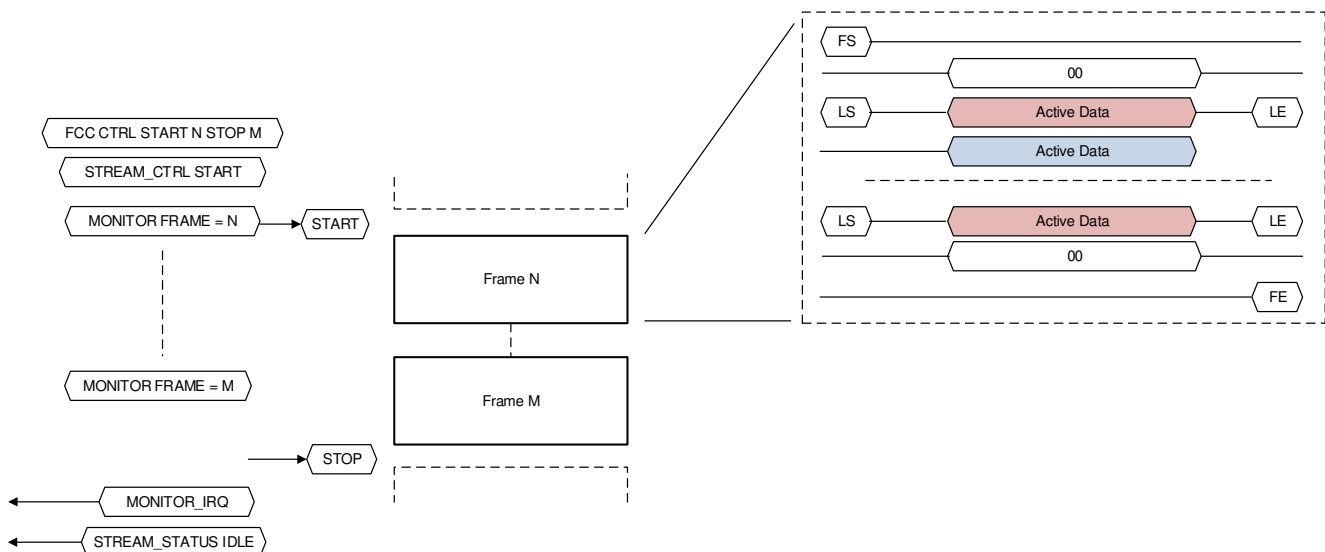

The system can perform a soft reset on the individual stream to clear the pixel interface and payload FIFO and allow the system to restart the stream from the next frame start.

**Figure 12-415. Stream Soft Reset After ECC Non-Recoverable Error**

#### 12.6.1.4.8.9 Stream Monitor Configuration

The CSI\_RX\_IF will use the monitor control (CSIRX\_STREAM0\_MONITOR\_CTRL - CSIRX\_STREAM3\_MONITOR\_CTRL) or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

**Figure 12-416. Stream Start and Stop Using Monitor Control**

The FW will use the FCC config control register (CSIRX\_STREAM0\_FCC\_CFG - CSIRX\_STREAM3\_FCC\_CFG) to perform a start and stop as soon as a frame count is detected. The FCC config control register will define the start and stop frame count and the stream will identify when

these values are matched. The stream output will begin when start frame is detected and then stop once the stop frame is reached. The virtual channel can be defined in CSIRX\_STREAM0\_FCC\_CTRL - CSIRX\_STREAM3\_FCC\_CTRL[4:1] FCC\_VC, and must match the virtual channels that are available to the stream in the CSIRX\_STREAM0\_DATA\_CFG - CSIRX\_STREAM3\_DATA\_CFG register.

The frame capture is enabled when CSIRX\_STREAM0\_FCC\_CTRL - CSIRX\_STREAM3\_FCC\_CTRL[0] FCC\_EN is set '1'

The FW can check the current frame counter value from the CSIRX\_STREAM0\_FCC\_CTRL - CSIRX\_STREAM3\_FCC\_CTRL[31:16] FRAME\_COUNTER

#### 12.6.1.4.8.10 Stream Monitor Frame Capture Control

To use Monitor Frame Capture Control Start and Stop operations:

1. Set Stop and Start values in config register (CSIRX\_STREAM0\_FCC\_CFG - CSIRX\_STREAM3\_FCC\_CFG). Set to '0' for free-running.
  - a. [31:16] FRAME\_COUNT\_STOP -> define desired value
  - b. [15:0] FRAME\_COUNT\_START -> define desired value
2. Set the Virtual Channel to the one that is enabled and the enable in register CSIRX\_STREAM0\_FCC\_CTRL - CSIRX\_STREAM3\_FCC\_CTRL.
  - a. [4:1] FCC\_VC -> define VC used
  - b. [0] FCC\_EN -> set to '1'

This will allow visual checking, by setting the Start/Stop as the following examples, this is the behaviour to be observed:

- Stop = 1 / Start = 1: Output (i.e. display) will show a Frame of the Input (i.e. camera)
- Stop = F / Start = 1: Output will show live image from the input during 14 frames and then will freeze in the last one.

Optionally software can read back the frame count value from register (CSIRX\_STREAM0\_FCC\_CTRL - CSIRX\_STREAM3\_FCC\_CTRL).

In order to do that, software will first need to enable the monitor control register.

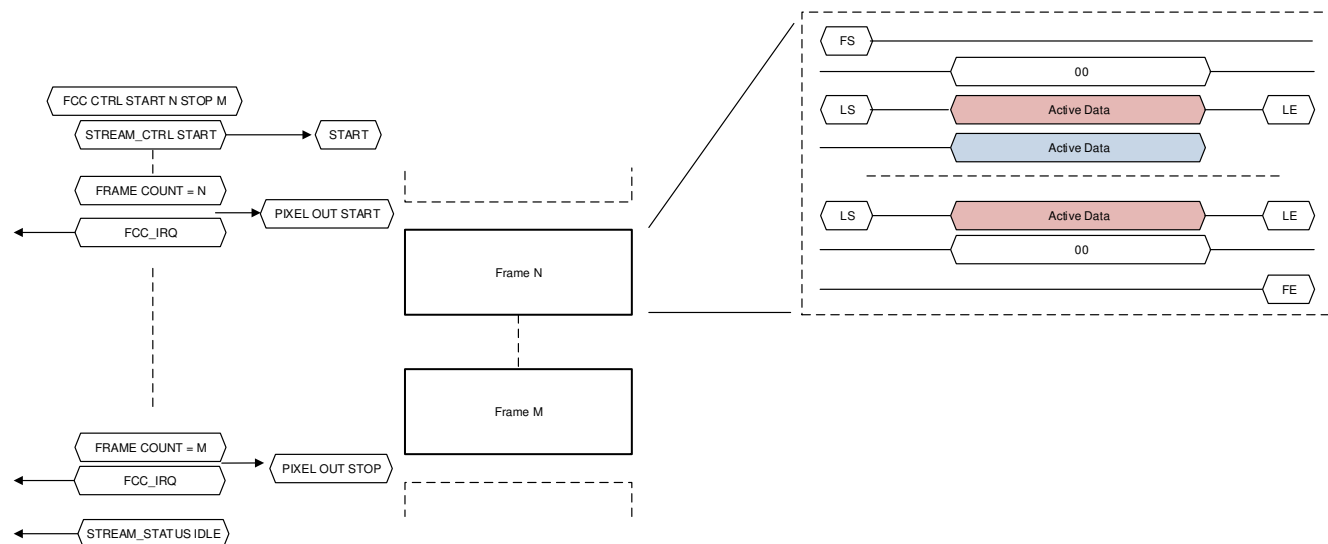

1. Define the same Virtual Channel as above and enable the monitor control register (CSIRX\_STREAM0\_MONITOR\_CTRL - CSIRX\_STREAM3\_MONITOR\_CTRL).
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
2. Read frame\_counter containing the current frame number being processed from CSIRX\_STREAM0\_FCC\_CTRL - CSIRX\_STREAM3\_FCC\_CTRL (only when frame numbers are coming from the protocol, not when internal counter)
  - a. [31:16] FRAME\_COUNTER -> read frame number value

The easiest way to check that the frame number matches the Start and/or Stop values defined, is to use the interrupts in CSIRX\_MONITOR\_IRQS register. To be able to do that you will need to allow those interrupts through the mask register CSIRX\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSIRX\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0's, meaning all interrupts are disabled.
  - a. [4] STREAM0\_FCC\_STOP\_IRQM -> set to '1'
  - b. [3] STREAM0\_FCC\_START\_IRQM -> set to '1'
2. Create an interrupt handler to read from CSIRX\_MONITOR\_IRQS.
  - a. [4] STREAM0\_FCC\_STOP\_IRQ -> read, if '1', Stop interrupt triggered
  - b. [3] STREAM0\_FCC\_START\_IRQ -> read, if '1', Start interrupt triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled if software is using Frame Counter Control features.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-417. Stream Frame Capture Control Flow Diagram**

#### 12.6.1.4.8.11 Stream Monitor Timer interrupt

To use the Stream Monitor Timer operations:

1. Set Count value in timer register (CSIRX\_STREAM0\_TIMER - CSIRX\_STREAM3\_TIMER). If set to 0 won't count but interrupt will still trigger every EOF or SOF.
  - a. [24:0] COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, define timer\_eof and set enable in the monitor controll register (CSIRX\_STREAM0\_MONITOR\_CTRL - CSIRX\_STREAM3\_MONITOR\_CTRL).
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
  - c. [10] TIMER\_EOF -> set to '1' to count from EOF, set to '0' to count from SOF
  - d. [9] TIMER\_EN -> set to '1'
  - e. [8:5] TIMER\_VC -> define VC used

Software should now use the interrupts in register CSIRX\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSIRX\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSIRX\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - a. [0] STREAM0\_TIMER\_IRQM -> set to '1'
2. Create an interrupt handler to read from monitor\_irqs.
  - a. [0] STREAM0\_TIMER\_IRQ -> read, if '1', timer interrupt is triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-418. Timer Interrupt Flow Diagram**

#### 12.6.1.4.8.12 Stream Monitor Line/Byte Counters Interrupt

To use the stream Monitor Line and Byte counters operations:

1. Set LineCount and ByteCount values in register (CSIRX\_STREAM0\_MONITOR\_LB - CSIRX\_STREAM3\_MONITOR\_LB).
  - a. [31:16] LINE\_COUNT -> define desired value
  - b. [15:0] BYTE\_COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, and set enable in register CSIRX\_STREAM0\_MONITOR\_CTRL.
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
  - c. [4] LB\_EN -> set to '1'
  - d. [3:0] LB\_VC -> set to VC used

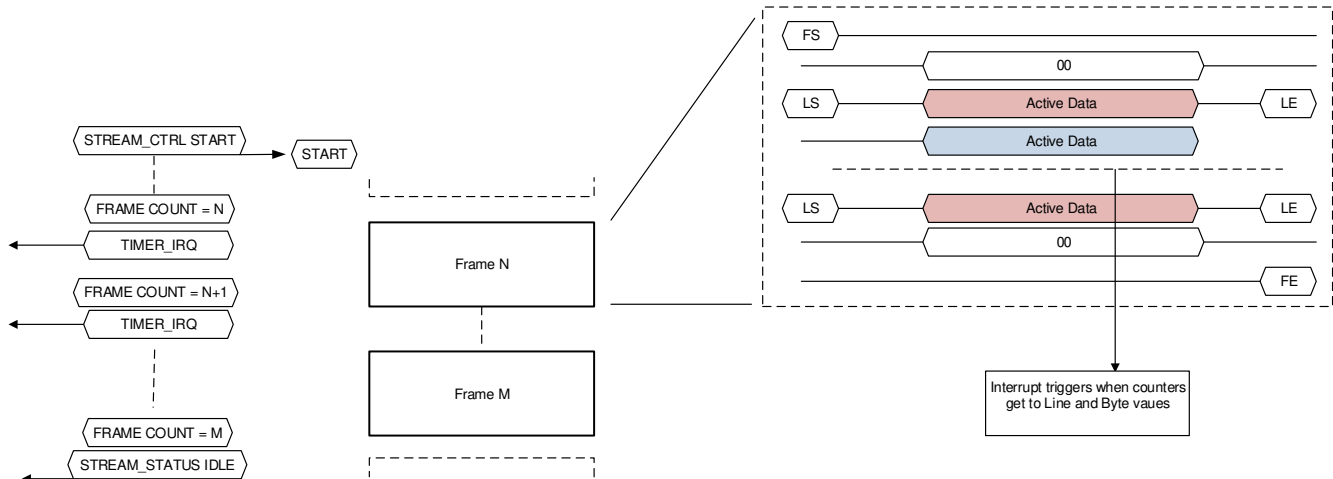

Software should now use the interrupts in register CSIRX\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSIRX\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSIRX\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - a. [7] STREAM0\_LINE\_CNT\_ERROR\_IRQM -> set to '1'
  - b. STREAM0\_LB\_IRQM [1] -> set to '1'
2. Create an interrupt handler to read from CSIRX\_MONITOR\_IRQS.
  - a. [7] STREAM0\_LINE\_CNT\_ERROR\_IRQ -> read, if '1', line count error interrupt is triggered
  - b. [1] STREAM0\_LB\_IRQ -> read, if '1', line/byte counter interrupt is triggered

Note that the interrupt will trigger on each frame when it reaches byte number BYTE\_COUNT in line number LINE\_COUNT.

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-419. Line/Byte Counters Interrupt Flow Diagram**

#### 12.6.1.4.8.13 Example Controller Programming Sequence (Single Stream Operation)

The single stream operation will provide the smallest multi-lane IP configuration with the reduced registers configuration removing some control and status registers. The stream will not require a large FIFO configuration and the clock rates will be matched to simplify the implementation to single pixel transfers using all the available interface bits, (i.e. up to 32).

**Figure 12-420. Basic Single Stream Use Case Illustration**

For single pixel stream configuration, elastic buffer, RAW8 Data type on VC2, one pixel per cycle:

1. Configure the number of DPHY\_RX lanes:
  - a. See CSIRX\_STATIC\_CFG register
2. Set Error Interrupt mask:
  - a. See CSIRX\_ERROR\_IRQS\_MASK\_CFG register
3. Set the Pixel Interface and FIFO configuration. See CSIRX\_STREAM0\_CFG - CSIRX\_STREAM3\_CFG.
  - a. Set [9-8] FIFO\_MODE to select the elastic buffer configuration -> '1'

- b. Set the FIFO fill level that will determines the FIFO depth that must be reached before data is output -> 0x0000
  - c. Select the number of pixels to be output on each cycle -> '0'.
  - d. Set the type of stream interface to "pixel" mode -> '0'
4. Select the virtual channel and data types to be processed. See CSIRX\_STREAM0\_DATA\_CFG - CSIRX\_STREAM3\_DATA\_CFG register.
  - a. Set [31-16] VC\_SELECT and virtual channel bits if not supporting all virtual channels -> 1h, 2h
  - b. Set [7] ENABLE\_DT0 and [5-0] DATATYPE\_SELECT0 values for one or both data types (default all DT) -> 0h, 1h, 2Ah
5. Enable the stream to begin processing the incoming data from the DPHY\_RX. See CSIRX\_STREAM0\_CTRL - CSIRX\_STREAM3\_CTRL.
  - a. Set [0] START bit -> '1'

The stream will begin to pass pixel data matching the configuration on the next frame start.

#### 12.6.1.4.8.14 CSI\_RX\_IF Programming Restrictions

The following CSI\_RX\_IF programming restrictions apply:

- Full line buffer mode is not supported.
- LS/LE detection has a restriction to be disabled
- Only use Pixel transmit mode can be used, never packet mode
  - In pixel mode only single, dual, or quad mode can be used. It is not allowed to mix these based on data format or virtual channels.
- LSB alignment only
- Video port(VP) stream interfaces must be programmed in the CSI\_RX\_IF to meet the following restrictions:
  - Raw 8-16 formats only
  - Dual pixel mode
  - Filtering for single virtual channel and single data type

#### Note

CSI\_RX\_IF has a limitation that any line must fully be exported on its stream interface before a new line or even end of frame is sent on the D-PHY interface. To meet this requirement, software will need to take into account export rates on stream interface(single, dual, quad modes) at 500MHz versus D-PHY 32-bits @ byte clock frequency to know when a new line or end of frame can be sent in after last line was sent over D-PHY interface.

Table 12-336 shows the CSI\_RX\_IF programming requirements for pixel modes and data sizes.

**Table 12-336. CSI\_RX\_IF Programming requirements for pixel modes and data sizes**

Format	Pixel transmit mode used	Size	Details
RAW(6-8), user defined 8-bit	Single	0	
RAW(6-8), user defined 8-bit	Dual	1	
RAW(6-8), user defined 8-bit	Quad	2	
RAW(10-16), user defined 16-bit	Single	1	
RAW(10-16), user defined 16-bit	Dual	2	
RAW20	Single	2	
YUV422-8	Single	0	must set dual mode=0
YUV422-8	Dual	0	must set dual mode=1
YUV422-10	Single	1	
YUV420-8	Single	0	must set dual mode=0
YUV420-8	Dual	0	must set dual mode=1
YUV420-10	Single	1	

#### 12.6.1.4.8.15 CSI\_RX\_IF Real-time operating requirements

Care must be taken on blanking requirements for next line, end of frame, or start of frame. The previous packets(long or short) must be fully consumed before any new line, end of frame, or start frame can be sent over the CSI interface. Software will get various error conditions if these are not met. Below are some sample equations to determine this blanking time. Note that this is not blanking data. High level details are that the internal FIFO must be completely empty prior to sending any thing new into it. below are some sample equations to determine how much time is needed to empty the FIFO and blanking time needed. Byte clock rates, pixel data type, and export modes play into the calculation as well.

$$\text{Byte\_clock\_rate} \times 8 \times \#\text{lanes} \times \text{Tcsi} = \text{pixel\_clock\_rate} \times \text{BPP} \times \text{Tpix} = \text{total bits} \quad (22)$$

BPP = Bits Per Pixel. This number is how many bits are sent per pixel clock cycle is based on single, dual, quad modes and data type.

Tcsi = Time for csi interface to complete 1 line

Tpix = Time for pixel interface to complete 1 line

Tpix16 = Tpix+16/pixel\_clock\_rate

(Tpix16-Tcsi) = required blanking time on CSI interface

Tpix16-Tcsi <= 0 implies 0

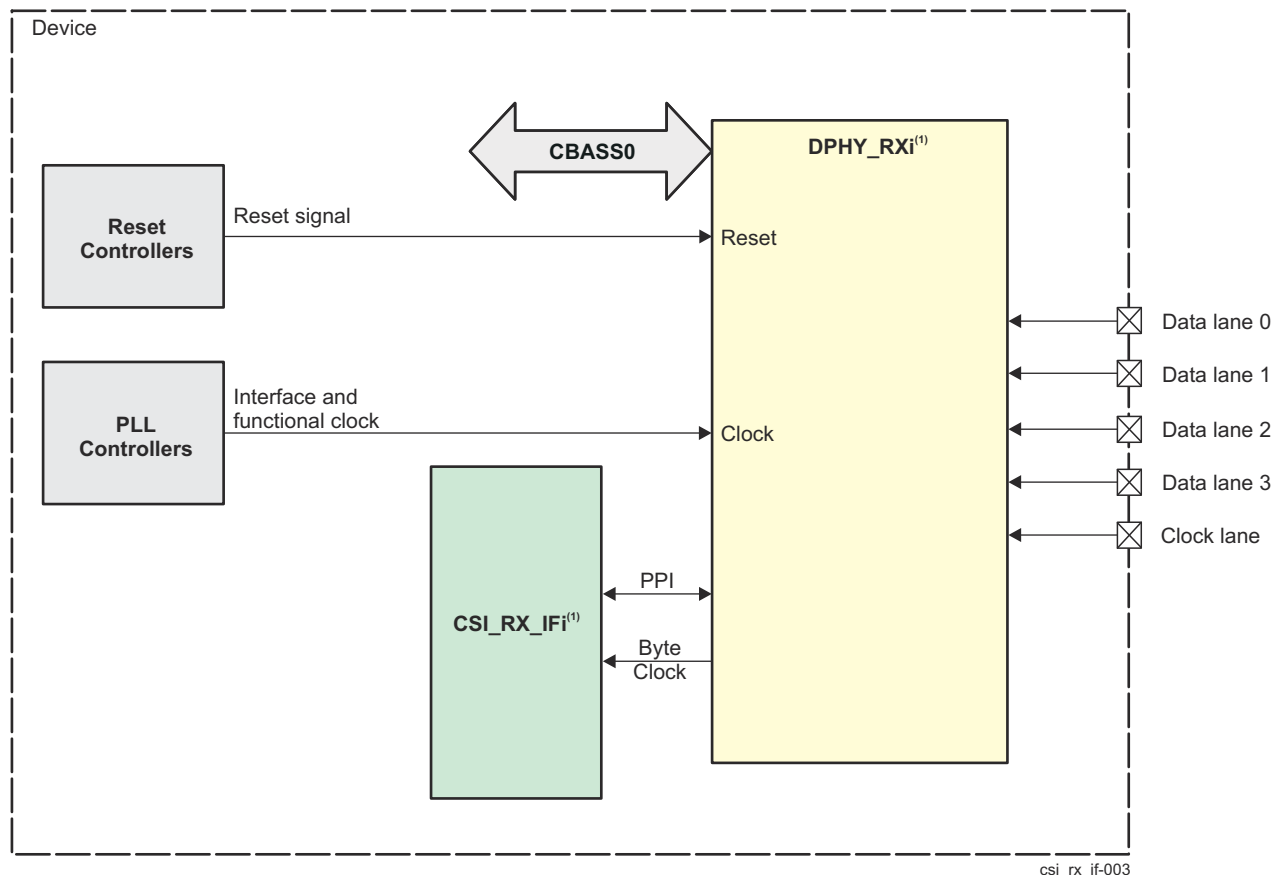

## 12.6.2 MIPI D-PHY Receiver (DPHY\_RX)

The following sections describe the MIPI D-PHY receiver (DPHY\_RX) module(s) in the device.

### 12.6.2.1 DPHY\_RX Overview

The integration of the DPHY\_RX camera physical port module allows the device to grab video streams from external sensor cameras and other CSI2 compliant sources.

Figure 12-421 shows the DPHY\_RX module overview.

A. i represents a DPHY\_RX instance. See the device datasheet for available domains and DPHY\_RX instances.

**Figure 12-421. DPHY\_RX Module Overview**

#### 12.6.2.1.1 DPHY\_RX Features

The DPHY\_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Clock lane control / interface logic type is **CIL-SCNN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **Clock**
  3. **N/A** forward, **N/A** reverse escape mode features
- Data lane control / interface logic type is **CIL-SFAN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **Forward** direction only for high speed mode
  3. **All** forward direction escape mode features are supported
  4. **No** reverse direction escape mode features are supported

- Data lanes can be independently operated in HS or ULP mode
- Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI\_RX\_IF controller)

#### 12.6.2.1.2 *Unsupported Features*

See the *Module Integration* section for information about unsupported features.

---

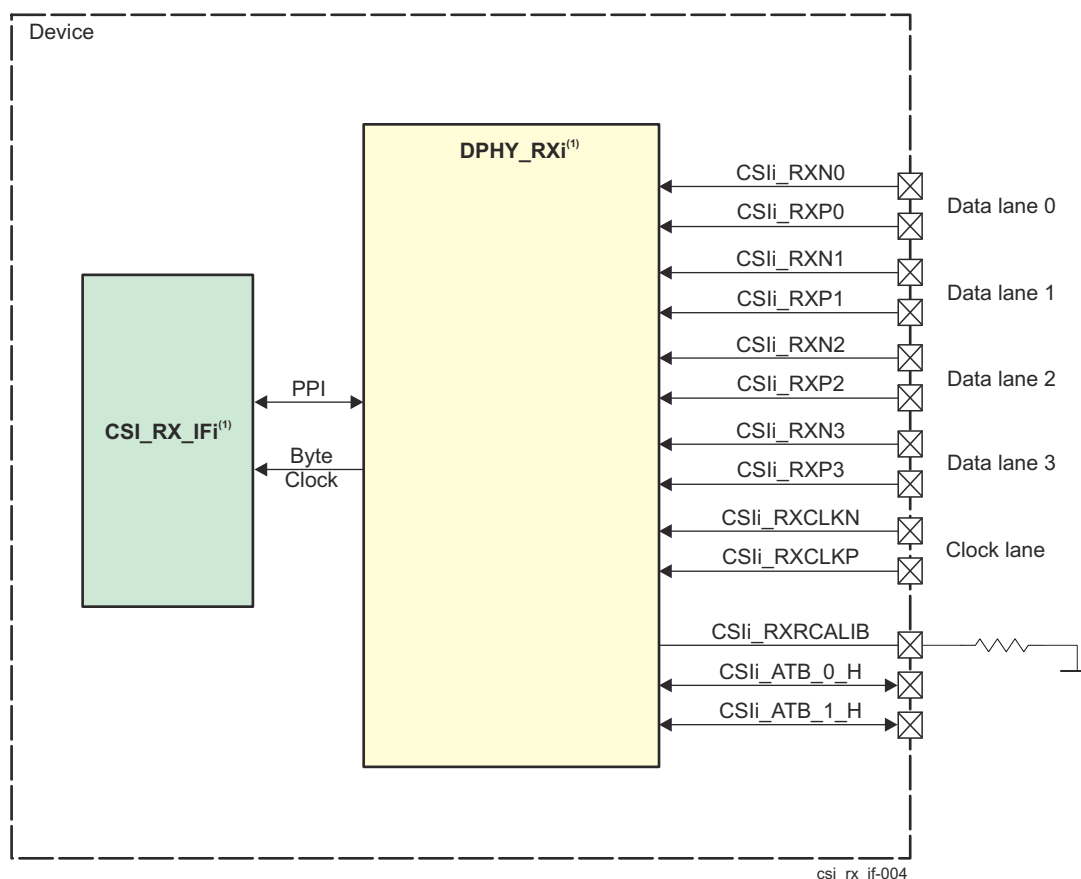

#### **Note**

Some features may not be available. See *Module Integration* for more information.

---

### 12.6.2.2 DPHY\_RX Environment

This section describes the DPHY\_RX application fields from an environment point of view (external connections).

A. i represents a DPHY\_RX instance. See the device datasheet for available domains and DPHY\_RX instances.

**Figure 12-422. DPHY\_RX Enviroment**

Table 12-337 describes the external signals of the DPHY\_RX.

**Table 12-337. DPHY\_RX I/O Signals**

Device Level Signal	I/O	Description
<b>DPHY_RXi<sup>(1)</sup></b>		
CSii <sup>(1)</sup> _RXN0	I	Lane 0 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP0	I	Lane 0 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXN1	I	Lane 1 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP1	I	Lane 1 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXN2	I	Lane 2 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP2	I	Lane 2 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXN3	I	Lane 3 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP3	I	Lane 3 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSii <sup>(1)</sup> _RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSii <sup>(1)</sup> _RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.

(1) i represents a DPHY\_RX instance. See the device datasheet for available domains and DPHY\_RX instances

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.6.2.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

## 12.6.2.4 DPHY\_RX Functional Description

### 12.6.2.4.1 DPHY\_RX Programming Guide

#### 12.6.2.4.1.1 Overview

This section details specific steps on how to program the DPHY\_RX

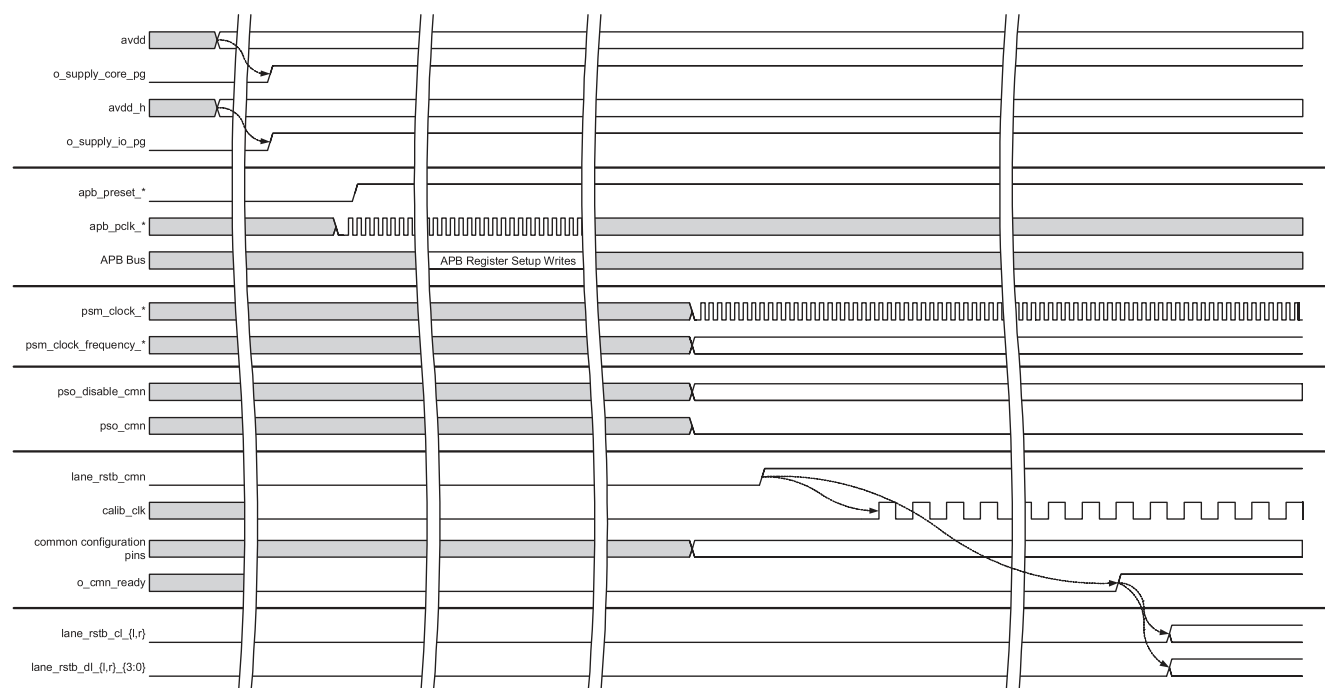

#### 12.6.2.4.1.2 Initial Configuration Programming

The DPHY\_RX operation shows the registers that are written during the startup sequence.

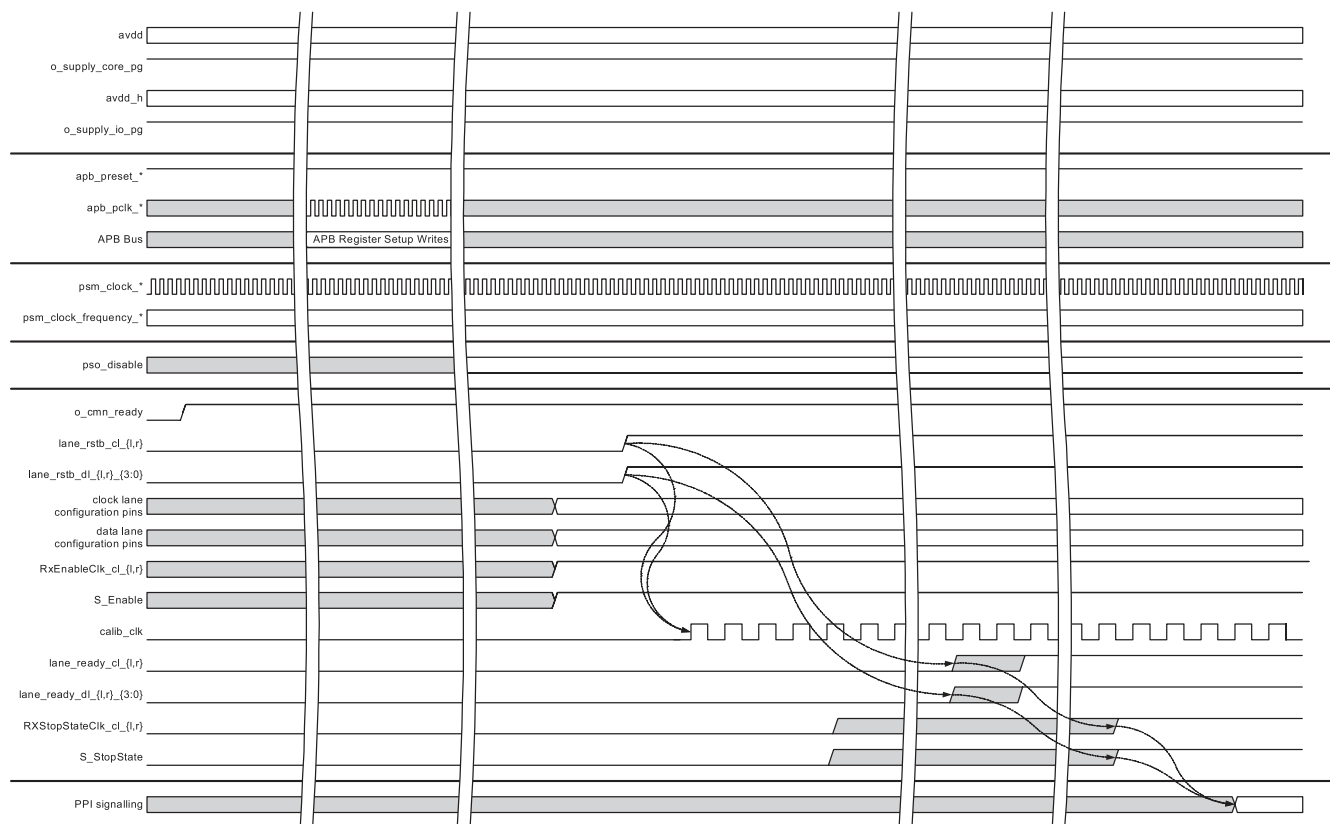

This section provides description and timing diagrams for DPHY\_RX operation. Unless otherwise described in this subsection, the DPHY\_RX PPI interface is compliant with the timing diagrams described in the MIPI D-PHY v1.2 specification.

#### 12.6.2.4.1.2.1 Start-up Sequence Timing Diagram

The common configuration pins noted in [Figure 12-423](#) are ipconfig\_cmn, pll\_ipdiv, pll\_fbdiv, pll\_opdiv, psm\_clock\_freq\_cmn. Drive these pins as per the pin description given in PHY pin list.

**Figure 12-423. Common Power Up and Initialization Timing Diagram**

**Figure 12-424. Lane Power Up and Initialization Timing Diagram**

**Figure 12-425. PHY Disable Timing Diagram**

For initial set up, the DPHY\_RX must be configured/set (registers and configuration input pins) for the common module prior to releasing it from reset, and the lane modules prior to releasing them from reset. Registers shall be configured (as required) between releasing the APB from reset and releasing the common / lanes from reset.

Note that in some cases, the option exists to configure a function using either a pin or a register. In such cases, both options will be specified and the you can select the preferred option.

#### 12.6.2.4.1.3 Common Configuration

**Table 12-338. Common Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Pin: psm_clock_freq PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 1	Set the PMA state machine clock frequency divider. Set either the pin or the register, as specified in the respective description, for the required PMA state machine clock.
PHY Pin: ipconfig_cmn PHY Register: DPHY_RX_MMR_SLV_LANE[11-9] IPCONFIG_CMN	Set the clock lane configuration. Set as specified in the description for the required clock lane configuration.

**Table 12-338. Common Configuration-Related Setup (continued)**

Configuration Register / Pin	Configuration Requirement
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT2[0] O_CMN_SSM_EN, DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT2[10] O_CMN_RX_MODE_EN	Enable the startup state machines for TX mode of operation. Set both register bits to 1'b1.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 2	Set the required power island phase 2 time. Set the register to 32'hAAAAAAAA.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[7:4] POWER_SW_2_TIME_CL_R, DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[3:0] POWER_SW_2_TIME_CL_L	Set the required power island phase 2 time. Set the register to 8'hAA

#### 12.6.2.4.1.4 Lane Configuration

**Table 12-339. Lane Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 0	Set the lane band control value. Set the register fields, as specified in the register description for the required data rate.

### 12.6.3 MIPI D-PHY Transmitter (DPHY\_TX)

This section describes the features and functions of the shared MIPI D-PHY Transmitter (DPHY\_TX).

#### 12.6.3.1 DPHY\_TX Subsystem Overview

The DPHY\_TX module provides one option for video output interfacing by implementing a four-lane MIPI D-PHY Transmitter.

The device includes one or more instances of DPHY\_TX module. See Module Integration for specifics.

##### 12.6.3.1.1 DPHY\_TX Features

The DPHY\_TX0 module supports the following main features:

- Compliance to MIPI D-PHY standard version 1.2.
- Supports up to 4 data lanes and 1 clock lane.
- Supports High Speed up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane.
- Supports Escape mode:
  - Remote triggers
  - LP-DT up to 10 Mbps
  - ULPS mode
- Clock Lane **Control** / Interface **Logic** type is **CIL-MCNN**: [HS-TX, LP-TX]
  1. **(M)** Controller
  2. **C**lock
  3. **N/A** forward, **N/A** reverse escape mode features.
- Data Lane **Control** / Interface **Logic** type is **CIL-MFAA**: [HS-TX, LP-TX, LP-RX, LP-CD]
  1. **(M)** Controller
  2. **F**orward direction only for High Speed mode
  3. **A**ll forward direction escape mode features are supported
  4. **A**ll reverse direction escape mode features are supported.
- Data Lanes can be independently operated in HS or ULP mode.
- Includes a CMN block with reference generators / resistor calibration and an integrated PLL.
- Fault detection:
  - Contention detection (for example, when RX and TX sides of same link drive opposite LP levels).

- Sequence error detection (corruption on lanes).

#### 12.6.3.1.2 *Unsupported Features*

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

---

#### 12.6.3.2 *Integration*

See the *Module Integration* section for information about clocks, resets and hardware requests.

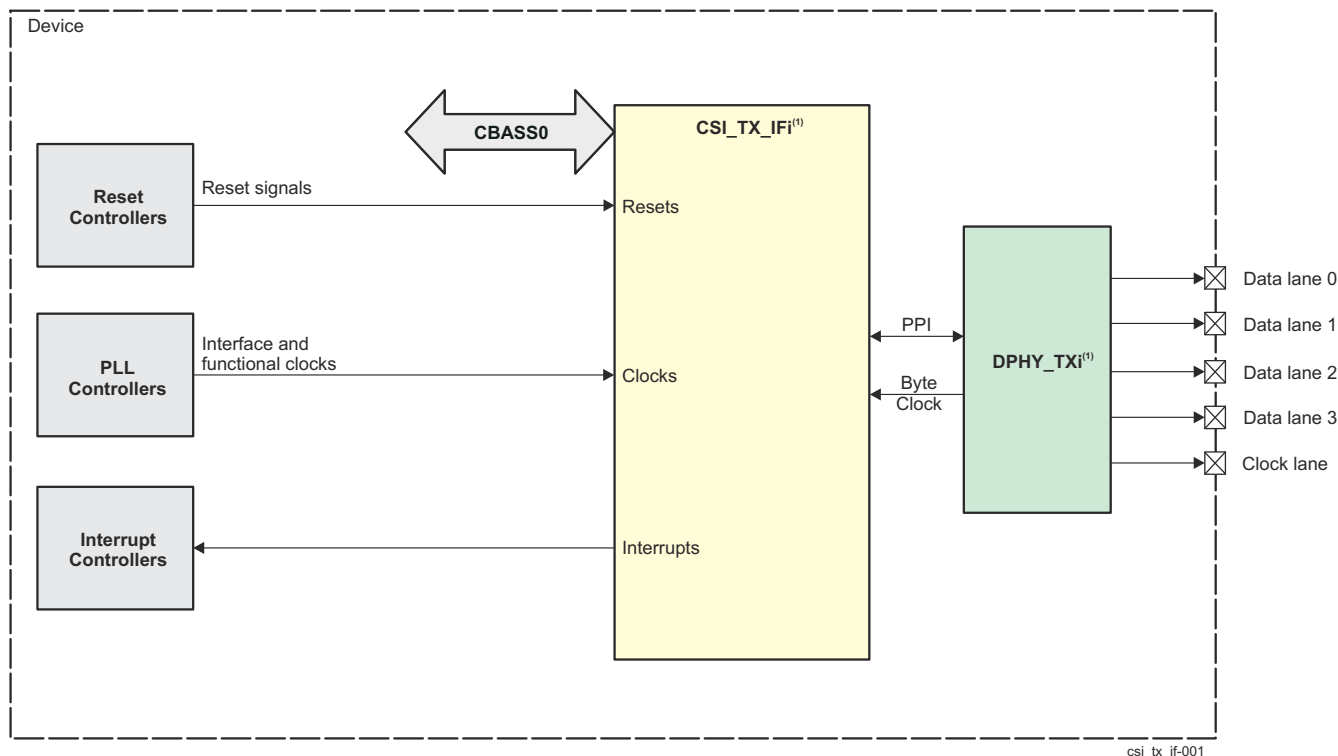

## 12.6.4 Camera Streaming Interface Transmitter (CSI\_TX\_IF)

The following sections describe the camera streaming transmitter interface (CSI\_TX\_IF) module in the device.

### 12.6.4.1 CSI\_TX\_IF Overview

The integration of the CSI\_TX\_IF module allows the device to stream out video data from memory, or retransmit from the CSI receivers as an optional loopback output for diagnostics, debug, and test purposes.

Figure 12-426 shows the CSI\_TX\_IF module overview.

A.  $i = 0$  to  $1$

**Figure 12-426. CSI\_TX\_IF Module Overview**

#### 12.6.4.1.1 CSI\_TX\_IF Ports

This section describes the CSI\_TX\_IF ports related to clocks, resets, and hardware requests.

**Table 12-340. CSI\_TX\_IF Clocks and Resets**

Clocks	
Module Clock Input	Description
CSI_TX_MAIN_CLK	Main functional(sometimes referred to as pixel clock) clock.
CSI_TX_VBUS_CLK	The VBUS clock runs at always half the speed of the CSI_TX_MAIN_CLK.
CSI_TX_ESC_CLK	20 MHz max clock input for low speed data transmission and some control signals.
DPHY_TXBYTECLKHS	The byte clock is the clock supplied by the DPHY_TX.
Resets	
Module Reset Input	Description
CSI_TX_RST	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state.

**Table 12-341. CSI\_TX\_IF Hardware Requests**

Interrupt Requests
--------------------

**Table 12-341. CSI\_TX\_IF Hardware Requests (continued)**

Module Interrupt Signal	Description	Type
CSI_TX_IF_CSI_INTERRUPT_0	Global interrupt that various re-synchronized sources converge into interrupt generation.	Level
CSI_TX_IF_CSI_LEVEL_0	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error on Stream2 (packet error on the stream interface)</li> <li>Retransmit error on Stream3 (packet error on the stream interface)</li> </ul>	Level
CSI_TX_IF_CSI_FATAL_0	ASF port fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CSI_NONFATAL_0	ASF port non-fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CDNS_RAM_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CDNS_RAM_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level

### 12.6.4.2 CSI\_TX\_IF Features

The CSI\_TX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3, MIPI CSI v2.1, and MIPI D-PHY v2.1
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_TX
- Programmable formats including YUV422, RGB, Raw, and User Defined (over 25 different formats supported); Limitations apply depending on the stream used
- 16 virtual channel support
- Configurable input streams supported:
  - Stream0:** DMA interface through a 128-bit PSI\_L connection for transfers from memory **OR** CSI\_RX retransmit:
    - 128bit wide pixel data with bursting
    - ByteValid per byte in Last Data Phase (LDP)
    - 32 thread IDs supported (virtual channel & data type combinations); Flexible number of threads (32 Max).
    - Unpacking PSI\_L data and converting to CSI video format
    - Internal FF based FIFO and external RAM based buffer
  - Stream1:** Color bar video data generator
    - 2 pixel wide
    - YUV422 8-bit format support only
    - Configurable frame/line size via registers
    - 1 programmable virtual channel
    - Internal FF based FIFO; No external buffer.
- Functional and data path error interrupts
- ECC support on external RAMs

#### 12.6.4.2.1 CSI\_TX\_IF Legacy Compatibility

The following lists changes that must be considered compared to previous generation CSI\_TX\_IF:

- YUV420 is not supported, YUV420 configuration registers/bitfields are not used
- Word count must be programmed in the CSI\_TX\_IF, not in the TX Core.
- CSI\_TX\_IF compatibility mode must be used in Stream0 when retransmitting from CSI\_RX\_IF

### 12.6.4.3 CSI\_TX\_IF Environment

The CSI\_TX\_IF has no dedicated pins. At the device level, the CSI\_TX\_IF video output goes through the shared(with DSS\_DSI) DPHY\_TX. See chapter *Shared MIPI D-PHY Transmitter (DPHY\_TX)*.

## 12.6.4.4 CSI\_TX\_IF Functional Description

### 12.6.4.4.1 CSI\_TX\_IF Block Diagram

Figure 12-427 depicts a simplified internal block diagram of the CSI\_TX\_IF and its surroundings.

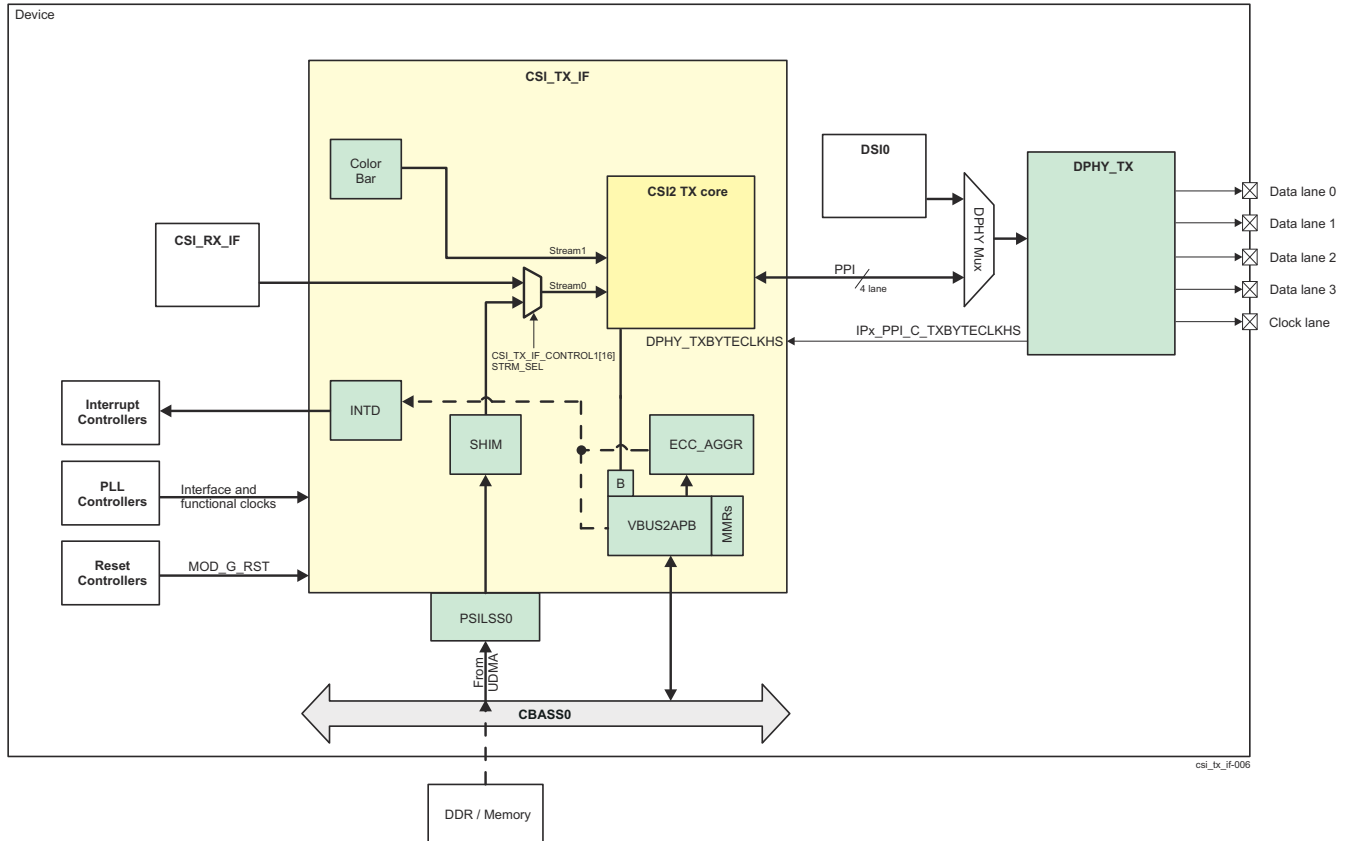

Figure 12-427. CSI\_TX\_IF Block Diagram

The CSI2 core streams 4 channels of data to the several export paths.

**Stream0 (from PSI\_L)** goes through the PSI\_L that converts 128(4x32) bits pixel data and converts it to single 32-bit CSI streaming protocol of pixel data. Each 128 bit set of PSI\_L data is split into N M-bit data transfers based on the SIZE\_CFG bitfield setting in the CSI\_TX\_IF\_DMACNTX\_j register for a given thread. See memory organization details in *CSI\_TX\_IF Data Memory Organization Details*. Via register mapping in the CSI\_TX\_IF\_DMACNTX\_j register the PSI\_L thread ID is mapped to a virtual channel and a data type. The CSI\_TX\_IF\_DMACNTX\_j register is the thread filter. There are 32 dma context registers. Figure 12-428 shows the stream to PSI\_L thread mapping.

Figure 12-428. CSI\_TX\_IF PSI\_L thread mapping

Software must take the following notes in consideration

- Interleaved data formats on single virtual channel and frame are supported.
- All PSI\_L threads that open a frame must be closed before a new PSI\_L thread can start a new frame. Until all channels close the frame other threads will be stalled.
- DATA is assumed in a specific organization for CSI\_TX\_IF to export data correctly. See memory organization details in *CSI\_TX\_IF Data Memory Organization Details*.
- Threads can only switch after full lines are received. PSI\_L pushback will occur on all other threads.
- Thread priority is 0 - 31 and after a line is received will be re-arbitrated in that order for the next thread to send.

Registers CSI\_TX\_IF\_L2L\_DELAY\_j control the line start to next line start. Also register CSI\_TX\_IF\_L2L\_DELAY\_j control the last line of frame to next start of frame first line start of next frame. Buffering of PSI\_L data is 2k×128 RAM.

**Stream0 (from CSI\_RX\_IF)** is a loopback stream from the CSI receiver muxed with PSI\_L data stream.

**Stream1** streams data from the Color Bar generator. It supports YUV422 8bit format only.

CSI\_TX\_IF\_COLOR\_PARAM register is used to control height and width information. Width is divided by 8 for each color section. Colors are defined below. Transfers are done on the Stream1 interface in 32-bit packed 8-bit pixel format(required programming in CSI\_TX\_IF core). Virtual channel and data type is configurable in CSI\_TX\_IF\_COLOR\_CNTL register. Data selection inside CSI\_TX\_IF controller maps data type information. CSI\_TX\_IF\_COLOR\_START\_DELAY register can configure delays from enabled to start. CSI\_TX\_IF\_COLOR\_LINE\_DELAY, and CSI\_TX\_IF\_COLOR\_FRAME\_DELAY register can delay last line to first line of new frame. Once enabled, it will continuously send out frames until disabled. Once disabled, it will stop at end of current frame. [Table 12-342](#) shows the Color Bar format.

**Table 12-342. CSI\_TX\_IF Color Bar format details**

Color	Y	CB	CR
White	235	128	128
Yellow	162	44	142
Cyan	131	156	44
Green	112	72	58
Magenta	84	184	198
Red	65	100	212
Blue	35	212	114
Black	16	128	128

csi\_tx\_if-015

**Figure 12-429. CSI\_TX\_IF PSI\_L Color Bar sample output**

### Note

It is a requirement that only PSI\_L/DMA, color bar, or CSI\_RX\_IF loopback streams are not active at the same point in time. The intended use model is not to have multiple combinations active at any given time. The main issue with this is that RAMs are not sized for concurrent operation and will likely overflow resulting in data loss.

#### 12.6.4.4.2 CSI\_TX\_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI\_TX\_IF by device LPSC. It is internally re-synchronized to the functional clock domain.

A software reset is triggered by configuring the CSI\_TX\_IF\_TX\_CONF[1] SOFT\_RESET\_REQUEST bit-field for protocol reset and/or module reset.

#### 12.6.4.4.3 CSI\_TX\_IF Clock Configuration

There are four clock domain in the CSI\_TX\_IF.

1. The CSI\_TX\_MAIN\_CLK(or also referred to as pixel clock) runs most of the logic. It needs to be same frequency as CSI\_RX\_MAIN\_CLK main clock (500MHz). When CSI\_TX\_MAIN\_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY\_TX. Said another way, CSI\_TX\_MAIN\_CLK must be at least the DPHY\_TXBYTECLKHS rate else FIFOs will overflow, crashing the module.
2. The CSI\_TX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_TX\_MAIN\_CLK (250MHz).
3. The DPHY\_TXBYTECLKHS is the clock supplied by the DPHY\_TX PLL and is divided down to byte clock. The DPHY\_TX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_TX is not in HS operation.
4. The CSI\_TX\_ESC\_CLK escape clock runs at 20MHz. CSI\_TX\_ESC\_CLK is rarely used by the CSI\_TX\_IF, usually is only to clock in some low speed control signals from DPHY\_TX. The ESC interface is a low speed DPHY common link to the camera/sensor.

Table 12-343 shows the CSI\_TX\_IF and DPHY\_TX inter-clock dependencies.

**Table 12-343. CSI\_TX\_IF Inter-clock Dependencies**

	CSI_TX_MAIN_CLK	CSI_TX_VBUS_CLK	DPHY_TXBYTECLKHS	CSI_TX_ESC_CLK
<b>Min freq</b>	DPHY_TXBYTECLKHS freq	CSI_TX_MAIN_CLK / 2 freq	N/A	N/A
<b>Max freq</b>	500MHz	CSI_TX_MAIN_CLK / 2 freq	312.5MHz	20MHz

#### 12.6.4.4.4 CSI\_TX\_IF Interrupt Events

##### 12.6.4.4.4.1 CSI\_TX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_TX\_IF interrupt signals. For detailed description and mapping of the interrupt to the device interrupt processors see *CSI\_TX\_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI\_TX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-344 lists the event generation and corresponding registers of the CSI\_TX\_IF controller.

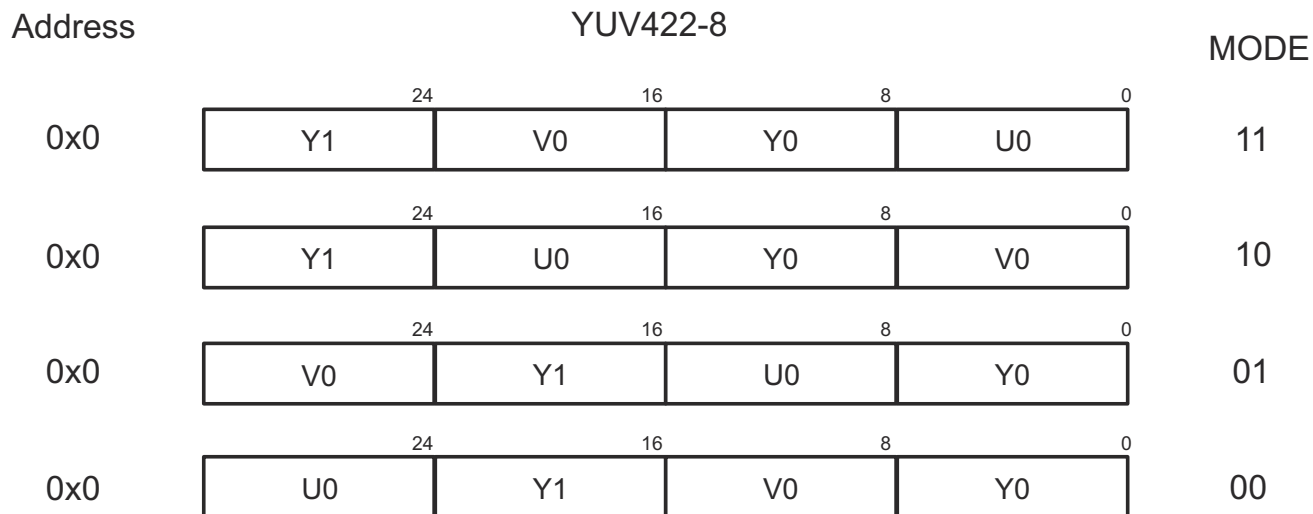

**Table 12-344. CSI\_TX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_TX_IF_MAIN_0_CSI_INTERRUPT	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Global interrupt that various re-synchronized sources converge into interrupt generation. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_LEVEL	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error</li> <li>Unselected stream error. An unselected DMA path or CSI_RX_IF loopback path is sending data when not selected</li> </ul> Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_CORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_UNCORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_UNCORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_FATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

#### 12.6.4.4.5 CSI\_TX\_IF Data Memory Organization Details

Figure 12-430 shows the YUV422-8 data organization in memory.

csi\_tx\_if-007

**Figure 12-430. CSI\_TX\_IF YUV422-8 Memory Data Organization**

[Figure 12-431](#) shows the YUV422-10 data organization in memory.

csi\_tx\_if-008

**Figure 12-431. CSI\_TX\_IF YUV422-10 memory data organization**

Figure 12-432 shows the RAW data organization in memory. User defined data types behave the same as RAW data types.

csi\_tx\_if-011

**Figure 12-432. CSI\_TX\_IF RAW (UNPACKED) memory data organization**

Figure 12-433 shows the RGB data organization in memory.

csi\_tx\_if-012

**Figure 12-433. CSI\_TX\_IF RGB memory data organization**

Figure 12-434 shows the RAW12 (PACKED) data organization in memory.

csi\_tx\_if-013

A. Where data does not fill out to a byte boundary, it is zero extended.

**Figure 12-434. CSI\_TX\_IF RAW12 (PACKED) memory data organization**

#### 12.6.4.4.6 CSI\_TX\_IF PSI\_L (DMA) Interface

The PSI\_L (DMA) interfaces is common for both CSI\_RX\_IF and CSI\_TX\_IF, see chapter *Camera Streaming Interface Receiver (CSI\_RX\_IF) and MIPI DPHY Receiver (DPHY\_RX)*, subsection *CSI\_RX\_IF PSI\_L (DMA) Interface*.

#### 12.6.4.4.7 CSI\_TX\_IF ECC Protection Support

The CSI\_TX\_IF has two ECC aggregators, one for byte clock (DPHY\_TXBYTECLKHS) and the other one for all other clocks. The ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_TX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregators on the CSI\_TX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. They provide a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUS interface for configuring and querying the ECC register set, see *CSI\_RX\_IF\_ECC Registers*. For complete details on the features and functions of the ECC aggregator, see *ECC Aggregator*.

#### 12.6.4.5 CSI\_TX\_IF Programming Guide

##### Note

Software must keep the CSI\_TX\_IF\_CONTROL1[0] PIXEL\_RESET register in the asserted state in the control register until all CSI\_TX\_IF controller registers are programmed. Only after all CSI\_TX\_IF controller programming can software de-assert CSI\_TX\_IF\_CONTROL1 register. If software has to reprogram any CSI\_TX\_IF controller registers it MUST have the control CSI\_TX\_IF\_CONTROL1 register reset asserted.

It is a restriction that LS/LE detection is disabled.

#### 12.6.4.5.1 CSI\_TX\_IF Programming (Configuration Mode)

Although it is always possible to read/write all control registers, it is strongly recommended writing to the control registers only while configuration mode is active. To enter configuration mode, the CSI\_TX\_IF\_TX\_CONF[2] CONFIGURATION\_REQUEST bit must be set. CSI\_TX\_IF enters configuration mode when transmission of any ongoing frame has ended and the configuration request bit is set. Configuration mode is the default state after reset. While configuration mode is active, the CSI\_TX\_IF\_STATUS[2] CONFIGURATION\_ACTIVE bit is set. Traffic at the pixel interface is ignored during configuration mode, and it is safe to write to control registers and change configuration.

To exit configuration mode, the CONFIGURATION\_REQUEST bit in the CSI\_TX\_IF\_TX\_CONF register must be cleared. The CSI\_TX\_IF then starts normal operation, with first new frame incoming after configuration mode exit.

During configuration mode, all interrupts are disabled.

#### Note

A mandatory assertion of soft reset occurs following the de-assertion of CONFIGURATION\_REQUEST. This ensures the controller is in a known state and all the parameters set in the configuration registers have been loaded correctly into the internal state. The DPHY\_TXBYTECLKHS must be active before the configuration request is completed.

#### 12.6.4.5.2 CSI\_TX\_IF System Initialization Programming

The power up/reset release of the system will clear all the register values to their reset conditions. Software must perform programming of the virtual channel and data type registers to match the system operation if the reset conditions do not match the required values. Software must ensure that all the data type select registers are programmed with valid values for the pixel\_dt\_sel\_if parameter used.

The CSI\_TX\_IF registers for all the DPHY\_TX related control and delays must be set before starting the system. The DPHY\_TX delays must be calculated using the system clock periods associated with CSI\_TX\_ESC\_CLK and DPHY\_TXBYTECLKHS. The wait burst time must be calculated using the relevant DPHY\_TX data sheet to ensure that all the lanes begin new requests at the same point.

Software must configure the FIFO fill level control registers, if required to suit clock ratios used and the desired payload control configurations. When all registers are programmed the configuration can be made active. The pixel streams can then start requests.

#### Note

The CSI\_TX\_IF is configured at design time, such that the reset values adopt a generic preferred Power\_On state. This reduces the programming steps required by the system for the general use case scenario.

#### 12.6.4.5.3 CSI\_TX\_IF Lane Control Programming

The CSI\_TX\_IF links to the DPHY\_TX clock and data lanes. After power up, software must identify that the DPHY\_TX is powered on and the DPHY\_TX PLL has locked. The DPHY\_TX controls for swapping the DP/DN control can be modified using the CSI\_TX\_IF\_DPHY\_CFG1 register if required.

Software must then program the enable for the clock lane and each data lane that is required. The DPHY\_TX lane signals can be checked using the CSI\_TX\_IF\_DPHY\_STATUS register to identify that the lane is in STOPSTATE and is ready for High Speed transmission. This register can also be used to identify when ULPS is active.

#### 12.6.4.5.4 CSI\_TX\_IF Virtual Channel and Data Type Management

The following section provides information on how the configuration of virtual channels and data types may be used in conjunction with one or more stream inputs to meet the system requirements.

#### 12.6.4.5.4.1 CSI\_TX\_IF Data Type Interleaving

The CSI\_TX\_IF can support interleaving of data types by configuring the pixel\_dt\_sel\_if inputs at the pixel interface to select the required data type and pixel count values.

#### 12.6.4.5.4.2 CSI\_TX\_IF Data Type Interleaving with Multiple Interfaces

The CSI\_TX\_IF will perform data type interleaving with one, two, or more pixel interfaces. In this scenario, Stream0 will be the master and one or more streams may be ganged together as slaves to the master stream. Therefore, for all the ganged streams, the virtual channel signals must be configured to the same value and the pixel streams must have the same active frame valid cycle (that is the virtual\_channel\_if\* and frame\_valid\_if\* must be wired in parallel). The STREAM\_IF\*\_SLAVE\_MODE bit in the STREAM\_IF\*\_CFG registers must also be set for all slaved streams. This ensures that only one frame start and frame end are generated for all the ganged streams. Note that the pixel 0 interface is always the master and slave bits exist for the other streams, in the control registers, to determine if they are to operate in master or slave mode.

In the case where streams are ganged together as master and slave(s), all ganged interfaces must have the same virtual channel value, but the pixel\_dt\_sel\_if inputs must be set to different values. Again, each of the interfaces can have the pixel\_dt\_sel\_if input change on a line by line basis, so that interleaving is done with all the ganged streams.

#### Note

Each stream must have exclusive use of the data types allocated to it.

Data type interleaving is only done when the frame is valid (CSI\_TX\_IF\_DEBUG\_PROT\*\_FSM[11] FRAME\_VALID\_IF\* bitfield input is asserted). The virtual channel will be sampled on the first cycle after the rising edge of the FRAME\_VALID\_IF input and this virtual channel will be used for all the packets originating from that stream during that frame. The FRAME\_VALID\_IF input must be the same on all ganged stream interfaces.

#### 12.6.4.5.4.3 CSI\_TX\_IF Virtual Channel Interleaving

The CSI\_TX\_IF can support interleaving of virtual channels by using two or more pixel interfaces and configuring the value of the virtual channels signal differently on each interface. The data streams can then be controlled using the pixel\_dt\_sel\_if inputs to select the data type for the lines. In this scenario, each pixel interface must have exclusive use of the virtual channel. Each stream will generate its own frame start and frame end synchronisation packets. In this case, all the stream protocol modules employing virtual channel interleaving must be configured as masters by clearing the STREAM\_IF\*\_SLAVE\_MODE bit in the STREAM\_IF\*\_CFG registers.

Note that the virtual channel control input is sampled at the rising edge of the frame\_valid\_if input, and thereafter remains fixed for that frame, therefore the virtual channel cannot be switched on a line-by-line basis for any single pixel interface. While it is possible to switch the Virtual Channel control input from frame to frame, the timing-critical switching required here would indicate a requirement for hardware rather than software control.

#### 12.6.4.5.4.4 CSI\_TX\_IF Virtual Channel and Data Type Interleaving

The CSI\_TX\_IF may be configured to perform a combination of the scenarios outlined in the previous sections if sufficient streams are available. One or more streams may be ganged with Stream0 to perform data type interleaving on the same virtual channel, whilst the remaining streams may be left autonomous to perform virtual channel interleaving.

In this case, the same rules governing the use of the virtual channels and data types must be observed. In this scenario, the virtual channel signals will be configured to the single value required for the ganged group (as they need to be controlled within the same frame valid active signal) and different values for those left to be autonomous (as they may generate their own frame start and frame end events). The slave stream for each virtual channel can have a different data type selected, and this may change on a line-by-line (or packet-by-packet) basis.

#### 12.6.4.5.5 CSI\_TX\_IF Line Control

The line control block uses the DPHY\_TXBYTECLKHS from the DPHY\_TX PPI interface to take the line data from the packet interface FIFO and transfer the bytes to the active lanes of the DPHY\_TX. The block detects when the DPHY\_TX is ready to transmit high speed data and the pixel stream has packets available.

The line control block performs pixel stream arbitration using the line control arbitration block when more than one pixel stream is generated in the configuration. The block performs all the clock and data lane control required to activate the high-speed transmission and return the lane to ULPS state as required.

##### 12.6.4.5.5.1 CSI\_TX\_IF Line Control Arbitration

The CSI\_TX\_IF controller uses a simple arbitration scheme for configurations with more than one pixel interface.

The arbitration has 2 levels; the first is a round-robin scheme and if no streams are granted by this a priority based scheme is used. The arbitration will select the first stream making a request if there is only one stream waiting or the first in the round robin after a stream has completed transmission. This means that there may be one cycle where the round-robin selector moves across a stream position that is not requesting to transmit.

The re-arbitration boundary is between packets except where line sync is used. In this case the line start packet, long packet and line end are grouped together.

The selected stream will pass the line data from the stream FIFO to the line control block for distribution to the active PPI lanes of the DPHY\_TX.

##### 12.6.4.5.6 CSI\_TX\_IF Lane Manager FSM

Data distribution to the available lanes is controlled via the lane manager FSM.

The state descriptions can be found in [Table 12-345](#).

**Table 12-345. CSI\_TX\_IF Lane Manager FSM State Description**

State (line_fsm_st_r)	Description
LINE_FSM_IDLE	Wait for new transmission to be ready. When start_hs_transmission_c is asserted then go to the transmission state per enabled lanes (lanes_enable_r)
LINE_FSM_BURST_1L	Transmit burst data over lane 0 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_2L	Transmit burst data over lanes 0 and 1 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_4L	Transmit burst data over all lanes until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_LRTE_EPD_SPACER	Insert spacer packets across each active lane. When finished, if EPD Option 1 then go to the LINE_FSM_LRTE_EPD_PDQ state, otherwise go to the LINE_FSM_IDLE state.
LINE_FSM_LRTE_EPD_PDQ	Tell D-PHY to initiate HS-IDLE state and insert PDQ.
LINE_FSM_BURST_END	Wait for being ready for new burst transmission. In this state counter counts until WAIT_BURST_TIME value in the register is reached.

##### 12.6.4.5.7 CSI\_TX\_IF Data Lane Control FSM

Data lanes control uses a simple FSM to sequence entry and exit of Ultra Low Power mode. This FSM observes inputs from the control registers and based on these inputs it generates PPI outputs for ULP mode.

[Table 12-346](#) shows the state descriptions.

**Table 12-346. CSI\_TX\_IF Data Lanes Control FSM State Description**

State (ulps_data_fsm_st_r)	Description
DATA_LN_IDLE	Idle state. In this state HS transmission can be issued if the Clock Lane is in HS mode.
DATA_LN_ULPS_REQ	Request to enter ULP state. Waiting for activation ULP confirmed by the ppi_ulps_active_not_dl input.

**Table 12-346. CSI\_TX\_IF Data Lanes Control FSM State Description (continued)**

State (ulps_data_fsm_st_r)	Description
DATA_LN_ULPS_ACTIVE	ULPS for Data Lanes is active. Waiting for the ulps_req_sync signal being low to exit ULPS.
DATA_LN_ULPS_EXIT	ULPS exiting, waiting for the time defined in the CSI_TX_IF_DPHY_ULPS_WAKEUP register.

#### 12.6.4.5.8 CSI\_TX\_IF Application Examples

This section details specific steps on how to program the CSI\_TX\_IF.

##### 12.6.4.5.8.1 CSI\_TX\_IF D-PHY Control and Configuration

The DPHY\_TX will use a PLL to provide the bit clock for transmission. The CSI\_TX\_IF controller uses the associated byte clock as a primary clock source and this must be active and stable before the CSI\_TX\_IF is ready to transmit high speed data.

Software must perform the programming of the PLL dividers and monitor the lock status. Software must also ensure the correct sequence of programming the PLL, DPHY\_TX and CSI\_TX\_IF to guarantee the clocks are active and resets are released, following the start-up sequence described in DPHY\_TX chapter (See chapter *Shared MIPI D-PHY Transmitter (DPHY\_TX)*).

##### 12.6.4.5.8.2 CSI\_TX\_IF Clock and Data Lane Enable

The DPHY\_TX lanes are controlled using the CSI\_TX\_IF\_DPHY\_CFG register. The clock enable will be asserted once the DPHY\_TX is configured, PLL is programmed and locked and the lanes are enabled. Enabling the clock lane will then make the TX clock module stay in stop state with the DP/DN pads in LP11. The TX clock high speed ready state will be detected once the TX clock lane has completed the preamble and begun to drive the high speed clock.

The configured number of data lanes will be enabled at the same time as enabling the TX clock. The data lane will remain in LP until the high-speed clock is stable and the CSI\_TX\_IF makes the request for the data lane transitions from stop state to active (LP11-LP01-LP00).

##### 12.6.4.5.8.3 CSI\_TX\_IF DP/DN Signal Swap

The DPHY\_TX may have the capability to swap the data pin polarity or invert the clock lane polarity - the CSI\_TX\_IF\_DPHY\_CFG1 register is available within the controller for driving these pad level controls (using the DPHY\_DIFF\_INVERT\_\* fields). The DPHY\_TX will identify any contention issues with the transmitter and flag this using the contention signals and error interrupt - this may be used by software to determine if the data pin or clock lane polarity switching is required or not (by optimizing to the minimum, preferably zero, rate of occurrence of contention issues).

In the DPHY\_TX, the IO pads for the clock and data lanes support swapping of the polarity of the signals DP-DN. All dphy\_differential\_invert\_\* outputs should be treated as asynchronous. Note that, if these signals need to be asserted, they should be asserted before releasing the DPHY\_TX reset.

Each lane can be controlled independently with the CSI\_TX\_IF\_DPHY\_CFG and CSI\_TX\_IF\_DPHY\_CFG1 registers.

##### 12.6.4.5.9 CSI\_TX\_IF DPHY\_TX Status

The status of clock and data lanes is available in the read only CSI\_TX\_IF\_DPHY\_STATUS register. The clock lane fields show the condition of the ppi\_tx\_ulps\_active\_not\_cl and ppi\_stopstate\_cl PPI inputs. The data lane fields show the ppi\_ulps\_active\_not\_dl\* and ppi\_stopstate\_dl\* PPI inputs.

All the status signals are based on the active enabled lane configuration.

The DPHY\_TX can signal error conditions for each lane for contention in low power transitions and signal errors at the start of high speed transitions, using the CSI\_TX\_IF\_DPHY\_IRQ register. The signals can be used to generate an error interrupt event if the relevant bits are set in the CSI\_TX\_IF\_DPHY\_IRQ\_MASK register. The flag can be cleared by writing to the CSI\_TX\_IF\_DPHY\_IRQ register.

#### 12.6.4.5.10 CSI\_TX\_IF ULPS Operation

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the CSI\_TX\_IF module.

#### 12.6.4.5.11 CSI\_TX\_IF System Frame Rate Measurement

The CSI\_TX\_IF provides an interrupt event to signal when the frame start (FS) and frame end (FE) packets are sent to the DPHY\_TX. These events are generated on a stream basis for each virtual channel and allow a system configured to perform virtual channel interleaving to capture the events, and to derive the frame rate achieved based on the flow control and clock configuration.

The system performance will be impacted by the FIFO sizing and any flow control mechanism used by the pixel streams, so this provides a mechanism for checking that the system is scaled correctly.

#### 12.6.4.5.12 CSI\_TX\_IF Configuration for PSI\_L

Table 12-347 lists the settings that must be programmed before enabling CSI\_TX\_IF controller and sending PSI\_L data.

**Table 12-347. CSI\_TX\_IF Configuration table for PSI\_L**

Format	Pixel transmit mode used	Size	Details
YUV420-8	single	0	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV420-10	single	1	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	single	0	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-10	single	1	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	packed	2	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
RGB888, RGB666	single	2	
RGB565, RGB555, RGB444	single	1	
RAW6-7 <sup>(1)</sup>	single	0	
RAW8 <sup>(1)</sup>	dual	1	
RAW8 <sup>(1)</sup>	quad	2	
RAW10 <sup>(1)</sup>	single	1	
RAW10 <sup>(1)</sup>	dual	2	
RAW12 <sup>(1)</sup>	single	1	No packing
RAW12 <sup>(1)</sup>	dual	2	No packing
RAW12(packed) <sup>(1)</sup>	single	0	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW12(packed) <sup>(1)</sup>	dual	1	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW14 <sup>(1)</sup>	single	1	
RAW14 <sup>(1)</sup>	dual	2	
RAW16 <sup>(1)</sup>	single	1	
RAW20 <sup>(1)</sup>	single	2	

(1) User defined/blanking/generic data types are programmed the same way as RAW data types.

#### 12.6.4.5.13 CSI\_TX\_IF Configuration for Color Bar

The following lists the Color Bar configuration requirements:

- Color bar must be set to packed YUV422-8 format, this is an extended datatype in CSI\_TX\_IF controller.
- Software must program CSI\_TX\_IF controller before enabling the color bar from the CSI\_TX\_IF\_COLOR\_CNTL[0] EN bit-field.
- Program CSI\_TX\_IF\_COLOR\_LINE\_DELAY, CSI\_TX\_IF\_COLOR\_FRAME\_DELAY, CSI\_TX\_IF\_COLOR\_START\_DELAY, and CSI\_TX\_IF\_COLOR\_PARAM registers with appropriate configurations. Update CSI\_TX\_IF\_COLOR\_CNTL with virtual channel and data type desired and enable it.

#### 12.6.4.5.14 CSI\_TX\_IF Error Recovery

When an underflow error occurs, software must reset the entire CSI\_TX\_IF by SoC PSC reset and restart over.

#### 12.6.4.5.15 CSI\_TX\_IF Power up/down Sequence

The following lists the power up/down sequence requirements:

1. Software must ensure no more PSI\_L traffic is directed toward the CSI\_TX\_IF module.
2. Software must then go through a tear down process on PSI\_L gasket inside CSI\_TX\_IF wrapper. Refer to chapter *PSI\_L* for tear down process.
3. Software must then check the stream idle values so that they are idle in the CSI\_TX\_IF\_CONTROL1 register.
4. Software must then stop all traffic inside the CSI\_TX\_IF controller and wait till it is idle.
5. After that software can then proceed to do PSC power down routine.

## 12.7 Timer Modules

### 12.7.1 Global Timebase Counter (GTC)

This section describes the global timebase counter (GTC) in the device.

#### 12.7.1.1 GTC Overview

The GTC module provides a continuous running counter that can be used for time synchronization and debug trace time stamping.

##### 12.7.1.1.1 GTC Features

The GTC supports the following features:

- 64-bit up counter
- No rollover during the lifetime of the device
- Compatible with ARMv8 system counter requirements:
  - Disabled at power-up
  - Register definition and memory map aligned to ARMv8 definition
  - Implements memory-mapped counter control and status frames
- Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
- Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

##### 12.7.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 12.7.1.2 GTC Functional Description

#### 12.7.1.2.1 GTC Block Diagram

The GTC is essentially comprised of a 64-bit up counter, a Gray encoder, a 64-bit multiplexer, and memory-mapped control registers. [Figure 12-435](#) shows a high-level block diagram of the GTC.

**Figure 12-435. GTC Block Diagram**

#### 12.7.1.2.2 GTC Counter

The counter is a 64-bit binary up counter that increments on every GTC\_CLK rising edge. The source for GTC\_CLK is selected through a mux which is controlled via the CTRLMMR\_GTC\_CLKSEL[2-0] CLK\_SEL register bit field.

The counter is disabled by default (at power-on-reset) and increments only when enabled by setting the *GTC\_CFG1\_CNTCR*[0] EN bit to '1'. The current counter value is readable via the combined COUNTVALUE bit field of both *GTC\_CFG1\_CNTCV\_HI* (upper 32 bits) and *GTC\_CFG1\_CNTCV\_LO* (lower 32 bits) registers.

When counting is disabled, a new counter value can be loaded via a software write to the combined COUNTVALUE bit field. In this case, when the counter gets re-enabled, it will start counting from the last value written to this field.

The counter can be optionally configured to stop incrementing when a debug halt signal is issued, by writing a '1' to the *GTC\_CFG1\_CNTCR*[1] HDBG bit. This condition is indicated through the *GTC\_CFG1\_CNTSR*[1] DBGH status bit.

##### 12.7.1.2.2.1 Steps to Clear the Counter Value to Zero

1. Disable the GTC
2. Clear GTC\_CNTCV\_LO (First)
3. Clear GTC\_CNTCV\_HI (Second)
4. Enable the GTC

Once the GTC is enabled, the GTC\_CNTCV\_HI bit will be cleared to zero.

#### 12.7.1.2.3 GTC Register Partitioning

The ARMv8 architecture spec requires specific system-level components, each with one or two register frames. To accommodate this, the GTC memory-mapped registers (MMRs) are divided into four separate regions (4KB each):

- Peripheral MMRs (GTC0\_GTC\_CFG0): This region includes standard peripheral identification registers and any other control registers not associated with the ARMv8 system timer functions.

- Counter control MMRs (GTC0\_GTC\_CFG1): This region includes registers that provide control over the operation of the system timer.
- Counter status MMRs (GTC0\_GTC\_CFG2): This region includes registers that provide a mechanism for reading the status of the system timer.
- Timer control MMRs (GTC0\_GTC\_CFG3): This region includes registers that identify and provide a control mechanism for memory-mapped timer implementations. For this device, no memory-mapped timers are implemented and only the minimum registers required to indicate the presence of no timers are necessary.

### 12.7.2 RTI-Windowed Watchdog Timer (WWDT)

This section describes the Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module in the device.

#### CAUTION

The RTI module shall be used to serve only as a Digital Windowed Watchdog (DWWD).

The Real Time Interrupt module provides timer functionality for operating systems and for benchmarking code. The module incorporates several counters, which define the timebases needed for scheduling in the operating system.

This module is specifically designed to fulfill the requirements for OSEK (“Offene Systeme und deren Schnittstellen für die Elektronik im Kraftfahrzeug”; “Open Systems and the Corresponding Interfaces for Automotive Electronics”) as well as OSEK/Time compliant operating systems.

The timers also provide the ability to benchmark certain areas of code by reading the counter contents at the beginning and the end of the desired code range and calculating the difference between the values.

#### 12.7.2.1 RTI Features

The RTI modules include the following main features:

- Windowed Watchdog Timer (WWDT) feature.
- Two independent 64 bit counter blocks (counter block0 or counter block1). Each block consists of
  - One 32 bit up counter
  - One 32 bit free running counter
  - Two capture registers for capturing the prescale and free running counter on a special event.
- Free running counter 0 can be incremented by either the internal prescale counter or by an external event.
- Four configurable compare registers for generating operating system ticks . Each event can be driven by either counter block0 or counter block1.
- Fast enabling/disabling of events.
- RTI clock input derived from any of the available clock sources, selectable in the System Module
- Optional capability to drive a pulse-width modulated signal out on an interrupt line.

#### 12.7.2.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

Some features may not be available. See *Module Integration* for more information.

### 12.7.2.3 RTI Functional Description

The MCU\_RTIO and RTI modules are hereinafter referred to as RTI module.

#### 12.7.2.3.1 RTI Digital Windowed Watchdog

---

##### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

---

##### Note

Digital windowed watchdog (DWWD) timer is implemented using the digital windowed watchdog function of the RTI modules. Real time interrupt functionality is not supported. In this mode, the timer should default to disabled and user can adjust the period as desired before enabling the watchdog.

---

In addition to the time-out boundary configurable via the digital watchdog (DWD), some applications may also want to configure the start-time boundary of the watchdog. This is enabled by the digital windowed watchdog (DWWD) feature.

### Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a non-maskable interrupt to the CPU. This is controlled by configuring the RTI\_RTIDWDRXNCTRL register. As stated earlier, when the watchdog needs to be enabled by software, the watchdog counter is disabled on a system reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The RTI\_INTR\_WWD interrupt handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key RTI\_RTIWDKEY register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the RTI\_INTR\_WWD handler does not service the watchdog in time, it could count down all the way to zero and wrap around. No second exception for a time out is generated in this case.

### Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD.

**Figure 12-436. RTI Digital Windowed Watchdog Timing Example**

**Figure 12-437. RTI Digital Windowed Watchdog Operation Block Diagram**

### 12.7.2.3.1.1 RTI Debug Mode Behavior

---

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

Once the system enters debug mode, the behavior of the RTI depends on the RTI\_RTIGCTRL[15] COS bit. If the bit is cleared and debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode.

The DWD counter will not decrement in debug mode and will hold its current value, regardless of the RTI\_RTIGCTRL[15] COS bit.

---

#### Note

The user must not service the watchdog while in debug mode.

---

### 12.7.2.3.1.2 RTI Low Power Mode Operation

The operation of the RTI module is guaranteed in run, doze and snooze mode. In sleep or hibernate mode all clocks will be switched off and the RTI module will not work.

In doze and snooze modes all parts of the RTI are active, since it has to be able to wake up the device with compare and timebases interrupts. Capturing events generated by the interrupt module is also possible since in both modes the peripheral modules are able to generate interrupts, which can trigger capture events. The RTI module will generate compare and timebases interrupts. The compare interrupts will periodically wake up the device.

---

#### Note

In the special case of doze mode with DPLL off, RTI\_FCLK might have a different period than with DPLL enabled, since RTI\_FCLK will be derived from the oscillator output. It has to be ensured that the RTI\_ICLK to RTI\_FCLK ratio is at least 3:1.

---

The DWD/DWWD remains active when the device enters low power mode as long as the RTI\_FCLK is kept active.

Whenever the LPSC that controls an RTI is in any state other than Enable (see , *Module States*), the RTI cannot count or generate interrupts. For more information, see , *Power Control Modules*.

During standard SoC warm reset the RTI and the rest of the SoC are reset. In this case, the RTI counters are stopped and interrupts are not issued. During reset-isolated warm reset, if an R5FSS is put in reset-isolation, then the associated RTI also becomes reset isolated. As such, the R5FSS and the RTI are not reset, but RTI stops counting and cannot generate interrupts until R5FSS is taken out of CLKSTOP (brought to Enable state).

### 12.7.2.3.2 RTI Digital Watchdog

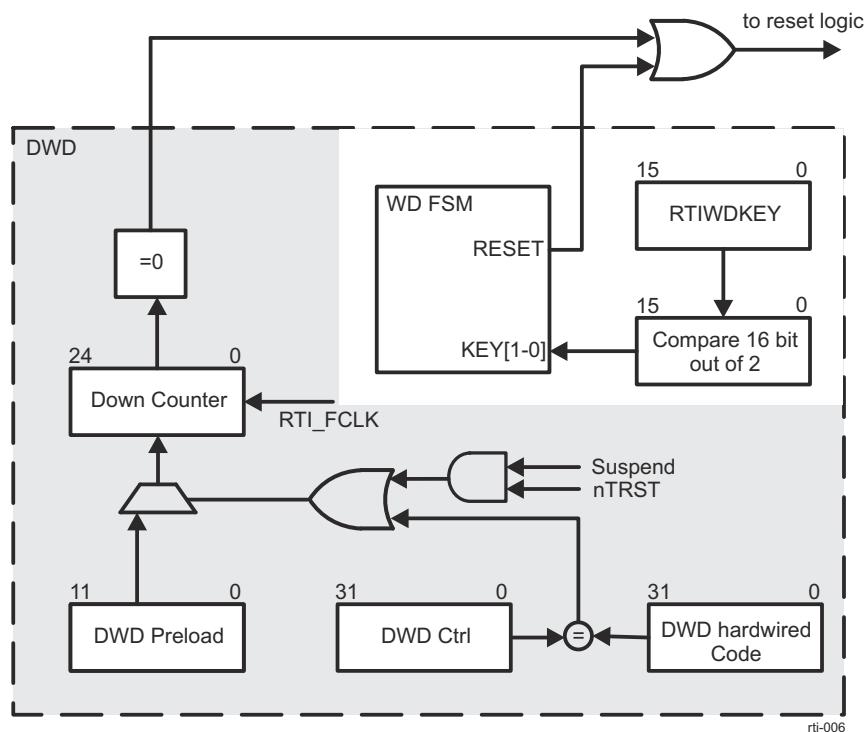

---

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

Some applications might use a digital watchdog (DWD) integrated in the RTI module. The digital watchdog generates resets after a programmable period, if no correct key sequence is written to the RTI\_RTIWDKEY register. [Figure 12-438](#) shows the digital watchdog functional block.

**Figure 12-438. RTI Digital Watchdog Functional Block Diagram**

The digital watchdog functionality is implemented such that it can be enabled by software.

The DWD starts counting down from the reset value of the RTI\_RTIDWDCNTR (DWD Counter Register). The DWD preload register can be configured at any time by the application according to the desired time-out period.

When enabled by software, the digital watchdog is disabled after system reset. If it should be used, it has to be enabled by writing A98559DAh to the RTI\_RTIDWDCTRL register. The DWD timeout period must be configured using the DWD preload register before the DWD is enabled. The DWD cannot be disabled by the application once it is enabled.

#### Note

When the DWD is enabled by software, any system reset will disable the DWD. This reset could have been generated by the watchdog itself.

If the correct key sequence is written to the RTI\_RTIDWDKEY register (E51Ah followed by A35Ch), the 25-bit DWD Down Counter is reloaded with the 12-bit preload value stored in RTI\_RTIDWDPRLD register. If any incorrect value is written to the RTI\_RTIDWDKEY register, a watchdog reset will occur immediately. A reset will also be generated, when the DWD Down Counter is decremented to 0.

The user has to take into account that the write to the RTI\_RTIDWDKEY register takes 3 RTI\_ICLK cycles. This needs to be considered for the DWD expiration calculation.

The DWD Down Counter will be decremented with RTI\_FCLK frequency. If the RTI\_FCLK is switched off via the disable registers of the Clock management, the DWD counter stops decrementing. The DWD module cannot generate a reset under this condition.

**Figure 12-439. RTI Digital Watchdog Operation**

The expiration time of the DWD Down Counter can be determined with following equation:

$$t_{exp} = (RTI\_RTIDWDPRLD + 1) \times 2^{13} / RTI\_FCLK \quad (23)$$

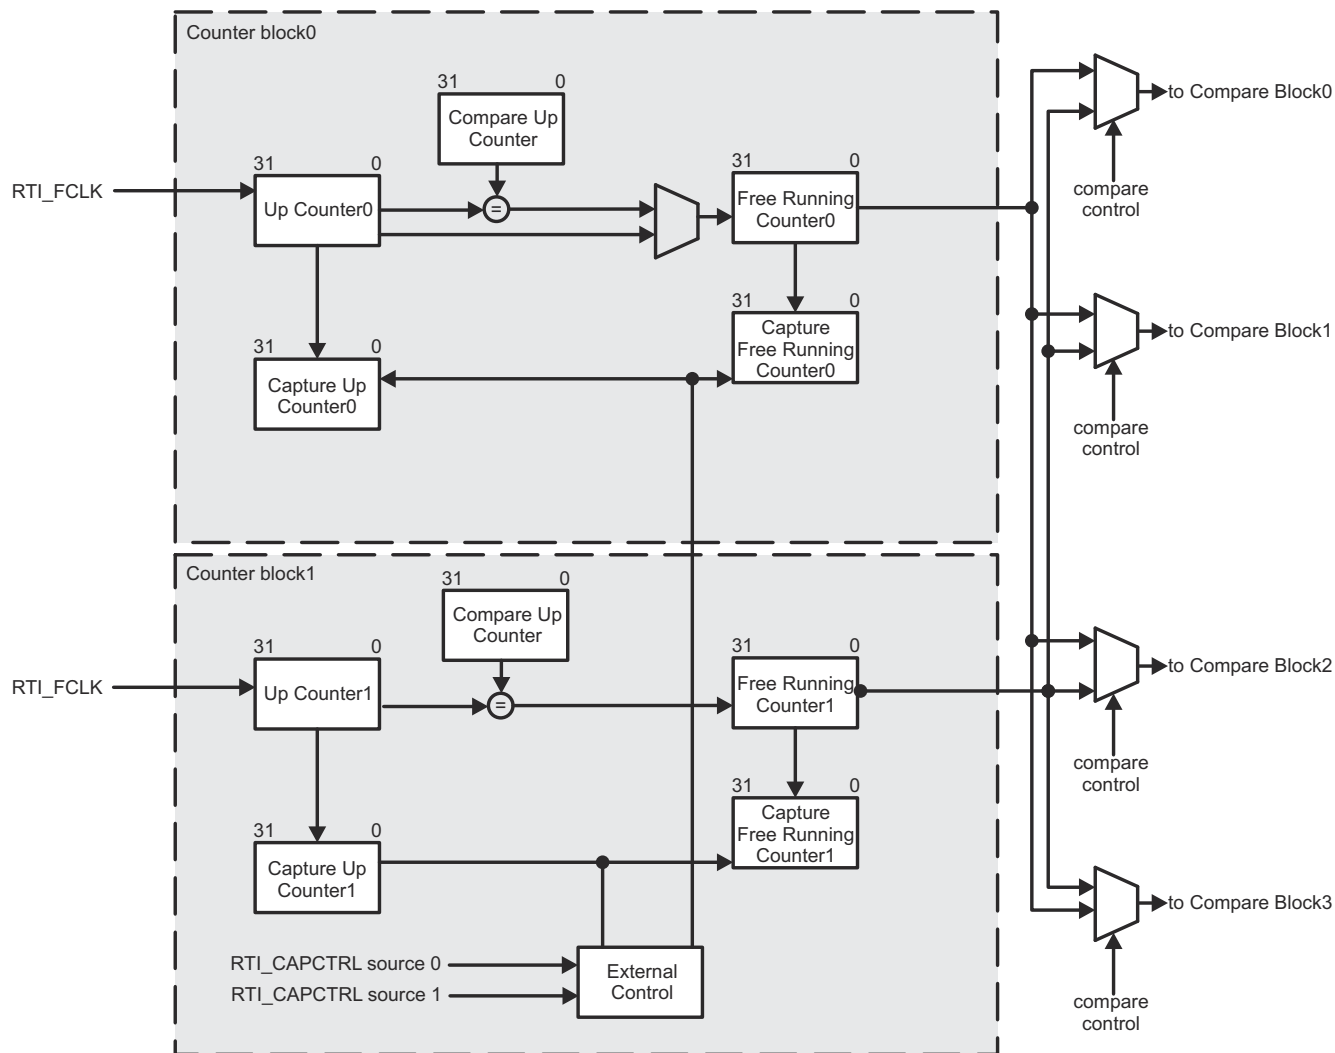

where  $RTI\_RTIDWDPRLD = 0 \dots 4095$

### 12.7.2.3.3 RTI Counter Operation

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Figure 12-440 shows the RTI module counter blocks. The RTI module supports two counter blocks.

rti-004

**Figure 12-440. RTI Counters Block Diagram**

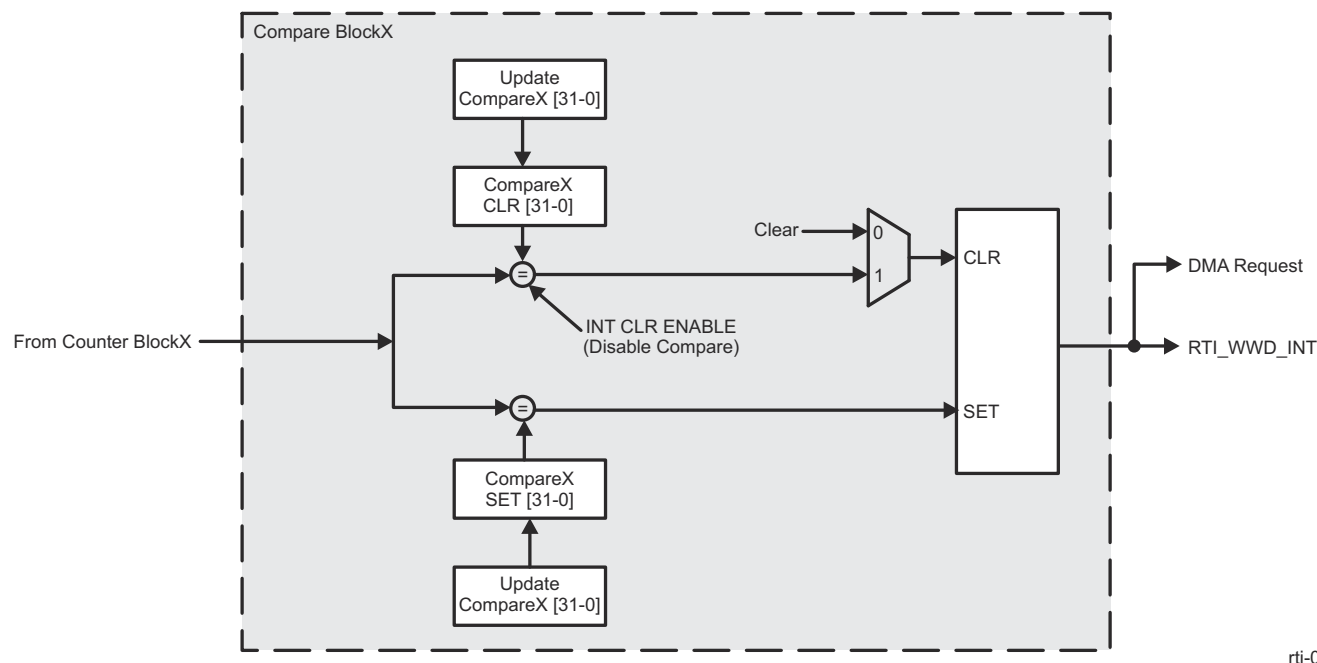

Each block consists of two 32 bit up counters - Up Counter (UC) and Free Running Counter (FRC). The Up Counter (RTI\_RTICAUC0 or RTI\_RTICAUC1 register) is driven by the RTI\_FCLK and counts up until the compare value in the Compare Up Counter register (RTI\_RTICPUC0 or RTI\_RTICPUC1) is reached. When the compare matches, the second counter (RTI\_RTICAFRC0 or RTI\_RTICAFRC1 register), which is a free running counter, is incremented. At the same time UCx is reset to zero.

To ensure the consistency of the counters, when both counter value have to be determined, the Free Running Counter has to be read first. This will ensure that at the CPU read cycle, the Up Counter value is stored in the counter register. The second read is done on the Up Counter register, which holds then the value of the counter cycle of the previous read on the Free Running Counter register.

Both blocks provide also a capture feature on external events. Two capture sources can trigger the capture event. Which event triggers block 0 or block 1 is configurable from the RTI\_RTICAPCTRL register. The sources are coming from the interrupt manager, in order to be able to generate a capture event when one of the peripheral modules has generated an interrupt. The peripheral, which can generate an event is configured in the interrupt manager. When the event is detected, UCx and FRCx are stored in Capture Up Counter (RTI\_RTICAUC0 or RTI\_RTICAUC1) and Capture Free Running Counter (RTI\_RTICAFRC0 or RTI\_RTICAFRC1) registers. The read order of the captured values has to be like the order of the actual counters. So the CAFRCx has to be read first and the CAUCx registers has to be read after the CAFRCx value

was determined. While the CAFRCx is read the CAUCx value is loaded into a shadow register to ensure data consistency, if during the two reads of the captured data another capture event happens. If the application fails to read the two registers before a second capture event happens, the previous data will be overwritten.

Figure 12-441 shows the block diagram for one compare block. The RTI module supports four compare blocks.

**Figure 12-441. RTI Compare Block Diagram**

In order to generate interrupt requests to the interrupt manager, there are four compare registers (RTI\_RTICOMP0, RTI\_RTICOMP1, RTI\_RTICOMP2, and RTI\_RTICOMP3). Each of the compare registers can be configured to work either on FRC0 (Counter block0) or FRC1 (Counter block1). When the counter value matches the compare value, an interrupt is generated. This sets an interrupt request line to the interrupt manager. The compare value gets updated automatically with the value stored in Update Compare (RTI\_RTIUDCP0, RTI\_RTIUDCP1, RTI\_RTIUDCP2, and RTI\_RTIUDCP3) registers when the compare matches. This gives the ability to generate periodic interrupts/DMA requests without having to update the compare value by software.

An optional feature allows an application to program another compare value which is then used to clear the interrupt request line. This feature is supported by four compare clear registers (RTI\_RTICOMP0CLR, RTI\_RTICOMP1CLR, RTI\_RTICOMP2CLR, and RTI\_RTICOMP3CLR). When the counter value matches the compare clear value, the interrupt line is cleared. This clears the interrupt request line to the interrupt manager. The compare clear value gets updated automatically with the value stored in Update Compare (RTI\_RTIUDCPx) registers when the compare matches.

### 12.7.3 Real-Time Clock (RTC)

#### 12.7.3.1 RTC Overview

The basic purpose for the RTC is to keep time of day. The other equally important purpose of RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. The final purpose of the RTC is to wake the rest of chip up from a power down state.

##### 12.7.3.1.1 RTC Features

The real-time clock (RTC) provides the following features:

- With Analog IP block
  - 2 digital voltage domains with integrated LVL/ISO cells
    - CORE or volatile domain, same as core SOC
    - RTC or Always ON domain
  - Without Analog IP block
    - 1 digital voltage domain, no lvl.iso
- 15 bit 32768Hz counter
- 48 bit seconds counter with +/- 1 30uS upto +/- 1 S drift adjustment every 4048 Seconds
- 256 bits of Scratch PAD
- 1 ON\_OFF compare event, 48-bits
- 1 OFF\_ON compare event, 48-bits
- 2 event outputs OFF\_ON and ON\_OFF to CORE
- Support active external 32768 Hz and inactive/gated 32768 Hz
- This allows HOST PROCESSOR to use some of the counter registers as general purpose
- CORE protection logic which enables loose ISO assertion
- Functional lockout, unlock by special vbusp sequence
- DFT lockout, unlock by special 1500 sequence
- HOST PROCESSOR can issue OFF now cmd
- HOST PROCESSOR can update MMRs without polling, thanks to HW Shadow/Auto Sync
- HOST PROCESSOR can read time without polling, thanks to HW Shadow/Auto Sync
- External IOs (*Optional*)
  - 4 wakeup inputs with active high/low including optional debounce
    - Async wake up supported
  - 1 pmic\_enable output
- Analog Interface (*Optional*)
  - 32 bit Analog Config output
  - ISO input
  - 32KHz input

#### 12.7.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 12.7.3.2 RTC Integration

This device includes a Real-Time (RTC) module to allow easy tracking of time and date and the generation of real time alarms.

The following tables provide pin level detail for each of the interfaces on this module.

[Table 12-348](#) describes the 1500 Interface for the DFT unlock circuit.

**Table 12-348. 1500 Interface**

Signal Name	Direction	Default Value	Description
jtag_wrck	In	1'd0	1500 wrapper clock
jtag_wrstn_n	In	1'd1	1500 wrapper reset (active low)
jtag_wsi	In	1'd0	1500 wrapper serial input
jtag_selectwir	In	1'd0	1500 select wrapper instruction register
jtag_shiftwr	In	1'd0	1500 shift wrapper register
jtag_updatewr	In	1'd0	1500 update wrapper register

**Table 12-348. 1500 Interface (continued)**

Signal Name	Direction	Default Value	Description
jtag_capturewr	In	1'd0	1500 capture wrapper register
jtag_wso	Out	1'd0	1500 wrapper serial out

Table 12-349 describes the PMIC Control External Wakeup and PMIC ON/OFF Control IOs.

**Table 12-349. PMIC Control IOs**

Signal Name	Direction	Default Value	Description
pmic_ext_wakeup0_io	In	1'd0	RTC Wakeup0
pmic_ext_wakeup1_io	In	1'd0	RTC Wakeup1
pmic_ext_wakeup2_io	In	1'd0	RTC Wakeup2
pmic_ext_wakeup3_io	In	1'd0	RTC Wakeup3
pmic_pmic_enable_io	Out	1'd1	RTC PMIC Enable 1 = ON 0 = OFF

**Table 12-350. Analog Interface**

Signal Name	Direction	Default Value	Description
ana_osc32k_clk	In	NA	Analog 32768 buffered Crystal clock If no analog, provide a near 32768 clock
ana_iso	In	1'd0	Analog ISO 1 = Isolated 0 = Not Isolated If no analog, tie 1'b0
ana_porz	In	NA	Analog PowerOnReset 1 = not asserted 0 = asserted This will assert when ON/BAT domain is powering up If no analog, then you can connect same reset which was used for rst_mod_g_rst_n You can also use por_rst_n class, it's a don't care
ana_cfg[31:0]	Out	TBD	Analog config If no analog, NC

**Table 12-351. PSC Interface**

Signal	Direction	Default Value	Description
pwri_clkstop_idle	Out	1'd1	The IP is in IDLE state, output of an IP
pwrs_clkstop_req	In	1'd0	Clock stop request
pwrs_clkstop_ack	Out	1'd0	Clock stop acknowledge

**Table 12-351. PSC Interface (continued)**

Signal	Direction	Default Value	Description
pwrw_clkstop_wakeup	Out	1'd0	Wakeup It requires clock stop protocol to be active and active vclk_clk
pwr_clk_clk_en	In	1'd1	Clock-gate enable to IP
pwr_clk_clk_en_ack	Out	pwr_clk_clk_en	Clock-gate enable acknowledge from IP

Table 12-352 describes the Main IP DFT Interface.

**Table 12-352. IP DFT Interface**

Signal Name	Direction	Default Value	Description
dft_partition_en	In	1'd0	dft_partition_en
dft_scan_en	In	1'd0	dft_scan_en
dft_clk_force_en	In	1'd0	dft_clk_force_en
dft_async_rst_sel	In	1'd0	dft_async_rst_sel
dft_test_async_rst_n	In	1'd1	dft_test_async_rst_n
dft_tft_mcp_dis	In	1'd0	Assert High to block MCP path
dft_local_clk_en	In	1'd0	dft_local_clk_en
dft_mode_atpg	In	1'd0	ATPG

The reset shown in Table 12-353 only goes to the core domain.

**Table 12-353. Reset Interface**

Signal Name	Direction	Default Value	Description
rst_mod_g_rst_n	In	1'd1	Module level main reset

The clock shown in Table 12-354 is used for all VBUS ports ref pll clock.

**Table 12-354. VBUS Clock Interface**

Signal Name	Direction	Default Value	Description
vclk_clk	In	1'd0	Single ended clock Nom freq 50MHz
vclk_cs_func_clk_en	In	1'd0	catscan enable on kp_ti_ipg_clk_l1

The clock shown in Table 12-355 is a buffered copy from the crystal oscillator clock.

**Table 12-355. OSC 32768Hz Clock Interface**

Signal Name	Direction	Default Value	Description
osc_32k_clk	Out	1'd0	Buffered clock out from ana_osc32k_clk

The clock shown in Table 12-356 is for the core domain in DFT mode.

**Table 12-356. DFT Clock Interface**

Signal Name	Direction	Default Value	Description
dftclk_clk	In	1'd0	Single ended clock

pr1_slv_xcnt[2:0]	In	3'd4	Good Byte Count
pr1_slv_byten[3:0]	In	{4{1'b1}}	Byte Enables
pr1_slv_wdata[31:0]	In	32'd0	Write Data
pr1_slv_wready	Out	1'b1	Write Ready
pr1_slv_rdatap[31:0]	Out	32'd0	Read Data (Pipelined)
pr1_slv_rready	Out	1'b1	Read Ready
pr1_slv_emudbg	In	1'b0	Emulation Debug Attribute

### 12.7.3.3 RTC Functional Description

#### 12.7.3.3.1 RTC Block Diagram

**Figure 12-442. RTC Block Diagram**

The RTC is composed of 3 major blocks, DIG\_CORE, DIG\_ON, and LVL\_ISO.

##### 12.7.3.3.1.1 DIG\_CORE uARCH

The DIG\_CORE block is on the CORE power domain which will power OFF/ON when the SOC powers OFF/ON. It contains, CORE IF logic, Shadow MMRs and MMR Sync logic.

The MMR Sync logic has 2 modes of operation

- Refresh/Sync after Core Reset
- Sync after HOST PROCESSOR Updates Shadow MMRs

##### Refresh/Sync after Core Reset Deassertion

After every Core Reset event, the MMR Sync logic we refresh ALL Shadow MMRs by copying the contents of ON MMRs into the Shadow MMRs.

##### Core Reset DeAssertion

The internal state machine Reads All MMRs in linear order

- If(GENRAL\_CTL..32K\_CLK\_EN = 1)

- Max delay of 2 32768Hz period delay
- If(GENRAL\_CTL..32K\_CLK\_EN = 0)
  - Max delay 1.2uS = 32 \* vbus\_clk period delay(27MHz)
  - It will not wait for high to low 32768 event to read MMRs

The internal state machine Sets SYNCPEND.RD\_DONE bit when the copy from the ON domain is completed. The host processor needs to wait for this status bit assertion before it reads the other MMRs

### Sync after HOST PROCESSOR Updates Shadow MMRs

host processor UNLOCK

host processor Wrts to MMRs

The ON domain MMRs will get updated after a finite delay

- If(GENRAL\_CTL..32K\_CLK\_EN = 1)
  - Max delay of 2 32768Hz period delay
- If(GENRAL\_CTL..32K\_CLK\_EN = 0)
  - Max delay 8uS = 32 \* vbus\_clk period delay
  - It will not wait for high to low 32768 event to read MMRs

The internal state machine sets SYNCPEND.WR\_DONE bit. This needs to get cleared before the next **HOST PROCESSOR Updates Shadow MMRs**

---

#### Note

The CORE domain has its own copy of the sub-second counter and second counter along with the compensation logic. The 2 domains will always be in sync after a reset or after host processor does a update to the counters or compensation

---

#### 12.7.3.3.1.2 DIG\_ON uARCH

The DIG\_ON block is in the always ON domain, the power is provided by the ANALOG Block. It contains the always ON MMRs which will preserve state of the Shadow MMRs when the CORE is OFF state.

The 15 bit 32768Hz counter and the 48 bit second counter maintains count when the CORE is OFF. It has 2 comparators one for OFF\_ON and one for ON\_OFF event. It has External Wakeup events which can get de-bounced to control the PMIC\_ENABLE. It controls the PMIC\_ENABLE output which can change state based on ON\_OFF, OFF\_ON, and HOST PROCESSOR OFF now events.

The functional lockout and the dft lockout (1500) logic resides in this domain.

#### 12.7.3.3.1.3 ISO\_LVL uARCH

The ISO\_LVL module constrains all DIG\_CORE <-> DIG\_ON Level/Isolation cells between these 2 domains. They use tibox to instantiate them. If No Analog support, then SOC integration team will not add in these RTC.

#### 12.7.3.3.1.4 DIG\_CORE to DIG\_ON updates uARCH

---

#### Note

If No Analog support, then DIG\_CORE and DIG\_ON will be on a common V domain.

---

This section defines how the DIG\_CORE Shadow MMRs maintain coherences with the DIG\_ON Live MMR domain. All vbusp transactions terminate in the DIG\_CORE block. All vbusp write transaction which require DIG\_ON updates is completed by the Shadow to Live HW sequencer.

This HW sequencer has 2 modes of operation.

- Immediate Write Mode
  - When GENRAL\_CTL..32K\_OSC\_DEP\_EN = 0
  - It will start the write updates immediately

- Delayed Write Mode
  - When GENERAL\_CTL.32K\_OSC\_DEP\_EN = 1
  - It will start the write updates after the first 32khz\_clk high to low transition

In Delayed Write Mode

For example, HOST PROCESSOR updates OFF\_ON\_S\_CNT\_LSW and OFF\_ON\_S\_CNT\_MSW.

After the HOST PROCESSOR completes the OFF\_ON\_S\_CNT\_MSW, the HW sequencer will start the process of updating the DIG\_ON domain at the first available 32khz\_clk is low cycle.

---

**Note**

32khz\_clk is already low, the circuit will wait next low cycle to insure we have the full low period to do all pending updates. The HOST PROCESSOR can observe the SYNCPEND.WR\_DONE bit, when set the write operations has completed to the DIG\_ON domain

---

---

**Note**

If GENERAL\_CTL.32K\_CLK\_EN = 0, then the HW sequencer will not wait for 32khz\_clk high to low event, since this will force 32khz\_clk low. This removes the dependency of an active 32768Hz clock

---

ALL MMR write transaction require full 4 Bytes writes in order to reduce the logic size of the DIG\_ON domain.

**RULE:** Require 4 Bytes writes (less logic and iso)

---

**Note**

ON domain MMRs have a write lock protection circuit to prevent corruption of the DIG\_ON domain during a power down event since ISO assertion can be late.

---

Due to this fact, the HOST PROCESSOR must first unlock write access by performing the unlock sequence, by simply writing Kick0 and Kick1 with the correct pattern and sequence. After this is done, the RTC is in an unlock date. The HOST PROCESSOR will need to relocking by writing any pattern to Kick1

### 12.7.3.3.2 CPU Interrupt Support

#### 12.7.3.3.2.1 CPU Interrupts

The RTC can produce one HW event output active high level and active high pulse. This one output will assert on 3 internal HW events.

1. Timer ON\_OFF event
2. Timer OFF\_ON event
3. External Wakeup event

HOST PROCESSOR can read the Interrupt MMR status to determine which events caused the RTC event output to assert. vbus\_clk can be on or off, the active high level will assert on either scenario. The 32768Hz clock must be active to cause a ON\_OFF or OFF\_ON event. The External Wakeup event can occur without 32768Hz clock if debounce is not enabled.

The Interrupt MMR programing model uses the standard Keystone3 schema which allows HOST PROCESSOR to issue debug event. Also, the enabling of the events are backed up in the ON domain, so HOST PROCESSOR will not enable to enable events on every power cycle of the CORE domain.

#### 12.7.3.3.3 Programming Usage Guide

##### 12.7.3.3.3.1 No Analog Support

#### DIG\_ON domain MMR Write Rules

- UnLock DIG\_CORE (Wrt Kick0 and Wrt Kick1)

- Keep it UnLock
- Write all MMRs in the same address order has MMRs from low to high
  - For example . Wrt Scratch Storage 0 through Scratch Storage 7
- HOST PROCESSOR poles until SYNCPEND.WR\_PEND is 0
  - Max completion is 60 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is set
  - Max completion is 10 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is clr
- HOST PROCESSOR is not allowed to perform new write without waiting for clearing of SYNCPEND.WR\_PEND

### After every new power up of the SOC

- Unlock RTC by writing correct pattern in Kick0 and Kick1
- Keep it UnLock
- HOST PROCESSOR can verify that 32Khz\_osc\_clk is toggling by reading SYNCPEND. 32K\_CLK\_OBS
- Should not be required, since the 32Khz\_osc\_clk will always will be active
- HOST PROCESSOR sets GENRAL\_CTL.32K\_OSC\_DEP\_EN
- Wait for 60 uSec
- Initialize ALL RTC MMRs in the DIG\_ON domain in the same order as the address map
- The RTCs MMRs do not have a reset state in general, only a few required MMRs bits have one.
- HOST PROCESSOR must initialize all bits of the MMRs which reside in DIG\_ON domain
  - le wrt <value>@0x00, <value>@0x04, <value>@0x08 ....<value>@0x50
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null
  - This means all DIG\_ON domain MMRs have been written to

RTC is now in an operational state and fully configured.

### 32768 MHz time adjustment

- HOST PROCESSOR UnLock RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR can write new time by writing to SUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

### 32768 MHz time drift adjustment

- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- SW determines drift rate
- HOST PROCESSOR updates or enables drift adjustment by HOST PROCESSOR write new COMP\_LSB and COMP\_MSB
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

#### 12.7.3.3.2 With Analog Support

### DIG\_ON domain MMR Write Rules

- UnLock DIG\_CORE (Wrt Kick0 and Wrt Kick1)
- Write all MMRs in the same address order has MMRs from low to high
- For example . Wrt Scratch Storage 0 through Scratch Storage 7
- ReLock DIG\_CORE (Wrt 0x0000\_0000 to Kick1)
- HOST PROCESSOR poles until SYNCPEND.WR\_PEND is 0
  - Max completion is 60 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is set
  - Max completion is 10 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is clr
- HOST PROCESSOR is not allowed to perform new write without waiting for clearing of SYNCPEND.WR\_PEND

### First Time Powered ON(DIG\_ON)

- Unlock RTC by writing correct pattern in Kick0 and Kick1
- HOST PROCESSOR updates ANALOG\_CTRL MMR
  - Set the correct parameters
  - Enable 32768Hz OSC
  - Wait for 3 seconds to allow the 32768Hz OSC to lock
- HOST PROCESSOR can verify that 32Khz\_osc\_clk is toggling by reading SYNCPEND. 32K\_CLK\_OBS
- HOST PROCESSOR sets GENERAL\_CTL.32K\_OSC\_DEP\_EN
- HOST PROCESSOR ReLock DIG\_CORE (Wrt 0x0000\_0000 to Kick1)

Initialize ALL RTC MMRs in the DIG\_ON domain in the same order as the address map except for the first 2 writes which should always be to the 2 KICK0/KICK1 MMRs to unlock write transaction and the last write which should relock by writing 0x0 to KICK1

- The RTCs MMRs do not have a reset state in general, only a few required MMRs bits have one.
- HOST PROCESSOR must initialize all bits of the MMRs which reside in DIG\_ON domain
- HOST PROCESSOR UnLock
- le wrt <value>@0x00, <value>@0x04, <value>@0x08 ....<value>@0x50
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null
- This means all DIG\_ON domain MMRs have been written to

RTC is now in an operational state and fully configured

### 32768 MHz time adjustment

- HOST PROCESSOR UnLock RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR can write new time by writing to SUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

### 32768 MHz time drift adjustment

- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- SW determines drift rate
- HOST PROCESSOR updates or enables drift adjustment by
  - HOST PROCESSOR write new COMP\_LSB and COMP\_MSB
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

### Update OFF\_ON and/or ON\_OFF times

- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null (ACTION PRE vs POST)
- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR update OFF\_ON\_S\_CNT\_LSW/MSW and/or ON\_FF\_S\_CNT\_LSW/MSW
- HOST PROCESSOR can update SCRATCH0/7
- HOST PROCESSOR update GENERAL\_CTL to enable if required
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

---

#### Note

The new OFF time must be at least 2 seconds in the future

---

### OFF NOW

- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- Optional (HOST PROCESSOR can update SCRATCH0/7)

- HOST PROCESSOR issues a SW\_OFF in GENRAL\_CTL
- HOST PROCESSOR does a dead loop, wait for power OFF

### Note

Note any Write to SW\_OFF will cause a Auto ReLock

#### 12.7.3.3.3.2.1 MMR Spurious WRT Protection

The module also contains a kicker mechanism (Figure 12-443) to prevent any spurious writes from changing the register values. This mechanism requires two MMR writes to the Kick0 and Kick1 registers with exact data values before the kicker lock mechanism is released. Once released, the MMRs are writeable. The Kick0 data is 83E7 0B13h; the Kick1 data is 95A4 F1E0h. Note that it remains in an unlocked state until an OCP reset or invalid data pattern is written to one of the Kick0 or Kick1 registers.

- Key0 = 83E7 0B13h
- Key1 = 95A4 F1E0h
- Locked = Write protection enabled
- Unlocked = Write protection disabled

**Figure 12-443. Kick Register State Machine Diagram**

- S0 is the Reset/Idle state
- S1 is an wrt cycle of 83E7 0B13h at Kick0 completed state
- S2 is the UNLOCK MMR WRT state
- S0 → S1 when wrt cycle of 83E7 0B13h at Kick0
- S1 → S2 when wrt cycle of 95A4 F1E0h at Kick1
- S1 → S0 when reset event
- S2 → S0 when reset event OR OCP wrt cycle of NOT 83E7 0B13h at Kick0 OR OCP wrt cycle at Kick1
- S2 → S1 when wrt cycle of 83E7 0B13h at Kick0

#### **12.7.3.3.2.2 Crystal Compensation**

In order to compensate for any inaccuracy of the 32768HZ oscillator, the HOST can perform a calibration of the oscillator frequency, calculate the drift compensation versus one-hour period and load the compensation registers with the drift compensation value. If the COMP\_REG value is positive, compensation occurs after the second change event. COMP\_REG cycles are removed from the next second. If the COMP\_REG value is negative, compensation occurs before the second change event. -COMP\_REG cycles are added to the current second. This enables to compensate with a 132 kHz period accuracy each 4096 Seconds. The waveform below summarizes positive and negative compensation effect.

**Figure 12-444. Compensation Illustration**

#### 12.7.3.3.4 Scratch Registers

The RTC provides eight general-purpose registers (SCRATCHx\_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx registers to be useful in indicating RTC states. For example, the SCRATCHx\_REG registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software

should write a unique value to one of the SCRATCHx\_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the SCRATCH register. To indicate unintentional power downs, the software should write a unique value to one of the SCRATCHx\_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the SCRATCH register is cleared. For more information, see *RTCSS Registers*.

#### **12.7.3.3.5 KS3 Clock Stop Protocol**

The IP is compliant to KS3 Clock Stop Protocol, please refer to its spec.

For this IP

- `pwri_clkstop_idle` = `!( RD_PEND or WR_PEND or EVENT_OFF_ON or EVENT_ON_OFF)`
- If any of these MMRs are set, `pwri_clkstop_idle` = 0 or busy
- `pwrs_clkstop_ack` will not assert per spec unless `pwrs_clkstop_req` == 1 and `pwri_clkstop_idle` == 1
- `pwrw_clkstop_wakeup` will not assert unless `pwrs_clkstop_ack` == 1 AND `vclk_clk` is active

It will assert `rtc_event_pend_intr` asserts

- The integration guideline is to always use `rtc_event_pend_intr` for wakeup event since it has NO dependencies on clock stop protocol nor active `vclk_clk` is required, just `32k_clk` needs to be active

## 12.7.4 Timers

This section describes the Timer modules for the device.

### 12.7.4.1 Timers Overview

All timers include specific functions to generate accurate tick interrupts to the operating system.

Each timer can be clocked from several different independent clocks. The selection of clock source is made from registers in the MCU\_CTRL\_MMR0/CTRL\_MMR0.

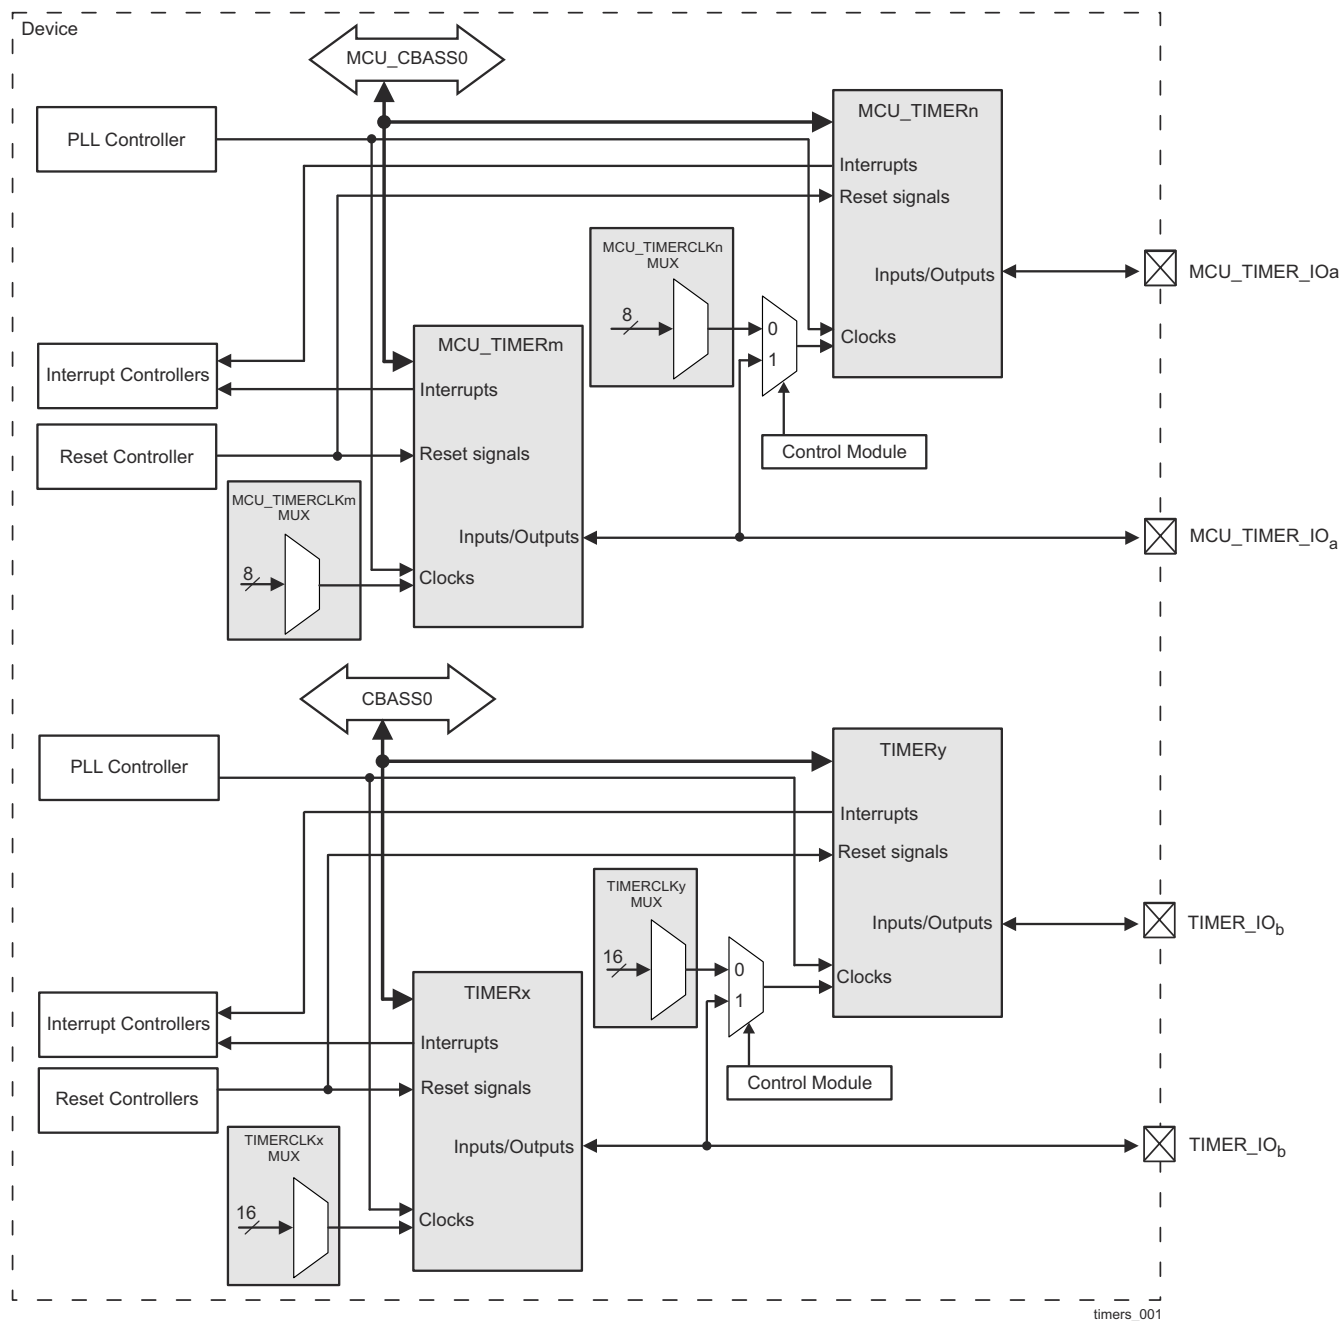

In the MCU domain the device provides 4 timer pins, one for each instance, to be used as MCU Timer Capture inputs or as MCU Timer PWM outputs.

In the MAIN domain the device provides 11 timer pins, one for each instance, to be used as Timer Capture inputs or as Timer PWM outputs.

Each odd numbered timer instance from each of the domains may be optionally cascaded with the previous even numbered timer instance from the same domain to form up to a 64-bit timer. For example, TIMER1 may be cascaded to TIMER0, MCU\_TIMER1 may be cascaded to MCU\_TIMER0, etc.

When cascaded, TIMER<sub>i</sub> acts as a 32-bit prescaler to TIMER<sub>i+1</sub>, as well as MCU\_TIMER<sub>n</sub> acts as a 32-bit prescaler to MCU\_TIMER<sub>n+1</sub>. TIMER<sub>i</sub> / MCU\_TIMER<sub>n</sub> must be configured to generate a PWM output edge at the desired rate to increment the TIMER<sub>i+1</sub> / MCU\_TIMER<sub>n+1</sub> counter.

[Figure 12-445](#) is an overview of the timers.

m = even instances of MCU Timer.

x = even instances of Timer.

#### Note

n = odd instances of MCU Timer.

#### Note

y = odd instances of Timer.

**Figure 12-445. Timers Overview**

#### 12.7.4.1.1 Timers Features

The following are the main features of the timer controllers:

- Target interface supports:
  - 32-bit data bus width
  - 32-bit access supported
  - 10-bit address bus width
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting)
- Generates a 1-ms tick clock with a 32.768 kHz functional clock sourced from the LFOSC

#### 12.7.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 12.7.4.2 Timers Environment

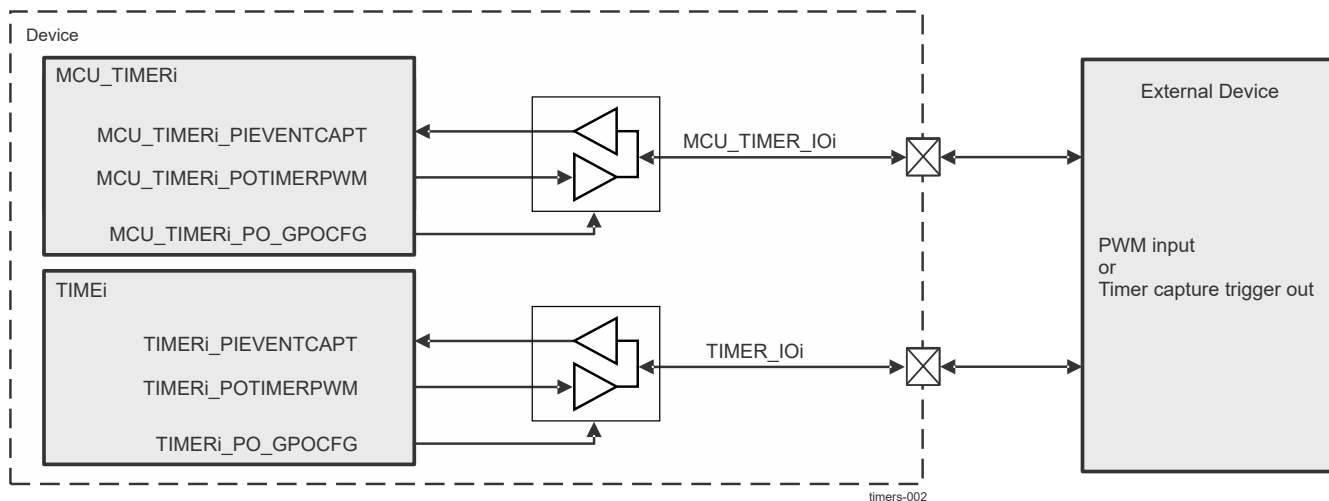

The MCU\_TIMER[3-0] and TIMER[11-0] modules are hereinafter referred to as timer module.

This section describes the timers external connections (environment).

#### 12.7.4.2.1 Timer External System Interface

Each timer can send or receive stimulus to/from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count.

Figure 12-446 shows the external system interface for the timers, and Table 12-360 describes the timer inputs and outputs.

#### Note

i represents a TIMER instance. See the device datasheet for available domains and TIMER instances.

**Figure 12-446. Timers External System Interface**

**Table 12-360. Timer I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCU_TIMERi<sup>(2)</sup></b>				
MCU_TIMER_IOi <sup>(2)</sup>	MCU_TIMERi <sup>(2)</sup> _PIEVENTCAPT	I/O	MCU_TIMERi <sup>(2)</sup> trigger input or	0
	MCU_TIMERi <sup>(2)</sup> _POTIMERPWM		MCU_TIMERi <sup>(2)</sup> output	
<b>TIMERi<sup>(2)</sup></b>				
TIMER_IOi <sup>(2)</sup>	TIMERi <sup>(2)</sup> _PIEVENTCAPT	I/O	TIMERi <sup>(2)</sup> trigger input or	0
	TIMERi <sup>(2)</sup> _POTIMERPWM		TIMERi <sup>(2)</sup> PWM output	

(1) When configured for that function; I = Input, O = Output

(2) i represents a TIMER instance. See the device datasheet for available domains and TIMER instances.

#### Note

Each MCU\_TIMER\_PO\_GPOCFG and TIMER\_PO\_GPOCFG signals are used as an output enable to control the function of the MCU\_TIMER\_IO[3-0], and respectively TIMER\_IO[11-0], as the PWM output (PO\_GPOCFG = 0) or capture input (PO\_GPOCFG = 1).

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, and others), see tables *Pin Attributes* in the device-specific Datasheet.

---

**12.7.4.3 Integration**

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.7.4.4 Timers Functional Description

Each timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the DMTIMER1MS\_IRQSTATUS\_SET and DMTIMER1MS\_IRQSTATUS\_CLR register for the interrupt features, and a dedicated bit of the DMTIMER1MS\_IRQWAKEEN register for a wake-up. In addition, timers have a mechanism implemented to generate an accurate tick interrupt.

For each timer implemented in the device, there are two possible clock sources:

- 32-kHz clock (sourced from the LFOSC)
- System clock

For more information of the selection of the input clock source, see *Clocking*.

Each timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

##### 12.7.4.4.1 Timer Block Diagram

[Figure 12-447](#) is a block diagram of the timers.

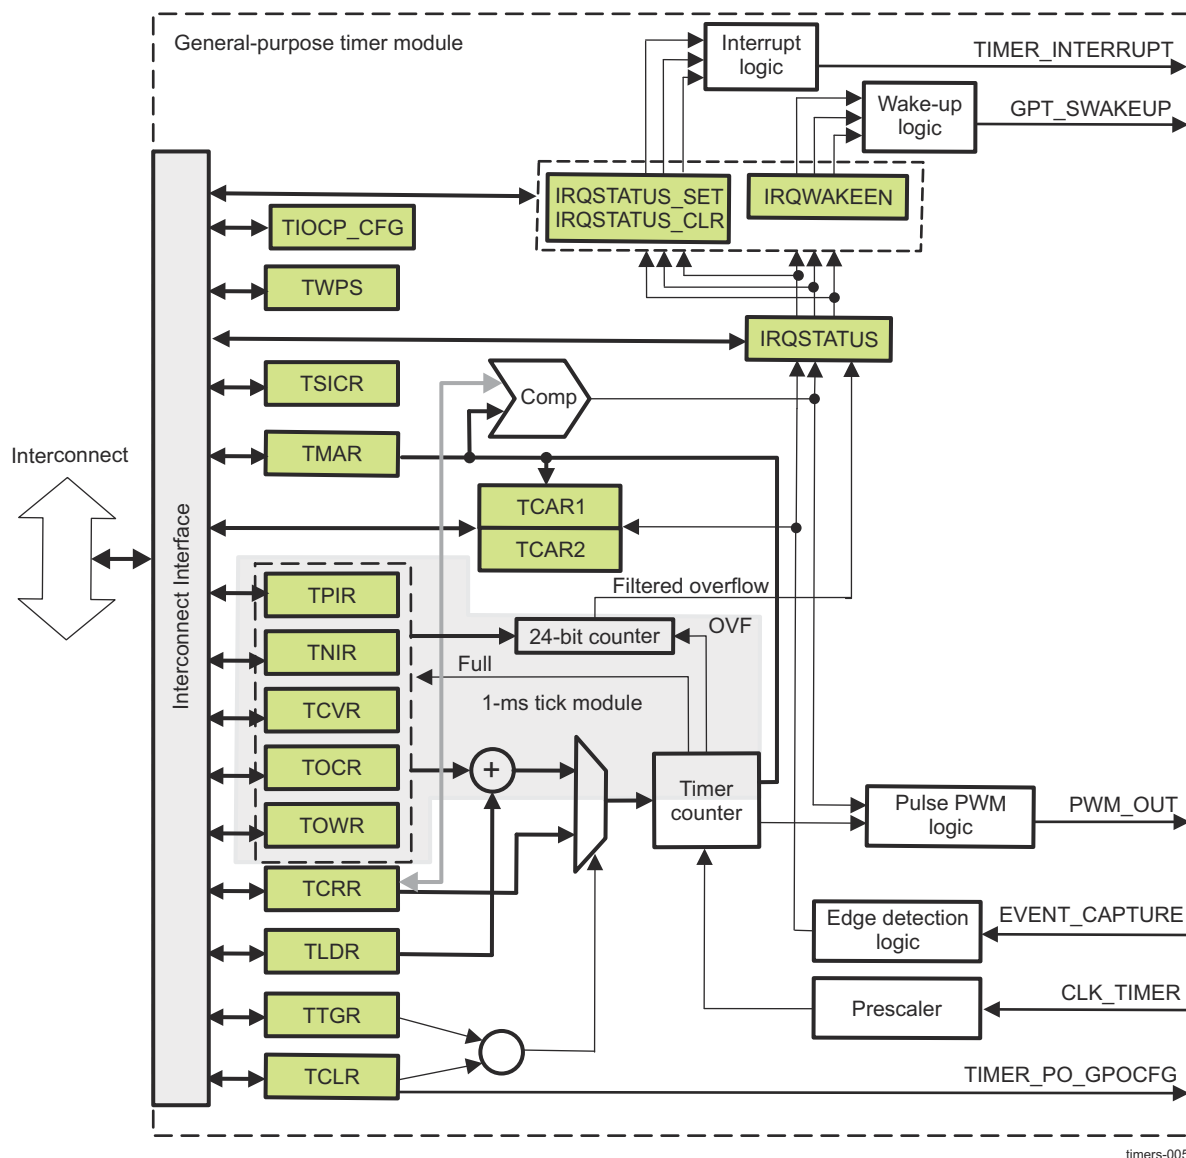

Figure 12-447. Timer Block Diagram

#### 12.7.4.4.2 Timer Power Management

##### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Module Integration* for specifics..

The way the timer acknowledges the LPSC clock stop request is configurable through the DMTIMER1MS\_TIOCP\_CFG[3-2] IDLEMODE bit field.

Table 12-361 lists the IDLEMODE settings and the related acknowledgment modes.

Table 12-361. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The clock stop request is unconditionally acknowledged from the timer, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.

**Table 12-361. IDLEMODE Settings (continued)**

IDLEMODE Value	Selected Mode	Description
01	No-idle	The clock stop request is never acknowledged from the timer. This mode is safe from a module point of view but is not efficient from a power-saving perspective because the clocks remain active.
10	Smart-idle	The timer acknowledges the clock stop request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and interrupt requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

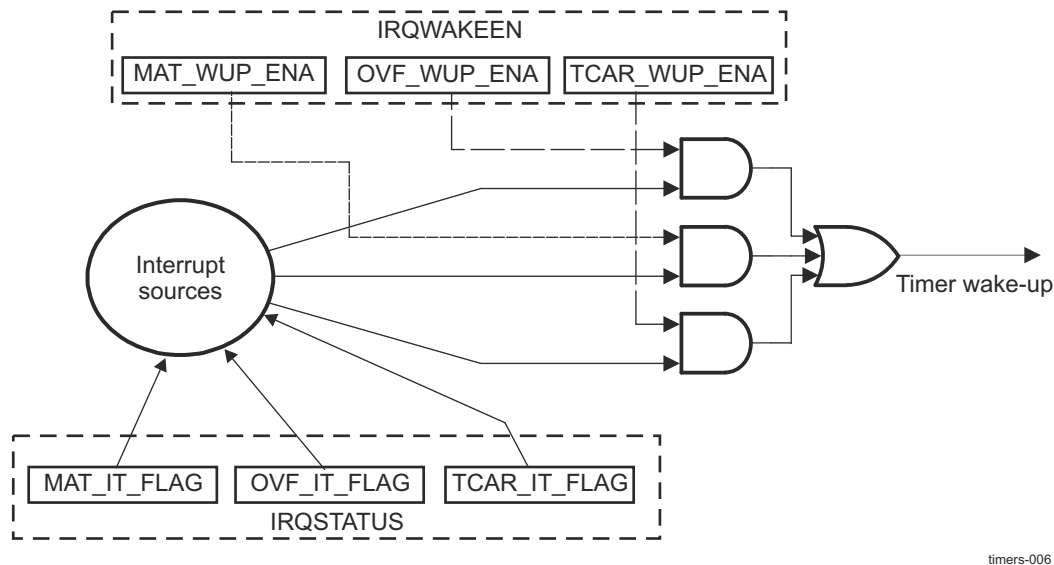

#### 12.7.4.4.2.1 Wake-Up Capability

##### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

If the DMTIMER1MS\_TIOCP\_CFG[3-2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wake-up mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the clock stop acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if configured in smart-idle with wake-up mode.

Figure 12-448 shows the wake-up request generation.

timers-006

**Figure 12-448. Wake-Up Request Generation**

The timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the Clock management sends a clock stop request. The expected source of the wake-up event is an overflow (DMTIMER1MS\_TCRR), a timer match (the compare result of DMTIMER1MS\_TCRR and DMTIMER1MS\_TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER\_PIEVENTCAPT).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (DMTIMER1MS\_IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

### Note

The status bit must be reset to re-enter idle mode.

#### 12.7.4.4.3 Timer Software Reset

DMTIMER1MS\_TIOCP\_CFG[0] SOFTRESET bit can initiate a software reset of the timer. This bit is autocleared to 0 when the reset is complete.

Before accessing or using the timer, the local host must ensure that internal reset is released by reading the DMTIMER1MS\_TIOCP\_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

#### 12.7.4.4.4 Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (DMTIMER1MS\_IRQSTATUS\_SET) and disabled in the interrupt-disable register (DMTIMER1MS\_IRQSTATUS\_CLR). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (DMTIMER1MS\_IRQSTATUS).

#### 12.7.4.4.5 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the DMTIMER1MS\_TCLR[0] ST bit). The timer counter register (DMTIMER1MS\_TCRR) can be loaded when stopped or on-the-fly (while counting). DMTIMER1MS\_TCRR can be loaded directly by a DMTIMER1MS\_TCRR write access with a new timer value. DMTIMER1MS\_TCRR can also be loaded with the value held in the timer load register (DMTIMER1MS\_TLDR) by a trigger register (DMTIMER1MS\_TTGR) write access. The loading of DMTIMER1MS\_TCRR is done regardless of the written value of DMTIMER1MS\_TTGR. The value of DMTIMER1MS\_TCRR can be read when stopped or captured on-the-fly by a DMTIMER1MS\_TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the DMTIMER1MS\_TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

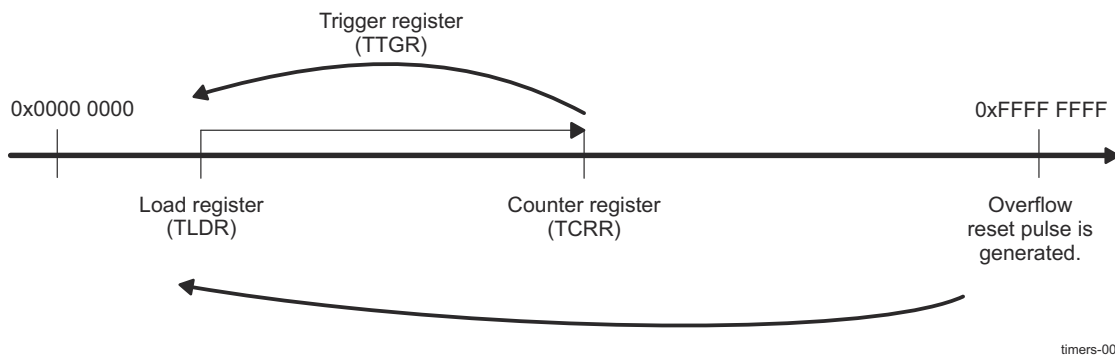

When the autoreload mode is enabled (the DMTIMER1MS\_TCLR[1] AR bit is set to 1), DMTIMER1MS\_TCRR is reloaded with the value of DMTIMER1MS\_TLDR after a counting overflow occurs.

### CAUTION

Do not put the overflow value (0xFFFF FFFF) in the DMTIMER1MS\_TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the DMTIMER1MS\_IRQSTATUS\_SET[1] OVF\_EN\_FLAG bit is set to 1). A dedicated output pin (POTIMERPWM) can be programmed in the DMTIMER1MS\_TCLR[12] PT bit through the DMTIMER1MS\_TCLR[11-10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The DMTIMER1MS\_TCLR[12] PT bit selects pulse/toggle modulation (the DMTIMER1MS\_TCLR[11-10] TRG bit field selects trigger mode).

Figure 12-449 shows the DMTIMER1MS\_TCRR timing value.

**Figure 12-449. DMTIMER1MS\_TCRR Timing Value**

#### 12.7.4.4.5.1 1-ms Tick Generation

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 kHz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-kHz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See [Figure 12-450](#).

#### Note

The only available source for a 32.768-kHz clock is the LFOSC. The HFOSC is not capable of generating a true 32.788-kHz frequency.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the DMTIMER1MS\_TPIR[31-0] POSITIVE\_INC\_VALUE bit field) and the timer negative increment register (the DMTIMER1MS\_TNIR[31-0] NEGATIVE\_INC\_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

timers-009

**Figure 12-450. Block Diagram of the 1-ms Tick Module**

The DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, and DMTIMER1MS\_TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the DMTIMER1MS\_TCRR[31-0] TIMER\_COUNTER bit field) is the value of the DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE bit field (period less than 1 ms) or the value of DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE –1 (period greater than 1 ms).

Table 12-362 lists the value loaded in the DMTIMER1MS\_TCRR according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

**Table 12-362. Value Loaded in DMTIMER1MS\_TCRR to Generate 1-ms Tick**

Add1 MSB	Add2 MSB	Add3 MSB	Value of DMTIMER1MS_TCRR Register
0	0	0	DMTIMER1MS_TLDR[31-0] LOAD_VALUE bit field
0	0	1	DMTIMER1MS_TLDR[31-0] LOAD_VALUE bit field
0	1	0	DMTIMER1MS_TLDR[31-0] LOAD_VALUE bit field
0	1	1	DMTIMER1MS_TLDR[31-0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	DMTIMER1MS_TLDR[31-0] LOAD_VALUE –1
1	1	1	DMTIMER1MS_TLDR[31-0] LOAD_VALUE –1

The values of the DMTIMER1MS\_TPIR and DMTIMER1MS\_TNIR registers are calculated using the following formulas:

- Positive increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6 - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

---

#### Note

$F_{\text{clk}}$  clock frequency (kHz)

$T_{\text{tick}}$  tick period (ms)

---

The timer overflow counter register (DMTIMER1MS\_TOCR) and the timer overflow wrapping register (DMTIMER1MS\_TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit DMTIMER1MS\_TOCR. When the values in the 24-bit DMTIMER1MS\_TOCR match the values in the 24-bit DMTIMER1MS\_TOWR and the timer overflow is asserted, the DMTIMER1MS\_TOCR is reset and an interrupt is generated to the DMTIMER1MS\_IRQSTATUS register.

---

#### Note

DMTIMER1MS\_TOWR has to be set to requested value. For example, if no interrupt needs to be masked DMTIMER1MS\_TOWR must be set to 0, if one interrupt needs to be masked DMTIMER1MS\_TOWR must be set to 1, if two interrupts need to be masked DMTIMER1MS\_TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFFF interrupts need to be masked is not possible.

---

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of timers remain unchanged.

For 1-ms tick with a 32.768-kHz clock:

- DMTIMER1MS\_TPIR[31-0] POSITIVE\_INC\_VALUE = 232,000
- DMTIMER1MS\_TNIR[31-0] NEGATIVE\_INC\_VALUE = -768,000
- DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE = 0xFFFF FFE0

---

#### Note

Any value of the tick period can be generated with the appropriate value of the DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, and DMTIMER1MS\_TLDR.

By default, the DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, DMTIMER1MS\_TCVR, DMTIMER1MS\_TOCR, and DMTIMER1MS\_TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

---

#### 12.7.4.4.6 Timer Capture Mode Functionality

When a transition is detected on the module input pin (PIEVENTCAPT), the timer value in the DMTIMER1MS\_TCRR can be captured and saved in the DMTIMER1MS\_TCAR1 or DMTIMER1MS\_TCAR2 register function of the mode selected in the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit. The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

The rising edge, falling edge, or both, can be selected in the DMTIMER1MS\_TCLR[9-8] TCM bit field to trigger the timer counter capture. The module sets the DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG bit when an active edge is detected, and at the same time, the counter value DMTIMER1MS\_TCRR is stored in timer capture register DMTIMER1MS\_TCAR1 or DMTIMER1MS\_TCAR2, as follows:

- If the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the DMTIMER1MS\_TCAR1 register, and the next events are ignored (no update

- on the DMTIMER1MS\_TCAR1 register and no interrupt triggering) until the detection logic is reset or the DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG is cleared by writing 1 to it.
- If the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the DMTIMER1MS\_TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the DMTIMER1MS\_TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on DMTIMER1MS\_TCAR1/DMTIMER1MS\_TCAR2 and no interrupt triggering) until the detection logic is reset or the DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the PIEVENTCAPT input pin.

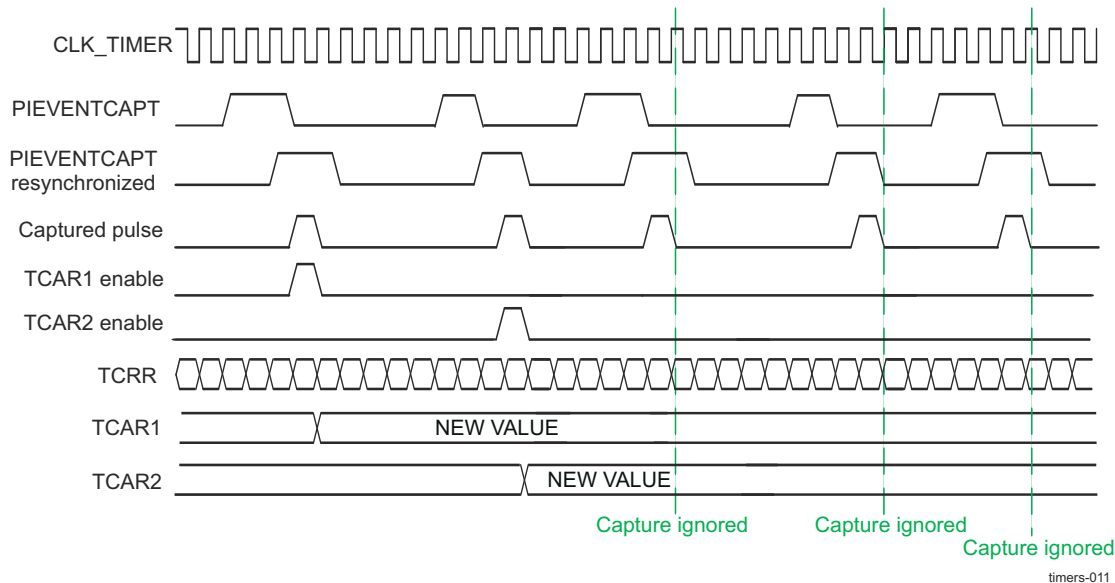

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG bit is cleared by writing 1 to it or when the edge detection mode bits (the DMTIMER1MS\_TCLR[9-8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the DMTIMER1MS\_IRQSTATUS\_SET[2] TCAR\_EN\_FLAG bit. See the examples in [Figure 12-451](#) and [Figure 12-452](#).

In [Figure 12-451](#), the value of the DMTIMER1MS\_TCLR[9-8] TCM bit field is 1h, and the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 0. Only the rising edge of PIEVENTCAPT triggers a capture in the DMTIMER1MS\_TCAR1 and DMTIMER1MS\_TCAR2 registers, and only the DMTIMER1MS\_TCAR1 register updates.

**Figure 12-451. Capture Wave Example for DMTIMER1MS\_TCLR[13] CAPT\_MODE = 0**

In [Figure 12-452](#), the value of the DMTIMER1MS\_TCLR[9-8] TCM bit field is 1h, and the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 1. Only the rising edge of PIEVENTCAPT triggers a capture in the DMTIMER1MS\_TCAR1 register on the first enabled event, and the DMTIMER1MS\_TCAR2 register updates on the second enabled event.

**Figure 12-452. Capture Wave Example for DMTIMER1MS\_TCLR[13] CAPT\_MODE = 1**

#### 12.7.4.4.7 Timer Compare Mode Functionality

When the compare-enable register DMTIMER1MS\_TCLR[6] CE bit is set to 1, the timer value (the DMTIMER1MS\_TCRR[31-0] TIMER\_COUNTER bit field) is continuously compared to the value held in the timer match register (DMTIMER1MS\_TMAR). The value of the DMTIMER1MS\_TMAR[31-0] COMPARE\_VALUE bit field can be loaded at any time (timer counting or stopped). When the DMTIMER1MS\_TCRR and the DMTIMER1MS\_TMAR values match, an interrupt is issued, if the DMTIMER1MS\_IRQSTATUS\_SET[0] MAT\_EN\_FLAG bit is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the DMTIMER1MS\_TMAR before setting the DMTIMER1MS\_TCLR[6] CE bit.

The dedicated output pin (POTIMERPWM) can be programmed in the DMTIMER1MS\_TCLR[12] PT bit through the DMTIMER1MS\_TCLR[11-10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

#### 12.7.4.4.8 Timer Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the DMTIMER1MS\_TCLR[5] PRE bit is set. The DMTIMER1MS\_TCLR[4-2] PTV bit field sets the  $2^n$  division ratio (prescaler value is  $2^{(PTV + 1)}$ ). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 12-363 lists the prescaler/timer reload values versus contexts.

**Table 12-363. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	DMTIMER1MS_TLDR[31-0]
DMTIMER1MS_TCRR write	Reset	DMTIMER1MS_TCRR[31-0]
DMTIMER1MS_TTGR write	Reset	DMTIMER1MS_TLDR[31-0]
Stop	Reset	Frozen

#### 12.7.4.4.9 Timer Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM (POTIMERPWM) output pin can be configured to toggle on an event. The DMTIMER1MS\_TCLR[11-10] TRG bit field determines on

which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

### Note

In toggle mode, when DMTIMER1MS\_TCLR[11-10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event.

The DMTIMER1MS\_TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the DMTIMER1MS\_TCLR[11-10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

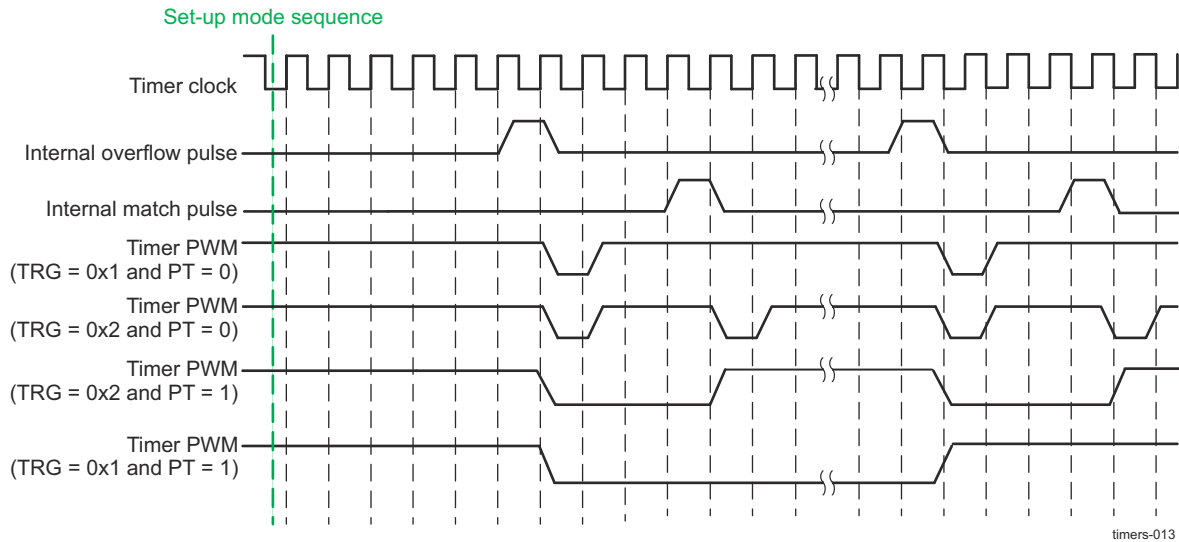

In [Figure 12-453](#), the internal overflow pulse is set each time the (0xFFFF FFFF – DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE + 1) value is reached, and the internal match pulse is set when the counter reaches the value of DMTIMER1MS\_TMAR. Depending on the value of the DMTIMER1MS\_TCLR[12] PT bit and DMTIMER1MS\_TCLR[11-10] TRG bit field, the timer provides pulse or PWM event on the output pin (POTIMERPWM).

The DMTIMER1MS\_TLDR and DMTIMER1MS\_TMAR must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the DMTIMER1MS\_TMAR and the value in the DMTIMER1MS\_TLDR must be at least two units. When match event is used, the compare mode DMTIMER1MS\_TCLR[6] CE bit must be set.

In [Figure 12-453](#), the DMTIMER1MS\_TCLR[7] SCPWM bit is set to 0. In [Figure 12-454](#), the DMTIMER1MS\_TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (DMTIMER1MS\_TCLR[7] SCPWM bit).

**Figure 12-453. Timing Diagram of PWM With DMTIMER1MS\_TCLR[7] SCPWM Bit = 0**

**Figure 12-454. Timing Diagram of PWM With DMTIMER1MS\_TCLR[7] SCPWM Bit = 1**

#### 12.7.4.4.10 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the DMTIMER1MS\_TCLR[5] PRE bit and DMTIMER1MS\_TCLR[4-2] PTV bit field)
- Value loaded into the DMTIMER1MS\_TLDR

Table 12-364 lists the prescaler clock ratio values.

**Table 12-364. Prescaler Clock Ratio Values**

DMTIMER1MS_TCLR[5] PRE	DMTIMER1MS_TCLR[4-2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$\text{OVF\_Rate} = (0\text{xFFFF FFFF} - \text{DMTIMER1MS\_TLDR} + 1) \times (\text{timer-functional clock period}) \times \text{PS}$$

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS =  $2^{(\text{PTV} + 1)}$  if prescaler is enabled, or PS = 1 if prescaler is disabled.

### CAUTION

Internal resynchronization causes any write to the DMTIMER1MS\_TCLR[1] ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write\_DMTIMER1MS\_TCLR\_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the DMTIMER1MS\_TCLR[1] ST bit.

### CAUTION

- In non-PWM mode, DMTIMER1MS\_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, DMTIMER1MS\_TLDR must be maintained at less than or equal to 0xFFFF FFDD.

For example, with a timer clock input of 32 kHz and the DMTIMER1MS\_TCLR[5] PRE bit set to 0, the timer output period is as listed in [Table 12-365](#).

**Table 12-365. Value and Corresponding Interrupt Period**

DMTIMER1MS_TLDR[31-0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 μs
0xFFFF FFFE	62.5 μs

#### 12.7.4.4.11 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the DMTIMER1MS\_TIOCP\_CFG[1] EMUFREE bit.

If the DMTIMER1MS\_TIOCP\_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the DMTIMER1MS\_TIOCP\_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (MCU\_TIMER\_IO[9-0] or TIMER\_IO[7-0]) is internally synchronized on two timer-clock rising edges.

#### 12.7.4.4.12 Accessing Timer Registers

All accesses are posted mode, under the assumption that  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ , until software reconfiguration. In addition, it is not recommended to access the timer registers prior to the PLLs generating the timer and interface clocks have been configured and the clocks have stabilized. All registers are 32 bits wide, accessible through the configuration interface with 32-bit access (read/write).

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- DMTIMER1MS\_TCLR
- DMTIMER1MS\_TCR
- DMTIMER1MS\_TLDR
- DMTIMER1MS\_TTGR
- DMTIMER1MS\_TMAR
- DMTIMER1MS\_TPIR
- DMTIMER1MS\_TNIR
- DMTIMER1MS\_TCVR
- DMTIMER1MS\_TOCR
- DMTIMER1MS\_TOWR

The following registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one interface clock cycle from command assertion:

- DMTIMER1MS\_TIDR
- DMTIMER1MS\_TIOCP\_CFG
- DMTIMER1MS\_IRQSTATUS
- DMTIMER1MS\_IRQSTATUS\_RAW
- DMTIMER1MS\_IRQSTATUS\_SET
- DMTIMER1MS\_IRQSTATUS\_CLR
- DMTIMER1MS\_IRQWAKEEN
- DMTIMER1MS\_TWPS
- DMTIMER1MS\_TSICR

#### **12.7.4.4.12.1 Writing to Timer Registers**

The host uses the configuration interface to write to the following registers synchronously with the timer interface clock:

- DMTIMER1MS\_TLDR
- DMTIMER1MS\_TCRR
- DMTIMER1MS\_TCLR
- DMTIMER1MS\_TIOCP\_CFG
- DMTIMER1MS\_IRQSTATUS
- DMTIMER1MS\_IRQSTATUS\_SET
- DMTIMER1MS\_IRQSTATUS\_CLR
- DMTIMER1MS\_IRQWAKEEN
- DMTIMER1MS\_TTGR
- DMTIMER1MS\_TSICR
- DMTIMER1MS\_TMAR
- DMTIMER1MS\_TPIR
- DMTIMER1MS\_TNIR
- DMTIMER1MS\_TCVR
- DMTIMER1MS\_TOCR
- DMTIMER1MS\_TOWR

#### **12.7.4.4.12.1.1 Write Posting Synchronization Mode**

This mode is used if the DMTIMER1MS\_TSICR[2] POSTED bit is set to 1 (default value).

This mode uses a posted write scheme to update any internal register (DMTIMER1MS\_TCLR, DMTIMER1MS\_TCRR, DMTIMER1MS\_TLDR, DMTIMER1MS\_TTGR, DMTIMER1MS\_TMAR, DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, DMTIMER1MS\_TCVR, DMTIMER1MS\_TOCR, and DMTIMER1MS\_TOWR). Therefore, the write transaction is immediately acknowledged on the configuration interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect, nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status (DMTIMER1MS\_TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the interface clock. Consequently, any read access to DMTIMER1MS\_TCRR does not add any resynchronization latency; the current value is always available.

---

**Note**

Because the overflow IRQ is generated when the value of DMTIMER1MS\_TCR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of  $(1 \times PS \times \text{timer functional clock period})$  before any read access to DMTIMER1MS\_TCR to ensure a correct reading of its content.

---

---

**Note**

If DMTIMER1MS\_TGR register is written during a posted write to DMTIMER1MS\_TCR, the value to be written to DMTIMER1MS\_TCR will be discarded.

If a posted write to DMTIMER1MS\_TCR is started, the user must not write to DMTIMER1MS\_TPIR or DMTIMER1MS\_TNIR before the DMTIMER1MS\_TCR write is finished, because the value of DMTIMER1MS\_TCR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

---

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ .

#### **12.7.4.4.12.1.2 Write Nonposting Synchronization Mode**

This mode is used if the DMTIMER1MS\_TSICR[2] POSTED bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the configuration interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the configuration interface frequency and the timer clock frequency.

#### **12.7.4.4.12.2 Reading From Timer Counter Registers**

---

**Note**

LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

---

The DMTIMER1MS\_TCR is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the DMTIMER1MS\_TCAR1 and DMTIMER1MS\_TCAR2 registers as they can be changed due to internal processes too.

#### **12.7.4.4.12.2.1 Read Posted**

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. The recommended functional frequency range is  $\text{freq}(\text{timer}) < \text{freq}(\text{interface clock})/4$ .

Read posted mode is used if DMTIMER1MS\_TSICR[2] POSTED = 0x1 or DMTIMER1MS\_TSICR[3] READ\_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the configuration interface, prior to the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to DMTIMER1MS\_TCRR, DMTIMER1MS\_TCAR1, DMTIMER1MS\_TCAR2, DMTIMER1MS\_TCVR, and DMTIMER1MS\_TOWR, which needs resynchronization from functional to interface clock domains.

Note that in Posted mode, if the DMTIMER1MS\_TCRR is read immediately after wake-up and the interface clock is off during idle state, then it is possible to get an old value from just before going to idle state due to the fact the interface clock is needed for synchronization.

In order to avoid this situation, another synchronization mechanism is used for the first read operation after idle state. The DMTIMER1MS\_TSICR[4] READ\_AFTER\_IDLE bit is used to enable/disable the mechanism.

When the synchronization mechanism is disabled (READ\_AFTER\_IDLE bit is set to 1), first read transaction takes only 2 interface clock cycles, but the read value of DMTIMER1MS\_TCRR could be wrong.

When the synchronization mechanism is enabled (READ\_AFTER\_IDLE bit is set to 0), first read value of DMTIMER1MS\_TCRR is correct, but the read transaction takes more than 2 interface clock cycles.

#### 12.7.4.4.12.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. Recommended functional frequency range is  $\text{freq}(\text{timer}) \geq \text{freq}(\text{interface clock})/4$ .

Read non-posted mode is used if DMTIMER1MS\_TSICR[2] POSTED = 0x0 and DMTIMER1MS\_TSICR[3] READ\_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the configuration interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to DMTIMER1MS\_TCRR, DMTIMER1MS\_TCAR1, DMTIMER1MS\_TCAR2, DMTIMER1MS\_TCVR, and DMTIMER1MS\_TOWR, which need resynchronization from functional to interface clock domains.

#### 12.7.4.4.13 Timer Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are DMTIMER1MS\_TCLR, DMTIMER1MS\_TLDR, DMTIMER1MS\_TCRR, DMTIMER1MS\_TTGR, DMTIMER1MS\_TMAR, DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, DMTIMER1MS\_TCVR, DMTIMER1MS\_TOCR, and DMTIMER1MS\_TOWR. For read operation, the registers affected by this selection are: DMTIMER1MS\_TCRR, DMTIMER1MS\_TCAR1, DMTIMER1MS\_TCAR2, DMTIMER1MS\_TCVR, and DMTIMER1MS\_TOWR.

The interface clock domain synchronous registers DMTIMER1MS\_TIDR, DMTIMER1MS\_TIOCP\_CFG, DMTIMER1MS\_IRQSTATUS, DMTIMER1MS\_IRQSTATUS\_SET, DMTIMER1MS\_IRQWAKEEN, DMTIMER1MS\_TWPS, and DMTIMER1MS\_TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one interface clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in DMTIMER1MS\_TSICR[2] POSTED bit. The DMTIMER1MS\_TSICR[3] READ\_MODE defines how the read operation is performed when the module is configured in non-posted mode (see DMTIMER1MS\_TSICR). The following cases are possible:

- DMTIMER1MS\_TSICR[2] POSTED = 0x1 and DMTIMER1MS\_TSICR[3] READ\_MODE = x (don't care): read and write operations are expected in posted mode.
- DMTIMER1MS\_TSICR[2] POSTED = 0x0 and DMTIMER1MS\_TSICR[3] READ\_MODE = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.

- DMTIMER1MS\_TSICR[2]POSTED = 0x0 and DMTIMER1MS\_TSICR[3] READ\_MODE = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

### 12.7.4.5 Timers Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 12.7.4.5.1 Timer Global Initialization

##### 12.7.4.5.1.1 Main Sequence – Timer Module Global Initialization

[Table 12-366](#) identifies the main steps for initializing the timer module when the module is to be used for the first time.

**Table 12-366. Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	DMTIMER1MS_TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	DMTIMER1MS_TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	DMTIMER1MS_TIOCP_CFG[3-2] IDLEMODE	0x-
Enable wake-up interrupt events.	DMTIMER1MS_IRQWAKEEN[2-0]	0x-
Select posted mode.	DMTIMER1MS_TSICR[2] POSTED	0x-

#### 12.7.4.5.2 Timer Operational Mode Configuration

##### 12.7.4.5.2.1 Timer Mode

##### 12.7.4.5.2.1.1 Main Sequence – Timer Mode Configuration

[Table 12-367](#) lists the steps in the timer mode configuration.

**Table 12-367. Timer Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Enable overflow interrupt.	DMTIMER1MS_IRQSTATUS_SET[1] OV_F_EN_FLAG	0x1
Load timer counter value.	DMTIMER1MS_TCRR	0x-
Load timer load value.	DMTIMER1MS_TLDR	0x-
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1

##### 12.7.4.5.2.2 Timer Compare Mode

##### 12.7.4.5.2.2.1 Main Sequence – Timer Compare Mode Configuration

[Table 12-368](#) lists the steps in the timer compare mode configuration.

**Table 12-368. Timer Compare Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Enable match interrupt.	DMTIMER1MS_IRQSTATUS_SET[0] MAT_EN_FLAG	0x1
Load timer counter value.	DMTIMER1MS_TCRR	0x-
Load timer compare value.	DMTIMER1MS_TMAR	0x-
Enable compare mode.	DMTIMER1MS_TCLR[6] CE	0x1
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1

### 12.7.4.5.2.3 Timer Capture Mode

#### 12.7.4.5.2.3.1 Main Sequence – Timer Capture Mode Configuration

Table 12-369 lists the steps in the timer capture mode configuration.

**Table 12-369. Timer Capture Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 12.7.4.5.2.3.2.	
Enable capture interrupt.	DMTIMER1MS_IRQSTATUS_SET[2] TCAR_EN_FLAG	0x1
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1
Detect event.	See Section 12.7.4.5.2.3.3.	

#### 12.7.4.5.2.3.2 Subsequence – Initialize Capture Mode

Table 12-370 lists the steps to initialize capture mode.

**Table 12-370. Initialize Capture Mode**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Select TIMER[11-0] or MCU_TIMER[3-0] Capture input at device pins TIMER_IO[11-0] for TIMER[11-0] or at pins MCU_TIMER_IO[3-0] for MCU_TIMER[3-0].	DMTIMER1MS_TCLR[14] GPO_CFG	0x1
Select single or second event capture.	DMTIMER1MS_TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	DMTIMER1MS_TCLR[9-8] TCM	0x-

#### 12.7.4.5.2.3.3 Subsequence – Detect Event

Table 12-371 lists the steps in detecting an event.

**Table 12-371. Detect Event**

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	DMTIMER1MS_IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	DMTIMER1MS_TCAR1 and/or DMTIMER1MS_TCAR2	
Clear capture interrupt request.	DMTIMER1MS_IRQSTATUS[2] TCAR_IT_FLAG	0x1

### 12.7.4.5.2.4 Timer PWM Mode

#### 12.7.4.5.2.4.1 Main Sequence – Timer PWM Mode Configuration

Table 12-372 lists the steps in the timer PWM mode configuration.

**Table 12-372. Timer PWM Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Select trigger output mode.	DMTIMER1MS_TCLR[11-10] TRG	0x-
Select pulse or toggle modulation PWM mode.	DMTIMER1MS_TCLR[12] PT	0x-
Select TIMER[11-0] or MCU_TIMER[3-0] PWM output at device pins TIMER_IO[11-0] for TIMER[11-0] or at pins MCU_TIMER_IO[3-0] for MCU_TIMER[3-0].	DMTIMER1MS_TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	DMTIMER1MS_TCLR[7] SCPWM	0x-

**Table 12-372. Timer PWM Mode Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Load timer load value.	DMTIMER1MS_TLDR	0x-
Load timer compare value.	DMTIMER1MS_TMAR	0x-
Enable compare.	DMTIMER1MS_TCLR[6] CE	0x1
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1

## 12.8 Internal Diagnostics Modules

### 12.8.1 Dual Clock Comparator (DCC)

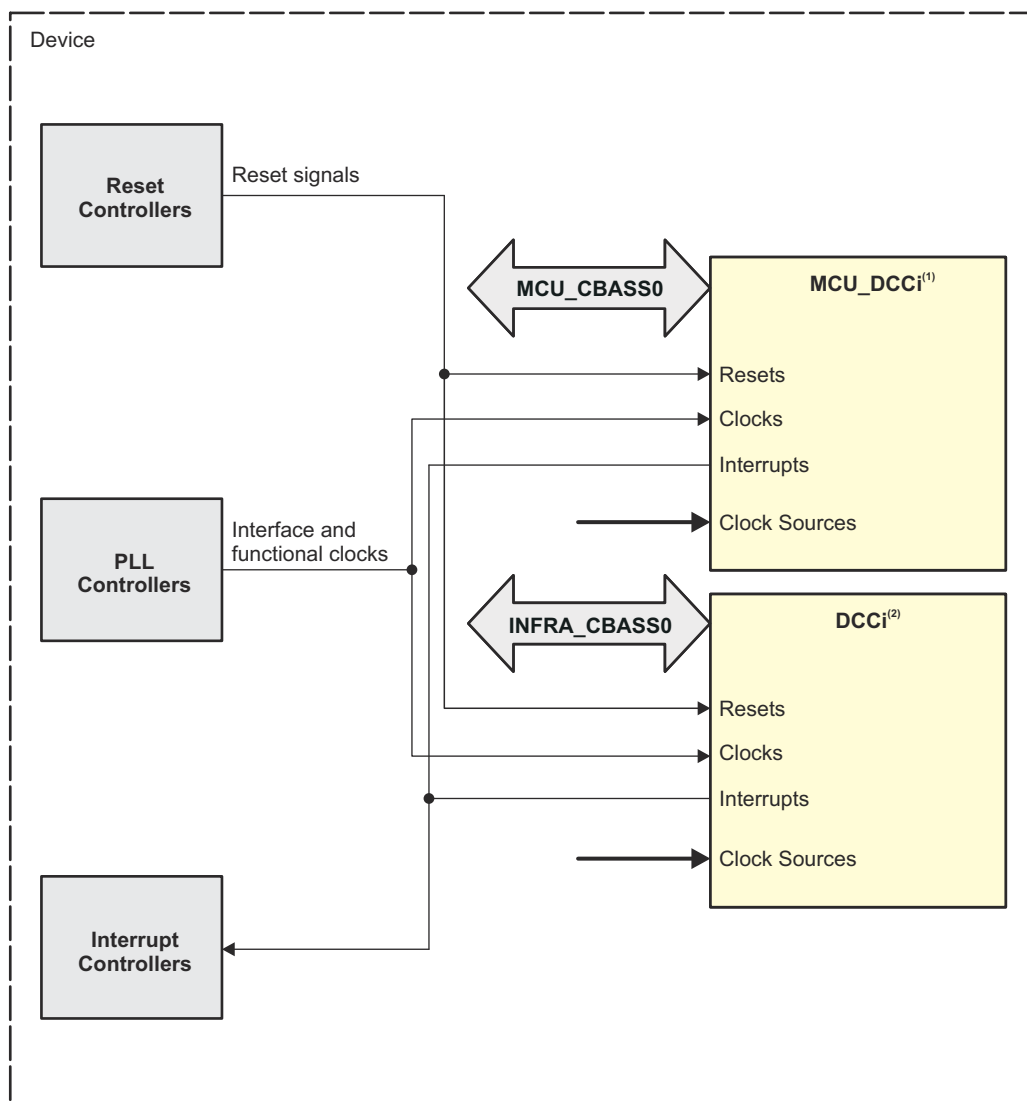

This section describes the Dual Clock Comparator (DCC) modules in the device.

#### 12.8.1.1 DCC Overview

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programmed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference.

The device has instances of DCC modules.

[Figure 12-455](#) shows the DCC modules overview.

dcc-001

1.  $i = 0$  to number of instances in MCU Domain.
2.  $i = 0$  to number of instances in MAIN Domain.

**Figure 12-455. DCC Modules Overview**

#### 12.8.1.1.1 DCC Features

The DCC uses two independent clock sources to detect when one is out of specification. Each DCC module implements the following features:

- Two independent counter blocks count clock pulses from each clock source
- Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
- Configurable timebase for error signal
- Error signal generation when one of the clocks is out of specification
- Clock frequency measurement

#### 12.8.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

## 12.8.1.2 DCC Functional Description

### 12.8.1.2.1 DCC Counter Operation

#### Note

For detailed DCC compute calculations, refer to [Continuous Monitor of the PLL Frequency With the DCC App Note](#).

The DCC has two parallel counters that count clock pulses for two independent clock sources:

- Counter0 generates a fixed-width counting window (VALID0) after a pre-programmed number of pulses (COUNT0). The values for VALID0 and COUNT0 can be programmed in DCC2\_DCCVALIDSEED0 and DCC2\_DCCCNTSEED0 registers respectively.
- Counter1 generates a fixed-width pulse (1 cycle) after a pre-programmed number of pulses (COUNT1). This pulse sets an error signal if Counter1 does not reach 0 during the time when VALID0 is running. The seed value for COUNT1 can be programmed in DCC2\_DCCCNTSEED1 register.

The error signal is generated by any one of the following conditions:

- Clock1 expires before the COUNT0 reaches 0.
- Clock1 expires after both COUNT0 and VALID0 reach 0.
- Clock1 not present.
- Clock0 not present.

Any of these errors causes the counters to stop counting. An application must then read out the counter values to determine what caused the error. Once the error is detected, the counters are stopped after 3 FICLK and 2 source clock cycles due to the cross clock domain synchronisation.

Reloads or restarts occur under two conditions:

- The module is reset or restarted through software (that is, software starts the module after reset, or software checks an error condition and decides to restart the module).
- COUNT0, COUNT1, and VALID0 all reach 0 without error.

#### CAUTION

The DCC module does not check jitter for Clock0 or Clock1.

As the counter preset signal is synchronized to either of the source clock domains, the counters begin downcounting after two corresponding source clock cycles.

The error signal is captured to the FICLK domain. There is 1 FICLK period uncertainty on either side of the fixed width counting window (VALID0) in generating the error signal since the counters work in different clock domains. This should be accounted for when setting the count value for VALID0.

[Figure 12-456](#) through [Figure 12-460](#) shows examples of counters relationship and error generation.

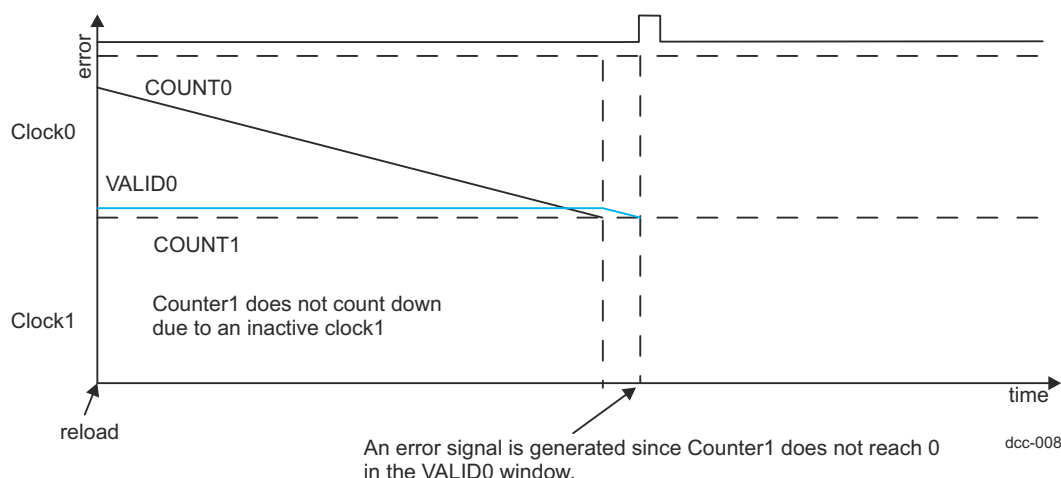

**Figure 12-456. DCC Clock0 and Clock1 With no Error**

**Figure 12-457. DCC Clock1 slower than Clock0 results in an error and stops counting**

**Figure 12-458. DCC Clock1 faster than Clock0 results in an error and stops counting**

**Figure 12-459. DCC Clock1 not present results in an error and stops counting**

**Figure 12-460. DCC Clock0 not present results in an error and stops counting**

#### 12.8.1.2.2 DCC Low Power Mode Operation

The DCC module does not function in Low Power Mode. It is the responsibility of software to stop the module before entering low power mode and to restart the module after exiting low power mode.

#### 12.8.1.2.3 DCC Suspend Mode Behavior

The DCC module will continue running regardless of the state of emulation. All registers are readable via emulation reads.

#### 12.8.1.2.4 DCC Single-Shot Mode

The DCC can be programmed to count down one time using single-shot mode. In this mode, the DCC stops operation when both COUNT0 and VALID0 reach 0.

At the end of one sequence in single-shot mode the DCC2\_DCCGCTRL[3-0] DCCENA bitfield is set to disabled, which stops further counting. Single-shot mode is enabled from the DCC2\_DCCGCTRL[11-8] SINGLESOT bitfield.

At the end of one sequence in single-shot mode, if there is no error which stops counting, then the done status bit is set in the DCC2\_DCCSTATUS[1] DONEFLG bitfield and a done interrupt DCC\_x\_INT is generated. Software must clear the done bit before restarting the counting.

#### **12.8.1.2.5 DCC Continuous mode**

When DCC runs in continuous mode both the counts shall get reloaded with seed value upon completion of counts without error. If the counts end in error DCC stops the operation and counts are not reloaded.

##### **12.8.1.2.5.1 DCC Continue on Error**

During debug, if there are events which are causing clocks to be anomalous over short period covering more than one evaluation window then it would be important to capture trajectory of error event and period around such event. To allow capturing the successive error events DCC can be programmed to continue after error. [3-0] CONT\_ON\_ERR shall be set to value other than "0101" to enable this mode. It is recommended to write "1010" to avoid single soft errors.

##### **12.8.1.2.5.2 DCC Error Count**

DCC also counts the number of error pulses generated since reset or since last time the error count is cleared. This is read/write register for CPU to clear when new trace of number of errors is required to be maintained.

##### **12.8.1.2.6 DCC Control and count hand-off across clock domains**

As the counters run in two different selectable clock domains and the register interface runs on the fixed bus clock domain, control signals and counter value hand-off have synchronizers implemented. These add to the margins of error while comparing the counts.

1. With all three counts synchronized to FICLK domain for comparison error detection there is delay in terms of FICLK domain.
2. Based on the error signal, the enable for the counters is synchronized back to the respective clock domains of the counters, which adds latency in terms of clock periods which are different, this would create a skew between start of count. Depending upon frequency ratios of the clocks used, the difference between two could vary.

Application needs to consider the worst case delay differences while measuring the clocks.

##### **12.8.1.2.7 DCC Error Trajectory record**

Once the clock errors out, the host can read the counter values to determine the extent of error to analyze type of failure. For short window comparisons this would become difficult, specially if there are back to back errors due to some transient event. Secondly, for random events which can cause an interrupt during the critical phase of application running, then event if not recorded may get overwritten and also not provide meaningful trace of error.

##### **12.8.1.2.7.1 DCC FIFO capturing for Errors**

DCC provides the FIFO for capturing COUNT0, VALID0, and COUNT1 information which captures all three counts upon "Error" event. For "Done" event no results are captured by default.

##### **12.8.1.2.7.2 DCC FIFO in continuous capture mode**

To track the VALID0 counter values regardless of "Error" or not, FIFOs can be configured to capture the count for each compare window. This is useful in validation and characterization exercise. [11-7] FIFO\_NONERR control when set to value other than "0101" this mode is set; it is recommended to write "1010" to avoid single soft errors. Note, this capture is applicable only in continuous mode and not in single shot mode.

##### **12.8.1.2.7.3 DCC FIFO Details**

The FIFO is 4 deep for each count and updates new count information for all the non-full FIFOs. Information is updated on every configured trigger of error or cycle completion. If full, the next values are not written till at-least one entry is read. Application owns responsibility to read the FIFOs uniformly to keep synchronisation between three entries of the FIFO. Both empty and full indications for individual FIFOs is provided through the .

##### **12.8.1.2.7.4 DCC FIFO Debug mode behavior**

Upon debug access, the FIFO pointers should not advance hence not impacting the functional behavior. This requirement is same as other functional blocks in the device.

#### **12.8.1.2.8 DCC Count read registers**

DCC has provision to read the counts during operation. This is performed using , , and registers. Read from these registers in default mode allows reading the present value of count. This is useful when in single shot mode or mode where DCC stops upon error.

These registers can be used to read the FIFO through the [7-4] FIFO\_READ configuration. Reads on the empty FIFO shall provide the contents of last pointed location. Application shall track the empty/full conditions of the FIFOs to track the count records consistently.

Regardless of FIFO\_READ configuration, the FIFO internally keeps updating records based on configured triggers till full.

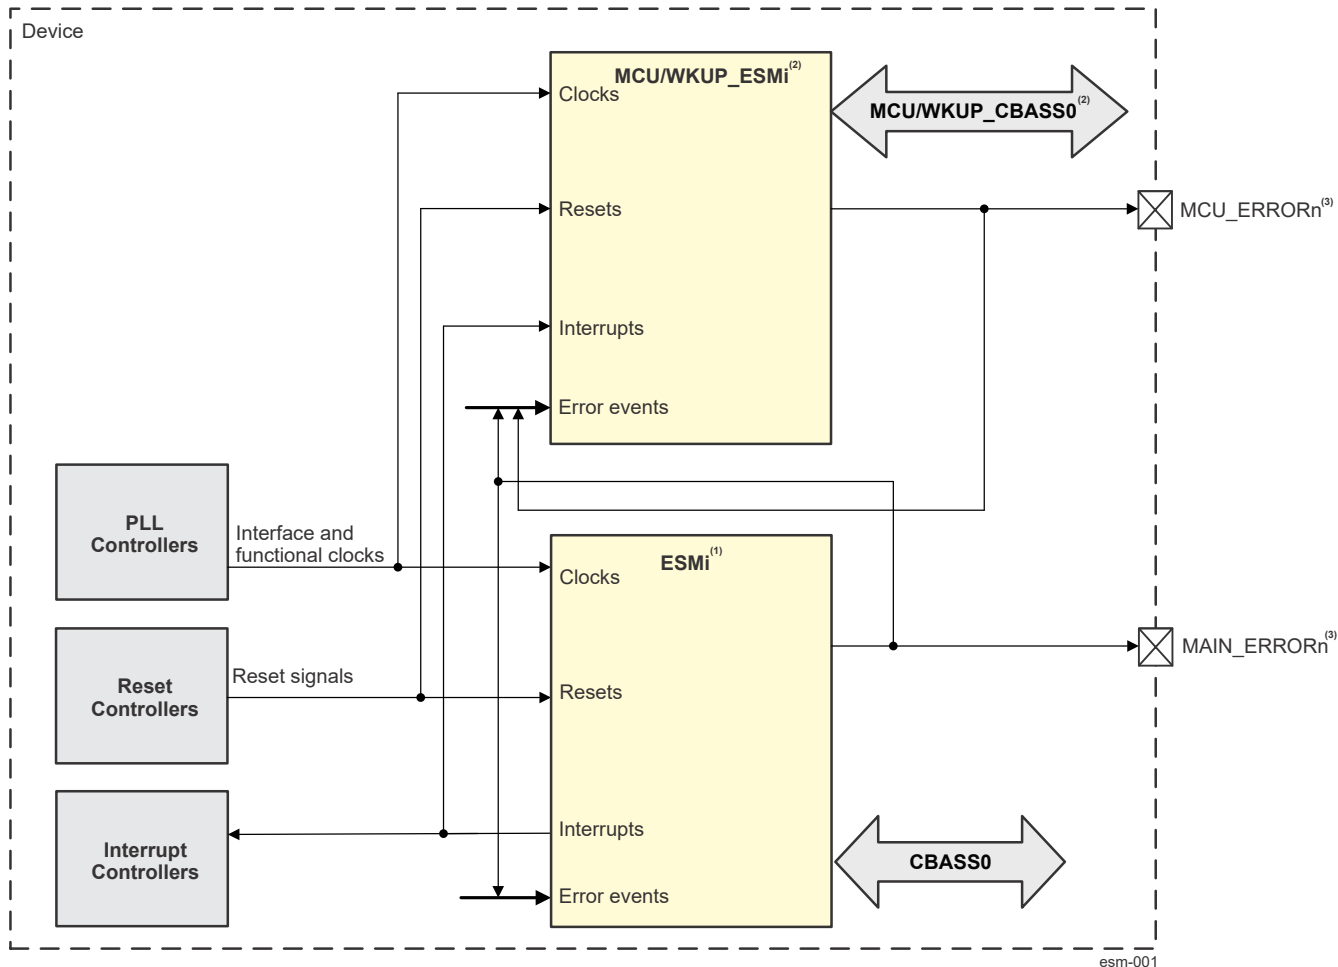

## 12.8.2 Error Signaling Module (ESM)

This section describes the Error Signaling Module (ESM) in the device.

### 12.8.2.1 ESM Overview

The Error Signaling Module (ESM) aggregates events and/or errors from throughout the device into one location. It can signal both low and high priority interrupts to a processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore an external controller is able to reset the device or keep the system in a safe, known state.

Figure 12-461 shows the ESM modules overview.

1. i represents a valid instance of ESM in a domain. Consult the device datasheet for available domains and ESM instances.
2. i represents a valid instance of ESM in a MCU or WKUP domain. Consult the device datasheet for available domains and ESM instances.
3. Not all pins are valid for all devices. Consult the device datasheet for specifics.

#### Note

The MAIN\_ERRORn pin, if valid, is used for observation only.

**Figure 12-461. ESM Modules Overview**

#### 12.8.2.1.1 ESM Features

Each ESM module implements the following features:

- Up to 1024 error event inputs
  - Implemented in groups of 32 events
  - Level or Pulse inputs (Pulse inputs are triple redundant)
- Selectable low and high priority interrupt error pin prioritization of each error event
- Error pin to signal severe device failure
  - Support of level or PWM modes
- Configurable timebase for error signal
- Error forcing capability
- Internal redundant flops on critical fields

#### **12.8.2.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

---

#### **Note**

Some features may not be available. See *Module Integration* for more information.

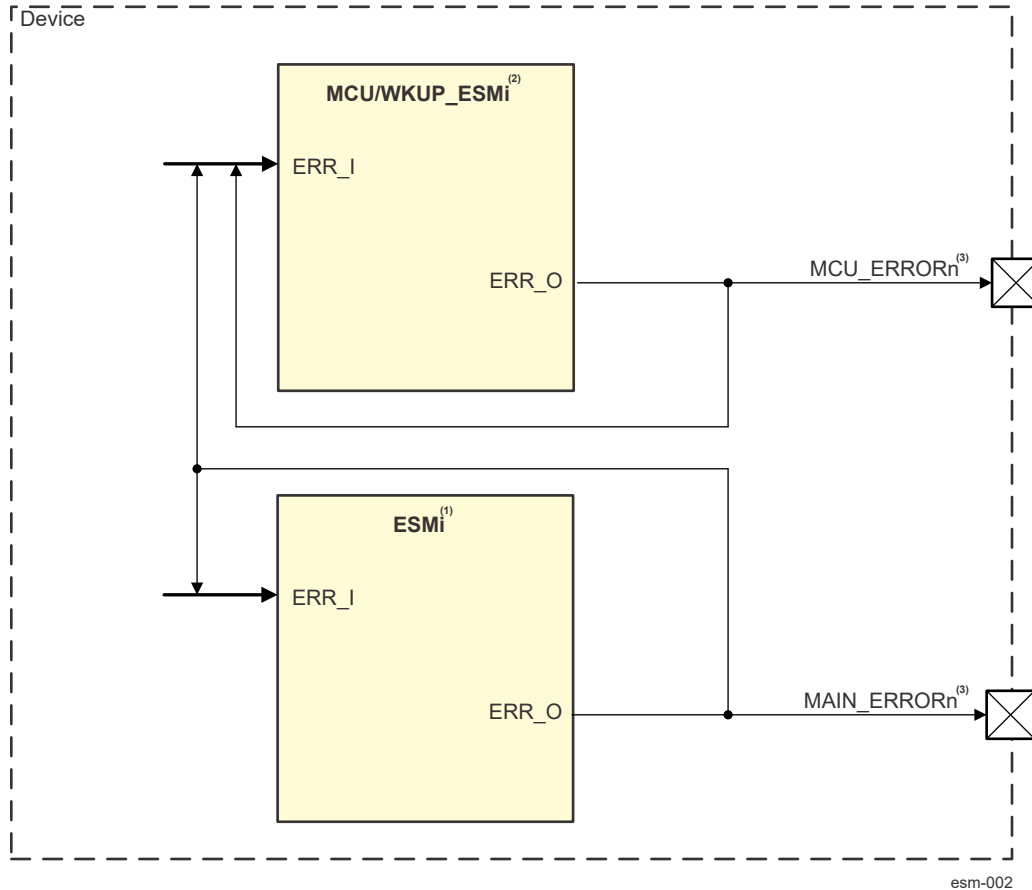

---

### 12.8.2.2 ESM Environment

The MCU\_ESM0 and ESM0 modules are hereinafter referred to as ESM module.

This section describes the ESM external connections (environment).

Figure 12-462 shows the ESM pins used for typical connections with external devices.

1. i represents a valid instance of ESM in a domain. See the device specific datasheet for available domains and ESM instances.
2. i represents a valid instance of ESM in a MCU or WKUP domain. See the device specific datasheet for available domains and ESM instances.
3. Not all pins are valid. See the device datasheet for specifics.

#### Note

The **MAIN\_ERRORn** pin, if valid, is used for observation only.

**Figure 12-462. ESM Modules Environment**

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.8.2.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.8.2.4 ESM Functional Description

The Error Signaling Module (ESM) centralizes fault reports. It provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration will also select whether the interrupt that is generated will be one of high priority or low priority.

By reporting the faults in a central location, the system may determine what caused the fault and what action can be taken. In general, the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin. This allows the system outside of the SoC to monitor for potentially fatal errors (errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) can operate in level or PWM modes. In level mode, the output will remain asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will go inactive (high). If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error. In PWM mode, the error will cause the output pin to maintain its value for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will continue the PWM pattern. If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if it fails, then the external system is still alerted. If it succeeds, then it can remove the ERROR pin assertion so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitor(s) of an existing error event.

[Figure 12-463](#) shows the ESM module block diagram. Note that not all instances may be pinned out in the device. For more information, see [Section 12.8.2.2, ESM Environment](#).

Figure 12-463. ESM Block Diagram

#### 12.8.2.4.1 ESM Interrupt Requests

The ESM module generates three output interrupts to the device interrupt controllers:

- Configuration error interrupt (see [Section 12.8.2.4.1.1](#))
- High priority error interrupt (see [Section 12.8.2.4.1.2](#))
- Low priority error interrupt (see [Section 12.8.2.4.1.3](#))

The error interrupt outputs are provided so that a processor in the device can be signaled to intervene when an error event occurs. Each error event input can be enabled, via software, to cause an error interrupt to occur (via the ESM\_INTR\_EN\_SET\_j register). Additionally, each error event input can be programmed to influence either the low priority (default) interrupt or the high priority interrupt (via the ESM\_INT\_PRIO\_j). The low priority interrupt is intended for events that are of interest, but do not require immediate intervention. For example, an indication that there was a single bit error that was corrected may signal a low priority interrupt, so that information can be collected for statistical purposes. A high priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error may be signaled as a high priority interrupt.

##### 12.8.2.4.1.1 ESM Configuration Error Interrupt

The configuration error interrupt (ESM\_INT\_CFG\_LVL\_0) indicates that there is an inconsistency in the configuration of one (or more) error group j registers (MMRs).

In such inconsistency in the internal copies of any of the MMRs caused by fault associated with error group j, the corresponding raw status will be set in the ESM\_ERR\_RAW register. If the corresponding bit is enabled in the ESM\_ERR\_EN\_SET register, a configuration error interrupt will be triggered.

When a configuration error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_ERR\_STS register to determine which group has a configuration error
2. Write the correct values to the following group registers:

---

**Note**

If there has been a configuration error, the values in the below registers cannot be guaranteed to be correct anymore. Therefore, software should maintain a copy of the correct values prior to an error to ensure that they can be re-programmed with the correct configuration.

---

- a. ESM\_INTR\_EN\_SET\_j
  - b. ESM\_INTR\_EN\_CLR\_j
  - c. ESM\_INT\_PRIO\_j
  - d. ESM\_PIN\_EN\_SET\_j
  - e. ESM\_PIN\_EN\_CLR\_j
3. Service any pending interrupts in steps 4, 5, and 6 below
- 

**Note**

The raw status of any pending interrupts may be inconsistent. Servicing the interrupt will return it to consistency via the error group ESM\_RAW\_j register.

---

4. Write 0x1 to the appropriate bits in the ESM\_ERR\_STS register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no additional errors, the level interrupt will go low
5. Write the end of interrupt vector to the ESM\_EOI register
  - a. If there are additional configuration error interrupts pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional low priority error interrupts pending, there will be no new pulse.

**12.8.2.4.1.2 ESM Low Priority Error Interrupt**

Events mapped to the low priority error interrupt (ESM\_INT\_LOW\_LVL\_0) are intended to be events of interest that should be addressed eventually, not events that require immediate attention. An example would be an event indicating a corrected error. The system may want to track this for statistical purposes, but it does not require immediate attention.

Any error event can be mapped to the low priority error interrupt. A low priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j register) and mapped to the low priority error interrupt (via ESM\_INT\_PRIO\_j register) and the raw status is set (via the ESM\_RAW\_j register).

When a low priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_LOW\_PRI register
    - a. If both [31-16]PLS and [15-0]LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
    - b. If either [31-16]PLS or [15-0]LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
      - i. First option: Record the value in [31-16]PLS and [15-0]LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority low priority error event
- 

**Note**

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

---

- ii. Second option:
  1. Read the ESM\_LOW register to determine which event group(s) have pending low priority error interrupts

2. Read the desired error group  $j$  ESM\_STS\_  $j$  register
  3. Identify which low priority interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.8.2.4.1.2.1](#)) or pulse (see [Section 12.8.2.4.1.2.2](#)) event.

#### 12.8.2.4.1.2.1 ESM Low Priority Error Level Event

When a low priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the low priority error level event at the source
2. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_  $j$  register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

#### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are low priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional low priority error level events enabled and pending, there will be no new pulse
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.1.2.2 ESM Low Priority Error Pulse Event

When a low priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_  $j$  register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are additional low priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional low priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.1.3 ESM High Priority Error Interrupt

Events mapped to the high priority error interrupt are intended to be events that require immediate intervention from the system because a potentially dangerous error has occurred. An example would be an event indicating an uncorrected error. The system will want to diagnose the issue and intervene to ensure there are no violations.

Any error event can be mapped to the high priority error interrupt. A high priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j) register and mapped to the high priority interrupt (via the ESM\_INT\_PRIO\_j) register and the raw status is set (via the ESM\_RAW\_j).

When a high priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_HI\_PRI register
  - a. If both [31-16] PLS and [15-0] LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
  - b. If either [31-16] PLS or [15-0] LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
    - i. First option: Record the value in [31-16] PLS and [15-0] LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority high priority error event.

---

#### Note

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

- ii. Second option:
      1. Read the ESM\_HI register to determine which event group(s) have pending high priority error interrupts
      2. Read the desired error group j/ESM\_STS\_j register
      3. Identify which high priority error interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.8.2.4.1.3.1](#)) or pulse (see [Section 12.8.2.4.1.3.2](#)) event.

#### 12.8.2.4.1.3.1 ESM High Priority Error Level Event

When a high priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the error event at the source
2. Write 0x1 to the appropriate bit in the error group j of the ESM\_STS\_j register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

---

#### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional high priority error level events enabled and pending, there will be no new pulse

4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register, but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.1.3.2 ESM High Priority Error Pulse Event

When a high priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_  $j$  register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional high priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.2 ESM Error Event Inputs

The ESM can have up to 1024 error event inputs, configurable by groups of 32. For the mapping of system interrupt error events to ESM interrupt inputs, see *Interrupt Sources*.

Level error events (active high) are synchronized to the ESM clock. This synchronized value is captured in to a flop.

Pulse error events use rising edge detection. Each pulse error event has 3 redundant inputs. Each input has its own edge detection logic. Multiple transmission protects against Single Event Upsets (SEUs, transient errors) causing a pulse to be lost during transmission and against failure of the edge detection logic. Once an edge has been detected on any of the three inputs, the ESM\_RAW\_  $j$  status is set. Subsequent pulses are likely to come concurrently or quickly enough that software will not have reacted yet. This logic is intentionally biased against false negatives and towards false positives. An SEU that causes an event where none actually occurred will cause software to be called in to action. Software must observe that there is no real error and clear the false status.

#### 12.8.2.4.3 ESM Error Pin Output

The error pin output (ERR\_O) is used to signal an external agent that it needs to (or may need to) intervene because of an error. Each error event input can be programmed, via software, to influence the error pin output (via the ESM\_PIN\_EN\_SET\_  $j$  register). The error pin output is active low or PWM based on the ESM\_EN[7-4] PWM\_EN field. This bit field should only be modified when the ESM is disabled, based on the ESM\_EN register.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this via a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, it will be driving the error pin so the device can hand over control to the ESM. The user may also add an external pull-down that is only active when the device is in reset.

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

The ESM has also a software error forcing capability on the error pin. That is, a force error can be set via the ESM\_EN[3-0] KEY bit field.

### CAUTION

The isolation value for the ERR\_O output of ESM is active (0). This is intended and supposed to protect against an accidental transition to a low power state. If the actual low power mode transition is intended, the PMIC should be made aware by software to ignore the ESM error signal. Otherwise device resets will be asserted from companion chip.

Figure 12-464 describes the behavior of the error pin. Not shown is that a reset (Power-On-Reset only) will immediately transition the error pin to the ESM\_RESET state and a Global Soft Reset will immediately transition the error pin to the ESM\_IDLE state. A pending error interrupt event is any error event with the raw state set and the error pin Influence enabled. There are two types of "clear" events associated with servicing the error pin. The first is to clear the status of the pending event (see Section 12.8.2.4.1 for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the error pin.

esm-007

**Figure 12-464. ESM Error Pin State Flowchart**

If an error event happens that has been programmed to influence the error pin, the error pin will assert (active low) for a minimum time (as programmed by the ESM\_PIN\_CNTR\_PRE register). In order for the error pin to de-assert, the following 3 things must happen:

1. The minimum time interval must expire
2. The event that caused the error pin to assert must be cleared (see Section 12.8.2.4.1)
3. A CLEAR (0x5) must be written to the ESM\_PIN\_CTRL register.

### Note

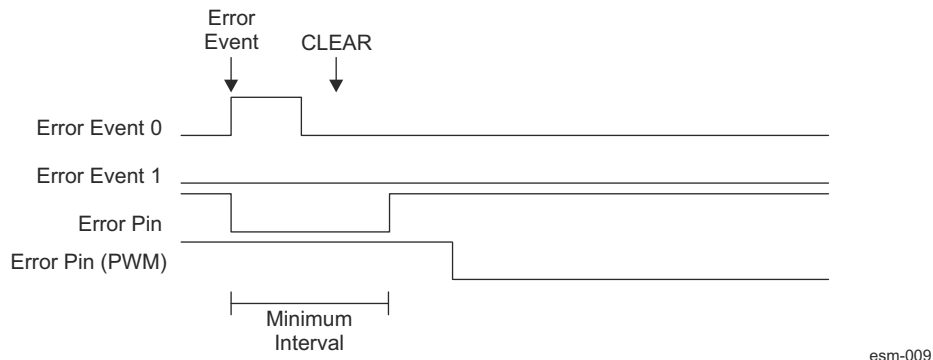

Step 3 should happen after step 2, but either (or both) of these steps may happen before or after step 1.

Figure 12-465 shows a typical error pin assertion.

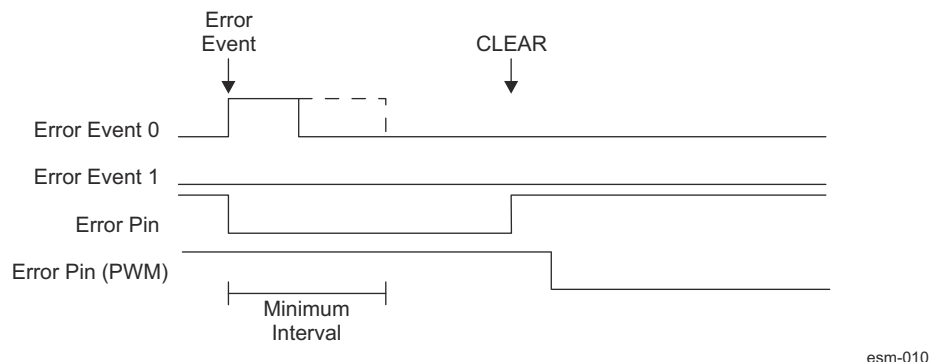

**Figure 12-465. ESM Error Pin Assertion**

If, during the minimum time, CLEAR is written to the error key, then the error pin will de-assert after the minimum time interval, as shown in Figure 12-466.

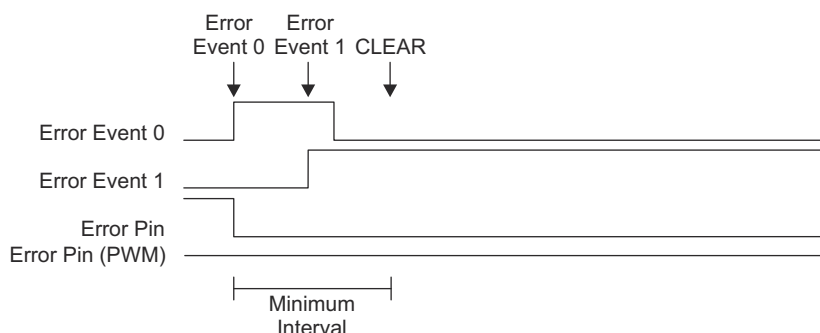

**Figure 12-466. ESM Error Pin Assertion with CLEAR during Minimum Interval**

If CLEAR is not written till after the minimum time interval, the error pin will de-assert when CLEAR is written. This is regardless of whether the error interrupt event itself is removed before or after the minimum time interval, as shown by the dotted line in Figure 12-467.

**Figure 12-467. ESM Error Pin Asserting with CLEAR after Minimum Interval**

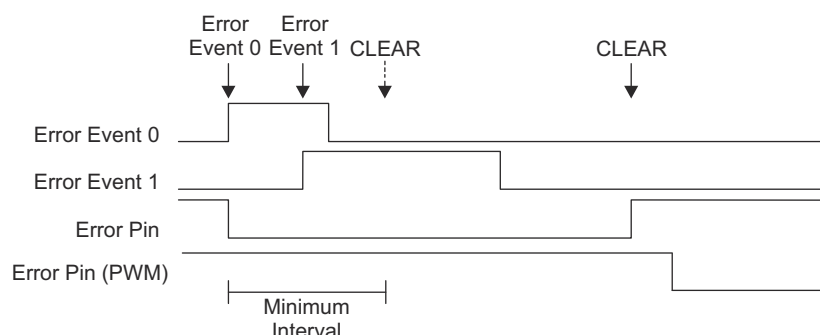

When in the ESM\_ERROR state and a CLEAR event happen, if there are still pending error events, the ESM stays in the ESM\_ERROR state with the error pin asserted. Multiple error events when in the ESM\_ERROR state do not reset the minimum time interval counter as shown in [Figure 12-468](#).

esm-011

**Figure 12-468. ESM Error Pin Asserting with Interval Reset by Additional Error Event(s)**

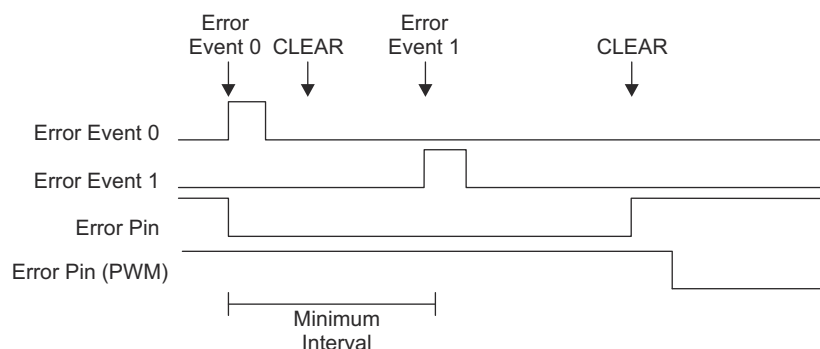

A CLEAR event causes a re-evaluation of whether there are any pending error events. As such, a single CLEAR can be used to clear the error pin after multiple error events. Multiple CLEAR events can occur (such as the one with the dotted arrow shown in [Figure 12-469](#)), but are not necessary. No matter how many error events occur nor when (or how many) CLEAR events occur, the error pin will always be asserted for at least the minimum time interval

esm-012

**Figure 12-469. ESM Error Pin Asserting with Single CLEAR for Multiple Events**

If all error events are cleared and the ESM is in the ESM\_WAIT state, waiting for the minimum time interval to expire, and a new error interrupt event occurs, the ESM will go back to the ESM\_ERROR state. The minimum time interval will not reset, but a new CLEAR event will be required as shown in [Figure 12-470](#).

esm-013

**Figure 12-470. ESM Error Pin Asserting with New Error During Minimum Time Interval**

Table 12-373 shows some common scenarios of how the error pin as well as the two associated registers (ESM\_PIN\_CTRL and ESM\_PIN\_STS) will be set.

**Table 12-373. ESM Error Pin Scenarios**

Scenario	Error Pin State Value	ESM_PIN_CTRL[3-0] KEY	ESM_PIN_STS[0] VAL status value	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x1	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin via software.

#### 12.8.2.4.4 PWM Mode

If the error output pin is in PWM mode then when no error is detected it will toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external PMIC that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external PMIC.

#### 12.8.2.4.5 ESM Minimum Time Interval

The minimum time interval is the minimum amount of time that the error pin will be asserted (active low) when an enabled error interrupt event happens. This value is system dependent, but should be enough time so that the external monitoring agent can always see the error pin asserted, but short enough so that if all of the error events are cleared, then the error pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the ESM\_PIN\_CNTR\_PRE register and the clock frequency of the ESM. Software must calculate the value accordingly. The Minimum Time Interval should be set according to the needs of the application.

#### 12.8.2.4.6 ESM Protection for Registers

The configuration for each error group *j* of registers are backed up by 3 flops in order to protect against single or double-bit errors. When written, all 3 bits are set to the same value. When read (and for functioning of the internal state machines) the value is the OR of all 3 bits. Whenever any of the bits disagree, the Configuration Error interrupt is asserted (if enabled). The registers covered by this mechanism are:

- ESM\_ERR\_RAW
- ESM\_ERR\_STS
- ESM\_ERR\_EN\_SET
- ESM\_ERR\_EN\_CLR
- ESM\_RAW<sub>j</sub>
- ESM\_STS<sub>j</sub>
- ESM\_INTR\_EN\_SET<sub>j</sub>
- ESM\_INTR\_EN\_CLR<sub>j</sub>
- ESM\_INT\_PRIO<sub>j</sub>
- ESM\_PIN\_EN\_SET<sub>j</sub>
- ESM\_PIN\_EN\_CLR<sub>j</sub>

The error pin control register ESM\_PIN\_CTRL contains a multi-bit field KEY. The key value ensures normal operation on the error pin and that an error even will be generated if one occurs. Software should periodically

read check the KEY bit field value and make sure it is 0x0. If the value is not 0x0, software must re-write it to this key value (unless in test mode forcing an error on the pin) to ensure the normal operation. [Table 12-374](#) lists the KEY values and their respective meaning.

**Table 12-374. ESM Error Pin Control Values**

ESM_PIN_CTRL[3-0] KEY	Description
N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
0x0 (Normal)	Normal operation mode - Error pin will activate when an enabled error event occurs.
0xA (Force Error)	Force error mode - Forces the error pin active. To clear the error pin (return to the ESM_IDLE state) write this field back to normal mode (writing a CLEAR event will also work). Force error mode must be set only while in IDLE. Attempting force error while in another state will have no effect.
0x5 (CLEAR)	CLEAR Event - generates a CLEAR event to the ESM state machine. KEY will return to normal mode (0x0) on the next cycle.
Other Values	All other values - Normal mode. Writing any of these values will have no effect. When reading any of these values indicates that one or more bits have experienced a single event upset, software should write the field back to 0x0. The ESM will continue to operate in normal mode.

The error pin counter pre-load register ESM\_PIN\_CNTR\_PRE should also be read and checked periodically by software.

#### 12.8.2.4.7 ESM Clock Stop

The ESM can only be put in to clock stop if all of the internal state machines are idle and the [3-0] KEY bit field for the global enable command is cleared in the ESM\_EN register.

### 12.8.3 Memory Cyclic Redundancy Check (MCRC) Controller

This chapter describes the Memory Cyclic Redundancy Check (MCRC) controller in the device.

#### 12.8.3.1 MCRC Overview

VBUSM CRC controller is a module which is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of a memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into MCRC Controller. The responsibility of MCRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. MCRC controller provides four channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

##### 12.8.3.1.1 MCRC Features

MCRC has the following features:

- Four channels to perform background signature verification on any memory subsystem
- Data compression on 8-, 16-, 32-, and 64-bit data size
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64-bit primitive polynomial
- Each channel has a CRC Value Register which contains the pre-determined CRC value
- Use timed base event trigger from timer to initiate DMA data transfer
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
- Three modes of operation:
  - Auto
  - Semi-CPU
  - Full-CPU
- For each channel, CRC can be performed either by MCRC Controller or by CPU
- Automatically performs signature verification without CPU intervention in AUTO mode
- Generates interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself
- Generates CRC fail interrupt in AUTO mode if signature verification fails
- Generates Timeout interrupt if CRC is not performed within the time limit
- Generates DMA request per channel to initiate CRC value transfer
- An 128-byte block burst address for the PSA register to DMA without constant mode bus attribute

##### 12.8.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

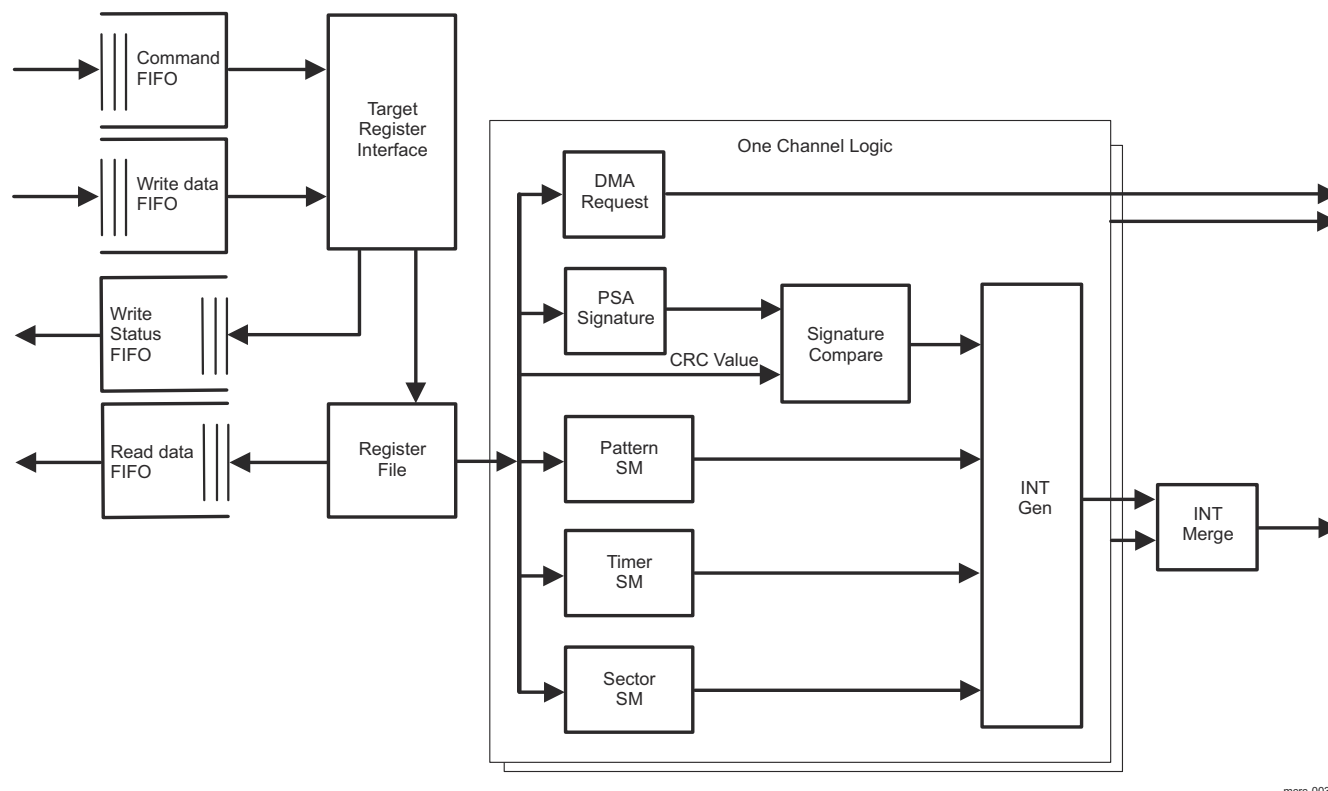

---

### 12.8.3.2 MCRC Functional Description

#### 12.8.3.2.1 MCRC Block Diagram

Figure 12-471 shows the MCRC internal blocks.

**Figure 12-471. MCRC Block Diagram**

- **Command FIFO:** The Command FIFO pipelines the commands to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 4 elements deep.
- **Write FIFO:** The Write FIFO pipelines the write data to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 2 elements deep.
- **Write Status FIFO:** The Write Status FIFO pipelines the write status back to the VBUSM. A write status will be issued on the final data phase of a write command. This FIFO is 2 elements deep.
- **Read Data FIFO:** The Read Data FIFO pipelines the read data back to the VBUSM. This FIFO is 3 elements deep.
- **Target Register Interface:** The Target Register Interface directs the written data to the register file.
- **PSA Signature:** The PSA Signature creates the signature of the data written. This data will then be compared to the CRC Value or read by software to determine goodness.
- **Pattern State Machine:** The Pattern State Machine determines when a block of data has been serviced.
- **Timer State Machine:** The Timer State Machine determines when overrun and under-run events are detected.
- **Sector State Machine:** The Sector State Machine determines when a sector error should be captured so the software can determine the errant block of data.
- **Signature Compare:** The Signature Compare block compares the current signature to the CRC Value register and sends the result to the Interrupt Generation block.

### 12.8.3.2.2 MCRC General Operation

There are four channels in MCRC controller and for each channel there is a PSA (Parallel Signature Analysis) Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC64\_0\_CRC\_REGL1-4).

A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8-, 16-, 32-, or 64-bit data. MCRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory of which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated.

A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by MCRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self-sustained CRC signature calculation can be achieved without any CPU intervention.

### 12.8.3.2.3 MCRC Modes of Operation

MCRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

#### 12.8.3.2.3.1 AUTO Mode

In AUTO mode, MCRC Controller in conjunction with DMA controller can perform CRC without CPU intervention. A sustained transfer of data to both the PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC64\_0\_CRC\_REGL1-4) are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to the CPU. A 16-bit, current sector ID register (MCRC64\_0\_CRC\_CURSEC\_REG1-4) is provided to identify which sector causes a CRC failure.

#### 12.8.3.2.3.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4). Instead of performing signature verification automatically, the CRC controller generates a compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4) and compare it to a pre-determined CRC value.

#### 12.8.3.2.3.3 Full-CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1). After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

### 12.8.3.2.4 PSA Signature Register

The 64-bit PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4 and MCRC64\_0\_PSA\_SIGREGLH1-4) is based on the primitive polynomial found in (EQ 1) to produce the maximum length LFSR (Linear Feedback Shift Register).

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (24)$$

- A. More details of the 64-bit primitive polynomial can be found at W. Stahnke, Primitive binary polynomials, Math. Comp. 27 (1973), 977–980.

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHI\_MODE bits (where i = 1 to 4). If CHI\_MODE=0x0 (Data Capture), a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

MCRC Controller should be used in conjunction with the on-chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA controller. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After a system reset and when AUTO mode is enabled, MCRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4) and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register (MCRC64\_0\_CRC\_REGL1-4). After the comparison the MCRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then MCRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. Software can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

MCRC Controller supports double word, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zeros before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bits because a compressed value is always expressed in 64 bits.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

#### 12.8.3.2.5 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the 64-bit PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4 and MCRC64\_0\_PSA\_SECSIGREGH1-4). PSA Signature Register is a read-only register. During Semi-CPU mode, the host CPU must read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete

interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enabled to generate when overrun condition occurs.

#### **12.8.3.2.6 CRC Value Register**

Associated with each channel there is a 64-bit CRC Value Register (MCRC64\_0\_CRC\_REGL1-4 and MCRC64\_0\_CRC\_REGH1-4).

The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, MCRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, MCRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU must not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked. The user software needs to configure the DMA to ensure that the DMA first writes to the MCRC64\_0\_CRC\_REGL1 followed by the MCRC64\_0\_CRC\_REGH1 register in during the AUTO Mode.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, MCRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

MCRC Controller supports double word, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bits.

#### **12.8.3.2.7 Raw Data Register**

The raw or un-compressed data written to the PSA Signature Register is also saved in the 64-bit Raw Data Register (MCRC64\_0\_RAW\_DATAAREGL1-4 and MCRC64\_0\_RAW\_DATAAREGH1-4). This register is read only.

#### **12.8.3.2.8 Example DMA Controller Setup**

DMA controller needs to be setup properly in either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

##### **12.8.3.2.8.1 AUTO Mode Using Hardware Timer Trigger**

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4). The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register (MCRC64\_0\_CRC\_REGL1-4). The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 12-472](#), a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, MCRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register (MCRC64\_0\_CRC\_REGL1-4) by DMA synchronized to each sector of memory.

A block of system memory is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the MCRC64\_0\_CRC\_PCOUNT\_REG1-4 and the number of sectors in one block is programmed in the MCRC64\_0\_CRC\_SCOUNT\_REG1-4 of the respective channel. MCRC64\_0\_CRC\_PCOUNT\_REG1-4 multiplies MCRC64\_0\_CRC\_SCOUNT\_REG1-4 and multiplies transfer size of each data pattern should give the total block size in number of bytes.

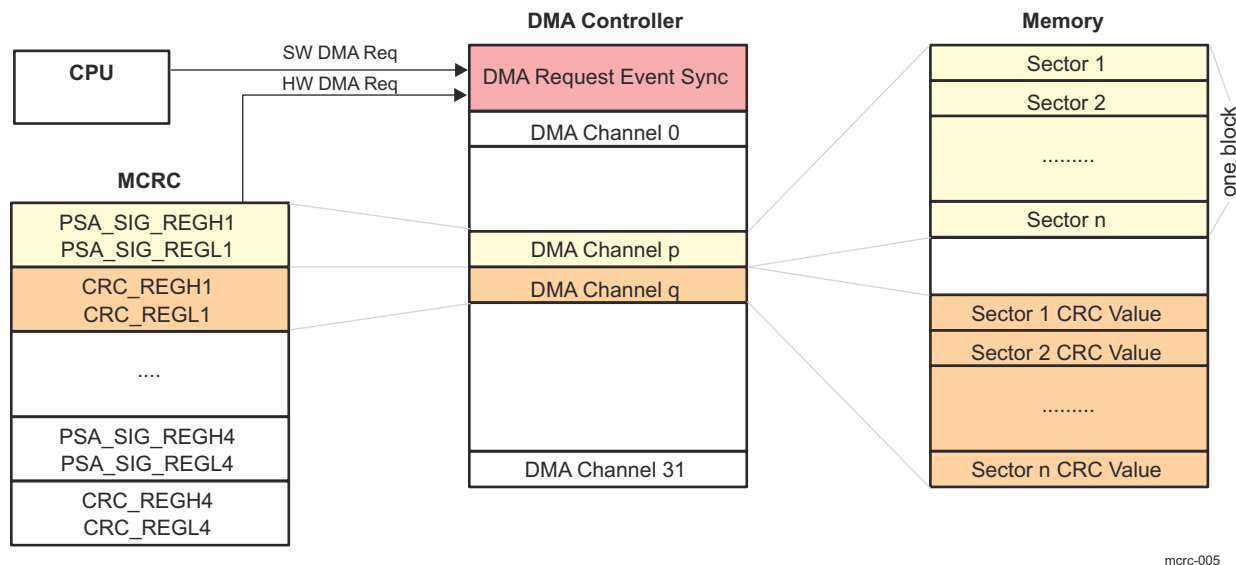

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that a hardware DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 12-472](#), a hardware DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by MCRC Controller.

**Figure 12-472. AUTO Mode Using Hardware Timer Trigger**

#### 12.8.3.2.8.2 AUTO Mode Using Software Trigger

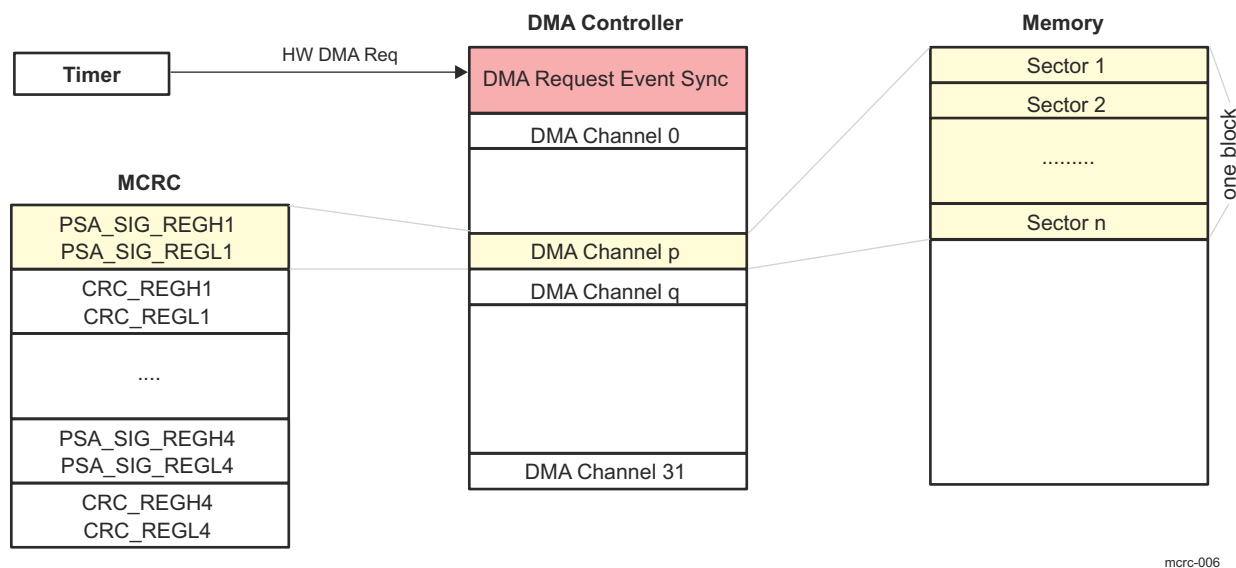

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. Please see [Figure 12-473](#) for illustration.

**Figure 12-473. AUTO Mode With Software CPU Trigger**

#### 12.8.3.2.8.3 Semi-CPU Mode Using Hardware Timer Trigger

During Semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. [Figure 12-474](#) illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

**Figure 12-474. Semi-CPU Mode With Hardware Timer Trigger**

**Table 12-375. DMA Request and Counter Logic Operation According to CRC Mode**

CRC Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full CPU	Inactive	Inactive	Inactive	Inactive

### 12.8.3.2.9 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register (MCRC64\_0\_CRC\_PCOUNT\_REG1-4). When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

#### Note

The data pattern count must be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

### 12.8.3.2.10 Sector Count Register/Current Sector Register

Each channel contains a 16-bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register (MCRC64\_0\_CRC\_CURSEC\_REG1-4). If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure it is advisable to use the following equation during CRC and DMA setup.

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count} \quad (25)$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail (CHi\_CRC\_FAIL) status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

Current sector register is reset when the PSA software reset is enabled.

#### Note

Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

### 12.8.3.2.11 Interrupts

CRC generate several types of interrupts per channel. Associated with each interrupt there is a interrupt enable bit (see MCRC64\_0\_CRC\_INTS). No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

**Table 12-376. Interrupt Conditions Per CRC Mode**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
AUTO	No	Yes	Yes	Yes	Yes
Semi-CPU	Yes	No	Yes	No	Yes

**Table 12-376. Interrupt Conditions Per CRC Mode (continued)**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
Full-CPU	No	No	No	No	No

#### 12.8.3.2.11.1 Overrun Interrupt

Overrun Interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register (MCRC64\_0\_CRC\_CURSEC\_REG1-4). If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4). If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

#### 12.8.3.2.11.2 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24-bit timeout counter per CRC channel. The timeout counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (MCRC64\_0\_CRC\_WDTPOLD1-4) and block complete timeout pre-load value (MCRC64\_0\_CRC\_BCTOPLD1-4). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of FICLK clock.

Watchdog timeout pre-load register (MCRC64\_0\_CRC\_WDTPOLD1-4) is used to check if DMA does supply a block of data responding to a request in a given time frame. Block complete timeout pre-load register (MCRC64\_0\_CRC\_BCTOPLD1-4) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with MCRC64\_0\_CRC\_WDTPOLD1-4 after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with MCRC64\_0\_CRC\_BCTOPLD1-4 the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with MCRC64\_0\_CRC\_BCTOPLD1-4 value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count × sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with MCRC64\_0\_CRC\_WDTPOLD1-4 value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

#### 12.8.3.2.11.3 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, MCRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

#### 12.8.3.2.11.4 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated

#### 12.8.3.2.11.5 Interrupt Offset Register

MCRC Controller only generates one interrupt request to interrupt manager. An interrupt offset register (MCRC64\_0\_CRC\_INT\_OFFSET\_REG) is provided to indicate the source of the pending interrupt with highest priority. [Table 12-377](#) shows the offset interrupt vector address of each interrupt in an ascending order of priority.

**Table 12-377. Interrupt Offset Mapping**

Interrupt Condition	Offset Value
Phantom	0x0
Ch1 CRC Fail	0x1
Ch2 CRC Fail	0x2
Ch3 CRC Fail	0x3
Ch4 CRC Fail	0x4
reserved	0x5-0x8
Ch1 Compression Complete	0x9
Ch2 Compression Complete	0xA
Ch3 Compression Complete	0xB
Ch4 Compression Complete	0xC
reserved	0xD-0x10
Ch1 Overrun	0x11
Ch2 Overrun	0x12
Ch3 Overrun	0x13
Ch4 Overrun	0x14
reserved	0x15-0x18
Ch1 Underrun	0x19
Ch2 Underrun	0x1A
Ch3 Underrun	0x1B
Ch4 Underrun	0x1C
reserved	0x1D-0x20
Ch1 Timeout	0x21
Ch2 Timeout	0x22
Ch3 Timeout	0x23
Ch4 Timeout	0x24

### 12.8.3.2.11.6 Error Handling

When an interrupt is generated, host CPU must take appropriate actions to identify the source of error and restart the respective channel in DMA and MCRC module. To restart a CRC channel user must perform the following steps in the ISR:

1. Write to software reset bit in MCRC64\_0\_CRC\_CTRL0 register to reset the respective PSA Signature Register
2. Reset the CHi\_MODE bits to 0 in MCRC64\_0\_CRC\_CTRL2 register as Data capture mode
3. Set the CHi\_MODE bits in MCRC64\_0\_CRC\_CTRL2 register to desired new mode again
4. Release software reset

The host CPU must use byte write to restart each individual channel.

### 12.8.3.2.12 Power Down Mode

MCRC module can be put into power down mode when the power down control bit MCRC64\_0\_CRC\_CTRL1[0] PWDN is set. The module wakes up when the PWDN bit is cleared. When MCRC controller is in power down mode, no data tracing alone will happen.

### 12.8.3.2.13 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is

to prevent debugger from reading the interrupt offset register, that is, during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No VBUSM bus error will be generated if reading from the unimplemented locations. .

CEMUDBG is the VBUSM suspend signal which need not explicitly indicate that whether CPU is in suspend mode or not. In data trace mode, a separate suspend signal CPU\_EMUSP, is used to indicate MCRC controller that the CPU is in suspend mode or not.

### 12.8.3.3 MCRC Programming Examples

#### 12.8.3.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2 Mbyte (256 k × 32-bit [doubleword]) is to be checked in the background of CPU. CRC is to be performed every 1 Kbyte (128 doubleword). Therefore there will be 2048 pre-recorded CRC values. For illustration purpose, we map MCRC64\_0\_CRC\_REGL1 register to DMA channel 1 and MCRC64\_0\_PSA\_SIGREGL1 register to DMA channel 2. Let's assume all DMA transfers are carried out in 64-bit transfer size.

##### 12.8.3.3.1.1 DMA Setup

- Setup DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Setup the destination address to the MCRC64\_0\_CRC\_REGL1. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1 to trigger a frame transfer.
- Setup DMA channel 2 with the source address from which the contents of memory to be verified. Setup the destination address to the MCRC64\_0\_PSA\_SIGREGL1. Program the element transfer count to 128 and the frame transfer count to 2048. Program the read and write element size to 64 bits. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request for channel 2 to trigger an entire block transfer.

##### 12.8.3.3.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 2. For example, software can setup the timer to generate a DMA request every 10 ms.

##### 12.8.3.3.1.3 CRC Setup

- Program the pattern count MCRC64\_0\_CRC\_PCOUNT\_REG1 to 128
- Program the sector count MCRC64\_0\_CRC\_SCOUNT\_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load (MCRC64\_0\_CRC\_BCTOPLD1-4) value to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected MCRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC64\_0\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC64\_0\_PSA\_SECSIGREGL1/H1 does not match the MCRC64\_0\_CRC\_REGL1/H1 Register. MCRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2 Mbytes are consumed. If the timeout counter reached zero before the entire 2 Mbytes are compressed, a timeout interrupt is generated. After 2Mbytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and MCRC Controller. The CRC is performed totally without any CPU intervention.

#### 12.8.3.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1 Kbytes is to be checked in the background of CPU. CRC is to be performed every 1 Kbytes. Therefore, there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 MCRC64\_0\_CRC\_REGL1/H1 to DMA channel 1 and channel 1 MCRC64\_0\_PSA\_SIGREGL1/H1 to DMA channel 2. Assume all transfers carried out by DMA are in 64-bit transfer size.

#### 12.8.3.3.2.1 DMA Setup

- Setup DMA channel 1 with the source address from which the pre-determined CRC value is stored. Setup the destination address to the MCRC64\_0\_CRC\_REGL1 Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1.
- Setup DMA channel 2 with the source address from which the memory area to be verified. Setup the destination address to the MCRC64\_0\_PSA\_SIGREGL1/H1. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a software DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

#### 12.8.3.3.2.2 CRC Setup

- Program the MCRC64\_0\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC64\_0\_CRC\_SCOUNT\_REG1 to 1
- Leaving the timeout count MCRC64\_0\_CRC\_BCTOPLD1 register with the reset value of zero means no timeout interrupt is generated
- Enable AUTO mode and all interrupts

After AUTO mode is selected the MCRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a software DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC64\_0\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC64\_0\_PSA\_SECSIGREGL1/H1 does not match the MCRC64\_0\_CRC\_REGL1/H1. MCRC Controller generate a DMA request on DMA channel 1 again after one sector is compressed. After 1 Kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

#### 12.8.3.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2 Mbytes is to be verified with the help of the CPU. CRC operation is to be performed every 1 Kbyte. Since there are 2 Mbytes (256 K doublewords) of memory to be check and we want to perform a CRC every 1 Kbytes (128 doublewords) and therefore there must be 2048 pre-recorded CRC values. In Semi-CPU mode, the MCRC64\_0\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

#### 12.8.3.3.3.1 DMA Setup

- Setup DMA channel 1 with the source address from which the memory area to be verified are mapped. Setup the destination address to the MCRC64\_0\_PSA\_SIGREGL1/H1. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

#### 12.8.3.3.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 1. For example, software can setup the timer to generate a DMA request every 10 ms.

#### 12.8.3.3.3.3 CRC Setup

- Program the MCRC64\_0\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC64\_0\_CRC\_SCOUNT\_REG1 to 2048

- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load value MCRC64\_0\_CRC\_BCTOPLD1 to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz
- Enable AUTO mode and all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the MCRC64\_0\_PSA\_SECSIGREGL1/H1. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2 Mbytes are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from MCRC64\_0\_PSA\_SECSIGREGL1 before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

#### 12.8.3.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2 Mbytes is to be checked with the help of the CPU. CRC operation is to be performed every 1 Kbyte. In CPU mode, the MCRC64\_0\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

##### 12.8.3.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the MCRC64\_0\_PSA\_SIGREGL1/H1 inside MCRC Controller. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After n data patterns are compressed, CPU can read from the MCRC64\_0\_PSA\_SIGREGL1/H1. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

## 12.8.4 ECC Aggregator

This section describes the common ECC aggregator functionality.

### 12.8.4.1 ECC Aggregator Overview

To increase functional and system reliability the memories (for example, FIFOs, queues, SRAMs and others) in many device modules and subsystems are protected by error correcting code (ECC). This is accomplished through an ECC aggregator and ECC wrapper. The ECC aggregator is connected to these memories (hereinafter ECC RAMs) and involved in the ECC process. Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory mapped configuration interface.

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. Each interconnect ECC component has the same serial interface for communication with the aggregator as the ECC wrapper. An ECC aggregator may be connected to both endpoints - the ECC wrapper and interconnect ECC component.

The ECC aggregator, ECC wrapper and interconnect ECC component are considered as single entity and are hereinafter referred to as ECC aggregator unless otherwise explicitly specified.

See *Module Integration* for device modules and subsystems which have ECC aggregator.

#### 12.8.4.1.1 ECC Aggregator Features

The ECC aggregator has the following features:

- Reduces memory software errors via single error correction (SEC) and double error detection (DED)
- Provides a mechanism to control and monitor the ECC protected memories in a module or subsystem
- SEC and DED over the system interconnect data bus and parity and redundancy for the system interconnect command and address buses
- Generates an interrupt for correctable error
- Generates an interrupt for non-correctable error
- Supports inject only mode for diagnostic purposes
- Supports software readable status for single and double-bit ECC errors and associated information such as row address where error has occurred and data bits that have been flipped
- Supports up to 256 ECC endpoints. An ECC endpoint can be either ECC RAM or interconnect ECC component.
- Detects single bit error via parity checking on:
  - Memory mapped configuration interface FIFO
  - Serial interface FIFO
  - Serial interface transaction
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Supports timeout mechanism on transactions over the ECC serial interface. Timeout occurrence results in a non-correctable error interrupt.
- Certain control bits have redundancy and if a bit flips an interrupt is generated

#### 12.8.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

#### 12.8.4.2 Integration

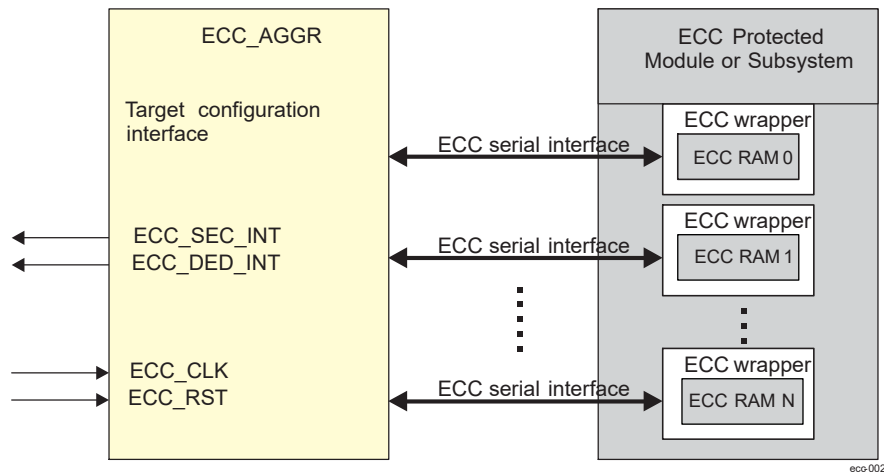

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.8.4.3 ECC Aggregator Functional Description

This section describes the architecture and functional details of the ECC aggregator.

#### 12.8.4.3.1 ECC Aggregator Block Diagram

Figure 12-475 shows the ECC aggregator block diagram.

**Figure 12-475. ECC Aggregator Block Diagram**

The ECC aggregator is connected to one or more ECC endpoints each of which has assigned a unique ID used when the endpoint is accessed for status information or configuration. The ECC aggregator provides software access to all ECC related registers through its memory mapped target configuration interface while the serial interface is used to communicate with the ECC endpoints. Upon detection of single or double-bit error the corresponding interrupt line is asserted.

#### 12.8.4.3.2 ECC Aggregator Register Groups

The ECC aggregator has ECC control, status and interrupt registers for each ECC endpoint in a module or subsystem. These registers are memory mapped and occupy 1 KB address space although part of it may contain reserved locations. The registers are split in the following types:

- **Global registers.** They are common to all ECC endpoints associated with the ECC aggregator and include the ECC\_VECTOR and ECC\_REV registers. Each ECC endpoint has assigned a unique ID. When this ID is written to the ECC\_VECTOR[10-0] ECC\_VECTOR field the corresponding endpoint is selected either for control or for status reading.
- **ECC control and status registers.** These registers are specific to each ECC endpoint and reside in the range from address offset 0x10 to 0x28, if the endpoint is ECC RAM or from 0x10 to 0x24, if the endpoint is interconnect ECC component. They are memory mapped but are accessed through the ECC serial interface. They are also selected by the ECC endpoint ID written to the ECC\_VECTOR[10-0] ECC\_VECTOR field. Because of latency on the serial interface the ECC control and status registers are read by performing special sequence as described in [Section 12.8.4.3.3](#). These registers have also different functionality for both types of endpoints - ECC RAM and interconnect ECC component.
- **Interrupt registers.** They include interrupt status, interrupt enable, interrupt disable, and EOI registers. For more information, see *Interrupts*.

#### Note

For description of each register, see *ECC\_AGGR Registers*.

### 12.8.4.3.3 Read Access to the ECC Control and Status Registers

Read accesses to the ECC control and status registers for each ECC endpoint represent read operations over the ECC serial interface and are triggered by performing the following sequence:

1. Software writes the following in the ECC\_VECTOR register:
  - The ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field to select particular ECC endpoint.
  - The register read address in the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field to select which register has to be read through the ECC serial interface.
  - A value of 0x1 in the ECC\_VECTOR[15] RD\_SVBUS bit to trigger read operation through the ECC serial interface.
2. Software polls the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit to check if it is 0x1. This indicates that the read operation on the ECC serial interface has completed.
3. Software reads the data from the register previously selected by the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field.

The following is an example for serial read operation:

1. Write 0x0010 8005 to the ECC\_VECTOR register. This sends read request to the ECC\_WRAP\_REV or ECC\_CBASS\_REV register (address = 0x10) associated with ECC endpoint with ID = 5.
2. Poll the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit until value of 0x1 is read.
3. Read the ECC\_WRAP\_REV or ECC\_CBASS\_REV register to get its value.

### 12.8.4.3.4 Serial Write Operation

Write operations over the ECC serial interface are performed as follows:

1. Software specifies the ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field. The ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field is a don't care but the ECC\_VECTOR[15] RD\_SVBUS bit must be set to 0x0.
2. Software performs regular write operation to the desired address. If the ECC endpoint ID has already been specified, step 1 can be skipped. Unlike serial read operations it is not necessary to always specify the endpoint ID before performing serial write operation.

The following is an example for serial write operation:

1. Write 0x0000 0008 to the ECC\_VECTOR register.
2. Write 0x0000 000F to the ECC\_CTRL register. This sends write request with data 0x0000 000F to the ECC\_CTRL register associated with ECC RAM with ID = 8.

### 12.8.4.3.5 Interrupts

The ECC aggregator generates the following interrupts:

- Correctable interrupt (ECC\_SEC\_INT) where hardware can correct the error but notifies the system in case of SEC.
- Non-correctable interrupt (ECC\_DED\_INT) where hardware cannot correct the error in cases of DED, parity check, redundancy check or timeout occurrence.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for an ECC endpoint by writing 0x1 to the corresponding bit of the following interrupt enable registers:
  - ECC\_SEC\_ENABLE\_SET\_REG0 through ECC\_SEC\_ENABLE\_SET\_REG7 for the correctable interrupt
  - ECC\_DED\_ENABLE\_SET\_REG0 through ECC\_DED\_ENABLE\_SET\_REG7 for the non-correctable interrupt
- On receiving an interrupt, software checks which ECC endpoint has caused the error by reading the following interrupt status registers:
  - ECC\_SEC\_STATUS\_REG0 through ECC\_SEC\_STATUS\_REG7 for the correctable interrupt
  - ECC\_DED\_STATUS\_REG0 through ECC\_DED\_STATUS\_REG7 for the non-correctable interrupt
- Software performs serial read operations as described in [Section 12.8.4.3.3](#) to read the following status registers that contain details about the error:

- If the endpoint is ECC RAM:
  - ECC\_ERR\_STAT1
  - ECC\_ERR\_STAT2
  - ECC\_ERR\_STAT3
- If the endpoint is interconnect ECC component:
  - ECC\_CBASS\_ERR\_STAT1
  - ECC\_CBASS\_ERR\_STAT2
- After the interrupt has been serviced, depending on the error type, software should clear the corresponding status bits in the ECC\_ERR\_STAT1 and ECC\_ERR\_STAT3 registers or in the ECC\_CBASS\_ERR\_STAT1 register. Software has to poll these registers to guarantee that status bits are cleared as there is no other indication for write completion over the ECC serial interface.  
The value of the \*\_PEND\_CLR fields in the ECC\_CBASS\_ERR\_STAT1 register must be read and then written back to decrement the count of each field back to 0x0. A further error capture into the ECC\_CBASS\_ERR\_STAT1 register does not occur unless all its fields are 0x0. The decrement value should not be larger than the read value. If a field in the ECC\_CBASS\_ERR\_STAT1 register should not be modified, write a value of 0x0 to that field.
- Software writes 0x1 to the corresponding end of interrupt register to clear the interrupt:
  - ECC\_SEC\_EOI\_REG for the correctable interrupt
  - ECC\_DED\_EOI\_REG for the non-correctable interrupt

#### 12.8.4.3.6 Inject Only Mode

There are modules that already perform the ECC generation and checking as part of their data path. In this case, the ECC wrapper may be configured in inject only mode, if needed. In this mode the ECC wrapper does not perform ECC detection and correction. The inject only mode allows users to inject single or double-bit errors so that the module logic can be tested for diagnostic purposes.

#### Note

There is no software control to enable inject only mode. It is configured via tie-off value. Inject only and ECC modes are mutually exclusive.

The interconnect ECC component also supports error injection mode. There is error injection logic for testing of the error checking logic (checkers). The injection logic can be configured to inject either single or double bit error and what data pattern to be used for injection (ECC\_CBASS\_CTRL[11-8] ECC\_PATTERN). The ECC\_CBASS\_ERR\_CTRL1 and ECC\_CBASS\_ERR\_CTRL2 registers should be written first to setup the injection. Then, either the ECC\_CBASS\_CTRL[3] FORCE\_SE or the ECC\_CBASS\_CTRL[4] FORCE\_DE bit must be set to 0x1 to start the injection. Both bits must not be set at the same time. If the injection should continue in incrementing mode, then the ECC\_CBASS\_CTRL[5] FORCE\_N\_BIT bit should be set to 0x1. Once the FORCE\_N\_BIT is set, then each successive injection can simply write the ECC\_CBASS\_CTRL register to set the FORCE\_SE or FORCE\_DE again. Reading 0x0 from either the FORCE\_SE or the FORCE\_DE bit indicates that the injection has completed, as these bits automatically clear when the checker indicates that it has performed the injection. The time for an injection to complete is not guaranteed, so some delay is needed between successive injections.

#### 12.8.5 ECC Aggregator Configurations

**Table 12-378. Properties of ECC Aggregator Instance COMPUTE\_CLUSTER0**

RAM ID Name	RAM ID	ECC Type	Inject Type	Accessi ble Flag	Row Width	RAM Size
CPU0_A53_DUAL_U_IDATA_SPRAM_BANK0_LO_ECC_S VBUS	0	ECC Wrapper	Inject only	Yes	42	10 KB

## 12.9 Display Subsystem and Peripherals

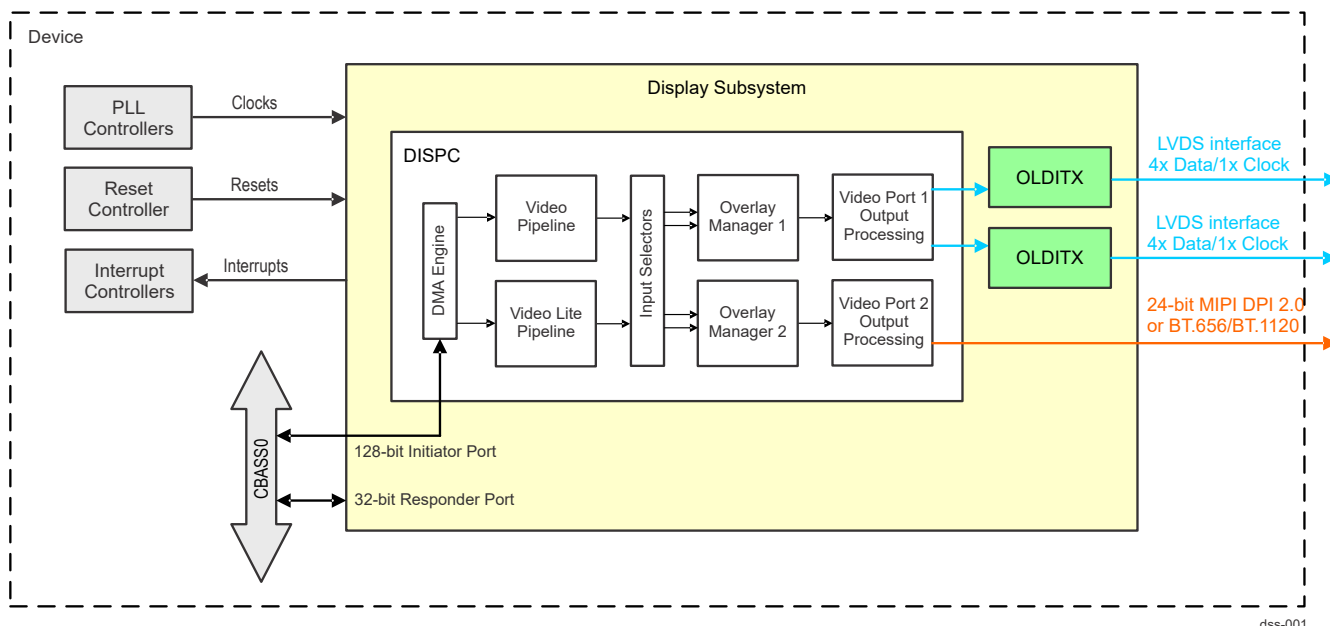

## 12.9.1 Display Subsystem (DSS)

This section describes the Display Subsystem (DSS) in the device.

### 12.9.1.1 DSS Overview

The Display Subsystem (DSS) is a flexible, multi-pipeline subsystem that supports high-resolution display outputs. DSS includes input pipelines providing multi-layer blending with transparency to enable on-the-fly composition. Various pixel processing capabilities are supported, such as color space conversion and scaling, among others. DSS includes a DMA engine, which allows direct access to the frame buffer (device system memory). Display outputs can connect seamlessly to an Open LVDS Display Interface transmitter (OLDITX), or can directly drive device pads as a Display Parallel Interface (DPI).

Figure 12-476 is a high-level overview of the display subsystem.

**Figure 12-476. DSS Overview**

#### 12.9.1.1.1 DSS Features

The Display Subsystem module includes the following features:

- Two display outputs
  - Up to 24-bit per pixel parallel or embedded sync output
  - Up to 200MHz pixel clock
  - Supports
    - 1920x1080@60fps
    - 1x 2048x1080 + 1x 1280x720 (constrained by DDR bandwidth)
  - Support for RGB/YUV422 modes
  - Support for progressive/interlaced modes
  - Two display pipelines support 2x OpenLDI 4-data/1clk link (either shared to provide a 4K display or mirroring the same display - independent displays on each OLDI are not supported)
- Two input display processing pipelines
  - One video pipeline supporting full RGB and 8/10-bit YUV data formats with 3/5-tap 16-phase scaler capable of 0.25x to 16x resizing.
  - One video\_lite pipeline supporting full RGB and 8/10 YUV data formats (no resizing support)
- Two Overlay Managers with multi layer alpha blending
- One DMA controller capable of supporting up to 2K input source width.

- 48-bit addressing (256 TB reach)
- On-the-fly X/Y-axis flip of the source (Flip/Mirror mode support)
- Safety check (freeze frame detection and data correctness check)

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

**12.9.1.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

### 12.9.1.2 DSS Environment

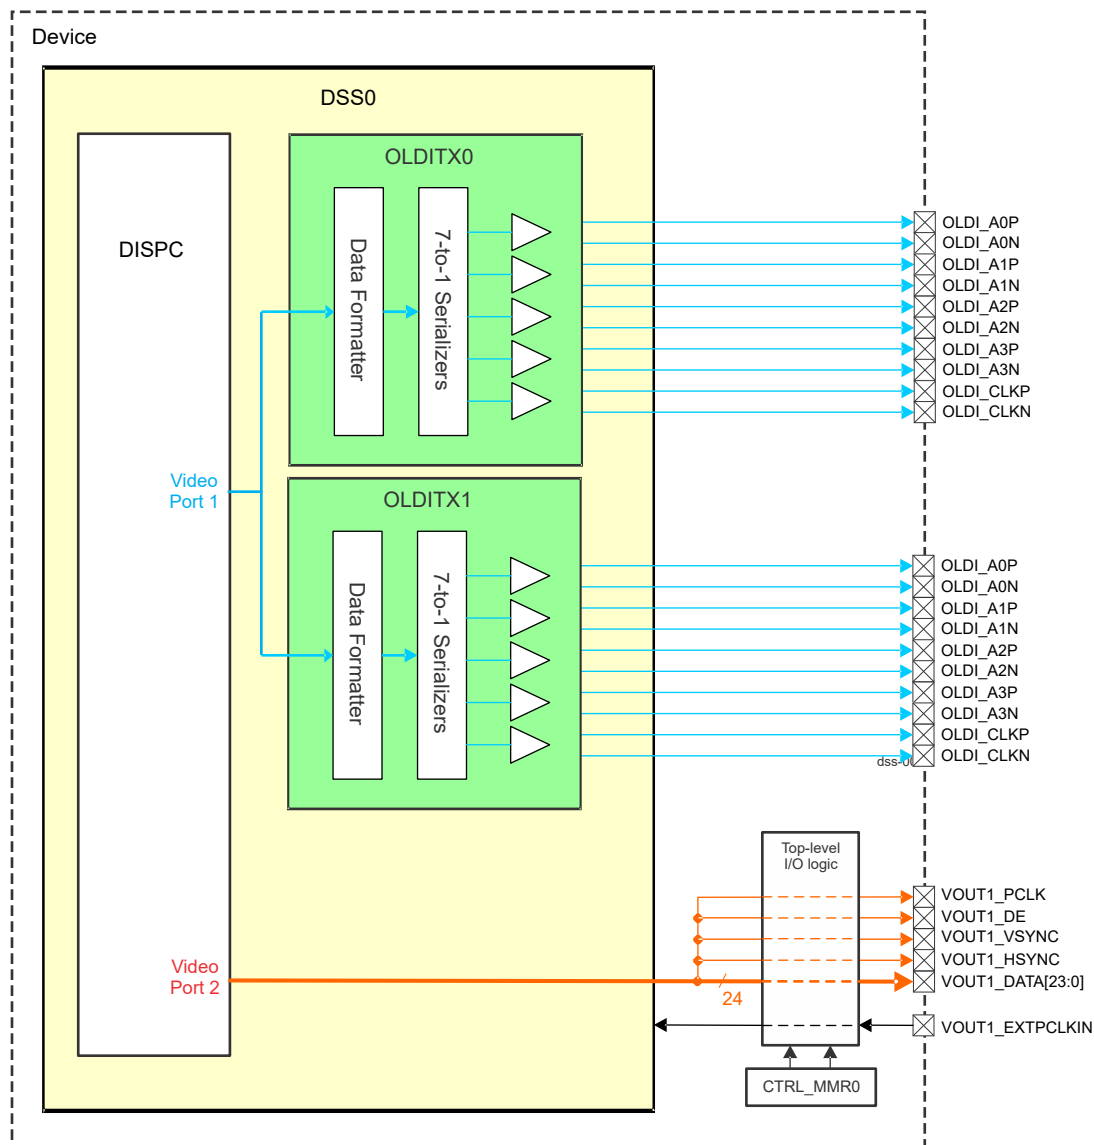

This section describes the interfaces handled by the display subsystem.

DSS supports two types of display interfaces:

- Display parallel interface via DISPC Video Port 2 (VP2) output. For more information, see [Section 12.9.1.2.1](#)
- Two low-voltage differential signaling (LVDS) interfaces, each with four data lanes and one clock lane, via Open LDI Transmitters (OLDITX0 and OLDITX1) connected to DISPC Video Port 1 (VP1) output. For more information, see [Section 12.9.1.2.2](#).

For more information on video ports configuration, see [Section 12.9.1.4.1.10, DISPC Video Port Outputs](#).

Figure 12-477 is a diagram of the DSS external connections.

**Figure 12-477. DSS Environment**

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.9.1.2.1 DSS Parallel Interface

The DISPC Video Port 2 (VP2) outputs the required data and control signals to device pads to support the following display interface modes:

- Parallel MIPI DPI 2.0 (Digital Pixel Interface): RGB 16/18/24-bit output with separate sync signals.
- BT.656/BT.1120 interface: YUV422 output (8/10-bit modes) with embedded syncs.

Table 12-451 describes the DISPC VP2 output signals.

**Table 12-451. DSS Signals for MIPI DPI 2.0 or BT.656/BT.1120**

Module Pin	Device Level Signal	Type <sup>(1)</sup>	Description	Module Pin Reset Value
DSS_DPI2_DATA[23:0]	VOUT1_DATA[23:0]	O	Pixel data output. RGB data for MIPI DPI 2.0 interface. YUV data for BT.656/BT.1120 interfaces.	0
DSS_DPI2_PCLK	VOUT1_PCLK	O	Pixel clock output. The maximum interface frequency is 165MHz.	0
DSS_DPI2_VSYNC	VOUT1_VSYNC	O	Vertical synchronization. The frame synchronization pulse (vsync) toggles after all the lines in a frame are transmitted and a programmable number of line clock cycles has elapsed at the beginning and the end of each frame.	0
DSS_DPI2_HSYNC	VOUT1_HSYNC	O	Horizontal synchronization. The line synchronization pulse (hsync) toggles after all pixels in a line are transmitted and a programmable number of pixel clock wait-states has elapsed at the beginning and the end of each line.	0
DSS_DPI2_DE	VOUT1_DE	O	Pixel data output-enable signal to indicate when data must be latched using the pixel clock.	0

(1) I = Input, O = Output, I/O = Input/Output

### Note

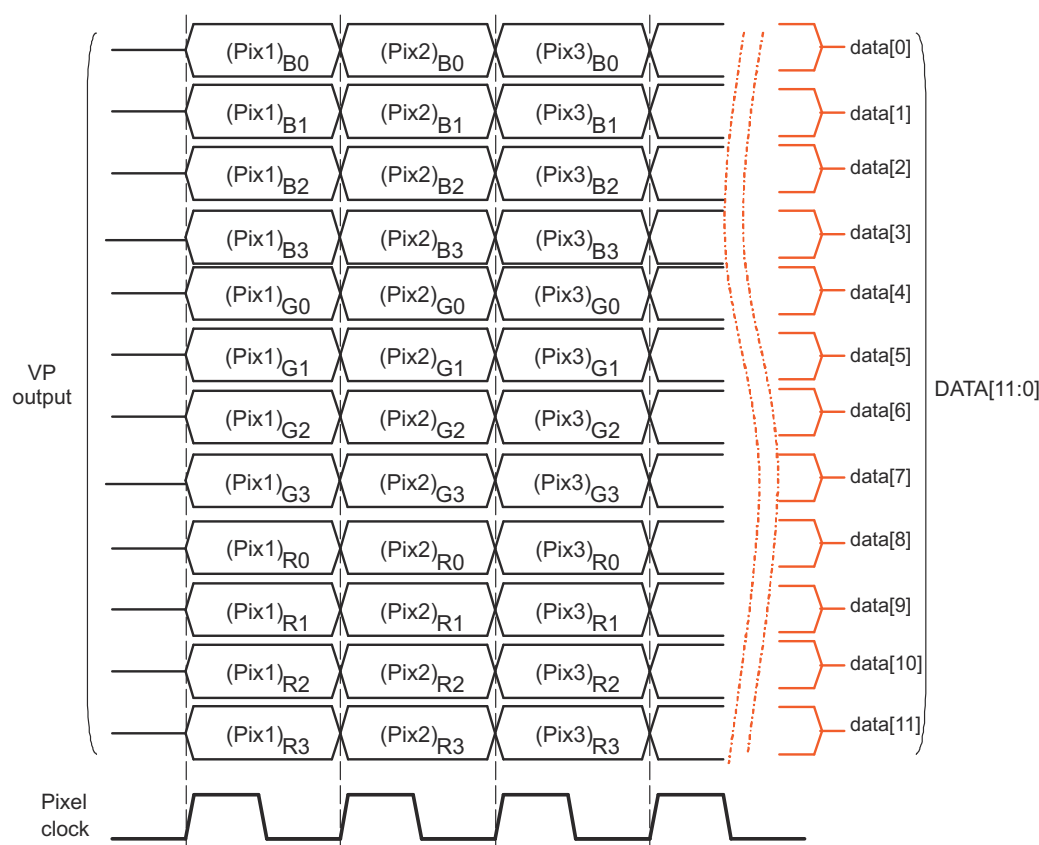

The effective output pixel clock rate for interleaved data formats (that is, BT.656 output mode or TDM (Time Division Multiplexed) output mode) will be either 1/2 or 1/3 of the maximum pixel clock rate, respectively, depending on the interleaving ratio.

#### 12.9.1.2.1.1 Pixel Data Formats

This section describes the pixel data bus for RGB formats and shows timing diagrams of transactions and synchronizations.

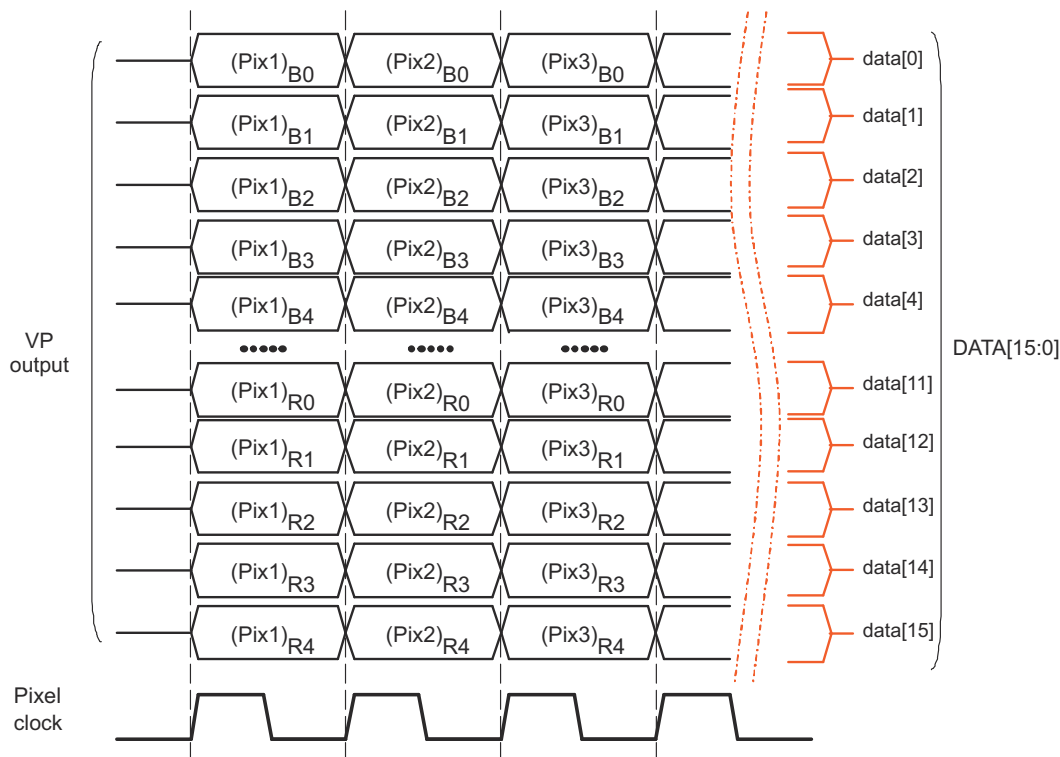

For the active matrix display type, one pixel per pixel clock is displayed. The diagrams represent the configuration of assertion of the data on the rising edge of the pixel clock. It is possible to program the interface timing to output the data on the falling edge of the pixel clock.

Figure 12-478 through Figure 12-481 show the interface to 12-, 16-, 18-, and 24-bit RGB active matrix displays. Each vertical line represents one output pixel. The width of the data bus can be configured through DSS\_VP1\_CONTROL[10-8] DATALINES register bitfield.

**Figure 12-481. DISPC Video Port Pixel Data - 24-bit RGB Active Matrix**

#### 12.9.1.2.1.2 Display Timing Diagrams

Figure 12-482 through Figure 12-485 show examples with timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC video ports directly drive these signals, which are related to the programmable fields listed in Table 12-452. For more information, see also Section 12.9.1.4.1.10.7, *DISPC VP Timing Generator and Display Panel Settings*.

**Table 12-452. DISPC Video Port Register Fields for Active Matrix Display**

Name	Register	Description
PPL	<a href="#">DSS_VP1_SIZE_SCREEN</a> [11-0] PPL value + 1	Pixels per line
LPP	<a href="#">DSS_VP1_SIZE_SCREEN</a> [27-16] LPP value + 1	Lines per panel
HBP	<a href="#">DSS_VP1_TIMING_H</a> [31-20] HBP value + 1	Horizontal back porch
HFP	<a href="#">DSS_VP1_TIMING_H</a> [19-8] HFP value + 1	Horizontal front porch
HSW	<a href="#">DSS_VP1_TIMING_H</a> [7-0] HSW value + 1	Horizontal synchronization pulse width
VBP	<a href="#">DSS_VP1_TIMING_V</a> [31-20] VBP value	Vertical back porch
VFP	<a href="#">DSS_VP1_TIMING_V</a> [19-8] VFP value	Vertical front porch
VSW	<a href="#">DSS_VP1_TIMING_V</a> [7-0] VSW value + 1	Vertical synchronization pulse width
ALIGN	<a href="#">DSS_VP1_POL_FREQ</a> [18] ALIGN	Alignment between HSYNC and VSYNC assertion
ONOFF	<a href="#">DSS_VP1_POL_FREQ</a> [17] ONOFF	HSYNC and VSYNC pixel clock control
RF	<a href="#">DSS_VP1_POL_FREQ</a> [16] RF	HSYNC and VSYNC pixel clock edge control
IEO	<a href="#">DSS_VP1_POL_FREQ</a> [15] IEO	Invert output enable
IPC	<a href="#">DSS_VP1_POL_FREQ</a> [14] IPC	Invert PCLK
IHS	<a href="#">DSS_VP1_POL_FREQ</a> [13] IHS	Invert HSYNC
IVS	<a href="#">DSS_VP1_POL_FREQ</a> [12] IVS	Invert VSYNC

- Active matrix timing configuration 1:
  - [DSS\\_VP1\\_POL\\_FREQ](#)[17] ONOFF = 0
  - [DSS\\_VP1\\_POL\\_FREQ](#)[16] RF = 0

The HSYNC and VSYNC signals are driven on the opposite edge of PCLK from the pixel data.

  - [DSS\\_VP1\\_POL\\_FREQ](#)[15] IEO = 0

- The DE signal is active high.
- `DSS_VP1_POL_FREQ[14] IPC = 0`
- The pixel data are driven on the rising edge of PCLK.
- `DSS_VP1_POL_FREQ[13] IHS = 0`
- The HSYNC signal is active high.
- `DSS_VP1_POL_FREQ[12] IVS = 0`
- The VSYNC signal is active high.
- `DSS_VP1_POL_FREQ[18] ALIGN = 0`
- The VSYNC and HSYNC assertion is not aligned.

**Figure 12-482. DISPC Display Timing Diagram of Configuration 1 (Start of Frame)**

**Figure 12-483. DISPC Display Timing Diagram of Configuration 1 (Between Lines)**

**Figure 12-484. DISPC Display Timing Diagram of Configuration 1 (Between Frames)**

**Figure 12-485. DISPC Display Timing Diagram of Configuration 1 (End of Frame)**

- Active matrix timing configuration 2:

- `DSS_VP1_POL_FREQ[17]` ONOFF = 1
- `DSS_VP1_POL_FREQ[16]` RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- `DSS_VP1_POL_FREQ[15]` IEO = 1

The DE signal is active low.

- `DSS_VP1_POL_FREQ[14]` IPC = 1

The pixel data is driven on the falling edge of PCLK.

- `DSS_VP1_POL_FREQ[13]` IHS = 1

The HSYNC signal is active low.

- `DSS_VP1_POL_FREQ[12]` IVS = 1

The VSYNC signal is active low.

- `DSS_VP1_POL_FREQ[18]` ALIGN = 0

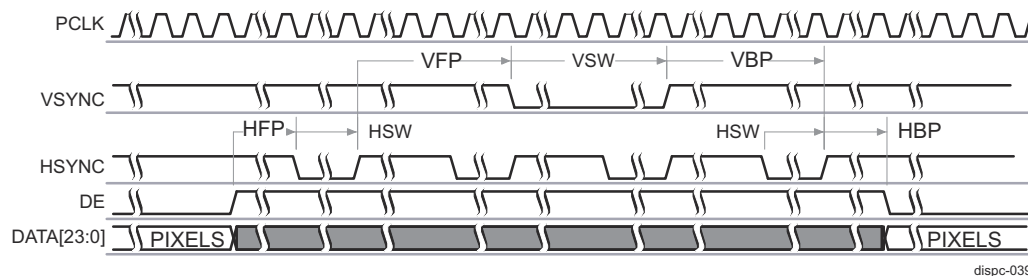

The VSYNC and HSYNC assertion is not aligned.

**Figure 12-486. DISPC Display Timing Diagram of Configuration 2 (Start of Frame)**

### 12.9.1.2.2 DSS LVDS Interface

The LVDS display interface is provided via two single-link OLDITX modules, which receives parallel RGB pixel data and synchronization signals from DSS DISPC Video Port 1 (VP1). The VP1 pixel data format and timings are the same as described for VP2 in [Section 12.9.1.2.1.1](#) and [Section 12.9.1.2.1.2](#), respectively. OLDITX works only with 18-bit or 24-bit RGB input source data.

The OLDITX translates 21-bit or 28-bit wide video and sync data into 3-bit or 4-bit wide serial data, 7-bits deep. The 24-bit serialized RGB pixel data is transmitted on four LVDS data lanes, clocked by one clock lane. OLDITX can also be configured to transmit only 18-bit RGB data (6-bits/pixel color component) on three LVDS lanes, when connected to a low-resolution display panel. In 18-bit configuration, only three LVDS data lanes and one clock lane are active. The fourth data lane is disabled.

[Table 12-453](#) describes the OLDITX output LVDS signals.

**Table 12-453. DSS OLDITX Signals for LVDS Interface**

Module Pin	Device Level Signal	Type <sup>(1)</sup>	Description	Module Pin Reset Value
OLDI_DATA0X	OLDI_A0P	O	OLDI differential data lane A0 (+)	-
OLDI_DATA0Y	OLDI_A0N	O	OLDI differential data lane A0 (-)	-
OLDI_DATA1X	OLDI_A1P	O	OLDI differential data lane A1 (+)	-
OLDI_DATA1Y	OLDI_A1N	O	OLDI differential data lane A1 (-)	-
OLDI_DATA2X	OLDI_A2P	O	OLDI differential data lane A2 (+)	-
OLDI_DATA2Y	OLDI_A2N	O	OLDI differential data lane A2 (-)	-
OLDI_DATA3X	OLDI_A3P	O	OLDI differential data lane A3 (+)	-
OLDI_DATA3Y	OLDI_A3N	O	OLDI differential data lane A3 (-)	-
OLDI_CLOCKX	OLDI_CLKP	O	OLDI differential clock lane CLK (+)	-

**Table 12-453. DSS OLDITX Signals for LVDS Interface (continued)**

Module Pin	Device Level Signal	Type <sup>(1)</sup>	Description	Module Pin Reset Value
OLDI_CLOCKY	OLDI_CLKN	O	OLDI differential clock lane CLK (-)	-

(1) I = Input, O = Output, I/O = Input/Output

Table 12-454 shows the supported LVDS pixel components mapping for 18-bit and 24-bit output data modes. The OLDI mapping type is defined in DSS0\_DSS\_OLDI\_CFG[3-1] MAP register field as follows:

- Type A = Single-link 18-bit. MAP = '000'.
- Type B = Single-link 24-bit JEIDA. MAP = '001'.
- Type C = Single-link 24-bit. MAP = '010'.
- Type D = Dual-link 18-bit. MAP = '100'.
- Type E = Dual-link 24-bit JEIDA. MAP = '101'.
- Type F = Dual-link 24-bit. MAP = '110'.

**Table 12-454. DSS OLDITX LVDS Data Format**

Mode	Single-link	Single-link	Single-link	Dual-link	Dual-link	Dual-link
	18-bit	24-bit JEIDA	24-bit	18-bit	24-bit JEIDA	24-bit

(1) Not used - output disabled.

(2) Reserved for other video channel (Single-Link Mode)

Figure 12-494 and Figure 12-495 show the LVDS data output bit format (that is, the pixel bit numbers onto LVDS interface bit numbers). The rising edge of the LVDS clock occurs two LVDS sub-symbols before the current cycle of data. The clock is composed of a 4 LVDS sub-symbol high time and a 3 LVDS sub-symbol low time.

**Figure 12-494. DSS OLDITX Pixel Bit Numbers on LVDS Output (Single-Link)**

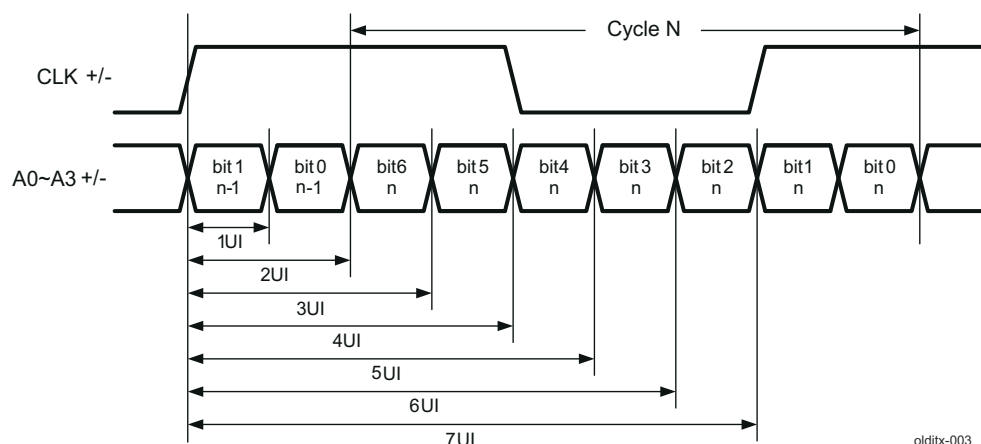

**Figure 12-495. DSS OLDITX Pixel Bit Numbers on LVDS Output (Dual-Link)**

Figure 12-496 and Figure 12-497 show the OLDITX input data mapped to LVDS output and the serial bit positions.

**Figure 12-496. DSS OLDITX Inputs Mapped to LVDS Outputs**

olditx-003

**Figure 12-497. DSS OLDITX LVDS Serial Bit Positions**

The OLDITX LVDS signal lines support a minimum bit time of 0.866 ns. This corresponds to a maximum pixel clock rate of 165 MHz (for a single link operation). A bit time period (known as TUI or Time Unit Interval) consists of several timing parameters:

- TCCS (Transmitter Channel-to-Channel Skew) - refers to the max skew across the differential data pairs within a link (in a single-link mode).
- SW - setup and hold time (internal data sample window) in the receiver.
- RSKM (Receiver Input Skew Margin) - the total time margin that remains after subtracting the sampling window (SW) size and the transmitter channel-to-channel skew (TCCS) from the time unit interval (TUI).

For more information on the OLDITX LVDS timing parameters, refer to device-specific Datasheet.

### 12.9.1.3 Integration

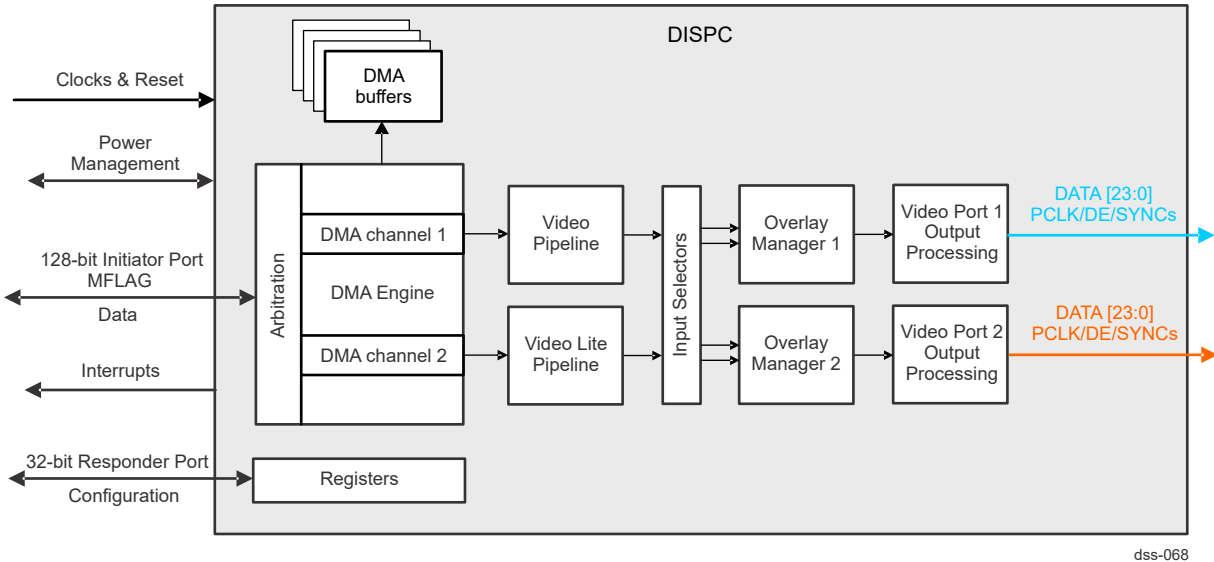

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.9.1.4 DSS Functional Description

#### 12.9.1.4.1 DISPC Functional Description

##### 12.9.1.4.1.1 DISPC Overview

Figure 12-498 is a simplified block diagram of DISPC.

**Figure 12-498. DISPC Architecture Overview**

The DISPC integrated within DSS is capable of fetching pixel data from the device system memory through its single initiator port, performing various pixel processing, and then providing the processed pixels to an external display panel. The internal DMA engine tightly coupled to the DISPC is used for the pixel data transfer from system memory (frame buffer). The DISPC DMA engine is in charge of scheduling the memory requests. Several processes are configurable in order to manage the video pipeline features (color space conversion, up-sampling, down-sampling) and overlay features. The internal timing generator logic generates the video port output signals based on VESA DMT and CEA-861 standards. The DISPC video port output can be connected to display panels either directly (for MIPI DPI 2.0 or BT.656/BT.1120 support), or through Open LDI transmitter.

#### Note

DISPC does not support any tiled frame buffer, nor any compressed frame buffer. DISPC has no internal capability to support rotation of the frame buffer.

#### Note

The display resolution is programmable and can be any width in the range [1:4096] pixels. The following limitations apply, related to the type of display or the processing done:

- Active Matrix screen + dithering forces a width multiple of 2 pixels
- Active Matrix + TDM may force a width multiple of 2 pixels

The display buffers in the system memory must consist of contiguous pixels.

##### 12.9.1.4.1.2 DISPC Clocks

DISPC has one clock domain for its internal logic and separate domains for each video port output.

The DISPC functional clock (DSS\_FUNC\_CLK) serves as the internal logic clock and also acts as the interface clock for the DISPC initiator and responder ports to system interconnect. There is no internal divisor on this clock.

The DISPC pixel clocks (DPI\_x\_IN\_CLK) serve as the clocks for the DISPC video port outputs to OLDITX0 and OLDITX1 modules (VP1 pixel clock DPI\_0\_IN\_CLK) or for the parallel display interface (VP2 pixel clock DPI\_1\_IN\_CLK). There are no internal divisors on the pixel clocks.

The frequency of DSS\_FUNC\_CLK clock must be greater or equal to the DPI\_x\_IN\_CLK clocks, in order to get the DISPC internal logic to function properly. The frequency of the DPI\_x\_IN\_CLK clocks depend on the output display resolution and required frame rate. For the maximum supported frequency ratings, refer to device-specific Datasheet.

All input clocks are asynchronous to each other. They can be generated by different sources.

The [DSS\\_COMMON\\_DSS\\_SYSCONFIG\[0\]](#) AUTOCLKGATING register bit is set by default to allow the auto-gating of the interface and functional clocks. The AUTOCLKGATING bit can be reset to disable the auto-gating of the clocks, if required.

DISPC provides also a clock-gating control on sub-module level, via configuration of the [DSS\\_COMMON\\_DISPC\\_CLKGATING\\_DISABLE](#) register fields.

#### 12.9.1.4.1.3 DISPC Resets

DISPC receives a single hardware reset signal. For more information, see *DSS Integration*.

To perform a software reset on the DISPC, set the [DSS\\_COMMON\\_DSS\\_SYSCONFIG\[1\]](#) SOFTRESET bit to 0x1. The [DSS\\_COMMON\\_DSS\\_SYSSTATUS\[0\]](#) DISPC\_FUNC\_RESETDONE bit indicates that the software reset is complete (for the DISPC internal logic) when its value is 0x1. When the software reset completes, the [DSS\\_COMMON\\_DSS\\_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

The completion of the software reset for the video ports logic is indicated in the [DSS\\_COMMON\\_DSS\\_SYSSTATUS\[3-1\]](#) DISPC\_VP\_RESETDONE register bit-field.

#### 12.9.1.4.1.4 DISPC Power Management

DISPC supports a power management protocol with the device Power Sleep Controller (PSC).

The (software) sequence, while performing a *clkstop\_req* to DISPC, is as follows:

1. Disable DISPC by programming the [0] ENABLE bit of [DSS\\_VP1\\_CONTROL](#) register to 0.
2. DISPC hardware completes the output of the current frame. Then hardware sets the [DSS\\_COMMON\\_DSS\\_SYSSTATUS\[9\]](#) DISPC\_IDLE\_STATUS register bit to 1.
3. Poll the DISPC\_IDLE\_STATUS bit to ensure that DISPC is in idle mode.
4. PSC initiates *clkstop\_req* to DISPC.
5. DISPC hardware acknowledges with *clkstop\_ack* immediately.

#### 12.9.1.4.1.5 DISPC Interrupt Requests

DISPC supports two active-high level sensitive interrupt output lines: DSS\_INT0 and DSS\_INT1. All DISPC sub-module interrupt events are fully mapped to both of these interrupts, as shown in Figure 12-499. There are two sets of IRQ aggregating registers, one set for each interrupt line, which enable fully independent monitoring and control of the interrupt events by two processor hosts at device level.

**Figure 12-499. DISPC Interrupts Generation**

Each of the interrupt signals indicates that one or more interrupt events are detected by the hardware. Each event is independently maskable for each interrupt output.

There are two level of interrupt events. The first level is used to indicate common events and is also source for the second level of interrupts. The second level of interrupt events consists of status and enable interrupt registers for each video pipeline and each video port.

Table 12-455 describes the first level of interrupt events with associated mask and status register fields. Each interrupt event is captured in an interrupt status register. Equivalent IRQSTATUS\_RAW registers exist, which are updated even if interrupts are not enabled. This allows software to get access to updated status for all interrupt events.

**Table 12-455. DISPC Interrupts - First Level**

The MISR signature generated does not match the expected signature, or the VP2 output frame freeze detection has triggered.

#### 12.9.1.4.1.6 DISPC DMA Engine

The DISPC DMA engine:

- Requests and supplies data from system memory to the VID and VIDL pipelines through the system interconnect, based on the configuration of the video pipeline settings.
- Is fully programmable and fetches pixel data via 128-bit requests using 1D burst.

Each pipeline has a dedicated DMA buffer and channel with independent settings. If a pipeline is disabled (that is, not used), then its DMA buffer can be assigned to another pipeline by configuring the [DSS\\_COMMON\\_DISPC\\_GLOBAL\\_BUFFER](#) register. For example, unused buffers for VIDL pipeline can be used by VID pipeline.

Each DMA channel supports a total of 8 line buffers, each of which can store 1280 32-bit pixels.

- The size of the DMA buffer associated to the video lite pipeline (VIDL1) is 8x320x128-bit.
- The size of the DMA buffer associated to the video pipeline (VID) is 8x320x128-bit.

The DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration has been programmed for the video layer), that is, the video window is present and the video pipeline is active.

##### 12.9.1.4.1.6.1 DISPC DMA Addressing and Bursts

For each line to be fetched, the DMA engine address generator:

- Calculates the pixel address
- Aligns the address
- Determines byte enable pattern
- Determines 1D burst length

The meaning of the address bits is as follows:

- Bits [31-0]: system (DDR) memory address (pixel address)
- Bits [37-32]: 32 bits + address extension

The address extension bits are defined by the programmable parameter [DSS\\_VID\\_BA\\_EXT\\_0/DSS\\_VID\\_BA\\_EXT\\_1](#) and [DSS\\_VID\\_BA\\_UV\\_EXT\\_0/DSS\\_VID\\_BA\\_UV\\_EXT\\_1](#) registers, optionally used to extend the BA memory addressing to 48-bit addressed external memory space (that is, to extend DISPC address space into 4GB+ space).

The DDR scan pixel addresses are generated by the DMA engine in order to read data from the system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The [DSS\\_VID\\_ROW\\_INC](#) register allow the access to a frame using 1D bursts (but as a two-dimensional block) by adding a fixed address offset at the end of a line. The ROW\_INC can also be used to skip lines from the input frame.

The byte address of each pixel in the frame buffer located in the system memory is determined by:

Pixel address = base\_address + x × (bpp/8) + y × (width × (bpp/8) + increment), where:

- "base\_address" corresponds to the base address defined by:
  - [DSS\\_VID\\_BA\\_0/DSS\\_VID\\_BA\\_1](#)[31-0] BA register bit-fields for all formats, and Y frame buffer in case of YUV-NV12 format. Optional extension bits in [DSS\\_VID\\_BA\\_EXT\\_0/DSS\\_VID\\_BA\\_EXT\\_1](#) registers.
  - [DSS\\_VID\\_BA\\_UV\\_0/DSS\\_VID\\_BA\\_UV\\_1](#)[31-0] BA register bit-fields for UV frame buffer in case of YUV-NV12 format. Optional extension bits in [DSS\\_VID\\_BA\\_UV\\_EXT\\_0/DSS\\_VID\\_BA\\_UV\\_EXT\\_1](#) registers.
- "bpp" corresponds to the number of bits per pixel defined by the [DSS\\_VID\\_ATTRIBUTES](#)[6-1] FORMAT register bit-field.
- "width" corresponds to the number of pixels per line defined by the [DSS\\_VID\\_PICTURE\\_SIZE](#)[11-0] MEMSIZE\_X + 1 register bit-field.
- "increment" corresponds to the number of bytes to skip between two contiguous lines defined by the [DSS\\_VID\\_ROW\\_INC](#)[31-0] ROWINC – 1 register bit-field.
- "x" corresponds to the pixel position on the x-axis.
- "y" corresponds to the pixel position on the y-axis.

### Note

Since the base address is aligned on pixel size boundary the horizontal resolution is one pixel. In case of YUV422 formats, the resolution is 4 bytes (2 pixels). In case of RGB24 packed format the resolution is 4 pixels. In case of Y frame buffer (YUV-NV12 format) the resolution is one byte. The vertical resolution is one line.

In case of YUV422 format, the number of pixels per line shall be a multiple of 2 pixels and the size of a pixel shall be considered as 2 bytes. In case of YUV420-NV12 or YUV420-NV21 format, the Y buffer shall be considered as an 8-bit frame buffer, and the CbCr shall be considered as a 16-bit frame buffer. The pixel size is 1 byte and 2 bytes, respectively for Y and CbCr.

For YUV420-NV12 or YUV420-NV21 format, the pixel values are defined in two separate buffers (Y and UV buffers). The first buffer consists of Y values (8 bits for each Y sample). The second buffer consists of CbCr values (16 bits for each pair of CbCr samples). The base address of the Y and UV buffers are as defined earlier in this section.

In case of interlaced mode, [DSS\\_VID\\_BA\\_0](#) and [DSS\\_VID\\_BA\\_UV\\_0](#) registers define the base address of the even field, and [DSS\\_VID\\_BA\\_1](#) and [DSS\\_VID\\_BA\\_UV\\_1](#) registers define the base address of the odd field.

The number of bytes to skip between pixels and between lines are defined using [DSS\\_VID\\_PIXEL\\_INC](#) and [DSS\\_VID\\_ROW\\_INC](#) registers, respectively. They define the values to be used for the Y buffer. For the CbCr buffer, the [DSS\\_VID\\_ROW\\_INC\\_UV](#) register define the values.

[Table 12-460](#) summarizes the register settings for a simple access of a picture in the system memory.

**Table 12-460. DISPC Register Settings for Accessing Image in Internal Memory**

Video Pipeline Registers	Value
<a href="#">DSS_VID_BA_0</a> <sup>(1)</sup> and <a href="#">DSS_VID_BA_1</a> <sup>(2)</sup>	The physical base address (PBA) of image in the memory for all formats and Y buffer.
<a href="#">DSS_VID_BA_EXT_0</a> and <a href="#">DSS_VID_BA_EXT_1</a>	Address extension bits of PBA for all formats and Y buffer.
<a href="#">DSS_VID_BA_UV_0</a> <sup>(1)</sup> and <a href="#">DSS_VID_BA_UV_1</a> <sup>(2)</sup>	The physical base address (PBA) of UV buffers image in the memory.
<a href="#">DSS_VID_BA_UV_EXT_0</a> and <a href="#">DSS_VID_BA_UV_EXT_1</a>	Address extension bits of PBA for UV buffers.
<a href="#">DSS_VID_PIXEL_INC</a>	1 or other in pixel incremental value.
<a href="#">DSS_VID_ROW_INC</a>	1 or other in row incremental value. Used for Y buffer.
<a href="#">DSS_VID_ROW_INC_UV</a>	1 or other in row incremental value. Used for UV buffer.

(1) Base address of even field, in case of interlaced mode.

(2) Base address of odd field, in case of interlaced mode.

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports only 1D burst. 1D burst is used, if the fetch data is linear in memory. The size of the burst can be one of the following values: 1x128-bit, 2x128-bit, 4x128-bit, or 8x128-bit. Because the burst size must be aligned to the burst boundary, in case of misalignment, the DMA engine may issue one or more smaller burst requests.

#### 12.9.1.4.1.6.2 DISPC Read DMA Buffers

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line, the DMA buffers are flushed according to the video port output associated with the particular video pipeline. The DMA engine restarts fetching data from the memory through the DSS Initiator port. Enabling or disabling the DISPC flushes the DMA buffers.

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data through the Initiator port.

- When low threshold (set in the [DSS\\_VID\\_BUF\\_THRESHOLD](#) [15-0] BUFLOWTHRESHOLD register bit-field) is reached, the DMA engine starts a request on the device interconnect to fill the DMA buffer.
- When high threshold (set in the [DSS\\_VID\\_BUF\\_THRESHOLD](#) [31-16] BUFHIGHTHRESHOLD register bit-field) is reached, the DMA engine stops requesting encoded pixels.

#### Note

The configuration of thresholds for optimal performance can be defined using the [DSS\\_VID\\_BUF\\_SIZE\\_STATUS](#) [15-0] BUFSIZE register field value, as follows:

- For high threshold: BUFSIZE (in number of 128-bit words) – 1
- For low threshold: BUFSIZE (in number of 128-bit words) – burst size (in number of 128-bit words)

The following limitations for BUFLOWTHRESHOLD values must be also considered:

- If the scaler in VID pipeline is disabled, BUFLOWTHRESHOLD can be programmed as low as interconnect latency and pixel output rate allow it.
- If the scaler in VID pipeline is enabled, BUFLOWTHRESHOLD must be programmed to guarantee that at least four full lines can be stored.

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes and the high threshold value. The preload ensures a minimum number of pixels present in the buffer. When the preload value is reached, the associated channel will start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the [DSS\\_VID\\_PRELOAD](#) [11-0] PRELOAD register bit-field, the [DSS\\_VID\\_ATTRIBUTES](#) [19] BUFPRELOAD register bit must be set to 0x0.

The vertical blanking between two frames must be long enough to allow fetching the number of pixels defined by the [DSS\\_VID\\_PRELOAD](#) register and preloading the whole video pipeline. If the value set in the preload register is greater than some overflow conditions detected by the hardware, then data will start to be read from the video DMA buffer before the preload value is reached. If SYNCLOST\_IRQ event occurs the video buffer needs to be increased (buffer merge). Preload value must be greater or equal to low threshold, and smaller or equal to high threshold value.

#### Note

When self-refresh mode is selected (which means that the data in the DMA buffer are used for multiple frames) the DMA buffers are not flushed at the end of each frame. Each DMA buffer has an independent control for selecting the self-refresh mode. For more information, see [Section 12.9.1.4.1.6.8.2, DISPC DMA Ultra-Low Power Mode](#).

#### 12.9.1.4.1.6.3 DISPC Flip/Mirror Support

DISPC supports on-the-fly source image flip along the x/y-axis for 8-bit/component formats (ARGB or YUV) to create a mirror effect on the source data. The DMA engine reads the source frame from right to left by requesting burst transfers for each line in negative address increments while performing each burst transfer as a linear incremental burst. The read data is repacked and stored in the line buffer incrementally - effectively storing the frame as a flipped image for the processing pipeline. The configuration of the flip/mirror operation is explained in [Table 12-461](#).

**Table 12-461. DISPC Flip/Mirror Configuration**

Flip Direction	FLIP Bit	Base Address	Byte Increment
Along Y-axis (vertical mirror)	1	Start of window	1
Along X-axis (horizontal mirror)	0	Start of last line of the window	-2(width of the line in bytes)
Along both X-axis and Y-axis (horizontal and vertical mirror)	1	Start of last line of the window	-2(width of the line in bytes)

In [Table 12-461](#):

- The FLIP bit is located in [DSS\\_VID\\_ATTRIBUTES](#) register.
- The base address of the video buffer must be configured as explained in [Section 12.9.1.4.1.6.1, DISPC DMA Addressing and Bursts](#).
- The number of bytes to increment at the end of the row in the video buffer can be configured through [DSS\\_VID\\_ROW\\_INC](#) and [DSS\\_VID\\_ROW\\_INC\\_UV](#) registers. For more information, see [Section 12.9.1.4.1.6.1, DISPC DMA Addressing and Bursts](#), and [Section 12.9.1.4.1.6.4, DISPC DMA Predecimation](#).

#### 12.9.1.4.1.6.4 DISPC DMA Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels out of the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1D burst. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the [DSS\\_VID\\_ROW\\_INC](#) and [DSS\\_VID\\_ROW\\_INC\\_UV](#) registers.
- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 out of 2 pixels, up to 1 of 2047 pixels, by setting the [DSS\\_VID\\_PIXEL\\_INC](#) register to the number of pixels to skip (n), multiplied by the size of a pixel (in bytes), +1. The condition to generate a burst is that there is at least one useful pixel per 128-bit OCP request. Therefore, when the pixels are 16/32-bit, the maximum number of pixels that can be skipped is 8/4. If PixelWidthInBytes+BytesToSkip is greater than 16, the programmed burst is changed into single request.

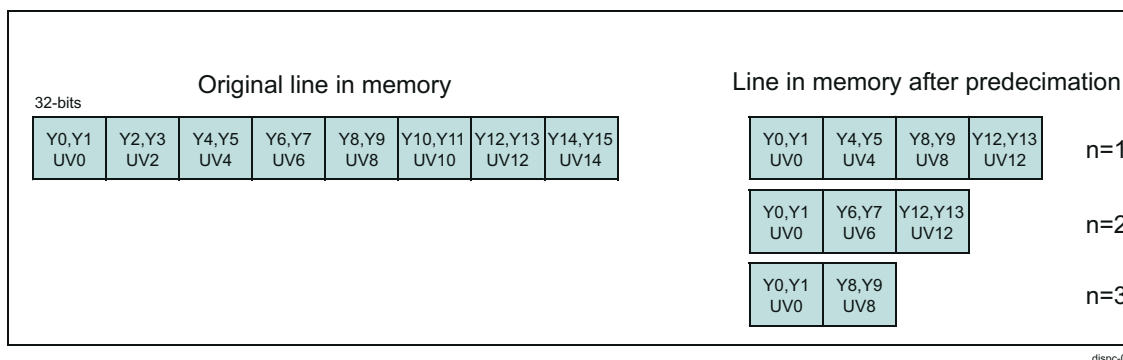

No decimation is supported when the input format is 1, 2, 4, or 8-bit BITMAP.

For RGB and YUV420 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the [DSS\\_VID\\_PIXEL\\_INC](#) register, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV422 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see [Figure 12-500](#)). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV422 format, caution must be taken because n equals the number of pixel data containers to skip, and not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

**Figure 12-500. DISPC YUV422 Predecimation**

#### 12.9.1.4.1.6.5 DISPC DMA MFLAG Mechanism

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read buffers.

The MFLAG mechanism is used when fullness of the DMA buffers is critical (close to underflow). The mechanism is implemented for all DMA buffers of the video pipelines.

Programmable buffer thresholds (forming hysteresis) are used to indicate when a local MFLAG signal is generated. The 1-bit MFLAG signal is generated on DISPC Initiator port in order to inform the system that the outstanding requests from DISPC shall be considered with higher priority in order to get faster interconnect responses. The MFLAG signal is asynchronous to any ongoing interconnect transaction.

Each pipeline maintains its own MFLAG bit. The MFLAG bit is asserted depending on the fullness of the DMA buffers associated with the pipeline and depending on the thresholds programmed by software. All MFLAG signals are OR-ed together to generate the single 1-bit MFLAG for the Initiator port connected to the DISPC DMA engine.

The threshold for video pipelines corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT\_MFLAG: High threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the [DSS\\_VID\\_MFLAG\\_THRESHOLD](#) [31-16] HT\_MFLAG register field.
- LT\_MFLAG: Low threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the [DSS\\_VID\\_MFLAG\\_THRESHOLD](#) [15-0] LT\_MFLAG register field.

Summary of the MFLAG value, based on DMA read buffer fullness:

- If DMA read buffer fullness < LT\_MFLAG, then MFLAG signal = 1
- If LT\_MFLAG < DMA read buffer fullness < HT\_MFLAG, then MFLAG signal = 1
- If DMA read buffer fullness > HT\_MFLAG, then MFLAG signal = 0

By default, the MFLAG mechanism is disabled ( [DSS\\_COMMON\\_DISPC\\_GLOBAL\\_MFLAG\\_ATTRIBUTE](#) [1-0] MFLAG\_CTRL register field = 0x0), and the MFLAG signal is low (de-asserted). The arbitration scheme for the pipelines is the same as described in [Section 12.9.1.4.1.6.7, DISPC DMA Arbitration](#). That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the MFLAG\_CTRL register field is set to 0x2, the MFLAG mechanism is enabled, and the MFLAG signal is dynamically set to 0 or 1, depending on DMA buffer fullness and programmed threshold levels, as explained previously in this section. In this case, the arbitration scheme for the pipelines is round-robin between those high-priority pipelines, which have asserted their local MFLAG signals. If there are no high-priority pipelines with their local MFLAG signals asserted, then the arbitration scheme is the same as described in [Section 12.9.1.4.1.6.7, DISPC DMA Arbitration](#).

The [DSS\\_COMMON\\_DISPC\\_GLOBAL\\_MFLAG\\_ATTRIBUTE](#) [6] MFLAG\_START bit defines the following additional rules for the MFLAG mechanism:

- If the MFLAG\_START bit is set to 0x0 (default value), then when the DMA buffer is empty at the beginning of the frame, the MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see [Section 12.9.1.4.1.6.2, DISPC Read DMA Buffers](#)). Then, based on the setting of the [DSS\\_COMMON\\_DISPC\\_GLOBAL\\_MFLAG\\_ATTRIBUTE](#) [1-0] MFLAG\_CTRL register field, the MFLAG signal is generated and DISPC internal logic is arbitrating between pipeline requests.
- If the MFLAG\_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the configuration of [DSS\\_COMMON\\_DISPC\\_GLOBAL\\_MFLAG\\_ATTRIBUTE](#) [1-0] MFLAG\_CTRL register field determines the generation of the MFLAG signal.

#### 12.9.1.4.1.6.6 DISPC DMA Priority Requests Control

The [DSS\\_COMMON\\_DSS\\_CBA\\_CFG](#) register controls the priority level for DMA requests going out to the memory through the system interconnect.

As explained in [Section 12.9.1.4.1.6.5, DISPC DMA MFLAG Mechanism](#), the DISPC Initiator port generates a 1-bit MFLAG output signal to raise the priority of all requests made on that port, if any of its DMA buffers runs critically low (determined by a set of user programmable threshold values for each buffer).

DSS uses the MFLAG signal from DISPC to set a 3-bit priority level output (*Mpriority*) for the Initiator port to either a low or high value (configurable in [DSS\\_COMMON\\_DSS\\_CBA\\_CFG](#) [2-0] PRI\_LO and [5-3] PRI\_HI register fields with optional values of 0~7) as follows:

- When MFLAG = 0, the PRI\_LO register field determines the value of the Mpriority output for the normal transactions.
- When MFLAG = 1, the PRI\_HI register field determines the value of the Mpriority output for the high-priority transactions.

This Mpriority output directly drives the respective input of the system interconnect port, which corresponds to the DISPC DMA Initiator port.

#### CAUTION

Upon a hardware reset, [DSS\\_COMMON\\_DSS\\_CBA\\_CFG](#) [2-0] PRI\_LO and [5-3] PRI\_HI register fields are set by default to 4 and 1, respectively. Afterwards, these priority level register fields can only be modified by a secure host.

#### 12.9.1.4.1.6.7 DISPC DMA Arbitration

The read requests sent to the system interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme can be modified by setting the priority attribute of each pipeline as defined in the [DSS\\_VID\\_ATTRIBUTES](#)[23] ARBITRATION register bit.

By default, all pipelines have the same priority (normal priority), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the system interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, then the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

#### 12.9.1.4.1.6.8 DISPC DMA Power Modes

##### 12.9.1.4.1.6.8.1 DISPC DMA Low Power Mode

Each DMA buffer can be associated to the pipeline or merged with other DMA buffers. The total number of DMA buffers for each individual pipeline is from 0 (pipeline inactive) to number of pipelines (in that case all the DMA buffers are associated to a single pipeline) supported by the DMA engine.

The user is responsible for configuring correctly the number of DMA buffers to guarantee no underflow. The DMA buffers allocated to each pipeline shall be greater or equal to the minimum required DMA buffer to support the throughput and the system latency.

When the size of the buffer is changed, the thresholds shall be re-programmed by the user to reflect the new DMA buffer configuration. Increasing the size of the buffer used enables to put the interconnect and the system memory in standby for a longer period, therefore, leading to a possible system power reduction.

The low power mode of the DISPC DMA can also be achieved by keeping the thresholds (bit-fields [31-16] BUFHIGHTHRESHOLD and [15-0] BUFLOWTHRESHOLD of [DSS\\_VID\\_BUF\\_THRESHOLD](#) register) farther apart. The farther they are there will be longer periods of idling on the DMA fetch interface resulting in lower power. The user needs to ensure a minimum value of BUFLOWTHRESHOLD, so that there is no underflow.

#### 12.9.1.4.1.6.8.2 DISPC DMA Ultra-Low Power Mode

In ultra-low power mode, the system interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. Then, the system interconnect is not used anymore to fetch new pixels for the following frames. The data are fetched once into the DMA buffer and then the following frames re-use the DMA buffer to display on the screen.

The programming of the ultra-low power mode is independent for each pipeline and is achieved via the [DSS\\_VID\\_ATTRIBUTES](#)[24] SELFREFRESH register bit. One pipeline may have all frame pixels into the DMA buffer and other pipeline may have to refill the DMA buffers along the display scan, because the frame buffer is too big to be stored in the DMA buffer.

Two ultra-low power modes can be entered, manual or automatic mode:

- **Manual self-refresh mode:** Starting self-refresh mode is done manually by setting the SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0. Software must first disable the SELFREFRESH bit during at least one frame in order to capture the data (by setting the GOBIT register bit of the video port the pipeline is associated with). Once the [DSS\\_VP1\\_CONTROL](#)[5] GOBIT bit has been set, the software must read the GOBIT bit to ensure that the frame has been loaded into the buffer, then it can set the SELFREFRESH bit to 1. Once SELFREFRESH is enabled, the fetch of data from the system memory is stopped for the following frames. The software needs to reset the SELFREFRESH bit in order to restart fetching data from system memory.
- **Automatic self-refresh mode:** By setting the [DSS\\_VID\\_ATTRIBUTES](#)[17] SELFREFRESHAUTO bit to 0x1, the transition from disabled to enabled for self-refresh mode is controlled by hardware. This allows the software to reset the SELFREFRESH bit to "disabled", and then automatically after the fetch of the first frame the hardware switches back SELFREFRESH bit to "enabled". The SELFREFRESH must be disabled during at least one frame in order to capture the data, so software must reset the bit to 0 every time the data in the DMA buffer needs to be updated. The hardware reads the data inside the DMA buffer without accessing the interconnect and system memory during the frame, then modifies the SELFREFRESH bit to reflect the current state of the self-refresh mode by setting the bit to 0x1.

#### 12.9.1.4.1.7 DISPC Pixel Data Formats

The video pipelines support various types of memory formats, as listed in [Table 12-462](#).

For BITMAP formats the nibble mode (pixels in each byte are packed in reverse order) can be enabled by setting the [DSS\\_VID\\_ATTRIBUTES](#)[10] NIBBLEMODE register bit to 0x1.

The pixel data format can be selected by loading the corresponding value from [Table 12-462](#) in the [DSS\\_VID\\_ATTRIBUTES](#) [6-1] FORMAT register field.

**Table 12-462. DISPC Supported Pixel Data Formats**

FORMAT Register Field Value		Pixel Format <sup>(4)</sup>	Component Bit Depth
Alpha	Alpha-X		
0x00	0x20	ARGB16-4444	4
0x01	0x21	ABGR16-4444	4

NA	See <sup>(2)</sup>	YUV420-NV21	8/10/12

- (1) The video pipelines support an optional 8-bit Alpha plane (separate buffer), if the pixel format of the source/destination buffer is either RGB16-565 or BGR16-565.
- (2) NV21 formats for YUV420 are indirectly supported through chroma swapping during the color space conversion.
- (3) 10bit/12bit versions of these YUV formats are also supported in both packed and unpacked (in 16-bit container) formats. For unpacked formats, both LSB or MSB alignments are supported. These configurations are set using a separate configuration register [DSS\\_VID\\_ATTRIBUTES2](#). Default is 8-bit packed format support.
- (4) All RGB formats with alpha component include both pre/non-pre-multiplied data support. Also, alpha can be disabled to work as X (can be replaced with global alpha value).

Figure 12-501 shows the pixel data memory organization for the bitmap pixel formats.

dispc-312

**Figure 12-512. DISPC YUV 12-bit Pixel Formats 2**

Figure 12-513 through Figure 12-515 show the pixel data memory organization for the YUV 10-bit/12-bit unpacked pixel formats in 16-bit container, together with some specific register settings.

YUV 10-bit/12-bit unpacked formats have the same component packing order as 8-bit formats except that each component is stored in a 16-bit container (with MSB or LSB bits within the 16-bit container not used depending on the MSB/LSB alignment).

ATTRIBUTES2.YUV\_SIZE = 1 or 2 (10b or 12b)

ATTRIBUTES2.YUV\_MODE = 1 (Unpacked)

ATTRIBUTES2.YUV\_ALIGN = 0 or 1 (LSB or MSB aligned)

YUV422 (1-plane)

10-bit unpacked LSB aligned

YUV2 4:2:2 – 10bit (0x3E)

**Figure 12-514. DISPC YUV 10-bit/12-bit Unpacked Pixel Formats 2**

### 12.9.1.4.1.8 DISPC Video Pipelines

DISPC includes two input pipelines:

- Video pipeline (VID)
- Video lite pipeline (VIDL1)

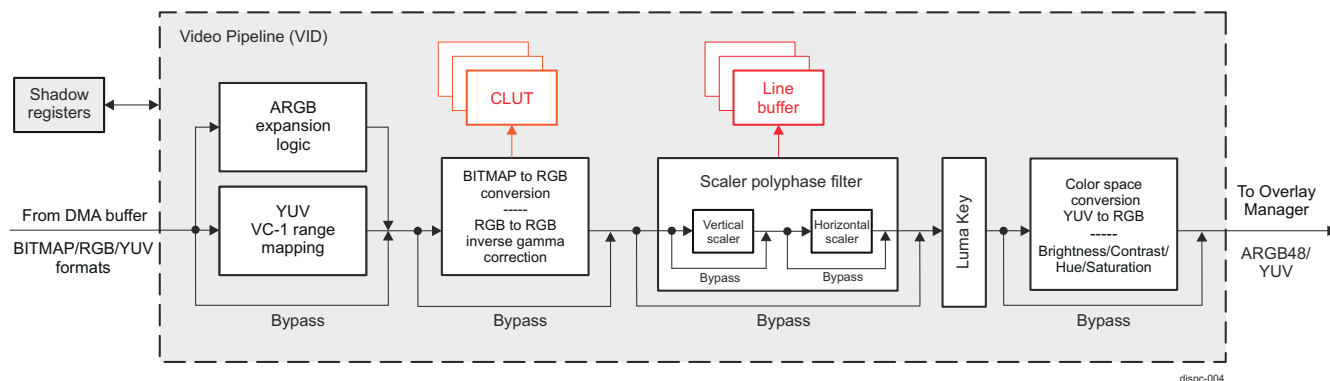

The video pipeline (VID) consists of:

- VC-1 range mapping unit for YUV422/YUV420 input formats;
- Replication logic for ARGB input formats;
- One 256 x 24-bit entries Color Look-up Table (CLUT);
- Polyphase-filter based resizer unit (scaler) supporting chroma upsampling;
- Color Space Conversion (CSC) unit (YUV to RGB), which can be used also for programmable BCHS (Brightness/Contrast/Hue/Saturation) control;

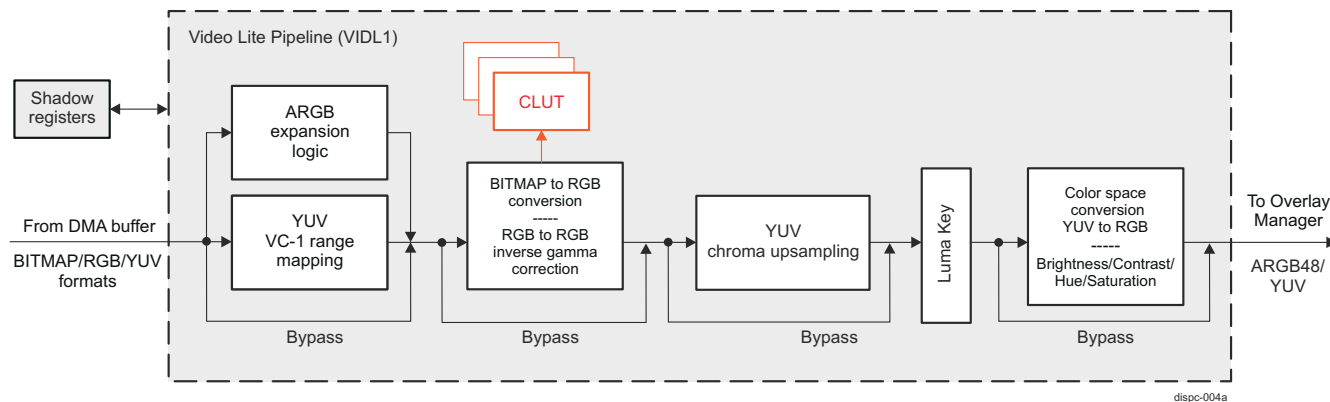

The video lite pipeline (VIDL1) is identical to the video pipeline (VID), except for:

- Polyphase-filter based resizer (scaler) is not included;
- Chroma upsampling is done using dedicated YUV420-to-422 and YUV422-to-444 upsamplers (instead of using the scaler);

Each pipeline processing block can be independently bypassed.

**Figure 12-516. DISPC Video Pipeline Configuration**

**Figure 12-517. DISPC Video Lite Pipeline Configuration**

The input of each pipeline is connected to the video DMA buffer controller. Each pipeline pixel output is always connected to the overlay managers (OVR1 and OVR2). Each pipeline configuration supports various BITMAP, RGB (ARGB and RGBA), and YUV formats, as listed in [Table 12-462, DISPC Pixel Data Formats](#).

The 256-entry CLUT is either used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format, or for RGB to RGB inverse gamma correction. For a BITMAP format data, scaling is not supported. Scaling and color

look-up table features are mutually exclusive. If the color look-up feature is enabled, then video pipeline scaler has to be disabled.

For chroma sub-sampled YUV formats (YUV422 and YUV420-NV12/NV21):

- VID pipeline: the scaler unit upsamples the chrominance data using both vertical and horizontal polyphase filters;
- VIDL1 pipeline: dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers are used;

For ARGB source data with less than/equal to 10-bit component data size the replication logic (ARGB expansion) converts the data to ARGB48 by replicating the MSBs into the LSBs:

- When scaling is disabled (or no scaler supported), the resulting ARGB48 data is directly provided to the pipeline output;
- When vertical scaling is engaged, the resulting ARGB48 data is first truncated to ARGB8888, and then converted to ARGB10101010 (by MSBs replication into LSBs), before being fed to the vertical scaler input;
- When vertical scaling is disabled, but horizontal scaling is engaged, the resulting ARGB48 data is directly provided to the horizontal scaler input;

A pipeline can be enabled by setting the [DSS\\_VID\\_ATTRIBUTES\[0\] ENABLE](#) register bit. If the video pipeline is disabled, the video window does not exist on the screen and the whole video pipeline and its DMA are inactive. Prior to enabling the video layer a valid configuration has to be set by the user.

#### Note

The DISPC input pipelines, VID and VID1L, will be commonly referred to as *video pipeline (VID)* in the following sections. Any differences in their functionality will be highlighted.

#### 12.9.1.4.1.8.1 DISPC VID Replication Logic

The replication logic (ARGB expansion) converts ARGB pixel formats into ARGB48 format by replicating the MSBs into the LSBs. The logic is always enabled.

[Table 12-463](#) shows how some of the ARGB formats supported by video pipelines are remapped into ARGB48 by default.

**Table 12-463. DISPC VID Replication: ARGB Pixel Formats Remapping into ARGB48-12121212**

Formats	A[11:0]	R[11:0]	G[11:0]	B[11:0]

RGBA16-4444	A[3:0]A[3:0]A[3:0]	R[3:0]R[3:0]R[3:0]	G[3:0]G[3:0]G[3:0]	B[3:0]B[3:0]B[3:0]
ARGB32-8888	A[7:0]A[7:4]	R[7:0]R[7:4]	G[7:0]G[7:4]	B[7:0]B[7:4]

#### 12.9.1.4.1.8.2 DISPC VID VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components to the full range (from the reduced data range) before displaying. The unit is used primarily for YUV4:2:0-NV12 (NV21) pixel format, but also can be applied to YUV4:2:2 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the [DSS\\_VID\\_ATTRIBUTES2\[0\] VC1ENABLE](#) bit to 0x1. The VC-1 range mapping must be enabled only for 8 bits/component YUV input data.

The [DSS\\_VID\\_ATTRIBUTES2](#) [3:1] VC1\_RANGE\_Y and [6:4] VC1\_RANGE\_CBCR bit fields are two 3-bit values programmed by the user.

The equations for the mapping process are:

$$Y_{out} = \text{CLIP}((((Y_{int} - 128) \times (VC1\_RANGE\_Y + 9) + 4) / 8) + 128)$$

$$C_b = \text{CLIP}((((C_b - 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$$

$$C_r = \text{CLIP}((((C_r - 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$$

#### Note

The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP () clips to 0 or 255 when minimum or maximum, respectively, is reached. Otherwise, the resulting output remains identical.

#### 12.9.1.4.1.8.3 DISPC VID Color Look-Up Table (CLUT)

The video pipeline supports a look up table to perform either of the following operations:

- Conversions of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB24 format (CLUT mode), or
- Inverse gamma correction on non-linear RGB source data (gamma mode)

The look-up table consists of 3 separate 256 x 8-bit memories and is indexed either by the source BITMAP data or by R/G/B component data. The table is loaded through direct register access by writing to the CLUT registers.

The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values using single access, or burst access in linear increment burst mode, into [DSS\\_VID\\_CLUT\\_0](#) through [DSS\\_VID\\_CLUT\\_15](#) registers. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table (see [Figure 12-518](#)).
2. Loop to Step 1, if there is a new access to the CLUT registers. Software can access other registers between two accesses to the CLUT registers.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the look-up table in CLUT mode is activated when a BITMAP format is selected in the [DSS\\_VID\\_ATTRIBUTES](#)[6:1] FORMAT register bit-field.

The usage of the look-up table for RGB inverse gamma correction can be enabled by setting [DSS\\_VID\\_ATTRIBUTES](#)[30] GAMMAINVERSION register bit.

**Figure 12-518. DISPC VID CLUT/Gamma Data Memory Organization**

#### Note

Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

#### 12.9.1.4.1.8.4 DISPC VID Chrominance Resampling

##### 12.9.1.4.1.8.4.1 Chrominance Resampling for VID Pipeline

The chrominance resampling from 8-bpc or 10-bpc to 12-bit color components is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV formats.

The usage of the scaler unit for resampling the chrominance of YUV420 and YUV422 is shown in [Figure 12-519](#) and [Figure 12-520](#), respectively. The settings of the scaler unit to perform chrominance resampling are described in [Section 12.9.1.4.1.8.5, DISPC VID Scaler Unit](#).

**Figure 12-519. DISPC VID YUV420 to ARGB48 Using Scaler Unit for Resampling Chrominance**

**Figure 12-520. DISPC VID YUV422 to ARGB48 Using Scaler Unit for Resampling Chrominance**

The vertical scaler is not a mandatory block for resampling the chrominance of YUV422 data, as shown in [Figure 12-520](#).

#### 12.9.1.4.1.8.4.2 Chrominance Resampling for VIDL1 Pipeline

VIDL1 pipeline does not include a scaler unit. Chroma upsampling is done using dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers.

VIDL1 pipeline converts YUV420 (chroma) data to YUV422 (chroma) using a simple vertical average filter (average of two adjacent chroma lines to generate a missing line except for the very bottom line which is generated by repeating the previous chroma line). If the video image is a sub-image of a larger video frame data, then the vertical Luma line offset from the top should be an even number.

VIDL1 pipeline converts YUV422 data to YUV444 format using a 4-tap filter (implementing the Catmull-Rom algorithm) to generate missing chroma data as shown below:

$$\text{Cout}[2*i] = \text{Cin}[i]$$

$$\text{Cout}[2*i+1] = \text{CLIP} \left( -1/16 * \text{Cin}[i-1] + 9/16 * \text{Cin}[i] + 9/16 * \text{Cin}[i+1] - 1/16 * \text{Cin}[i+2] \right)$$

The missing chroma data is generated as a simple weighted average of the surrounding 4 chroma values, which is equivalent to a 4x1 filter kernel with values: [-1/16, 9/16, 9/16, -1/16]. In this algorithm, edge effects are treated by repeating the first and last pixel.

#### 12.9.1.4.1.8.5 DISPC VID Scaler Unit

#### Note

Only VID pipeline includes a resizer unit (scaler). VIDL1 pipeline does not include a scaler.

The programmable scaler filter works with all supported video formats, including formats with alpha channel. Alpha channel is scaled with the same parameters as RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. An RGB 64-bit source (16 bits per component) is truncated to 8-bit, if scaler is enabled. Otherwise, it will be truncated to ARGB48 format in the scaler bypass mode. 10-bit/12-bit YUV source is also truncated to 8-bit, since the scaler is enabled to either upsample the chroma component and/or resize the YUV frame data directly.

The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering. The filtering can be used for various processing:

- Up-sampling of the picture
- Down-sampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

The following limitations must be considered:

- The up-sampling ratio is up to x16.
- The down-sampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The down-sampling ratio using 5-tap configuration is down to x0.25 for RGB format.

### Note

The user must set the correct size and position of the original video before resize in order for the up-sampled/down-sampled video to be displayed inside the screen boundaries.

Figure 12-521 shows an example of video up-sampling, with corresponding video window attributes.

**Figure 12-521. DISPC Video Window Attributes**

The video window attributes can be configured in the following register bit-fields:

- Source data format (input to the scaler unit) in [DSS\\_VID\\_ATTRIBUTES](#) [6-1] FORMAT bit-field
- Video picture width in system memory (frame buffer) in [DSS\\_VID\\_PICTURE\\_SIZE](#) [11-0] MEMSIZEEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed except for YUV 422 formats. In case of YUV2422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Video picture height in system memory (frame buffer) in [DSS\\_VID\\_PICTURE\\_SIZE](#) [27-16] MEMSIZEY bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed.
- Video window width at pipeline output (after resizing) in [DSS\\_VID\\_SIZE](#) [11-0] SIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen width minus the horizontal start location of the window on the screen.

- Video window height at pipeline output (after resizing) in [DSS\\_VID\\_SIZE](#) [27-16] SIZEY bit-field. The window height is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen height minus the vertical start location of the window on the screen.
- Video window overlay X-position in [DSS\\_OVR1\\_ATTRIBUTES\\_0](#) [17-6] POSX bit-field. See [Section 12.9.1.4.1.9, DISPC Overlay Managers](#).
- Video window overlay Y-position in [DSS\\_OVR1\\_ATTRIBUTES\\_0](#) [30-19] POSY bit-field. See [Section 12.9.1.4.1.9, DISPC Overlay Managers](#).
- For configuration of LPP and PPL video port output display parameters, see [Section 12.9.1.4.1.10.7, DISPC VP Timing Generator and Display Panel Settings](#).

For vertical up-sampling and down-sampling in a 3-tap configuration, the equations are:

For RGB formats	For YUV formats
$Aout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Rout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Gout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Bout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	$Yout(n) = \left( \sum_{i=-1}^{i=1} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cbout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Crout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispcc-013

(26)

For vertical and horizontal up-sampling and down-sampling in a 5-tap configuration, the equations are:

For RGB formats	For YUV formats
$Aout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Rout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Gout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Bout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	$Yout(n) = \left( \sum_{i=-2}^{i=2} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cbout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Crout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispcc-012

(27)

### Note

The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

The coefficients are different for Y and Cr/Cb filtering because the calculations are independent due to the chrominance resampling for YUV422 and YUV420.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of:

- Six lines of 1280 × 32 bits for 5-tap configuration
- Three lines of 2560 × 32 bits for 3-tap configuration

Table 12-464 lists some of the scaler supported configurations.

**Table 12-464. DISPC VID Line Buffer Width for Scaler Unit**

Pixel Format	Maximum Input Width (Pixels) for 5-tap	Maximum Input Width (Pixels) for 3-tap
32 bits per pixel (ARGB32-8888, ARGB-2101010, etc.)	1280 pixels wide <sup>(1)</sup>	2560 pixels wide
YUV420, YUV422	2560 pixels wide	4096 pixels wide

- (1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler, so that horizontal down-scaling can be supported with a minimum clock ratio equal to 1. The maximum output width is limited to 1280 pixels in order to be able to support clock ratio of 1 due to the 6th video line buffer. The 6th video line is also used in order to start the next output line generation while the video pipeline output is being stalled by the overlay manager (either due to display in blanking period and/or in background pixel period). The 6th line buffer is actually 48-bit wide to allow storage of ARGB48 format pixel data.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing the last line is duplicated, if the scaling logic requires loading more lines and the last line has been reached.

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated, if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has a 10-bit input and a 12-bit output. The horizontal scaling stage takes the resulting 12-bit input and produces 12-bit output.

Figure 12-522 and Figure 12-523 show the scaler macro-architecture for components A, R, G, and B. Figure 12-524 and Figure 12-525 show the scaler macro-architecture for components Y, Cr, and Cb.

#### Note

The scaling and CSC clipping is set by the same bit, [DSS\\_VID\\_ATTRIBUTES\[11\] FULLRANGE](#).

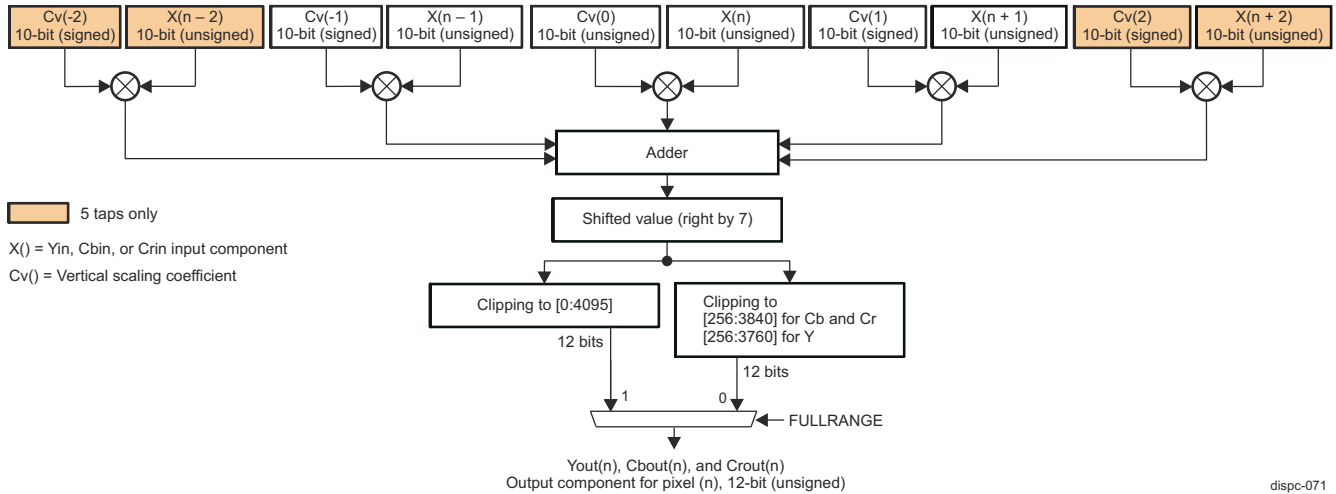

**Figure 12-522. DISPC VID Macro-Architecture of the Horizontal Scaling for A, R, G, and B Components (5-tap Restriction)**

**Figure 12-523. DISPC VID Macro-Architecture of the Vertical Scaling for A, R, G, and B Components (5 and 3 taps)**

### Note

In [Table 12-465](#), the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS\_VID\_FIR\_COEF\_V0\_0 to DSS\_VID\_FIR\_COEF\_V0\_8, and DSS\_VID\_FIR\_COEF\_V12\_0 to DSS\_VID\_FIR\_COEF\_V12\_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS\_VID\_FIR\_COEF\_H0\_C\_0 to DSS\_VID\_FIR\_COEF\_H0\_C\_8, and DSS\_VID\_FIR\_COEF\_H12\_C\_0 to DSS\_VID\_FIR\_COEF\_H12\_C\_15, and DSS\_VID\_FIR\_COEF\_V0\_C\_0 to DSS\_VID\_FIR\_COEF\_V0\_C\_8 and DSS\_VID\_FIR\_COEF\_V12\_C\_0 to DSS\_VID\_FIR\_COEF\_V12\_C\_15 are used) .

The VID scaler unit vertical and/or horizontal sampling is selected by configuring the [DSS\\_VID\\_ATTRIBUTES](#)[8-7] RESIZEENABLE bit field.

Prior to enabling the video up/down-sampling block a valid configuration has to be set by the user. After configuring the required VID registers change the DSS\_VP\_CONTROL[5] GOBIT register bit of the video port the video pipeline is associated with. The software has to wait before setting the GO bit that the hardware has reset the bit. The software reset is not recommended since the application cannot guarantee to be able to reset it before the H/W.

The following fields define the configuration of the video up-sampling/down-sampling block in the VID pipeline for ARGB and YUV formats:

- Vertical upsampling and downsampling increment value in the [23-0] FIRVINC bit field of DSS\_VID\_FIRV (for ARGB and Y) and DSS\_VID\_FIRV2 (for CbCr) registers. The unsigned integer value range is  $2^{23}$ . Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left( \frac{MEMSIZEY+1}{SIZEY+1} \right)$$

dispc-066

- Horizontal upsampling and downsampling increment value in the [23-0] FIRHINC bit field of the DSS\_VID\_FIRH (for ARGB and Y) and DSS\_VID\_FIRH2 (for CbCr) registers. The unsigned integer value range is [1:16384]. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left( \frac{MEMSIZEH+1}{SIZEH+1} \right)$$

dispc-067

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS\_VID\_ACCUV\_0 and DSS\_VID\_ACCUV\_1 (for ARGB and Y), and DSS\_VID\_ACCUV2\_0 and DSS\_VID\_ACCUV2\_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts. The DSS\_VID\_ACCUV\_0 register is used for progressive output, while for interlace output both DSS\_VID\_ACCUV\_0 and DSS\_VID\_ACCUV\_1 registers are used. The DSS\_VID\_ACCUV2\_0 and DSS\_VID\_ACCUV2\_1 registers are used in the same manner for progressive or interlace output.

- Vertical upsampling and downsampling line buffer configuration via the [DSS\\_VID\\_ATTRIBUTES](#)[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS\_VID\_ACCUH\_0 and DSS\_VID\_ACCUH\_1 (for ARGB and Y), and DSS\_VID\_ACCUH2\_0 and DSS\_VID\_ACCUH2\_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts. The register DSS\_VID\_ACCUH\_0 is used for progressive output, while for interlace output both DSS\_VID\_ACCUH\_0 and DSS\_VID\_ACCUH\_1 registers are used. The DSS\_VID\_ACCUH2\_0 and DSS\_VID\_ACCUH2\_1 are used in the same manner for progressive or interlace output.

[Table 12-466](#) lists the scaler vertical and horizontal accumulator values and phases.

**Table 12-466. DISPC VID Scaler Vertical and Horizontal Accumulator Phases**

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS\_VID\_FIR\_COEF\_V0\_0 to DSS\_VID\_FIR\_COEF\_V0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symmetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS\_VID\_FIR\_COEF\_V0\_C\_0 to DSS\_VID\_FIR\_COEF\_V0\_C\_8 registers.
- Vertical upsampling and downsampling coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS\_VID\_FIR\_COEF\_V12\_0 to DSS\_VID\_FIR\_COEF\_V12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS\_VID\_FIR\_COEF\_V12\_C\_0 to DSS\_VID\_FIR\_COEF\_V12\_C\_15 registers.
- Horizontal upsampling and downsampling central coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS\_VID\_FIR\_COEF\_H0\_0 to DSS\_VID\_FIR\_COEF\_H0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symmetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).

- Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS\_VID\_FIR\_COEF\_H0\_C\_0 to DSS\_VID\_FIR\_COEF\_H0\_C\_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS\_VID\_FIR\_COEF\_H12\_0 to DSS\_VID\_FIR\_COEF\_H12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS\_VID\_FIR\_COEF\_H12\_C\_0 to DSS\_VID\_FIR\_COEF\_H12\_C\_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS\_VID\_FIRH2 and DSS\_VID\_FIRV2, and DSS\_VID\_ACCUV2\_0/DSS\_VID\_ACCUV2\_1 and DSS\_VID\_ACCUH2\_0/DSS\_VID\_ACCUH2\_1 registers need to be configured differently than DSS\_VID\_FIRH and DSS\_VID\_FIRV, and DSS\_VID\_ACCUH\_0/DSS\_VID\_ACCUH\_1 and DSS\_VID\_ACCUV\_0/DSS\_VID\_ACCUV\_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

#### 12.9.1.4.1.8.6 DISPC VID Color Space Conversion YUV to RGB

The Color Space Conversion (CSC) unit converts the video-encoded pixel values from YUV444 format into ARGB48 format (12-bit value per component A, R, G, and B, with A fixed at 0xFFFF).

In case of YUV420 or YUV422 formats, a chrominance resampling to YUV444 is performed before converting the YUV into RGB values (see [Section 12.9.1.4.1.8.4, DISPC VID Chrominance Resampling](#)). The YUV422/YUV420 to YUV444 chrominance resampling is a pre-processing to the color space conversion.

[Figure 12-526](#) and [Figure 12-527](#) show the  $3 \times 3$  11-bit coefficients used to convert from YUV444 into ARGB48. The value of A component is fixed at 0xFFFF in the output. The coefficients are set according to the standard used to encode the pixel data in YUV color space. [Table 12-467](#) summarizes the coefficients with their respective register bit fields.

**Table 12-467. DISPC VID CSC - YUV to RGB Register Settings**

Coefficients	Register Fields
R <sub>Y</sub>	<a href="#">DSS_VID_CSC_COEF0</a> [10-0] C00
R <sub>Cr</sub>	<a href="#">DSS_VID_CSC_COEF0</a> [26-16] C01
R <sub>Cb</sub>	<a href="#">DSS_VID_CSC_COEF1</a> [10-0] C02
G <sub>Y</sub>	<a href="#">DSS_VID_CSC_COEF1</a> [26-16] C10
G <sub>Cr</sub>	<a href="#">DSS_VID_CSC_COEF2</a> [10-0] C11
G <sub>Cb</sub>	<a href="#">DSS_VID_CSC_COEF2</a> [26-16] C12
B <sub>Y</sub>	<a href="#">DSS_VID_CSC_COEF3</a> [10-0] C20
B <sub>Cr</sub>	<a href="#">DSS_VID_CSC_COEF3</a> [26-16] C21
B <sub>Cb</sub>	<a href="#">DSS_VID_CSC_COEF4</a> [10-0] C22
Y offset	<a href="#">DSS_VID_CSC_COEF5</a> [15-3] PREOFFSET1
Cr offset	<a href="#">DSS_VID_CSC_COEF5</a> [31-19] PREOFFSET2
Cb offset	<a href="#">DSS_VID_CSC_COEF6</a> [15-3] PREOFFSET3

- Limited video data range conversion

If the active range for the luminance samples (Y) is [256:3760] and for the chrominance samples (Cb and Cr) is [256:3840], the following equation in [Figure 12-526](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the [DSS\\_VID\\_ATTRIBUTES\[11\] FULLRANGE](#) bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

**Figure 12-526. DISPC VID CSC YCbCr to RGB Equation (Limited Video Range), 12-Bit Outputs**

In [Figure 12-526](#), the offset values (-256, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-467, DISPC VID CSC - YUV to RGB Register Settings](#).

- Full video data range conversion

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the following equation in [Figure 12-527](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the [DSS\\_VID\\_ATTRIBUTES\[11\] FULLRANGE](#) bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

**Figure 12-527. DISPC VID CSC YCbCr to RGB Equation (Full Video Range), 12-Bit Outputs**

In [Figure 12-527](#), the offset values (0, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-467, DISPC VID CSC - YUV to RGB Register Settings](#).

#### Note

In case of YUV420-NV21 data, the coefficients for Cr and Cb must be swapped in order to correctly support YUV420-NV21 format.

The scaling and CSC clipping is set by the same bit, [DSS\\_VID\\_ATTRIBUTES\[11\] FULLRANGE](#).

#### 12.9.1.4.1.8.7 DISPC VID Brightness/Contrast/Saturation/Hue Control

The brightness/contrast/saturation controls are implemented in the same Color Space Conversion (CSC) block by making adjustments to the conversion coefficients and input/output offset values as shown in [Figure 12-528](#):

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * B0 & m * k * C0 \\ m * A1 & m * k * B1 & m * k * C1 \\ m * A2 & m * k * B2 & m * k * C2 \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-101

**Figure 12-528. DISPC VID Brightness/Contrast/Saturation Equation for YUV to RGB**

In [Figure 12-528](#) the following terminology is used:

- A/B/C coefficients and the offset parameters are for YUV to RGB conversion. See [Table 12-468](#) below for coefficients and offsets mapping to register fields.

- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness offset (b) is added to Y\_offset\_adj. The allowed range (for 8-bit example) is:  $-128 \leq b \leq +127$  (where  $b=0$  means brightness bypass).

The hue adjustment can also be built into the above equation (Figure 12-528) to comprehend the following Cb/Cr hue angle adjustments:

$$Cb\_hue\_adj = (Cb * \cos \emptyset + Cr * \sin \emptyset)$$

$$Cr\_hue\_adj = (Cr * \cos \emptyset - Cb * \sin \emptyset), \text{ where } \emptyset \text{ is the desired hue angle (with } \emptyset=0 \text{ meaning hue adjustment bypass)}$$

The final combined matrix equation for controlling brightness/contrast/saturation/hue (BCSH) during YUV to RGB conversion is shown in Figure 12-529

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-102

**Figure 12-529. DISPC VID Brightness/Contrast/Saturation/Hue Equation for YUV to RGB**

Gain and offset terms in the above equation (Figure 12-529) are programmed in the hardware registers as adjusted CSC coefficients (11-bit signed) and offset values (13-bit signed) to control the brightness, contrast, saturation and hue. Mapping of the coefficients and offsets to register fields is provided in Table 12-468. Outputs are clipped to keep the output values in the proper range.

**Table 12-468. DISPC VID BCSH Register Settings for YUV to RGB**

Coefficients	Register Fields
A0	DSS_VID_CSC_COEF0[10-0] C00
B0	DSS_VID_CSC_COEF0[26-16] C01
C0	DSS_VID_CSC_COEF1[10-0] C02
A1	DSS_VID_CSC_COEF1[26-16] C10
B1	DSS_VID_CSC_COEF2[10-0] C11
C1	DSS_VID_CSC_COEF2[26-16] C12
A2	DSS_VID_CSC_COEF3[10-0] C20
B2	DSS_VID_CSC_COEF3[26-16] C21
C2	DSS_VID_CSC_COEF4[10-0] C22
Y offset	DSS_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS_VID_CSC_COEF6[15-3] PREOFFSET3
R offset	DSS_VID_CSC_COEF6[31-19] POSTOFFSET1
G offset	DSS_VID_CSC_COEF7[15-3] POSTOFFSET2
B offset	DSS_VID_CSC_COEF7[31-19] POSTOFFSET3

For RGB input formats, the same CSC block can be used to adjust contrast, brightness, saturation, and hue using the matrix equation from Figure 12-530.

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

Coefficients a/b/c are related to A/B/C (for RGB to YUV and YUV to RGB conversions) as follows:

$$\begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} = \begin{bmatrix} A0 & B0 & C0 \\ A1 & B1 & C1 \\ A2 & B2 & C2 \end{bmatrix} - 1$$

dispc-103

**Figure 12-530. DISPC VID Brightness/Contrast/Saturation/Hue Equation for RGB Input**

In [Figure 12-530](#) the following specifics apply:

- A/B/C coefficients and the RGB offset parameters mapping to register fields is provided in [Table 12-468](#).
- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness is controlled by the RGB offset values.
- The Hue angle is used to adjust hue. Hue  $\emptyset=0$  means hue adjustment bypass.

Outputs are clipped to keep the output values in the proper range.

#### 12.9.1.4.1.8.8 DISPC VID Luma Key Support

The video pipeline supports luma key transparency for Blue-ray video layer composition. When enabled, Y value of each pixel will be checked against luma key range values. The range values are defined in [DSS\\_VID\\_LUMAKEY](#) register fields, as follows:  $[11-0] \text{ LUMAKEYMIN} < Y < [27-16] \text{ LUMAKEYMAX}$ . If this condition is true, then the pixel alpha value will be forced to zero (transparent) to make the pixel transparent during the blending process in the overlay manager.

#### 12.9.1.4.1.9 DISPC Overlay Managers

An overlay manager (OVR) is responsible for compositing selected input layers together to generate the final display output frame. DISPC implements two identical overlay managers (see [Figure 12-498](#), *DISPC Architecture Overview*):

- OVR1, with output connected to Video Port (VP1).
- OVR2, with output connected to Video Port (VP2).

Each OVR is preceded by a programmable input pipeline selector which re-maps the outputs of the selected input pipeline according to the overlay manager z-order configuration.

The output of each OVR is connected to the Color Phase Rotation (CPR) unit through a gamma table of the corresponding video port.

dispc-104

**Figure 12-531. DISPC Overlay Manager and Input Selector**

### Note

The DISPC overlay managers, OVR1 and OVR2, will be commonly referred to as *overlay manager (OVR)* in the following sections.

#### 12.9.1.4.1.9.1 DISPC Overlay Input Selector

The overlay input selector before the overlay manager is a n-input to n-output crossbar switch. As such, any input can be connected to any output in the selector. The selection is based on the z-order layer selection in the overlay configuration through the following register fields:

- [DSS\\_OVR1\\_ATTRIBUTES\\_0](#)[4-1] CHANNELIN field for layer 0, z-order 0
- [DSS\\_OVR1\\_ATTRIBUTES\\_1](#)[4-1] CHANNELIN field for layer 1, z-order 1

The z-order determines the order in which the selected layers are blended together to generate the final output by the overlay manager:

- The lowest enabled order input is the bottom-most layer, just above the background color
- The highest enabled order input is the top-most layer

The OVR input selector also passes the following attributes from the selected input pipeline to the corresponding selector output port:

- Source pipeline size attributes:
  - Number of pixels per line (from [DSS\\_VID\\_SIZE](#) [11-0] SIZEX register field)
  - Number of lines (from [DSS\\_VID\\_SIZE](#) [27-16] SIZEY register field)
- Source pipeline global blending level (from [DSS\\_VID\\_GLOBAL\\_ALPHA](#) register)

Then, the overlay manager uses the above listed attributes as input layer attributes along with POSX and POSY overlay manager configuration parameters. POSX and POSY can be configured as follows:

- For layer 0, z-order 0, in [DSS\\_OVR1\\_ATTRIBUTES\\_0](#)[17-6] POSX and [30-19] POSY register fields
- For layer 1, z-order 1, in [DSS\\_OVR1\\_ATTRIBUTES\\_1](#)[17-6] POSX and [30-19] POSY register fields

### Note

The output of an input pipeline can be mapped to more than one overlay manager simultaneously, if and only if the following conditions are true:

- All video port timing generators controlling the overlay managers are identically programmed (same frame width/height with same blanking parameters running at same frame rate) and clocked by the same pixel clock source, and ...
- The pipeline output is positioned on each display output at the same frame position.

The software is responsible for managing the pipeline assignment and setting up the video port timing generators properly in order to avoid any resource conflicts that may cause the DSS to lock up (sync loss).

#### 12.9.1.4.1.9.2 DISPC Overlay Mechanism

The overlay mechanism consists of displaying more than one layer (VID and/or VIDL1 pipeline layers) using:

- A priority rule based on the display Z-order (selected by configuring the overlay input selector, as described in [Section 12.9.1.4.1.9.1](#))
- Transparency color keys configuration (destination and source transparency)
- Alpha blending values (using the alpha component of each pixel or a global alpha value set by the user)
- Size and position attributes of the source window data, as described in [Section 12.9.1.4.1.9.1](#)

The overlay manager is configured using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order to the window on the screen. If the Z-order value of window A is lower than the Z-order to layer B, then layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see [Section 12.9.1.4.1.9.2.1, Overlay Alpha Blender](#), and [Section 12.9.1.4.1.9.2.2, Overlay Transparency Color Keys](#)).

Figure 12-532 gives an example of how input pipeline frame outputs are merged together to generate the final display output.

dispc-019

**Figure 12-532. DISPC Overlay Example and Display Attributes**

As shown in Figure 12-532, each input pipeline generates one rectangular sub-frame output in ARGB48 format. The overlay is responsible for positioning the sub-frame in the display output frame (specified by [DSS\\_VP1\\_SIZE\\_SCREEN](#)[11-0] PPL and [27-16] LPP video port register fields), using the overlay window position parameters (specified by [DSS\\_OVR1\\_ATTRIBUTES\\_0](#) / [DSS\\_OVR1\\_ATTRIBUTES\\_1](#) [17-6] POSX and [30-19] POSY overlay register fields), and the window size parameters (specified by [DSS\\_VID\\_SIZE](#)[11-0] SIZEX and [27-16] SIZEY pipeline register fields). When the overlay manager does not require the input pipeline data (either because it is currently outputting the background color pixel or it is being stalled by the VP output module), the overlay manager stalls the input pipeline.

When there are no video-encoded pixels at a specific position, the programmable solid background color appears. The solid background color is set in the [DSS\\_OVR1\\_DEFAULT\\_COLOR](#) and [DSS\\_OVR1\\_DEFAULT\\_COLOR2](#) registers.

The entire pixels of the video window have to be inside the display screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width must be adjusted by software to limit the right edge of the window inside the display screen. The same is also true for the video layer height in the input pipe line configuration.

### 12.9.1.4.1.9.2.1 Overlay Alpha Blender

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format (alpha in the source pixel data is converted to 8-bit alpha value in the input pipeline logic):
  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see [Table 12-469](#)).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see [Table 12-469](#)).
  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF, and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value can be set in the [DSS\\_VID\\_GLOBAL\\_ALPHA](#) register of the input pipeline, and is updated in synch with the selected output channel.
- The modulated alpha blending value (that is, a total alpha blending value, when a combination of the pixel alpha blending value A and a global alpha blending are present) is determined as:  $\text{Alpha} = (\text{Pixel Alpha} \times \text{Global Alpha}) / 256$ .

[Table 12-469](#) shows the remapping and the percentage of alpha blending achieved.

**Table 12-469. DISPC Overlay Alpha Blending – ARGB**

Alpha Blending 1-Bit Value (ARGB16-1555)	Alpha Blending 4-Bit Value (ARGB16-4444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x0	0x00	100% (transparent)
N/A	0x1	0x11	93.33%
N/A	0x2	0x22	86.6%
N/A	...	...	...
N/A	0xE	0xEE	6.6%
0x1	0xF	0xFF	0% (opaque)

### Premultiplied Alpha

The image ARGB may have its RGB component already premultiplied with the alpha (AR'G'B') where:

- $R' = A * R$
- $G' = A * G$
- $B' = A * B$

In that case, the processing is as follows:

- Color components of premultiplied layers are multiplied with the global alpha, if global alpha is not equal to 0.
- Color components of the composed underlying layer are multiplied with  $(1 - A * \text{global alpha})$ .

The additional premultiplied alpha option is accessible through the [DSS\\_VID\\_ATTRIBUTES](#) [28] PREMULTIPLYALPHA register bit of the input pipeline. The following settings are available:

- PREMULTIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the overlay manager.
- PREMULTIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

### Note

There is no alpha blending between the background and the next layer (layer-0) above it.

Layer-0 cannot be pre-multiplied, if the overlay output is driving the display, since that layer (or the background color) defines the bottom most layer. In this case, layer-0 alpha is 1 always.

#### 12.9.1.4.1.9.2.2 Overlay Transparency Color Keys

The overlay manager supports two color transparency modes - source and destination. These modes cannot be active at the same time.

The source transparency is tied to the top most layer, so the layer to have this transparency applied to has to be mapped to the highest z-ordered input (layer-1) of the overlay manager. The destination transparency is tied to the bottom most layer, so the layer to have this transparency applied to has to be mapped to the lowest z-ordered input (layer-0) of the overlay manager.

The source and destination transparencies are defined as following:

- Source color transparency: Top layer pixel that meets the source transparency color check is made transparent.
- Destination color transparency: Top layer pixel is made transparent, only if the bottom layer pixel does not meet the destination transparency color check.

The transparency color key is enabled via the [DSS\\_OVR1\\_CONFIG\[10\]](#) TCKLCDENABLE register bit.

The minimum transparency color values are specified in the TRANSCOLORKEY field of the [DSS\\_OVR1\\_TRANS\\_COLOR\\_MIN](#) and [DSS\\_OVR1\\_TRANS\\_COLOR\\_MIN2](#) registers.

The maximum transparency color values are specified in the TRANSCOLORKEY field of the [DSS\\_OVR1\\_TRANS\\_COLOR\\_MAX](#) and [DSS\\_OVR1\\_TRANS\\_COLOR\\_MAX2](#) registers.

The transparency color key values defined in the registers are compared with the pixel values. If each color component (R, G, and B) is in the range defined by MIN and MAX, then there is a match. If at least one of the color component is not in the range, then there is no match.

##### • Source transparency color key

The values of the source transparency color key define the range of encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value inside the valid range are not visible, and the encoded pixel values of the under layers or solid background color are visible.

The source transparency color key can be used with YUV and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care, since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison, in case the original format is YUV.

The scaler can be enabled as a preprocessor in the video pipelines. The pixel scaling processing can be considered in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the [DSS\\_OVR1\\_CONFIG\[11\]](#) TCKLCDSELECTION register bit to 0x1.

[Figure 12-533](#) shows an example of source transparency color key usage. The pixels with the transparency color key are not displayed. Instead, pixels of the resulting layer underneath are shown.

**Figure 12-533. DISPC Overlay Source Transparency Color Key Example**

- **Destination transparency color key**

The destination transparency color key values define the range of the encoded pixels in layer-0 (bottom layer), which are not going to be displayed. That is, the encoded pixel values matching the destination color key value range are pixels not visible on the screen. Pixels at the same position in the layers above layer-0 are visible. The destination transparency color key is applicable in the layer in the background only when there is an overlap between the layer in background position and the layer just above it, otherwise, the destination transparency color key is ignored. See [Section 12.9.1.4.1.9.2, DISPC Overlay Mechanism](#), for details on layer position depending on the Z-order parameter.

The destination transparency color key can be used only with RGB formats (ARGB, RGB, xRGB, RGBA, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison in case the original format is YUV.

The scaler can be enabled as a preprocessor in the pipelines. The pixel scaling processing must be considered in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the [DSS\\_OVR1\\_CONFIG\[11\]](#) TCKLCDSELECTION register bit to 0x0.

[Figure 12-534](#) shows an example of the destination color key usage. The pixels from layer-0 (bottom layer) equal to the transparency color key are not displayed and are replaced by the pixels from layer-1 (top layer). All other layer-0 pixels, different from the transparency color key, are displayed over layer-1.

**Figure 12-534. DISPC Overlay Destination Transparency Color Key Example**

#### 12.9.1.4.1.9.3 Overlay 3D Support

In order to support S3D (Stereoscopic 3D) by combining in hardware left and right frames into the same output frame, the following configurations (defined by HDMI 1.4b standard specification) can be used:

- Separate pipeline mode: Left/Right or Top/Bottom. One layer is used for left/top and another layer is used for right/bottom.

#### 12.9.1.4.1.9.4 Overlay Color Bar Insertion

Each overlay manager supports a simple internal color bar insertion in each display output path to enable testing of display output interface without using the frame buffer data from the memory.

The colors are: White, Yellow, Cyan, Green, Magenta, Red, Blue, Black, as shown in below. These make three primary colors, three secondary colors, white, and black.

**Figure 12-535. DISPC Overlay Internal Color Bar**

When the [DSS\\_OVR1\\_CONFIG](#) [1] COLORBAREN register bit is set to 1, the overlay output data is replaced by the predefined ARGB48 color bar data.

When color bar mode is used, the color space conversion matrix should be appropriately programmed, so that it can convert the full-range RGB to the desired color format.

**Table 12-470. DISPC Overlay Color Bar Table**

Color	G	B	R
White	0xFFFF	0xFFFF	0xFFFF
Yellow	0xFFFF	0	0xFFFF
Cyan	0xFFFF	0xFFFF	0
Green	0xFFFF	0	0
Magenta	0	0xFFFF	0xFFFF
Red	0	0	0xFFFF
Blue	0	0xFFFF	0
Black	0	0	0

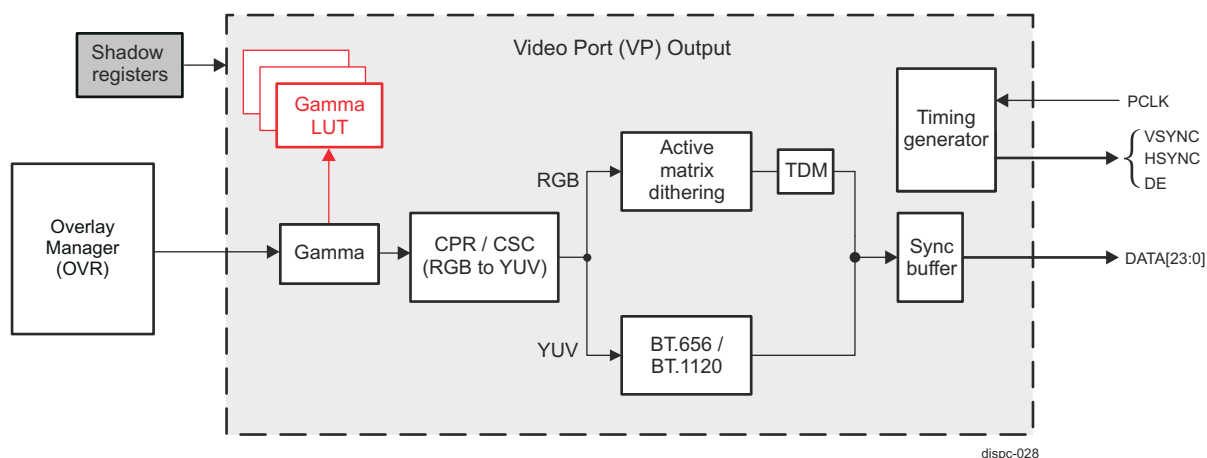

#### 12.9.1.4.1.10 DISPC Video Port Outputs

DISPC implements two identical Video Port (VP) outputs:

- VP1 processes data received from Overlay Manager 1 (OVR1)
- VP2 processes data received from Overlay Manager 2 (OVR2)

A VP output path consists of several processing blocks (see [Figure 12-536](#)):

- Gamma correction unit
- Color phase rotation (CPR) unit, also used for RGB to YUV color space conversion (CSC)
- Active matrix dithering with TDM (multiple cycle output format)
- BT.656/BT.1120
- Timing generator
- Async buffer

**Figure 12-536. DISPC VP Output Architecture**

The Color Space Conversion (CSC) processing can be configured to occur either before or after the gamma correction in the VP output module via the [DSS\\_VP1\\_CONFIG](#) [26] COLORCONVPOS register bit. For RGB to YUV color space conversion, the conversion must be done after the gamma correction. For other RGB output applications, the conversion must be done before the final gamma correction.

#### Note

The DISPC video port (VP) outputs, VP1 and VP2, will be commonly referred to as *video port (VP)* in the following sections.

#### 12.9.1.4.1.10.1 DISPC VP Gamma Correction Unit

The VP supports a look up table to perform the gamma correction on the display output. The look up table consists of 3 separate 256x8-bit memories, which are indexed by R/G/B component data.

When performing gamma correction, the selected encoded pixel values from the video pipeline path are sent by the overlay manager to the gamma curve table. Each R/G/B component of the encoded pixel value is used as a pointer to index 1 out of 256 x 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to R, G, or B component. The table is loaded by software via the [DSS\\_VP1\\_GAMMA\\_TABLE\\_0](#) through [DSS\\_VP1\\_GAMMA\\_TABLE\\_15](#) registers. It is possible to load only part of the table. For each access to the table, the 24-bit value is associated with index in the table by concatenating the 24-bit value (LSB of 32-bit access) and the 8-bit index value (MSB of the 32-bit access).

The sequence to load the gamma table is:

1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in linear increment burst mode, into the 64-byte region starting at [DSS\\_VP1\\_GAMMA\\_TABLE\\_0](#) register address. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table.
2. Loop to step #1, if there is a new access to the gamma table register. The software can access other registers between two accesses to the gamma table register.

Software needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the gamma table is activated by setting [DSS\\_VP1\\_CONFIG](#) [2] GAMMAENABLE register bit.

[Figure 12-537](#) describes the format of one of the gamma curve values in the memory.

**Figure 12-537. DISPC VP Output Gamma Table Write Data Format**

#### 12.9.1.4.1.10.2 DISPC VP Color Phase Rotation Unit

If required, a color phase rotation (CPR) processing can be applied on the "gamma" data before the spatial/temporal dithering.

The CPR can be selected to correct the non-pure white backlight of the display panel by using a programmable matrix to convert the 36-bit RGB pixel value into a new 36-bit RGB pixel value. The matrix is programmed through a set of nine 11-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is enabled by setting the [DSS\\_VP1\\_CONFIG](#) [15] CPR bit to 0x1.

The CPR processing is expressed by the equation shown in [Figure 12-538](#). [Table 12-471](#) lists all coefficients with their respective register bitfields for settings.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_r & R_g & R_b \\ G_r & G_g & G_b \\ B_r & B_g & B_b \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dispc-023

<a href="#">DSS_VID_CSC_COEF7</a> [31-19] POSTOFFSET3	-	B offset

#### 12.9.1.4.1.10.3 DISPC VP Color Space Conversion - RGB to YUV

The RGB to YUV color space conversion (CSC) in the video port is done by using the same programmable logic used for CPR. If CPR is also required, then the process can be combined with the CSC processing by adjusting matrix coefficients. [Table 12-471](#) lists the associated coefficients with their respective register bit-fields. The CSC processing is enabled by setting the [DSS\\_VP1\\_CONFIG](#) [24] COLORCONVENABLE register bit.

The color space conversion can be selected in order to convert from 36-bit RGB to YUV444. The conversion matrix is programmed through a set of nine 11-bit signed coefficients. The result is clipped to [256:3760] for the luminance and [256:3840] for the chrominance, when a full-range YUV output is not desired (equivalent to clipping to [16..235] and [16..240] in 8-bit video). In this case the [DSS\\_VP1\\_CONFIG](#) [25] FULLRANGE register bit must be set to 0x0.

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-098

**Figure 12-539. DISPC VP CSC RGB to YUV Matrix (FULLRANGE=0)**

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], then the values Y, Cb, and Cr are clipped to the range [0:4095]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full-range (when [DSS\\_VP1\\_CONFIG](#) [25] FULLRANGE = 0x1).

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-099

**Figure 12-540. DISPC VP CSC RGB to YUV Matrix (FULLRANGE=1)**

In order to provide YUV422 data to the BT.656 or BT.1120 blocks, the YUV444 format is further converted to YUV422 by sub-sampling the chrominance values. The hardware does this by averaging two-by-two the

chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion in the VP is enabled.

#### 12.9.1.4.1.10.4 DISPC VP BT.656 and BT.1120 Modes

Each VP output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for a VP output is done by setting [DSS\\_VP1\\_CONFIG](#) [20] BT656ENABLE or [21] BT1120ENABLE register bit, respectively

#### Note

It is not possible to enable BT.656 and BT.1120 mode simultaneously on the same output.

[Figure 12-541](#) shows signal mapping on video port DATA[23:0] output data bus. Bits 9 to 0 are dedicated for BT.656 mode (10-bit). In BT.656 mode however, for compatibility with existing 8-bit interfaces, the two LSBs are ignored and only bits [9-2] are effectively used.

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.656									

**Figure 12-541. DISPC VP Data Mapping for BT.656 Mode**

[Figure 12-542](#) shows signal mapping on video port DATA[23:0] output data bus for BT.1120 mode. Bits [19-10] (CbCr) and [9-0] (Y) are used in 20-bit mode. Bits [19-12] (CbCr) and [9-2] (Y) are used in 16-bit mode (YCbCr422).

**Figure 12-542. DISPC VP Data Mapping for BT.1120 Mode**

VP outputs support both interlace and progressive content in BT.656/BT.1120 modes. For more information on timings configuration, see [Section 12.9.1.4.1.10.7, DISPC VP Timing Generator and Display Panel Settings](#).

#### Note

In progressive BT.656/BT.1120 mode the maximum output resolution will be limited, as it requires two pixel clock cycles to send out one pixel.

#### 12.9.1.4.1.10.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the

blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY...). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

The sequence in the BLANKING region of the data stream is therefore: 80h, 10h, 80h, 10h.....80h, 10h

For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see [Section 12.9.1.4.1.10.7](#), *DISPC VP Timing Generator and Display Panel Settings*.

#### 12.9.1.4.1.10.4.2 DISPC BT Mode EAV and SAV

The End of Active Video (EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes ( FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in [Figure 12-543](#), with the function of each bit described in [Table 12-472](#).

MSB				LSB			
1	F	V	H	P3	P2	P1	P0

**Figure 12-543. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes**

**Table 12-472. DISPC BT Mode Bit Function**

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V, and H. This dependency is shown in [Table 12-473](#).

**Table 12-473. DISPC BT Mode Status of Protection Bits in Function of F, V, and H**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0

**Table 12-473. DISPC BT Mode Status of Protection Bits in Function of F, V, and H (continued)**

F	V	H	P3	P2	P1	P0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

#### 12.9.1.4.1.10.5 DISPC VP Spatial/Temporal Dithering

The active spatial/temporal dithering logic can be enabled to minimize the color banding when displaying the data on an LCD panel with color depth lower than 24-bit. The dithering logic is integrated after the color/gamma conversion blocks and before the TDM (Time Division Multiplexed) block. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control (the value of removed bits and the frame number). The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the [DSS\\_VP1\\_CONTROL\[31-30\]](#) SPATIALTEMPORALDITHERINGFRAMES register field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, both spatial and temporal processing are applied to the pixels. The number of frame is initialized before enabling the spatial/temporal dithering logic. It must be never changed by the software while the spatial/temporal logic is enabled. The spatial/temporal dithering logic is enabled by setting the [DSS\\_VP1\\_CONTROL\[7\]](#) STDITHERENABLE bit to 0x1.

#### Note

- If the interface data bus is smaller than the pixel format size and spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, then by programming the pixel components replication active/inactive the MSB is replicated to the LSB of the interface data bus.

#### 12.9.1.4.1.10.6 DISPC VP Multiple Cycle Output Format (TDM)

The pixels (only RGB components) after the active matrix dithering unit are formatted on one or multiple cycles (from 1 to 3 cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is selected through the [DSS\\_VP1\\_CONTROL\[24-23\]](#) TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the [DSS\\_VP1\\_DATA\\_CYCLE\\_0](#) register for the first cycle, the [DSS\\_VP1\\_DATA\\_CYCLE\\_1](#) register for the second cycle, and the [DSS\\_VP1\\_DATA\\_CYCLE\\_2](#) register for the third cycle. The output interface data bus width, when TDM mode is enabled ([DSS\\_VP1\\_CONTROL\[20\]](#) TDMENABLE register bit = 1), can be 8, 9, 12, or 16 bits, configurable through the [DSS\\_VP1\\_CONTROL\[22-21\]](#) TDMPARALLELMODE register field.

When the TDM is disabled ([DSS\\_VP1\\_CONTROL\[20\]](#) TDMENABLE = 0), the video port output interface data bus width is configured through the [DSS\\_VP1\\_CONTROL\[10-8\]](#) DATALINES register field.

When using TDM mode, only up to 24 bits per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

[Figure 12-544](#) through [Figure 12-547](#) show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

**Figure 12-547. DISPC VP TDM 16-Bit Interface Settings**

#### 12.9.1.4.1.10.7 DISPC VP Timing Generator and Display Panel Settings

Each video port output has a dedicated timing generator supporting progressive and interlaced mode. It is clocked using the pixel clock and is configured to generate the video data and sync signals to match the desired video display standard timings.

Two-level configuration for enabling the video ports exists:

- Via the individual [DSS\\_VP1\\_CONTROL\[0\] ENABLE](#) register bit for each VP. It allows each VP to be independently controlled by two different hosts.
- Via the common [DSS\\_COMMON\\_DISPC\\_GLOBAL\\_OUTPUT\\_ENABLE\[2-0\] VP\\_ENABLE](#) register field. It allows two or more VP timing generators to be in sync by enabling them simultaneously with a single register write.

Both ENABLE and VP\_ENABLE register fields must be set in order for a VP (timing generator) to start.

Figure 12-548 shows the timing generator display parameters.

**Figure 12-548. DISPC VP Display Timing Parameters**

The width of VP output data bus is configured in the [DSS\\_VP1\\_CONTROL\[10-8\] DATALINES](#) register field, when TDM feature is disabled. When TDM is enabled, the width of the output data bus is defined according to [Section 12.9.1.4.1.10.6, DISPC VP Multiple Cycle Output Format \(TDM\)](#).

The size of the display panel is defined by:

- Number of lines per frame, [DSS\\_VP1\\_SIZE\\_SCREEN\[27-16\] LPP](#) bit field, with a value from 1 to 4096
- Number of pixels per line, [DSS\\_VP1\\_SIZE\\_SCREEN\[11-0\] PPL](#) bit field, with a value from 1 to 4096

Standard HSYNC/VSYSNC timing generation is programmable as follows:

- Horizontal front porch is set in the [DSS\\_VP1\\_TIMING\\_H\[19-8\] HFP](#) bit field.
- Horizontal back porch is set in the [DSS\\_VP1\\_TIMING\\_H\[31-20\] HBP](#) bit field.
- Horizontal synchronization pulse width is set in the [DSS\\_VP1\\_TIMING\\_H\[7-0\] HSW](#) bit field.
- Vertical front porch is set in the [DSS\\_VP1\\_TIMING\\_V\[19-8\] VFP](#) bit field.
- Vertical back porch is set in the [DSS\\_VP1\\_TIMING\\_V\[31-20\] VBP](#) bit field.
- Vertical synchronization pulse width is set in the [DSS\\_VP1\\_TIMING\\_V\[7-0\] VSW](#) bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the [DSS\\_VP1\\_TIMING\\_H](#) and [DSS\\_VP1\\_TIMING\\_V](#) registers:

- Progressive mode:
  - Horizontal blanking (12 bits) is set in the {[DSS\\_VP1\\_TIMING\\_V\[3-0\] VSW](#), [DSS\\_VP1\\_TIMING\\_H\[7-0\] HSW](#)} register fields (up to 2048 bytes of horizontal blanking supported).

- Vertical frame blanking No 1 is set in the [DSS\\_VP1\\_TIMING\\_V\[19-8\]](#) VFP bit field.
- Vertical frame blanking No 2 is set in the [DSS\\_VP1\\_TIMING\\_V\[31-20\]](#) VBP bit field.
- Number of lines per frame is set in the [DSS\\_VP1\\_SIZE\\_SCREEN\[27-16\]](#) LPP bit field.
- Number of pixels per line is set in the [DSS\\_VP1\\_SIZE\\_SCREEN\[11-0\]](#) PPL bit field.
- Interlaced mode:
  - Horizontal blanking (12 bits) is set in the {[DSS\\_VP1\\_TIMING\\_V\[3-0\]](#) VSW, [DSS\\_VP1\\_TIMING\\_H\[7-0\]](#) HSW} register fields (up to 2048 bytes of horizontal blanking supported).
  - Vertical field blanking No.1 for Even Field is set in the [DSS\\_VP1\\_TIMING\\_H\[19-8\]](#) HFP bit field.
  - Vertical field blanking No.2 for Even Field is set in the [DSS\\_VP1\\_TIMING\\_H\[31-20\]](#) HBP bit field.
  - Vertical field blanking No.1 for Odd Field is set in the [DSS\\_VP1\\_TIMING\\_V\[19-8\]](#) VFP bit field.
  - Vertical field blanking No.2 for Odd Field is set in the [DSS\\_VP1\\_TIMING\\_V\[31-20\]](#) VBP bit field.
  - Number of lines per field (even) is set in the [DSS\\_VP1\\_SIZE\\_SCREEN\[27-16\]](#) LPP bit field.
  - Delta number of odd field compared to even field (in a single line) is set in the [DSS\\_VP1\\_SIZE\\_SCREEN\[15-14\]](#) DELTA\_LPP bit field. The DELTA\_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field must be set to zero for YUV420 format.
  - Number of pixels per line is set in the [DSS\\_VP1\\_SIZE\\_SCREEN\[11-0\]](#) PPL bit field.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the [DSS\\_VP1\\_POL\\_FREQ\[12\]](#) IVS, [13] IHS, and [15] IEO register bits. These signals can be gated by setting the [DSS\\_VP1\\_CONFIG \[7\]](#) VSYNCGATED and [6] HSYNCGATED register bits. In addition, the alignment between VSYNC and HSYNC signals can be programmed via the [DSS\\_VP1\\_POL\\_FREQ\[18\]](#) ALIGN register bit.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the [DSS\\_VP1\\_POL\\_FREQ\[14\]](#) IPC register bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the [DSS\\_VP1\\_POL\\_FREQ\[16\]](#) RF bit.

#### Note

To set the pixel clock, CTRL\_MMR\_DPIO\_CLK\_CTRL[8] DPIO\_CLK\_CTRL\_DATA\_CLK\_INVDIS setting should always be opposite the [DSS\\_VP1\\_POL\\_FREQ\[14\]](#) IPC setting, and CTRL\_MMR\_DPIO\_CLK\_CTRL[9] DPIO\_CLK\_CTRL\_SYNC\_CLK\_INVDIS setting should always be opposite the [DSS\\_VP1\\_POL\\_FREQ\[16\]](#) RF setting.

For example, if CTRL\_MMR\_DPIO\_CLK\_CTRL[8] DPIO\_CLK\_CTRL\_DATA\_CLK\_INVDIS is set to 0, [DSS\\_VP1\\_POL\\_FREQ\[14\]](#) IPC should be set to 1.

Each VP output can be configured in progressive output mode or interlaced output mode. The selection is done by writing into the bit-field [DSS\\_VP1\\_CONFIG \[22\]](#) OUTPUTMODEENABLE register bit. The default setting is for progressive mode. The selection can be changed only when the corresponding VP output is disabled. The configuration is independent for each VP output. It is possible to change the configuration of one of the VP outputs while the other VP is enabled.

The pixel clock for each VP output can be gated by setting the [DSS\\_VP1\\_CONFIG \[5\]](#) PIXELCLOCKGATED register bit.

The hold time of the pixels on the data bus is determined in clock cycles by the [DSS\\_VP1\\_CONTROL\[16-14\]](#) HT register field.

#### 12.9.1.4.1.11 DISPC Safety Features

For safety critical system applications, DSS supports the following safety features in hardware:

- Data correctness check: To verify intended data is shown correctly on the display.
- Freeze frame detection: To notify a possible frame freeze, when there is no change in the display frame over multiple frame periods.

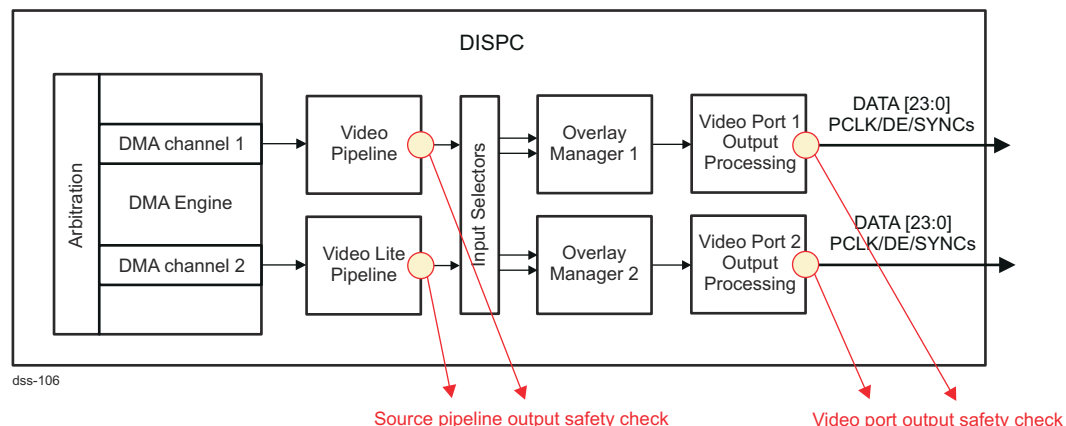

These features are implemented by collecting signatures from user-defined regions within each pipeline output frame and the final display output frame, and comparing them to reference signatures provided by the user

(software) and/or to previously saved signatures. The signature from each region is generated by using a MISR (Multiple Input Signature Register) module.

#### 12.9.1.4.1.11.1 Safety Check Regions

DSS supports the following safety check regions to implement the safety features:

- Video pipelines: One safety check region at the output of each video pipeline.
- Video port outputs: Up to four sub-regions within the active video output area of the final display output of each video port.

**Figure 12-549. DISPC Safety Check Regions**

Table 12-474 lists the parameters supported by each of the safety check regions, together with the associated register control fields.

**Table 12-474. DISPC Safety Check Regions Parameters**

Safety Region Parameter	Video Pipeline Control Register	Video Port Sub-region 0 Control Register	Video Port Sub-region 1 Control Register	Video Port Sub-region 2 Control Register	Video Port Sub-region 3 Control Register
X position	DSS_VID_SAFETY_POSITION[11-0] POSX	DSS_VP1_SAFETY_POSITION_0[11-0] POSX	DSS_VP1_SAFETY_POSITION_1[11-0] POSX	DSS_VP1_SAFETY_POSITION_2[11-0] POSX	DSS_VP1_SAFETY_POSITION_3[11-0] POSX
Y position	DSS_VID_SAFETY_POSITION[27-16] POSY	DSS_VP1_SAFETY_POSITION_0[27-16] POSY	DSS_VP1_SAFETY_POSITION_1[27-16] POSY	DSS_VP1_SAFETY_POSITION_2[27-16] POSY	DSS_VP1_SAFETY_POSITION_3[27-16] POSY

Figure 12-550 shows examples of one safety region in the video pipeline output stage and up to 4 possible regions in the final video port output stage.

dss-107

**Figure 12-550. DISPC Safety Check Region Examples**

The safety region in the video pipeline captures data only if the embedded alpha data is not equal to 0 (that is, non-transparent pixels). The safety regions in the display video port output captures all active video pixels within the region boundary. The (up to four) regions in the display output should be typically non-overlapping areas of the screen, but the hardware does not restrict them to be non-overlapping.

Figure 12-551 shows the locations within DISPC data path where the data is analyzed.

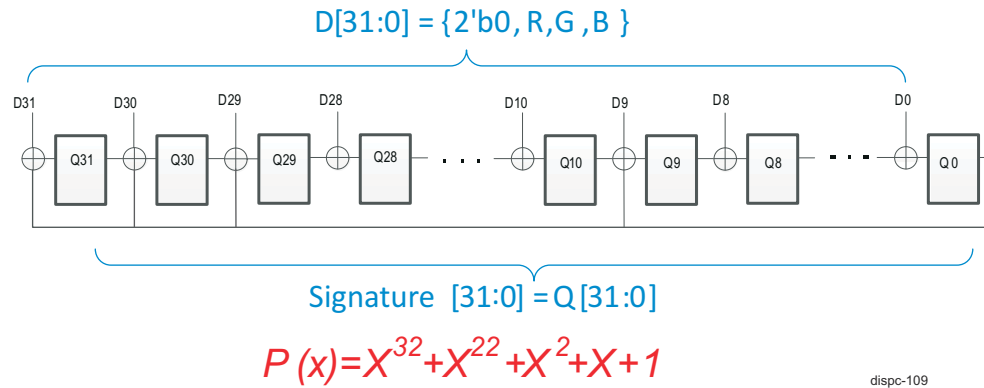

**Figure 12-551. DISPC Safety Check Locations**

#### 12.9.1.4.1.11.2 Safety Signature Generator Using MISR

A 32-bit multiple input signature register (MISR) with 32-bit Galois LFSR polynomial,  $P(x)=X^{32}+X^{22}+X^2+X+1$ , is used to capture a signature of active video pixel data (the 10 MSB bits of each color component) for each safety region, as shown in Figure 12-552 and the algorithm below it.

**Figure 12-552. DISPC Safety 32-bit MISR Implementation**

The MISR (32-bit Galois LFSR based) signature generation algorithm is as follows:

Tap\_polynomial = 32'hE000\_0200

lfsr\_q = seed // initial LFSR value - any non zero value should work

For each (pixel data in the safety region) {

data\_in[31:0] = { 2'b0, r,g,b } // 10 MSB bits of R,G,B components

lfsr\_d = (data\_in(lfsr\_q >> 1))

If (lfsr\_q[0]) lfsr\_d = lfsr\_d<sup>Tap\_polynomial</sup>

lfsr\_q = lfsr\_d

}

signature = lfsr\_q

All MISRs are initialized at the beginning of each frame with a non-zero "seed" value either with the default constant value (0xFFFF\_FFFF) or with the programmable seed configuration value in SAFETY\_LFSR\_SEED register for each group of regions (refer to Table 12-474, *DISPC Safety Check Regions Parameters*). Note that a same seed must be used to compare signatures between two frames. If different than the default seed value is desired, then a SEEDSELECT parameter must be set before the corresponding SAFETY\_LFSR\_SEED register is configured with the customer seed value.

All captured signatures from safety regions are memory mapped to read-only registers SAFETY\_CAPT\_SIGNATURE for each video port (refer to Table 12-474, *DISPC Safety Check Regions Parameters*). A SAFETY\_CAPT\_SIGNATURE register is updated with the signature from each sub-region at the end of every frame. This register returns the signature of the last frame data when the MISR is enabled. When MISR is disabled, this register is cleared.

The MISR aliasing (faulty signature matches fault-free signature) probability is:

$$(2^{(L-n)}-1)/(2^L-1) \approx 2^{(L-n)}/2^L = 2^{-n} \text{ for large } L, \text{ where}$$

n = length of signature register

L = length of input sequence

Using the above approximation, the result is:

n=4, aliasing probability = 6.25%

n=16, aliasing probability = 0.0015%

...

n=32 (as in DISPC MISR), aliasing probability is  $\sim 2^{-32}$  (negligible)

#### 12.9.1.4.1.11.3 Safety Checks

If the data correctness check is enabled (see [Table 12-474, DISPC Safety Check Regions Parameters](#)):

- When a new signature is generated, it is compared against the reference signature provided by the software. A SAFETY\_REF\_SIGNATURE register must be configured with a reference signature data, see [Table 12-474, DISPC Safety Check Regions Parameters](#).
- If signatures do not match, an interrupt event is generated to indicate data mismatch.

If the freeze frame detection is enabled (see [Table 12-474, DISPC Safety Check Regions Parameters](#)):

- When a new signature is generated, it is first compared against the saved signature (from previous frame).
- If signatures match, an internal counter used to keep track of the number of frames with no data change (for the region) is incremented.
- If signatures do not match, the counter is cleared.
- If the counter value is greater than the user programmed freeze frame detection threshold value (see [Table 12-474, DISPC Safety Check Regions Parameters](#)), an interrupt event (VIDSAFETYREGION\_IRQ or VPSAFETYREGION\_IRQ, see [Section 12.9.1.4.1.5, DISPC Interrupt Requests](#)) is generated to indicate a possible freeze frame detection. The threshold value must be configured with the maximum number of identical successive frames allowed before an interrupt is generated.
- After the comparison, the signature is saved as the previous signature.
- The counter is cleared when the interrupt event is generated or when freeze frame detection check is disabled.

This frame freeze is different from the display frozen due to pipeline lock up. In that case, the DISPC will generate an SYNCLOST\_IRQ and/or DMA VIDBUFFERUNDERFLOW\_IRQ interrupt. The freeze frame detection is for source data frozen while the DSS is working normally.

The two safety checks are continuously performed over multiple frames as long as their mode enable register bits are set.

#### 12.9.1.4.1.11.4 Safety Check Limitations

The safety check will only be available when the DISPC is outputting RGB/YUV component data with separate sync signals. The safety functions are not available for following modes:

- YUV422 embedded sync modes (BT.656 and BT.1120)
- RGB TDM (Time Division Multiplex) mode

#### 12.9.1.4.1.12 DISPC Security Management

##### 12.9.1.4.1.12.1 Security Implementation

DSS supports the following security features:

- Secure mode configuration
- Illegal connection prevention

#### Secure Mode

DISPC supports a secure mode configuration register ([DSS\\_COMMON1\\_DISPC\\_SECURE](#)) which defines the "secure mode: attribute of each pipeline, overlay manager, and video port instance in DISPC. This register can only be modified by a host with an appropriate secure privilege (MReqSecure=1). When the secure bit corresponding to an instance is set by a secure host, the instance is deemed to be in "secure mode" and the DISPC hardware prevents the output of the instance getting connected to a non-secure downstream module. Also, any DMA transfer initiated by a secure pipeline will have its OCP in-band signal MReqSecure set to HIGH to indicate that is a secure mode transaction request.

By default, all pipelines, overlay managers, and video port instances are in a "non-secure mode". The `DSS_COMMON1_DISPC_SECURE` register bits are active, only when the `DSS_COMMON1_DISPC_SECURE_DISABLE[0]` SECURE\_DISABLE register bit is configured properly to 0x0. When the SECURE\_DISABLE bit is set to 0x1, the `DSS_COMMON1_DISPC_SECURE` register bits are non-active and DISPC will behave as non-secure module.

### Illegal Connection Prevention

DISPC hardware enforces the following rules to prevent an illegal connection:

- Secure input pipeline can only connect to a secure overlay manager: If any host (secure or non-secure) configures an overlay manager input selection to connect a secure input pipeline to a non-secure overlay manager, then the DISPC hardware will block the connection and issue a "security violation" interrupt (SECURITYVIOLATION\_IRQ) to alert the host.

Figure 12-553. DISPC Secure Bit Setting and Illegal Connection Block

#### 12.9.1.4.1.12.2 Secure Mode Configuration

The secure bit of `DSS_COMMON1_DISPC_SECURE` register is set/reset by a secure transaction. When the secure bit has been set, the software in "secure mode" is responsible for checking the DISPC configuration. The secure bit is propagated by DISPC to the system Interconnect in order to qualify all DISPC requests as secure or non-secure requests, based on the secure bits defined in the control register.

When DISPC accesses the frame buffer, in the case the secure bit has been reset and the frame buffer has been set secure, the display controller will receive an "error" in response of non-secure requests.

#### 12.9.1.4.1.13 DISPC Shadow Registers

Some DISPC registers are termed *shadow registers*. The shadow registers allow the software to modify them at any time, without direct effect on the DISPC hardware configuration. When all the values for a given configuration are written into the shadow registers, software must set only one register bit to validate the configuration. When the hardware reaches the end of the current frame and sees that the bit has been set by software, the new configuration is now the configuration used by the hardware.

The `DSS_VP1_CONTROL[5]` GOBIT bit enables the hardware to use the new configuration, for all shadow registers associated with each VP output.

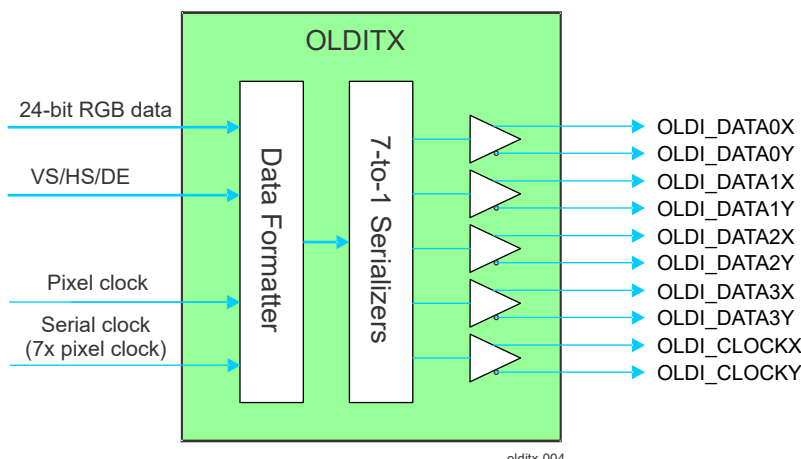

The registers are statically associated to a particular output (for example, timing registers) or dynamically associated to one output at a time (for example, video registers).

### 12.9.1.4.2 OLDITX Functional Description

#### 12.9.1.4.2.1 OLDITX Overview

The OpenLDI transmitter (OLDITX) supports serialized RGB pixel data transmission between host and flat panel display over LVDS (Low Voltage Differential Sampling) interface. The LVDS interface complies with ANSI/TIA/EIA644-A standard (Electrical Characteristics of Low Voltage Differential Signaling (LVDS) Interface Circuits). The OLDITX consists of 7-to-1 data serializers, and 4-data and 1-clock LVDS outputs. The OLDITX translates 21 or 28-bit wide video/sync data into LVDS data, 3 or 4 bits wide and 7 bits deep. At a maximum pixel rate of 170 MHz, the speed of a single LVDS data lane is 1.19 Gbps providing a total throughput of 4.76 Gbps over a single OLDI link.

Figure 12-554 shows the high level overview of the OLDITX module.

**Figure 12-554. OLDITX Block Diagram**

#### 12.9.1.4.2.2 OLDITX Clocks

OLDITX receives one pixel clock, OLDI\_FWD\_P\_CLK. The pixel clock rate is 1/7 of serial clock rate in single-link mode and 2/7 of serial clock rate in dual-link mode.

OLDITX receives one serial clock (OLDI\_PLL\_CLK) to perform 7-to-1 serialization. OLDI\_PLL\_CLK is 3.5x or 7x OLDI\_FWD\_P\_CLK frequency, where 25MHz < OLDI\_FWD\_P\_CLK (freq) < 170MHz.

For more details on OLDITX clocks, see *DSS Integration*.

#### 12.9.1.4.2.3 OLDITX Resets

There are two resets for the OLDITX module:

- Hardware reset, OLDITX\_RST.
- Software reset, OLDITX\_SW\_RST, driven by DSS0\_VP\_DSS\_OLDI\_CFG[12] SOFTRST register bit. The software reset is combined with OLDITX\_RST to drive the reset to all the sub-modules.

The reset status of OLDITX module can be read in DSS0\_COMMON\_DSS\_SYSSTATUS[5] OLDI\_RESETDONE register bit.

#### 12.9.1.4.2.4 OLDITX Input Interface

The input to the OLDITX is a standard DPI interface bus (direct output of a DSS DISPC video port), which consists of the following signals:

- VSync and HSync sync signals
- DE, data enable (active video signal)
- RGB[23:0] parallel data

OLDITX receives 18-bit or 24-bit RGB input source data from the DSS DISPC video port. The DSS interface is clocked on the rising edge of OLDI\_FWD\_P\_CLK pixel clock (whose frequency is exactly 1/7 of the

OLDI\_PLL\_CLK serial clock). The DATA, VS, HS, and DE signals are treated as data to be mapped onto the LVDS output shifter. The start of accepting and processing the DSS interface data happens after DSS0\_VP\_DSS\_OLDI\_CFG[0] ENABLE bit is asserted to 0x1 and synchronized to the internal pixel clock.

#### 12.9.1.4.2.4.1 OLDITX 24-bit RGB Input

The 24-bit RGB input source data (either non-dithered or dithered to 24-bit) coming from the DSS DISPC video port is expected to have the components mapping shown in [Table 12-475](#). The DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit must be set for 24-bit input.

**Table 12-475. OLDITX 24-bit RGB Input for 24-bit LVDS Output**

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R[7:0]								G[7:0]								B[7:0]							

Both 18-bit and 24-bit LVDS output mappings are supported with this 24-bit input format. For 18-bit LVDS output mapping however, the 6 MSB bits of each component are mapped to the output as shown in [Table 12-476](#). OLDITX does not support dithering to reduce 24-bit RGB input to 18-bit RGB LVDS output. If dithering is required, then DSS DISPC must perform the dithering and send the data to OLDITX as an 18-bit panel data as shown in [Section 12.9.1.4.2.4.2, OLDITX 18-bit RGB Input](#).

**Table 12-476. OLDITX 24-bit RGB Input for 18-bit LVDS Output**

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R[5:0]						Unused		G[5:0]						Unused		B[5:0]						Unused	

#### 12.9.1.4.2.4.2 OLDITX 18-bit RGB Input

The 18-bit RGB source data (typically dithered to 18-bit) coming from the DSS DISPC video port is expected to have the component mapping shown in [Table 12-477](#). The DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit must be set for 18-bit input. Only 18-bit LVDS output mapping is supported with this input type.

**Table 12-477. OLDITX 18-bit RGB Input**

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused						R[5:0]						G[5:0]						B[5:0]					

#### 12.9.1.4.2.5 OLDITX Output Mode Configuration

OLDITX0 and OLDITX1 support:

- Single link output mode: This is a single stream format for which up to four serial data lanes (four LVDS pairs) are used to transmit a video stream. An additional lane is used to transmit the pixelclock.
- 2x Single-link (duplication) output mode: This is a dual stream format for which up to four serial data lanes are used to transmit each video stream (8 total). An additional lane is used to transmit each pixel clock.
- Dual link output mode: This is a single stream format which up to eight serial data lanes are used to transmit a video stream. An additional two lanes are used to transmit the pixelclock.

A single OpenLDI interface is capable of driving up to WUXGA (1920x1200@60p, 162 MHz pixel clock) resolution, and can be used as long as the receiving display or link bridge device can accept the video output from the device through a single OLDI link. Typically, only display resolutions less than 1366x768 require a single link interface. Adding the second interface for dual-link operation does not increase available bandwidth, but decreases required pixel clock by half.

The sequence of bringing up OLDITX in single link mode is as follows:

1. Configure all PLLs that provide the required OLDITX clocks (see [Module Integration](#)).
2. Keep OLDITX\_SW\_RST in the default reset state 0 (controlled via DSS0\_VP\_DSS\_OLDI\_CFG[12] SOFTRST register bit).
3. Configure the following parameters:

- Input video data and pixel clock source, in DSS0\_VP\_DSS\_OLDI\_CFG[4] SRC register bit
  - OLDITX module enable, in DSS0\_VP\_DSS\_OLDI\_CFG[0] ENABLE register bit
  - DE input polarity, in DSS0\_VP\_DSS\_OLDI\_CFG[7] DEPOL register bit
  - Combining of links, in DSS0\_VP\_DSS\_OLDI\_CFG[11] DUALMODESYNC register bit:
    - Zero for single-link(s)
    - One for dual-link
  - Link mode, in DSS0\_VP\_DSS\_OLDI\_CFG[5] MODE register bit:
    - Zero for single stream
    - One for stream duplication
  - Mapping of video to LVDS channel (for single link mode), in DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP register field:
    - A, B, or C Types for single-link
    - D, E, or F Types for dual-link
  - Input data format (for 18-bit LVDS output), in DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit
  - Test pattern enable (must be 0 for normal operation), in DSS0\_VP\_DSS\_OLDI\_CFG[13] TPATCFG register bit
4. Software checks that the PLLs are stable and locked.
  5. Release OLDITX\_SW\_RST = 1 (by configuring DSS0\_VP\_DSS\_OLDI\_CFG[12] SOFTRST register bit).
  6. Software waits for DSS0\_COMMON\_DSS\_SYSSTATUS[5] OLDI\_RESETDONE register bit = 1.
  7. DSS sends RGB data.

Typically, OLDITX should be configured to send out 24-bit RGB data on four LVDS data lanes. But, it can also be configured (via DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP register field) to send only 18-bit RGB data (6-bits/component) on three LVDS lanes, when connecting to a low resolution monitor. In this configuration, only 4 LVDS pairs (3 data lanes + 1 clock lane) are active, while the 4th data lane is disabled. When OLDITX is configured to send out 18-bit LVDS-mapped data, then the DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit must be used to select the format of the input source data bus (for more information, see [Section 12.9.1.4.2.4, OLDITX Input Interface](#)).

#### Note

Software may change the mode of operation by first asserting low the OLDITX\_SW\_RST reset, then follow the sequence described in this section.

Software needs to ensure that OLDITX\_SW\_RST is asserted low, if the PLLs are not locked.

For more information on LVDS data format mapping and LVDS data output bit format, see [Section 12.9.1.2.2, DSS LVDS Interface](#).

#### 12.9.1.4.2.6 OLDITX Loopback Test Mode

OLDITX supports data loopback mode to check for DC faults in the digital (parallel to serial conversion logic) and analog (LVDS transmitter) data signal path.

In the loopback test mode, the sending module (DSS DISPC) drives all OLDITX input signals (data and sync) to either all 1s or 0s. All 1s and all 0s will be captured as a static 1 or 0 at the output of the LVDS loopback receiver (enabled only during the test mode). To ensure that there are no faults in the parallel to serial conversion logic path, a simple pattern check of 1s or 0s is performed on the serializer data and reported back along with the LVDS loopback value. These signals are then passed back to DSS and mapped to the DSS0\_VP\_DSS\_OLDI\_LB[9-0] LBRDATA register field for test software to read.

For loopback testing of the clock differential output signals, OLDITX drives all 0s or 1s pattern (based on the DSS0\_VP\_DSS\_OLDI\_CFG[10] LBDATA register bit configuration) instead of the normal clock pattern, when the loopback test is enabled.

Since there is no de-serializer in the loopback path, the loopback mode is intended for facilitating a system diagnostic testing with a constant data output (all 0s or 1s) at low-speed. In normal operation, the loopback mode must be disabled.

When loopback is enabled in DSS0\_VP\_DSS\_OLDI\_CFG[9] LBEN register bit, the loopback of data in this order from MSB to LSB {all\_0\_1[4:0], oldi\_ch\_ret\_clock, oldi\_ch\_ret\_data[3:0]} will be returned in DSS0\_VP\_DSS\_OLDI\_LB[9:0] LBRDATA register field.

### Verifying loopback

Set up OLDITX for a single mode and select the DSS input data. Configure the parameters as shown for either Case 1 or Case 2 below. Set DSS0\_VP\_DSS\_OLDI\_CFG[9] LBEN = 1 and enable OLDITX to start sending data. Check after 10 pixel clock periods.

Case 1, all 0's stuck-at test:

- DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP = 000
- DSS0\_VP\_DSS\_OLDI\_CFG[10] LBDATA = 0
- OLDI\_0\_DATA[23:0] = all 0's (this is input data from DSS)
- OLDI\_0\_HS, OLDI\_0\_VS, OLDI\_0\_DE = 0's (these are input signals from DSS)

Check:

- DSS0\_VP\_DSS\_OLDI\_LB[9-5] LBRDATA = 11111
- DSS0\_VP\_DSS\_OLDI\_LB[4-0] LBRDATA = 00000

Case 2, all 1's stuck-at test:

- DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP = 000
- DSS0\_VP\_DSS\_OLDI\_CFG[10] LBDATA = 1
- OLDI\_0\_DATA[23:0] = all 1s (this is input data from DSS)
- OLDI\_0\_HS, OLDI\_0\_VS, OLDI\_0\_DE = 1's (these are input signals from DSS)

Check:

- DSS0\_VP\_DSS\_OLDI\_LB[9-5] LBRDATA = 11111
- DSS0\_VP\_DSS\_OLDI\_LB[4-0] LBRDATA = 11111

Note that DSS0\_VP\_DSS\_OLDI\_LB[3] LBRDATA = 1. In functional operation, the LVDS A30:A36 in 18-bit single mode are not being driven by input data, rather all 0's. In loopback mode, each of A30:A36 is driven by OLDI\_0\_DE. In other single modes, the "reserved or NA" bit fields, as described in the LVDS data format mapping tables in [Section 12.9.1.2.2, DSS LVDS Interface](#), are driven by OLDI\_0\_DE in loopback mode.

## 12.9.2 MIPI Display Serial Interface (DSI) Controller

### 12.9.2.1 DSI Block Diagram

The MIPI DSI v1.3.1 Transmitter Controller (DSITX) provides an interface that receives data and control from the host processor display system using either the DPI or SDI input bus interfaces. The DSITX will translate the incoming pixel information and control signals into an internal packed byte format, in the case of DPI, or pass in the prepacked SDI byte format, before the internal byte format data is packetized and sent to the MIPI DSI Compatible display via the MIPI D-PHY physical interface. It supports video and command mode displays and can work in multi-display mode using virtual channel identification on the packets.

The DSITX controller provides two interfaces for connection to a display panel. Normal operation for a panel supporting DCS commands can be done using either SDI interface, or using the APB (Advanced Peripheral Bus) access to DIRECT\_CMD registers. Video streaming applications can only use the SDI or DPI interface. The DSI controller supports flow control using the SDI video interface.

The DSITX implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI specification v1.3. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes).

The DSITX controller block diagram is illustrated in [Figure 12-555](#).

Figure 12-555. DSITX Controller Block Architecture

### 12.9.2.2 DSI Clocking

The DSI receives all the clocks from DISPC or DPHY\_TX modules. There are no other dedicated PLLs. For more details on DSI clocks mapping at DSS and SoC level, see *DSI Integration*.

The DSI requires multiple clocks running asynchronously, that are shown in [Table 12-478](#).

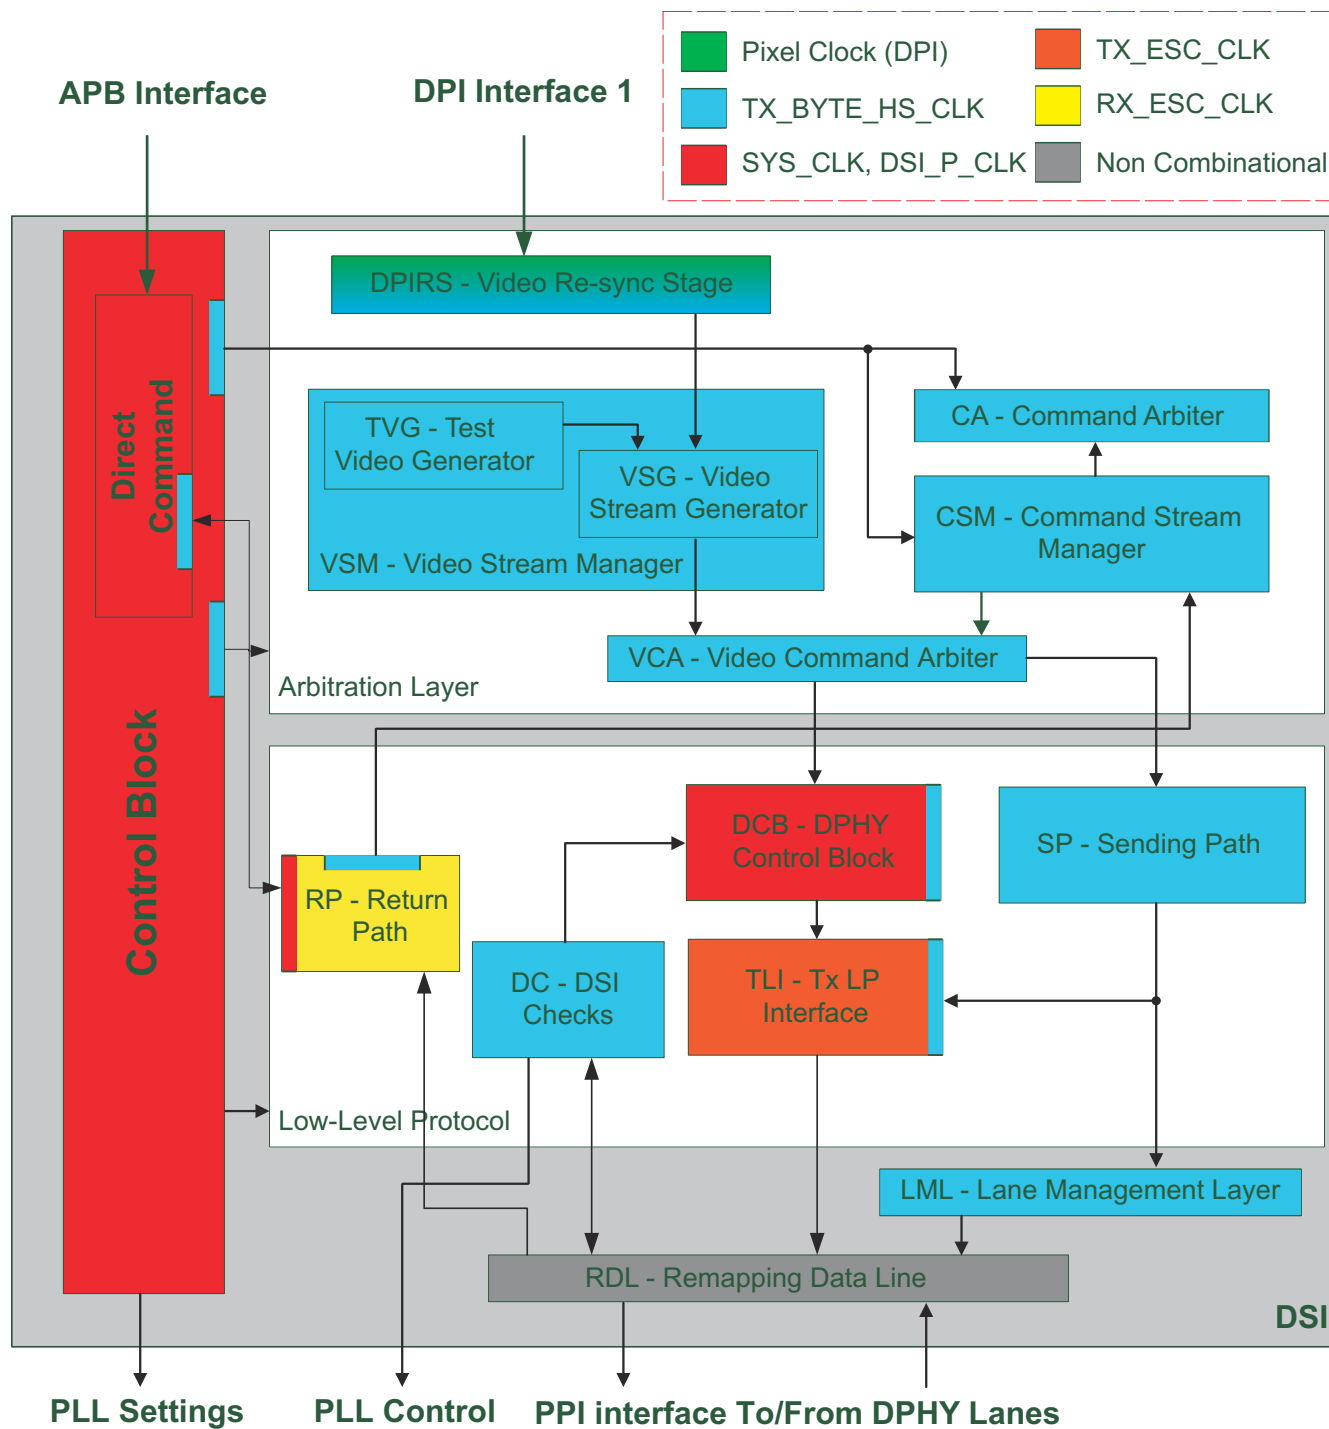

Table 12-478. DSI Clocking

Clock	Direction	Min	Max	Constraints	Description
dpi_0_clk (Async to all other clocks)	Input	7 MHz	425 MHz	$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_hs\_clk}} \times \text{active\_lanes} \times 8 / (\text{bits\_per\_pixel})$	Used for DPI interface only. Frequency range depends on expected data rate with respect of number of data lanes, data lane frequency and frame rate

**Table 12-478. DSI Clocking (continued)**

Clock	Direction	Min	Max	Constraints	Description
sys_clk (Async to all other clocks)	Input	7 MHz	250 MHz	1. Cannot be slower than $\text{tx\_byte\_hs\_clk} \times \text{datapath\_size} / \text{if\_datasize}$ (risk of underrun) in SDI mode. 2. Must be greater than: $\text{rx\_esc\_clk} \times 8$ . 3. Speed should be sufficient to provide enough data in SDI operation. 4. Must be faster than the $\text{tx\_byte\_hs\_clk}$ for Direct command operation.	Main functional clock Also used for the VBUS/APB interface
dphy_0_tx_byte_hs_clk (Async to all other clocks)	Input	10 MHz	312.5 MHz	The max value in SDI interface operation depends on sys_clk: can't exceed sys_clk freq x if_datasize datapath_size Otherwise 312.5 MHz to match the 2.5Gbps limit on DPHY v1.3 specification	DPHY PPI Byte Clock Frequency set by the DPHY and its High Speed input clock ( $\text{tx\_byte\_hs\_clk} = \text{dphy bit rate} / 8$ ) Maximum limit due to risk of underrun
dphy_0_tx_esc_clk (Async to all other clocks)	Input	1 MHz	20 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 20 MHz	TX Escape Clock
dphy_0_rx_esc_clk (Async to all other clocks)	Input	1 MHz	10 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 10 MHz	RX Escape Clock

Figure 12-556 describes the clock scheme and domains of the DSI\_TX.

dsi\_spruij7-057

Figure 12-556. DSITX Clock Scheme and Domains

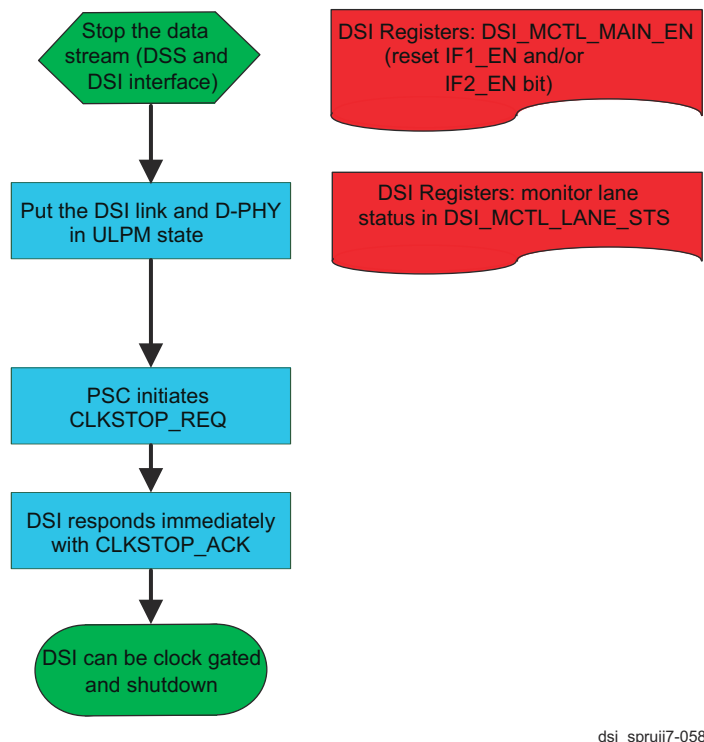

### 12.9.2.3 DSI Reset

The DSI has one active low reset input. The entire internal logic is reset by this reset. Internal resets (synchronous and asynchronous) for different clock domains are generated internally (synchronized to the respective clock domain).

### 12.9.2.4 DSI Power Management

The DSI implements a power management protocol to interface to a PSC (Power and Sleep Controller) module SoC level.

Figure 12-557 shows the expected sequence from SW while performing a *clkstop\_req* to the DSI.

**Figure 12-557. DSI Clock Gate / Power Off Procedure**

### 12.9.2.5 DSI Interrupts

Table 12-479 shows the interrupts that are generated by the DSI module.

**Table 12-479. DSI Interrupts**

Interrupt (n = 0)	Description	Source Module	Source Signal Name
dsi_#n_func_intr	DSI-#n Func Interrupt	DSI Controller	dsi_irq_n
dsi_#n_safety_error_fatal_intr	DSI #n Internal Diagnostic Fatal interrupt	DSI Controller	asf_int_fatal
dsi_#n_safety_error_nonfatal_intr	DSI #n Internal Diagnostic Non-fatal interrupt	DSI Controller	asf_int_nonfatal
ecc_intr_uncorr_level_sys_intr	ECC aggr uncorrectable error	-	-

### 12.9.2.6 DSI Internal Interfaces

#### 12.9.2.6.1 Video Input Interfaces

DSITX supports following video streaming interfaces:

- DPI (Uncompressed video stream)
- SDI (Serial Display Interface)

The DSI does not require DSI sub-link support. Therefore, only one video mode source is supported.

### 12.9.2.6.3 SDI (Serial Data Interface)

DSITX uses a SDI interface (32-bit) to receive active video data from an internal frame memory using a DMA or other data pull mechanism. The interface uses req/ready handshake signaling to control the data flow.

The DSITX SDI Interface supports one of the following modes:

- Command-only

SDI-DSI Interface requires following signals:

- dsi\_if\_valid
- dsi\_if\_stall
- dsi\_if\_start (Line Start)
- dsi\_if\_frame\_sync (frame\_sync)
- dsi\_if\_data

The SDI interface of DSI\_TX receives data directly from DSS VP output and is functional when the user configures the DSS to operate in COMMAND\_STALLMODE (DSS0\_VP\_CONTROL[11] STALLMODE = '1' and DSS0\_VP\_CONTROL[12] STALLMODETYPE = '0').

#### 12.9.2.6.3.1 Secure Display Support

Only secure peripherals can be connected to a secure DPI (VP) output of DSS. In order to support this requirement, the DSS exports a secure qualifier to the DSI\_TX. Inside the DSI a SECURE register is implemented (DSI\_WRAP\_DPI\_SECURE), which contains SECURE bits, [0] DPI\_0\_SECURE and [1] DPI\_0\_SECURE\_VIOLATION, corresponding to the DPI port. These SECURE bits can only be set or reset by a secure host (vbusp transactions with secure qualifier set).

The behavior of DSI module for different settings of SECURE register bit and SECURE qualifier from DSS is as shown below:

**Table 12-481. Secure Display Support**

SECURE Register Bit (DSI)	SECURE mqualifier (DSS)	Security Violation Status	Comments
0	0	0	Data is passed (non-secure DSS data through non-secure DSI)
1	0	0	Data is passed (non-secure DSS data through secure DSI)
1	1	0	Data is passed (secure DSS data through secure DSI)
0	1	1	<b>Security Violation.</b> Data is blocked (secure DSS data through non-secure DSI)

Once a security violation is detected, it is captured in the DSI\_WRAP\_DPI\_SECURE[1] DPI\_0\_SECURE\_VIOLATION register status bit.

### 12.9.2.7 DSI Programming Guide

This section describes the programming guidelines for the DSI Controller and D-PHY.

The goal of this section is to present more in detail how the DSI link should be used at application level plus some scenarios of use of the DSI link (start-up, display switch on/off, dual-display).

#### 12.9.2.7.1 Application Guidelines

The purpose of this section is to provide guidelines on how to drive the DSI host controller, provide general sequence of operations and some typical application notes.

### 12.9.2.7.1.1 Overview of a Display Subsystem

Figure 12-559 shows an overview of a display subsystem. It covers the point to point interfaces between the DPI/SDI and DSI blocks. Other blocks and interfaces are included to give a better understanding of the environment for this interface.

A DSI interface is made up from one DSI controller and one D-PHY block. D-PHY is the physical layer of the DSI interface. The DSI block handles protocol. The DSI interfaces support displays that comply with the MIPI DSI standard.

The displays can be of either command mode type or video mode type. Command mode displays have a frame memory that can hold the entire image. The display is refreshed from this memory and only changes of the display content are sent over the display interface. Video mode displays do not have this memory and thus all data for every refresh must be transferred in real time.

The SDI block can support one display in command mode. By using command mode displays and rerouting of connections, between display updates, more than two displays can be connected and active.

Figure 12-559. Example Display Subsystem Showing Controller and PHY Blocks

#### 12.9.2.7.1.2 D-PHY And DSI Configuration

The DPHY and DSI controller must be configured before any panel video display can be used. All accesses to the DPHY to configure it for use with the DSI Controller should be performed through the DPHY own APB interface .

#### 12.9.2.7.1.3 DSI Controller Initialization

The DSI controller will always require the DPHY and data path configuration to be set after power up and any hard reset. The minimum sequence should define the data path lane configuration; mappings, available lanes, DPHY power, resets and lane swap. All these register values should be set before the DSI controller is enabled for functional operation.

The DSI registers are accessed through the APB interface. The programming sequence for command, video and controller configuration must follow a sequence of accesses to ensure the clock gate control updates the internal nodes before the link is enabled.

All DSI\_VID\_xxx registers must be programmed, if required, before the write to the DSI\_VID\_MAIN\_CTL register.

All DSI\_MCTL\_DPHY\_xxx registers must be programmed, if required, before the write to the DSI\_MCTL\_MAIN\_DATA\_CTL register to set the [0] LINK\_EN bit.

#### 12.9.2.7.1.4 Panel Configuration Using Command Mode

The DSI controller can provide DCS command access using either the SDI interface or through the APB interface control of the DIRECT COMMAND registers (see [Table 12-482](#)). The panel registers will be programmed using the LP mode before the high-speed video is enabled. Commands can either be sent using the command interface or through the Command FIFO using the APB registers.

The command FIFO access is done through the APB Command mode registers by forming packets of DCS commands. The DCS commands can be found in the MIPI DCS specification or the display panel data sheet.

DCS commands are essentially register write or read transfers to panel registers. The initialization of a panel will require APB register writes to fill the FIFO with the DCS commands. The commands can be grouped into a long packet by sending the packet split into 4 bytes to fill the FIFO using a write to the DSI\_DIRECT\_CMD\_WRDAT register.

**Table 12-482. DSI Direct Command Mode Registers**

DSI Register	Description
DSI_DIRECT_CMD_SEND	Direct Command - trigger the direct command sending - write only
DSI_DIRECT_CMD_MAIN_SETTINGS	Direct Command - main settings
DSI_DIRECT_CMD_STS	Direct Command - status - read only
DSI_DIRECT_CMD_RD_INIT	Direct Command - stop read operation
DSI_DIRECT_CMD_WRDAT	Direct Command - data to write byte 0 to 3
DSI_DIRECT_CMD_FIFO_RST	Direct Command- reset the write FIFO pointer

Each DCS command packet to be sent can be built by first selecting the packet configuration using the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS. The DCS Command data types are defined in the DSI specification based on the number of parameters that are expected to be sent. Configuration of a panel display will normally use DCS write data types.

[Table 12-483](#) shows the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS register bit description.

**Table 12-483. DSI Main Settings Register Description**

DSI_DIRECT_CMD_MAIN_SETTINGS Register Bit	Description
[24] CMD_LP_EN	Enables LP sending for the command request.
[23:16] CMD_SIZE	Size of the command in case of write command - when written value is bigger than 0x10, the value is rounded to 0x10 for write - when size is bigger to 0x2 for read it is rounded to 0x2.
[15:14] CMD_ID	In case of read/write command, Virtual Channel of the command.
[13:8] CMD_HEAD	In case of read/write command, data type of the command:
	0x05      DCS Write      0 parameters      Short Packet
	0x15      DCS Write      1 parameter      Short packet
	0x39      DCS Long Write      N parameters      Long Packet
[3] CMD_LONGNOTSHORT	This bit must be tied to one.
[2:0] CMD_NAT	Nature of the direct command: 000: write command.

Once the packet is loaded, issue a DIRECT\_CMD\_SEND (via the DSI\_DIRECT\_CMD\_SEND register) and the data will be sent in LP mode.

### 12.9.2.7.1.5 VIDEO Interface Configuration

The DSI video operation requires the configuration of the VSG and TVG registers to match the panel configuration. The two video interface options will also require careful selection of the clock and registers to achieve error free video streaming.

The DSITX controller supports the mechanism for initial skew calibration for D-PHY data rates greater than 1.5 Gbps.

### DPI Video Interface Operation

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. If this is the case, then the blanking and active data periods must be matched up. The DSI controller will match its frame timing to the incoming DPI **VSYNC**, if it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered.

The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So, programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

Program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

The timing should also be matched per line, therefore the blanking and active periods should match. DPI horizontal timing is measured in pixels, whereas the DSI controller uses bytes. If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure the FIFO depth and vsync\_delay is suitable.

The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. Additionally, the PPI short packets and packet headers that are inserted by the controller must be accounted for. HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and footer (4 + 2 bytes) and the HSE short packet (4 bytes). HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (6 bytes). HFP should be reduced by 6 bytes to account for the long packet header and footer. Finally, for lines with no active data, the BLKLINE\_PULSE\_PCK is the total size minus 20 bytes (14 for HSA, 6 for the remaining blanking which is all combined into a single packet).

Program the DSI horizontal size registers as follows:

- HSA = (DPI\_HSA × bpp/8) - 14
- HBP = (DPI\_HBP × bpp/8) - 12
- HACT = (DPI\_HACT × bpp/8) NOTE: (DPI\_HACT × bpp/32) must be an integer.
- HFP = (DPI\_HFP × bpp/8) - 6
- BLKLINE\_PULSE\_PCK = ((DPI\_HSA + DPI\_HBP + DPI\_HACT + DPI\_HFP) × bpp/8) - 20;

### TVG Generator

The TVG oversees generating dummy data (to display something even if there is no video stream running). It is also able to ease verification or validation of the DSI without having a complete environment (application or verification test bench). The controller has a Test Video Generator that can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-560 presents TVG MODE patterns.

**Figure 12-560. TVG MODE Patterns**

The TVG generates a data stream in the same format than the one specified for the normal functional video stream (as set in VSG register). The content of that flow is specified by registers. Those registers specify the following information: Image size: Number of bytes per line (see TVG\_LINE\_SIZE[14:0] register) and number of lines per frame (TVG\_NBLINE[12:0]).

Image kind: Single color, vertical stripes or horizontal stripes (see TVG\_MODE[1:0] register). Stripe width: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128 (see TVG\_STRIPE\_SIZE[2:0] register).

Pixel kind: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB (see VID\_PIXEL\_MODE[3:0] register).

Color one: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered (see COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers).

Color two: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered. (see COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers). Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

An example of the sequence is as follows:

- Select TVG for video stream generation instead of SDI 1 interface:
  - IF1\_EN bit to 0 (stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL:
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register:
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.

- Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
- Stripes size in TVG\_STRIPE\_SIZE field.
- Image size in TVG\_IMG\_SIZE register.

**Note:** The number of lines per frame and number of bytes per line. It is required that TVG settings on active area match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL:
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register. Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.9.2.7.2 Application Considerations

The following sections outline the normal operation of the DSITX controller and the programming and sequences require to operate the DSITX controller for normal video and command operation.

##### 12.9.2.7.2.1 D-PHY Timings Control

Several DPHY timing constraints must be respected by the system, which are described in this section. When a switch in ULP is requested, the application should be aware that the D-PHY needs 1 ms to leave this state (this timing is guaranteed by the DSI itself). It makes no sense to start an ULP request if the expected time in ULP is short.

When PLL power down is asserted, the system should continue to assert for a specific minimum period of time (PLL internal requirement – please refer to DPHY documentation). Please note that shutting down the PLL implies that no clock is present on tx\_byte\_hs\_clk input and thus the DSI link is stopped; even if the system-side interface clocks remain active, no more HS transfers can be done.

Force\_stop, ppi\_c\_force\_tx\_stop (clock lane) and ppi\_d\_force\_tx\_stop (1 per data lane), can be useful to resolve certain deadlock situations, for example: DSI target does not give back control to controller, or critical DPHY error. When a 'force stop mode' is issued by the application, the system should maintain this state on the bus to ensure the request is correctly considered by the D-PHY cells and the **stop\_state** is asserted and direction signal is deasserted.

reg\_wait\_burst\_time (for the LML) must be programmed to ensure that two HS bursts are separated by at least 100 ns. The value will be based on the period of the tx\_byte\_clk cycle.

VCA: When trying to interleave commands to video stream, it is assumed that only write/read commands and BTA request are sent (no TE). The reason is that such transfers are slow and difficult to predict in term of duration. They could take longer than the slots available for video. The read commands are unpredictable and may cause some break in the video stream, however, they can still be used, if an appropriate response time can be guaranteed. It is the responsibility of the system integrator and the application to plan and implement recovery procedures when the video stream is stalled due to a read that takes too long.

##### 12.9.2.7.2.2 Control Block

Most of the register contents must be resynchronized against a DSI internal clock (tx\_hs\_byte\_clk). This means there is a certain time to pass data from one clock domain to the other. If two writes in the same register are too close, the register itself is updated but the synchronization may fail.

The formula to calculate the number of system clock periods between two writes is:

$$\text{nb\_cycle}(\text{dsi\_p\_clk}) = 6 * (\text{f}_{\text{dsi\_p\_clk}} / \text{f}_{\text{tx\_byte\_hs\_clk}} + 1)$$

The application must respect a period of TX ns between two write accesses to the same register (there is no issue writing different registers back-to-back).

[Table 12-484](#) shows an example of required time between two write accesses.

**Table 12-484. Example of Required Time between Two Write Accesses**

$f_{\text{dsi\_p\_clk}}$	$f_{\text{tx\_byte\_hs\_clk}}$	TX minimum time between 2 writes accesses
200 MHz	106 MHz	~ 90 ns
160 MHz	10 MHz	~ 650 ns
200 MHz	10 MHz	~ 650 ns

Another place where asynchronous behaviour may interfere with programming in the CB is the direct command status register `DIRECT_CMD_STS`. Some of the bits of this register are set when a pulse (that lasts one clock period) coming from `tx_hs_byte_clk` domain is observed (after resynchronization on `dsi_p_clk`) and is reset when the clear bit is written. In use case where `tx_byte_hs_clk` is slow (10 MHz range), the bit can be read and a clear attempted before the end of the source pulse. This can result in the re-assertion of the bit immediately after it is cleared. For that reason, it is recommended to wait for a while between reading the bits of the `DIRECT_CMD_STS` register and clearing them.

### Application Issues

Some register fields cannot take all the possible values but are restricted to a certain number of combinations (mode control). The DSI controller does not check that all the fields match a valid setup so it is the responsibility of the system integrator and the application to check that the written values are amongst the permitted combinations. Amongst the register fields that fall in to this category are most of the mode settings (stop mode, recovery mode, direct command type, image sizes, etc.)

### Programming Coherency

The application level must ensure that the register configurations are valid for the system to operate correctly. There are several possible combinations are possible in the CB registers however should be avoided. A few examples:

- No HS transfer should be enabled when PLL is shut-off.
- TVG should not be run when the video interface is running.
- No access (from interface or from register) should be attempted while TBG is active.
- Prior to shut-down of the DPHY PLL, application should verify that the DSI link is in proper state. If the bit that enables BTA is not set and that any operation implying a BTA is sent, the system is stalled. Then the bit that enables BTA must be aligned with application needs. Moreover, read enable or TE enable cannot be set if `bta_en` is not set (these operations cannot be enabled when BTA is not enabled).
- TE feature must not be enabled in SDI interface.

#### 12.9.2.7.2.3 Video Coherency

In video mode, there are a lot of sizes defined for the video stream generation. This data corresponds to the payload of the various generated packets and not to their duration. However, they are closely linked. It is the responsibility of the system integrator and the application to use correct sizes to ensure the correct video timing and behaviour, because the system may use 1 to 4 active data lanes with a fixed number of bytes for the header/checksum overhead. In the same way, when programming D-PHY time (to switch from LP to HS), the application must consider D-PHY time plus overhead due to LLP and LML crossing time (see [Section 12.9.2.7.7.2, Video stream settings \(VSG\)](#)).

### VSG Control

Start and stop sequences can take a long time to be performed. If the requests are not maintained up to the time the status bit are indicating effective start or stop, they can be ignored and the VSG may not have started or stopped as expected by application. It is then up to the application to carefully manage the request and to verify that requests are being processed before changing the state of the VSG.

### Test Generator:

The DSITX provides test generator to provide a video data stream. When using TVG, all sources can be used (provided VCA permits it) however the SDI interface must not be programmed to send video data and must be restricted to command mode.

The pixel modes supported are: RGB 16-, 18-, 24-, 30- and 36-bit; YCbCr422 16-bit; and YCbCr420 12-bit (note that additional YCbCr422 20-bit and YCbCr420 24-bit may be supported using SDI interface, but are restricted to command mode only).

The supported display sizes are listed below:

- QQVGA (160 x 120) - 15/20/30/60 fps - RGB 16-18-24 (-30 and 36) bits per pixels
- QCIF (176x144), QCIF + (176x208 and 176x220) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QVGA (320x240) - 15/20/30/60 fps - RGB R16-18 and 24 bits per pixels
- CIF (352x288), CIF + (352x416 or 352x440) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- 1/2 VGA (320x480) and 2/3 VGA (640x320) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- VGA (640x480) - 15/20/30/60 fps - RGB 16-18-24(-30 and 36) bits per pixels
- WVGA (800x480 - 848x480 - 854x480 - 852x480) - RGB 15/20/30/60 fps - 16-18 and 24 bits per pixels
- SVGA (800x600) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QHD (960x540) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- XVGA (1024x768) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- Full HD (1920x1080) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- WUXGA(1920x1200) - 15/20/30/60/(120 fps – 16 bpp only) 16, 18 and 24 bits per pixels
- 4Kx4K(4096x4096) - 15/20/30 fps - 16-18 and 24 bits per pixels

### 12.9.2.7.3 Start-up Procedure

The start-up sequence described in [Figure 12-561](#) assumes that the rest of the chip is ready (all clocks are present except tx\_byte\_hs\_clk, application it is ready...) and that the DSI is ready (reset de-asserted).

The following is the most common start up sequence:

Firstly, application layer programs and enables the PLL, then waits for a period for the PLL to lock (minimum time will be defined by the PHY documentation). At the end of the minimum wait period, the application layer should poll the PLL lock status register periodically to confirm lock status, repeating until confirmed. At the end of this step, it is assumed that a clock is present on the tx\_byte\_hs\_clk input (this step may be replaced by an interrupt-based alternative if available from the selected DPHY or provided in the system integration logic).

During the time taken by the PLL to lock, the application can program the configuration registers and prepare the DSI link. This can also be done after the PLL is locked. It should at least configure enough to be able to use LP mode to send direct commands.

Enable clock and data lane(s) per the needs. This action is only concerned with programming registers that control the D-PHY lane enable signal. The active lane configuration with the DSI\_MCTL\_MAIN\_PHY\_CTL and DSI\_MCTL\_MAIN\_EN registers must be programmed to match, i.e. for two data lanes (0 and 1).

- DSI\_MCTL\_MAIN\_PHY\_CTL (0x08) register – LANE3/4\_EN - bits[2:1] set to zero to disable lanes 2/3.
- DSI\_MCTL\_MAIN\_EN (0x24) register – DAT3/4\_EN fields - bits[6:5] set to zero to disable lanes 2/3.

Start the lane in the DCB. The DCB state machine puts the lanes in the correct state to be ready.

At this step, the DSI link should be able to access to display - at least in LP mode. If the system (DSI link and display) is fully programmed, code to display image can be started. If display characteristics must be read from the display and the system is programmed in LP mode, this is time to read the displays parameters to allow correct programming of the DSI. A new round of programming can then take place to set-up the system, based on the parameters which have been read fro the display.

The DSI internal setting is now completed and it is ready to accept data. The application can now enable the interface so that the stall signal is removed and that DSI link can accept data.

When the procedure described above is terminated, it does not imply that display itself is ready. At this stage, the D-PHY and DSI link are ready to send/receive data to/from display and thus application may still need to initialize the display itself.

dsi\_spruij7-005

**Figure 12-561. Start-up Procedure Summary**

#### 12.9.2.7.4 Interrupt Management

There are numerous error and status conditions that can be monitored via the interrupt mechanism. The edge on which these conditions are generated is programmable.

Each interrupt source has four associated registers:

1. The status register itself "<sts\_reg>"
2. a control register "<sts\_reg>\_ctl" to control corresponding interrupt behaviour
3. a flag register "<sts\_reg>\_flag" to observe when interrupt/event has been triggered
4. A clear register "<sts\_reg>\_clr" to clear the event flag register.

The decision of which status bits (<sts\_bit>) can generate interrupt is taken when the corresponding enable bit "<sts\_bit>\_en" is set in the status control register. In the same register the status bit edge "<sts\_bit>\_edge" states on which edge of the status bit the interrupt is triggered. When the selected edge is observed, the flag bit "<sts\_bit>\_flag" is set. The interrupt signal is an OR of all flag bits that are enabled. When the register "<sts\_reg>\_clr" is written with the bit "<sts\_bit>\_clr", the "<sts\_bit>\_flag" is cleared.

##### 12.9.2.7.4.1 Error and Status Registers

The error register bank handles storing all error flags that are identified. It also stores some status bits that must be observable and detectable by the application. These status and error registers can generate an interrupt on the rising or falling edge if this generation is enabled.

This mechanism is different depending on the nature of the status or error bits. For those that are generated in the DSI block (basically all status and error bits except direct command), the status bits cannot be easily controlled and toggle according to the internal status meaning only the current value is observed in the status/error register itself.

If the interrupt generation is enabled with the associated enable bit, a rising edge (associated edge bit set to 0) or a falling edge (associated edge bit set to 1) of that status bit toggles the corresponding flag bit. At the end, all the flag bits are put together with an OR to generate the interrupt signal. The flag register can be reset by writing in the clear register.

The described behavior can be summarized by the following pseudo-HDL. The signal named signal\_sts\_bit is the bit that is observable by reading status bit.

- reg\_sts\_q is the status register (accessible via APB)
- reg\_flag\_sts\_q is the flag register
- clear\_the\_flag is set when the register clear is written
- edge\_sts\_ctl is the edge bit
- enable\_sts\_ctl is the enable bit

```
reg_sts_d <= signal_sts_bit;
```

```
reg_flag_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
```

- '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
- '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;

```
irq_n <= NOT (OR_OF_ALL(reg_flag_sts_q AND enable_sts_ctl));
```

The code is slightly different in cases where the observed bit is a generated condition (in the control block), as is the case for the direct command status and error flags. The status/error information is automatically generated but is cleared only when writing in the corresponding clear bit. The interrupt generation behaves similarly to the error condition cases, however, as the status falling edge is observed only when the bit is cleared, it is not possible to use the falling edge detection on flag (however the code is kept as-is to provide a standard implementation method). This leads to the following code:

- reg\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
- '1' WHEN the\_sts\_bit (Note 1) = '1' AND reg\_sts\_q = '0' ELSE -- (see Note)

- reg\_sts\_q;
- reg\_flag\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
  - '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
  - '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;
- int <= NOT(OR\_OF\_ALL(reg\_flag\_sts\_q AND enable\_sts\_ctl));

**Note:** In some case (pulse generated), the rising edge detection is not done and the code becomes simply '1' WHEN signal\_sts\_bit = '1' ELSE...

#### 12.9.2.7.4.2 Interrupt Management for Direct Command Registers

The following direct command status bits/registers are only set when error is generated and only cleared when the clear bit is written:

- all the status bits of the register DSI\_DIRECT\_CMD\_RD\_STS
- all the status bits of the register DSI\_DIRECT\_CMD\_STS
- all the status bits except bit 0 (cmd\_transmission) of the register DSI\_DIRECT\_CMD\_STS

As these registers are reset only when the clear register is written, it is not possible to detect the falling edge on them to generate interrupts. Only the rising edges can generate the interrupt.

**Note:** There can be issues with detection when using the bits for all the signals that are a pulse generated in the tx\_byte\_hs\_clk domain. When the speed of that clock is slower in relation to dsi\_p\_clk, it is possible to have the interrupt set, the bit read and the clear attempted before the end of the tx\_byte\_hs\_clk pulse, after the clear, the bit is set again.

#### 12.9.2.7.5 Direct Command Usage

The direct command mechanism is a way to send commands (with a maximum size of direct\_cmd\_fifodepth bytes) by writing and reading registers. It allows commands to be sent that are not allowed through the SDI-DSI interface (DSI commands, triggers), to perform read operations or to send DCS / generic write / generic read operations when the DSI link is not fully programmed and cannot use the SDI interface for commands.

Figure 12-562 shows direct command management sequence.

Basically, the procedure to do so is as follows:

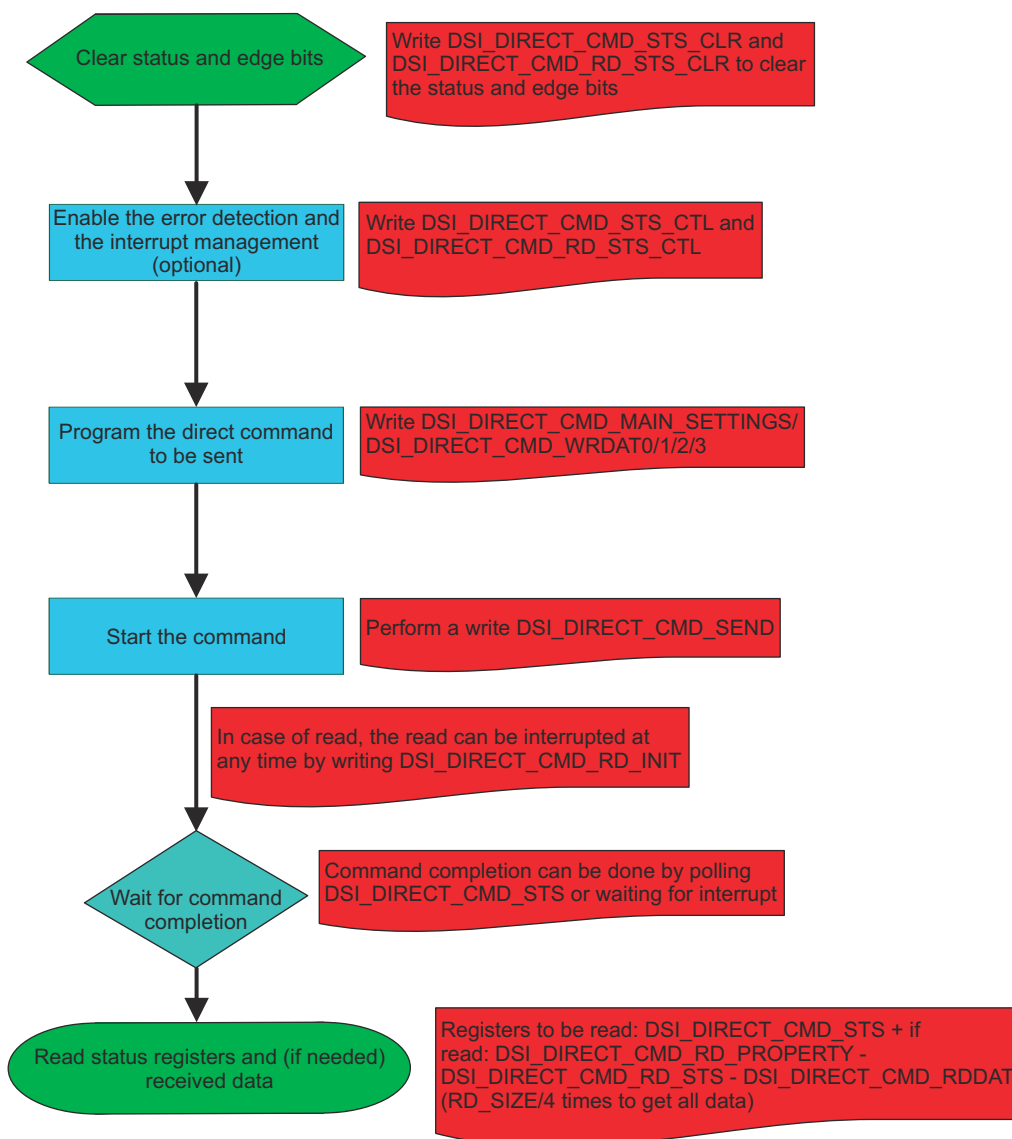

- Clear the status bits (when reading the status bits, only the DSI reads the current access status).
- Program the various registers that define the command to send.
- Write the direct\_cmd\_send register. Writing in that register (any value) triggers the command sending mechanism.

The command should be started only if the command request is amongst the defined ones for DCS or Generic Write or Read with 0, 1, or more parameters:

- DCS Write codes 0x05, 0x15, 0x39
- DCS Read codes 0x06
- Generic Write codes 0x03, 0x13, 0x23, 0x29
- Generic Read codes 0x04, 0x14, 0x24

**Note:** The direct\_cmd\_main\_settings register can use other data type values for cmd\_head to support future types and no check is performed for invalid types.

- Wait for the assertion of the command\_completed bit in the direct\_cmd\_sts register (or any of the relevant bits that indicate a specific command termination). Instead of polling the registers, it is possible to enable the corresponding interrupts and wait for its detection.
- Read the received data and (if any) the different status bits.

ds\_i\_spruij7-006

**Figure 12-562. Direct Command Management**

There are several checks performed when sending a direct command to verify that requested command sizes are supported and to check that the requested command exists (otherwise the request to send the command is ignored).

- For Short packets commands the DCS and Generic Read and Write the data size is rounded to maximum of 2.
- For Long packet DCS and Generic Read and Write the data size is rounded to the maximum size of the FIFO.
- No checks are made for the write FIFO having the expected number of bytes programmed into the CMD\_SIZE in the dir\_cmd\_main register. In this case the data written out will loop back through the value in the FIFO.

At completion of a read command, registers can be read (they contain read data and/or errors detected during the communication) and trigger events are sent to the application to announce the request completion (using the status and error register bank).

When a read request is performed, the read data is put in the RP FIFO. If more bytes are sent, they are ignored and errors are set accordingly. The received read can then be accessed by reading several times the register that gives an access to the FIFO.

For every new command, several status bits are present: one signals that a command is being transmitted (cmd\_transmission). When the command is complete, several bits can be toggled to signal it (write\_completed, trigger\_completed, te\_received, read\_completed and read\_completed\_with\_err).

Some complex commands provide intermediate information. For BTA requests, there is a bit that signals when the BTA request has been sent (BTA\_completed) and another one that signals when the DSI is controller of the D-PHY interface again (BTA\_finished). For commands that imply a BTA, some other bits specify whether specific data has been received (such as trigger, acknowledge with or without error).

#### 12.9.2.7.5.1 Trigger Mapping Information

Triggers are one of the groups of direct commands that can be sent and received using the DPHY in Low Power escape mode. The trigger\_val[3:0] bits (in the registers DIRECT\_CMD\_MAIN\_SETTINGS and DIRECT\_CMD\_STS) are used to define which of the four possible trigger entry codes has to be sent or has been received. The register fields described above are copied in signal ppi\_d1\_tx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_MAIN\_SETTINGS) or are a copy of ppi\_d1\_rx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_STS). Only one bit out of the four should be set else the D-PHY behavior is not very precisely defined. [Table 12-485](#) gives the trigger mapping in the system.

**Table 12-485. Trigger Mapping**

Trigger name	Trigger entry code	trigger_val	meaning in TX direction	meaning in RX direction
trigger 0 - reset	01100010	1b0001	Reset	Not affected by DSI spec
trigger 1 - unknown 3	01011101	1b0010	Not affected by DSI spec	TE response <sup>(1)</sup>
trigger 2- unknown 4	00100001	1b0100	Not affected by DSI spec	Acknowledge with no error <sup>(1)</sup>
trigger 3 - unknown 5	10100000	1b1000	Not affected by DSI spec	Not affected by DSI spec

(1) These triggers are not observed in the trigger\_val field of the direct\_cmd\_sts register because they are used by the DSI link for a specific purpose.

**Trigger Reset** – This will request from the display and expects an immediate reset of the DSI command/video mode with all pending requests in TX sending path FIFO for transfer to be discarded.

**Acknowledge** – This is a response to DSITX controller. The host processor may request a command acknowledge and error information related to any transmission by asserting Bus Turnaround with the transmission. The peripheral shall respond with ACK Trigger Message if there are no errors and with Acknowledge and Error Report packet if any errors were detected in previous transmissions. Appropriate flags shall be set to indicate what errors were detected on the preceding transmissions.

If the transmission was a Read request, the peripheral shall return READ data without issuing additional ACK Trigger Message or an Acknowledge and Error Report packet if no errors were detected. If there was an error in the Read request, the peripheral shall return the appropriate Acknowledge and Error Report unless the error was a single-bit correctable error. In that case, the peripheral shall return the requested READ data packet followed by Acknowledge and Error Report packet with appropriate error bits set.

**Tearing Effect** - The Tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. Users are responsible for selecting the command mode for the VC using the TE feature and selecting the polling or automatic mechanism.

The user is responsible for ensuring that there is a delay after a trigger is issued by the host to the panel, before any other action, message or trigger is performed. When the host issues a reset trigger, the system will expect the controller to stop and re initialise the clock and data links. All other triggers issued by the host will be application specific and are outside the scope of this document.

#### 12.9.2.7.5.2 Command Mode Settings

The command mode is enabled on the SDI interface. This is controlled using the register `mctl_main_en`. Other settings can be set using the registers: `mctl_main_data_ctrl` (to decide about TE usage, read enable...); and `cmd_mode_ctl` (Virtual Channel of the command packets, arbitration between requests of the two interfaces, possibility to use LPDT, TE timer programming and padding value in case of an error).

When programming Direct READ commands, a BTA request is sent automatically following the read transmission, for the peripheral to respond – it is therefore not necessary to explicitly send a BTA request at that time. The system must allow the BTA request to be completed and the bus returned to the host before issuing any new read or write command. The system must either: poll the `read_completed` (and `read_completed_with_err`) status bits; or, wait for an interrupt caused by these bits before issuing any new command.

When programming Direct WRITE commands, it is advisable to ensure that each transaction can complete successfully before moving on to a subsequent command. There are two recommended methods to achieve this, either: explicitly request a BTA between write transactions while checking for the associated interrupt or polling the appropriate status flag (this method also provides the added security of an ACK response from the peripheral); or allowing a gap between commands sufficient to allow completion of the first before commencing with the second. The recommended approximate gap time required to ensure that all commands complete successfully is equivalent to 100 TX ESC byte periods. If required (for instance, to minimize the start-up time), it is also possible to calculate the minimum delay time required for each transaction, based on the TX escape clock frequency used in the application and the length of each command (no active video transmission should be enabled at the time – a typical use case would be peripheral parameter configuration). As with read operations, any write operation followed by an explicit BTA request must allow the BTA to be completed and the bus returned to the host before issuing any new read or write command.

For single parameter commands, the upper bytes of the 32-bit value written to the Direct Command write data register (`direct_cmd_wrdat`) should be masked to zero to comply with the DSI specification requirement that unused parameter locations are set to zero. For zero parameter writes, assuming there have been previous write commands sent, it is necessary to clear the sending path FIFO by writing to the `direct_cmd_fifo_rst` register to clear the data path, then write a zero value to the `direct_cmd_wrdat` register to send the zero parameter write command.

**Note:** Failure to follow these procedures may result in non-zero data in the unused parameter locations; this may or may not affect the peripheral, however it is recommended to use the process described to ensure compliance with the DSI specification in this regard.

If STOP mode is forced during a command mode read or write transaction, all outstanding transactions should be considered lost and all status and error flags should be disregarded and cleared. Similarly, if an LPDT read data operation is stopped by writing to the `STOP_READ_OPERATION` field of the `DIRECT_CMD_RD_INIT` register, the status for the aborted read operation should be disregarded and cleared before resuming normal operation.

#### 12.9.2.7.5.3 Bus Turnaround Sequence

The command operation can request a read or an acknowledge response from the panel after a long sequence of packets is sent. The Bus turnaround is also used to control the Tearing Effect control.

When a Bus Turnaround is requested from the command stream manager, the DPHY will be given a turn request. The request will make the DPHY interface perform a sequence of LP states (LP11-10-00-10-00) to indicate that it is releasing control of the DP/DN signals. The DPHY Direction signal will change once it detects the Panel side driving the LP00-10-11 states. The panel will then be able to send any response packets (see section 0) and release the bus by issuing a bus turnaround sequence to the controller DPHY. The DSITX controller DPHY will detect the sequence and change the direction signal once the pattern is sent and LP00 state is valid for 2-3 TX\_ESC\_CLK cycles.

Figure 12-563 shows Bus turnaround timing sequence from controller to panel and panel to controller.

**Table 12-486. TE Timeout Programming (continued)**

te_timeout(11)	te_timeout(10)	timeout value
1	1	2048 × te_timeout<9:0>

#### 12.9.2.7.5.5 Tearing Effect Control on Panels with Frame Buffer

Display panels will use command mode sequencing when an on-board frame buffer is used to store the video image rather than using the video streaming and synchronisation packets to control the update of the image information. This means that the host display driver must know when the panel is processing the image and avoid changing pixel information before it is updated. The mechanism is known as the tearing effect. The DSITX controller can support two schemes as outlined in the MIPI DSI specification.

#### TE control using the Polling Method

For polling to the display module, the host processor shall detect the current scan line information with a DCS command such as **get\_scan\_line** to avoid Tearing Effects. DSITX controller will issue a READ using this command until it gets to the expected value for the last line.

#### DCS Command - get\_scanline (45h)

##### Command

**Direction** H->D

**Hex Code** 0 1 0 0 0 1 0 1 45h

##### Parameter 1

**Direction** D->H

**Hex Code** N15 N14 N13 N12 N11 N10 N9 N8 XXh

##### Parameter 2

**Direction** D->H

**Hex Code** N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-564. get\_scan\_line Command**

#### Description

The display module returns the current scanline, N, used to update the display device. The total number of scanlines on a display device is defined as VSYNC + VBP + VACT + VFP. The first scanline is defined as the first line of V Sync and is denoted as Line 0.

In Sleep Mode, the value returned by **get\_scanline** is undefined. See [MIPI-DPI] for definitions of VSYNC, VBP, VACT, and VFP.

- In 2D mode, the scanline value of the display memory and the display panel is the same.
- In 3D Mode, the scanline value of the display memory and the display panel can be different; **get\_scanline** shall return the current scanline of the display panel.

## Restrictions

None

## TE control using the Automatic Method

For TE-reporting from the display module, the TE-reporting function is enabled and disabled by three DCS commands to the display module controller: `set_tear_on`, `set_tear_scanline`, and `set_tear_off`. See [MIPI-DCS] for details.

`set_tear_on` and `set_tear_scanline` are sent to the display module as DSI Data Type 0x15 (DCS Short Write, one parameter) and DSI Data Type 0x39 (DCS Long Write/write\_LUT), respectively. The host processor ends the transmission with Bus Turn-Around asserted, giving bus possession to the display module.

Since the display module DSI Protocol layer does not interpret DCS commands, but only passes them through to the display controller, it responds with a normal Acknowledge and returns bus possession to the host processor. In this state, the display module cannot report TE events to the host processor since it does not have bus possession.

To enable TE-reporting, the host processor shall give bus possession to the display module without an accompanying DSI command transmission after TE reporting has been enabled. This is accomplished by the host processor protocol logic asserting (internal) Bus Turn-Around signal to its D-PHY functional block. The PHY layer will then initiate a Bus Turn-Around sequence in LP mode, which gives bus possession to the display module.

Since the timing of a TE event is unknown to the host processor, the host processor shall give bus possession to the display module and then wait for up to one video frame period for the TE response. During this time, the host processor cannot send new commands, or requests to the display module, because it does not have bus possession.

## DCS Command - `set_tear_on` (35h)

### Command

Direction H->D

Hex Code 35h

### Parameter

Direction H->D

Hex Code X X X X X X M XXh

**Figure 12-565. `set_tear_on` Command - 1**

## Description

This command turns on the display module Tearing Effect output signal on the TE signal line. The TE signal is not affected by changing set\_address\_mode bit B4. set\_tear\_on has one parameter that describes the Tearing Effect Output Line mode.

If M = 0 (Mode 0):

The Tearing Effect Output line consists of V-Blanking information only.

**Figure 12-566. set\_tear\_on Command - 2**

If M = 1 (Mode 1):

The Tearing Effect Output Line consists of both V-Blanking and H-Blanking information.

**Figure 12-567. set\_tear\_on Command - 3**

The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI- DPI] for definitions of tvdl, tvdh, thdl and thdh.

## Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tearing Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

## DCS Command - set\_tear\_scanline (44h)

### Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 0 44h

### Parameter 1

Direction H->D

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

### Parameter 2

Direction H->D

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-568. set\_tear\_scanline Command - 1**

### Description

This command turns on the display module Tearing Effect output signal on the TE signal line when the display module reaches line N. The TE signal is not affected by changing set\_address\_mode bit B4.

The Tearing Effect Line On has one parameter that describes the Tearing Effect Output Line mode.

After issuing a set\_tear\_scanline command to the display module, the Tearing Effect output signal, e.g. as in DBI- 2 systems, shall be a delayed version of V-Blanking information as illustrated in [Figure 12-569](#).

**Figure 12-569. set\_tear\_scanline Command - 2**

Note that set\_tear\_scanline with N = 0 is equivalent to set\_tear\_on with M = 0. The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI-DBI] for definitions of tvdi and tvdh and [MIPI-DSI] for definition of display module line numbers. In 2D mode, the scanline value of the display memory and the display panel is the same.

### Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tear Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

### DCS Command - set\_tear\_off (34h)

#### Command

Direction H->D

Hex Code 0 0 1 1 0 1 0 0 34h

Parameters None

## Description

This command turns off the display module Tearing Effect output signal on the TE signal line.

dsi\_spruij7-014

**Figure 12-570. set\_tear\_off Command**

## Restrictions

This command has no effect when the Tearing Effect output is already off.

### 12.9.2.7.5.6 Return Path Operation

The DSI Return Path behaves like a target, by collecting data from the DPHY receive interface when the DPHY is configured to accept a transmission from the peripheral. The RP receives 6 signals from the DPHY (see [Table 12-487](#)).

The data (and trigger) reception is inactive if the DPHY PPI direction signal is at low level. When it is active, data is received using the RX ESC\_CLK clock (the clock is transmitted with the data itself - see D-PHY protocol description from MIPI) and may stop if there is a pause in the data transmission but data is generated on clock falling edge. New data is available on rx\_data\_esc on a rising edge of the clock, if both rx\_lpd\_t\_esc and rx\_valid\_esc are asserted.

**Table 12-487. Interface Between Return Path and DPHY**

Signal Name	I/O	From/To	Description
rx_lpd_t_esc	I	DPHY	Escape Low Power data receive mode This active high signal is asserted to indicate that the lane module is in low-power data receive mode. While in this mode, received data bytes are driven onto the rx_data_esc output when rx_valid_esc is active. The lane module remains in this mode with rx_lpd_t_esc asserted until a stop state is detected on the lane interconnect.
rx_trigger_esc(3:0)	I	DPHY	Escape trigger received These signals indicate that an escape trigger command has been received. Only one of these signals will be asserted at any time and the signal will remain asserted until the lane module returns to stop state.
rx_data_esc(7:0)	I	DPHY	Escape receive data For Low Power data receptions, this eight-bit value is driven by the D-PHY and is valid on rising edges of rx_clk_esc with rx_valid_esc asserted. The bit connected to rx_data_esc[0] was received first.
rx_valid_esc	I	DPHY	Escape receive data valid This signal indicates that the lane module is driving data on rx_data_esc and expects the protocol layers to take the data at the current rising edge of rx_clk_esc. There is no "ready" signal to throttle the receive data.

**Table 12-487. Interface Between Return Path and DPHY (continued)**

Signal Name	I/O	From/To	Description
stop_state_dl1	I	DPHY	Lane is in stop state This signal indicates that the lane module is in STOP state. Note that this signal is asynchronous to any clock in the protocol interface.
direction	I	DPHY	Lane direction. When this signal is high, the lane module is in receive mode. When direction is low, the lane module is in transmit mode. (Mnemonic: 1 = Input, 0 = Output.)

The received data messages are identified as one of two possible types:

- Trigger
- Read packet

**Trigger** messages are passed almost directly to the register (reg\_req = reg\_trigger = 1 and reg\_rd\_data<3:0> equals to trigger value during one clock cycle). However, triggers are decoded to see if they are a TE trigger or an acknowledge with no error.

- The TE data is passed separately to the CSM using csm\_te\_received pin. It needs to be resynchronized with tx\_byte\_clk byte clock because of the CSM working clock domain.
- The acknowledge is only passed to register using reg\_req and reg\_ack pins. All other trigger values are passed undecoded to the registers without any processing. It is the responsibility of the application to decode and decide what to do with them.

**Read Packet:** When data is received, the system waits for the 4 bytes of the **HEADER**, and performs an ECC correction (if it is enabled) and then decodes the packets.

The following cases are considered when the system performs the ECC check:

- If the received command is not in the list of legal display opcodes, (i.e. errors in the packet header), it discards that packet and all further incoming bytes, even if they are legal packets (until the next BTA - i.e. direction change). It sends errors to the register bank (err\_undecodable and uncorrectable\_err). This may also result in an EOT error being reported as no further bytes have been decoded. But even if ECC correction shows an uncorrected error, decoding is attempted (if the errors are in the ECC byte or in the payload bytes, the opcode can be understood and data correctly recovered). In this case only err\_uncorrectable error bit is sent to register and it falls in the situation of regular commands (acknowledge with error or read).
- If "an acknowledge with error", the two status bytes are sent to the registers (reg\_req = 1 and reg\_ack\_err = 1 and reg\_rd\_data<15:0> contains the correct value).
- If the message type is a short read (either DCS or generic), data is passed to the registers (2 bytes without any specific decoding). Interface signals must be set accordingly and the two bytes are sent to registers (reg\_req = reg\_start = reg\_end = reg\_read = 1 with data and dscnotgen set accordingly). Size information is decoded in the first byte of the received packet depending on the data type information and then sent to register using reg\_size port.
- If a long read, the size is sent to the register using reg\_size. The system goes to **LONG state**. All data received are sent to register using reg\_data and are used for checksum detection. If during receive, return packet fifo (in control block) becomes full (rd\_data\_fifo\_full), the error flag err\_oversize must be set. All remaining data is used for checksum calculation but are not transferred to registers. When the number of received bytes is equal to the packet size, the system will check the **CHECKSUM**. The two checksum bytes are never transferred to register. They are used to make checksum detection and indicate err\_checksum status.
- If the transfer is shorter than the size specified in the header, the error err\_wrong\_length is issued along with any subsequent errors such as err\_missing\_eot (if needed). The case where it is longer drives to a tentative checksum decoding that generates an error and by a tentative to decode a new header (that is in fact a part of the previous packet) that drives to an error err\_undecodable and the throwing of the rest of the received bytes (with corresponding errors such as err\_missing\_eot).

- If it is an EoT packet, it is not passed to the control block. The following data is ignored (if any). If the system is waiting for **EoT**, this is the only action. If system is not waiting for EoT packet, the err\_eot\_with\_err is sent.
- If after an "acknowledge with error", the system waits for EoT packet and counts 4 bytes but is not able to decode them, it emits an err\_eot\_with\_err and err\_undecodable.
- If direction is removed at a "wrong" time (i.e before the fourth byte of a small packet, the system stops to works but emit errors to the register: err\_receive with eventually err\_missing\_eot.

The DSI is designed to support multi-peripheral integration, the virtual channel of the received packet is also stored in register using reg\_vc port.

The application FW layer is responsible of all read actions, it is assumed that once a read is requested, application reads return packets before requesting other read actions. Based on this assumption, the receive FIFO implemented in the register block is cleared each time a read action is started. All data not read before the new read command are lost.

A re-initialization of the return path is also performed using register access on reg\_init\_rp.

All errors related to short or long received data packets should be captured in the register when the direction changes (to capture all errors at the same time and not generate several errors and possibly several interrupts on the same reverse transaction). As soon as an error is detected on a packet, the error must be recorded and maintained up to the end of the packet transfer.

The maximum packet size supported by the DSI return path is 16 bytes. If a longer packet is received, only the first 16 bytes are available (by register way) for application.

#### **12.9.2.7.5.7 EoT Packet Management**

The DSI protocol states that, in the sending path, only the HS transmission requires use of EoT packet. For transfer from display to host, it is not recommended to use EoT but it is possible. The host needs to be able to detect the EoT packet and then behaves accordingly.

In case the display makes use of the EoT packet, the bit disp\_eot\_gen must be set to one. In that case, if after the ECC correction, the packet header is 0x08, we've detected an EoT packet and all bytes that may arrive between this packet and the direction change must be ignored.

If additional data is received between the EOT packet and the next BTA (end of read process), or if an unwanted EOT packet is detected, the unwanted bytes must be rejected and err\_receive is asserted.

If the EoT packet is not detected although it should be present, the error err\_missing\_eot is set. If after an "acknowledge with error", 4 bytes are received before BTA but are not identified as EoT (because of errors), it is assumed these 4 bytes are the EoT. In that case, the error err\_eot\_with\_err has to be set with err\_undecodable.

#### **12.9.2.7.5.8 ECC Correction**

The DSITX controller uses the packet header ECC information to detect and correct one error, and can detect two or more errors without correction.

#### **12.9.2.7.5.9 LP Transmission and BTA**

The DSI host may send a command sequence and then request an acknowledge message from the panel. The host will send the command and release the bus by performing a BTA sequence. The panel will then respond with an acknowledge message (or error response) followed by a BTA to return the bus to the host. This sequence is illustrated in Overview of a Display Subsystem.

Overview of a Display Subsystem.

[Figure 12-571](#) shows LP transmission timing diagram.

The Host will not be able to transmit any other packets once the BTA is sent to the panel and will expect either an ACK trigger or response LPDT message with a payload. The system must ensure there is sufficient time to send any command and issue the BTA, receive the response (Trigger, Short or long packet) and accept the BTA from the panel, if this request is made in the line blanking intervals.

Figure 1-1: Command and Response Sequence

The diagram illustrates the communication flow between a host and a panel. The sequence of messages is as follows:

- Command or Video Transmission
- Command Read
- Host BTA
- Panel Response
- Panel BTA

The Panel Response is detailed as follows:

- ESC Sequence LP11, LP10, LP00, LP01, LP00
- TRIGGER 00100001
- ESC Exit LP10, LP11

The detailed response structure is further broken down into the following fields:

- ESC Sequence LP11, LP10, LP00, LP01, LP00
- LPDT 11100001
- DT eg
- Data LSB
- Data MSB
- ECC
- ESC Exit LP10, LP11

The detailed response structure is further broken down into the following fields:

- ESC Sequence LP11, LP10, LP00, LP01, LP00
- LPDT 11100001
- DT (0x29 DCS LP)
- WC LSB
- WC MSB
- ECC
- Data0
- Data1
- ...
- Data WC-1
- CRC LSB
- CRC MSB
- ESC Exit LP10, LP11

The panel response time will be based on the tx\_esc\_clk used inside the panel and the expected number of bytes for the payload. The expected responses are illustrated in the blocks in the MIPI DSI standard.

There are several low-power scenarios which consist of switching off various parts of the design:

1. Switch D-PHY cells in ULP mode when there is no data to be sent (bits `clk_lane_ulpm_en`, `dat1_ulpm_en`, `dat2_ulpm_en`, `dat3_ulpm_en` and `dat4_ulpm_en` in register `mctl_main_en` set to one with ULP mode enabled in register `mctl_main_phy_ctl`). Please, note that the time to leave ULP state is 1 ms and needs to be set in clock cycles in the register `mctl_ulpout_time`.
2. Switch the DPHY byte/bit clock PLL off (refer to DPHY documentation for control sequence). In this case, the D-PHY cell can only transmit data in LPDT thus maximum bandwidth is 10 Mbits/s).
3. More drastic methods are to shut-down some parts of the design. The D-PHY and the DSI themselves can be shut down.

When D-PHY and DSI are both shut-down and the display is powered down, the restart is a normal start procedure as described in [Section 12.9.2.7.3, Start-up procedure](#).

When only the D-PHY is stopped, it is placed in either the stop or ULP state. Restarting the D-PHY is similar to the regular start-up procedure, however, after the lanes are enabled by the DSI Controller (clk<sub>lane</sub>\_en, dat1\_en, dat2\_en, dat3\_en and dat4\_en in register mctl\_main\_en are set), the D-PHY generates a rising edge on the stopstate signal to indicate to the DSI Controller that the enable request has been effective within the D-PHY. After that the start-up procedure may continue up to the point that the DSI link is ready to begin transmission.

Note that when setting the D-PHY into the ULP state, the application needs to wait enough time between the time it sets the ULP request in register and the time the D-PHY is disabled – this ensures that the ULP request is detected on the D-PHY interface.

### 12.9.2.7.7 Video Mode Settings

All values contained in the Control Block (CB) registers must be set with meaningful values and are expressed with a range of different units: clock cycles, bytes, number of lines.

#### 12.9.2.7.7.1 Video Stream Presentation

In Figure 12-573, it shows the list of packets that can be part of a video stream and the associated register fields. In the four following figures (Figure 12-574, Figure 12-575, Figure 12-576, Figure 12-577), different video streams that can be generated are presented.

dsi-017

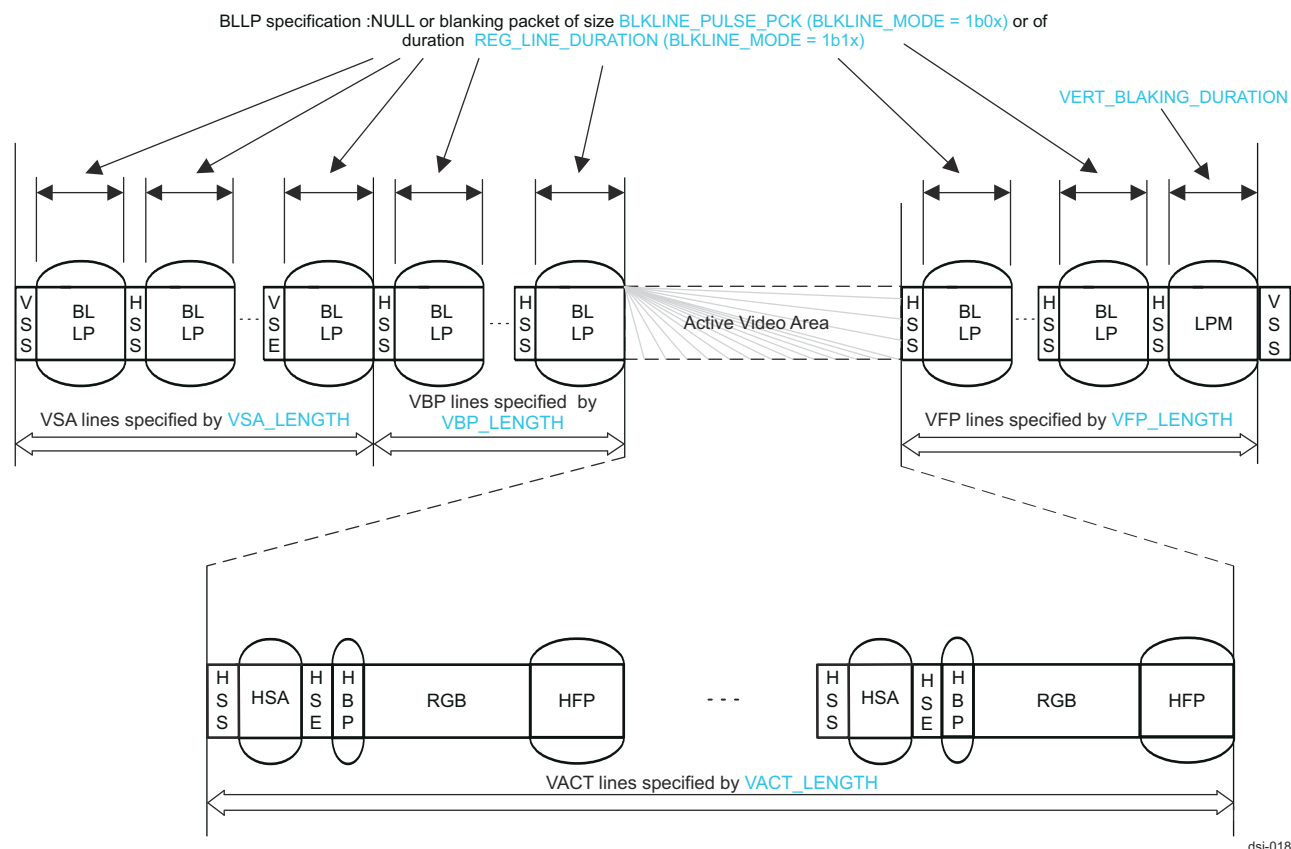

**Figure 12-573. DSI Packet Terminology**

**Red text** - behaviour not possible.

**Blue text** - register fields used to specify the packet size.

The BLLP (Blanking – Low Power) periods allow the DPHY link to perform the following sequences:

- Host Transmit blanking packets in HS.
- Host Transmit command packets in HS or LP (Escape mode).
- Host Transmit packets using interleaving to a different virtual Channel in HS or LP (Escape mode).
- Host performs BTA and waits for response packets from the panel using Escape Mode followed by a panel BTA.

**Figure 12-574. Video Pulse Mode (Non-Burst) Timing Diagram**

### Note

This sequence is no longer specified in the MIPI spec Version 1.02.00 28-Jun-2010 but supported by the DSI-controller.

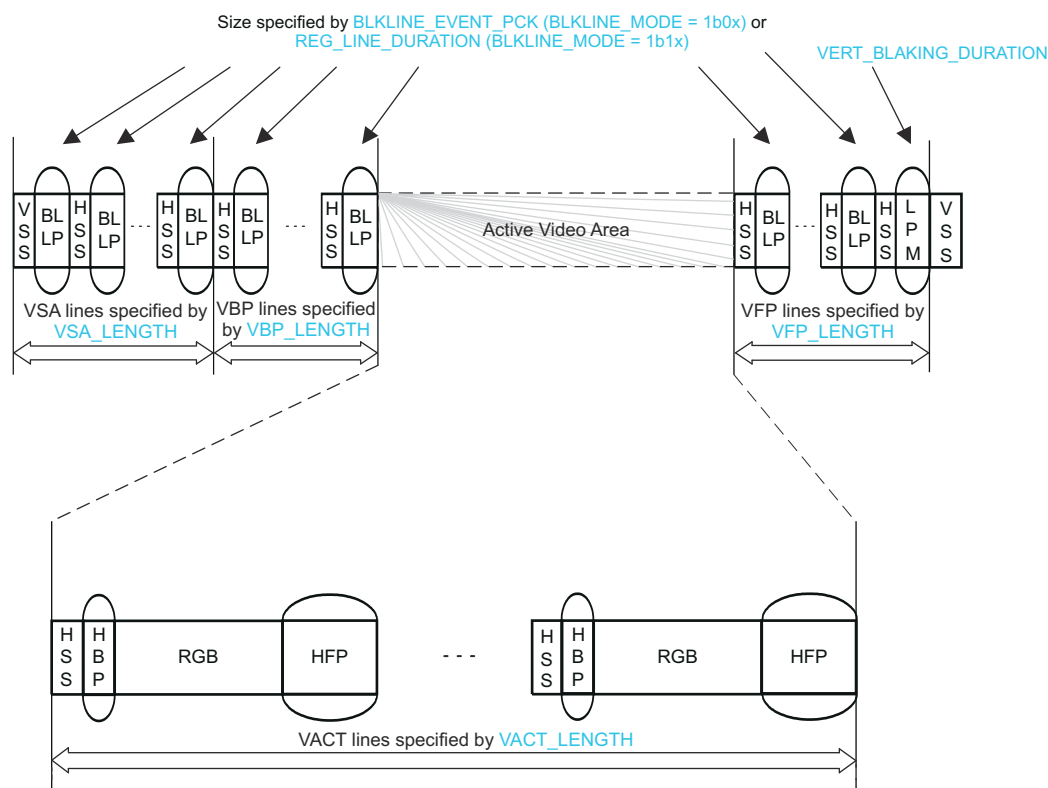

**Figure 12-575. Video Pulse Mode (Non-Burst)**

### Note

In the MIPI spec 1.02.00 June 2010, the line (VSE/HSA/HSE/BLLP) has been moved from VSA lines part to the VBP lines part. The sequence is the same but in the design the VSA lines has one more line and the VBP lines has one line less. This must be considered during the VSA and VBP register programming if the DSI MIPI spec 1.02.00 is used as reference.

dsi-020

**Figure 12-576. Video Event Mode (Non-Burst)**

burst\_mode = sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

dsi-021

**Figure 12-577. Video Sync Event in Burst Mode**

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

Burst Mode operation requires the tx\_byte\_clk to be set to double the bit rate compared to the non-burst case. The calculations for the video parameters must then be increased to match the higher rate. The DPI FIFO must also be large enough to store at least half of the active line bytes before the output transmission begins otherwise it will underrun.

#### 12.9.2.7.7.2 Video Stream Settings (VSG)

The following is all the registers that need to be set before using the video in SDI or DPI interface operation.

- vid\_vsize1, 2
- vid\_hsize1, 2
- vid\_blksize1, 2
- vid\_pck\_time
- vid\_dphy\_time
- vid\_error\_color1, 2
- vid\_vca\_setting1, 2
- vid\_main\_ctl – programmed last in sequence of vid registers to apply to DSI registers

This section addresses the dependencies between all video registers, and details how the TVG and VCA registers must be set per VSG registers.

#### vid\_main\_ctl

- header information must correspond with the vid\_pixel\_mode used to control the generation of the recovery streams. The header information is used to be enable management of future cases where the DSI link could be used to pass streams with formats that differ feom those currently supported directly.
- sync\_pulse\_horizontal can only be asserted if sync\_pulse\_active = 1.

When `sync_pulse_active` is set to one, the HSYNC pulses are emulated only during the active part of the frame. When both `sync_pulse_horizontal` and `sync_pulse_active` are set, the HSYNC pulses are present on all lines of the frame.

**vid\_vsize** - the variables are expressed in line numbers in this register.

- `vsa_length` should be at least one (in order VSG can insert at least the vertical synchronization start VSS line) and greater or equal to 2 when pulse mode (`sync_pulse_active` = 1).
- `vbp_length` 0 to 63.
- `vfp_length` must be greater than 0.
- `vact_length` must be greater than 0.
- `vid_hsize1`: - the numbers are expressed in number of bytes (the fields are specifying the payload).

**vid\_hsize1** - the numbers are expressed in number of bytes (the fields are specifying the payload of the corresponding packet).

- `hsa_length` need to be at least set to one if pulse mode is enabled. The expected normal operating range is 1 to 255, large values for the HAS length will impact on the size of the DPI FIFO required.
- `hbp_length` can have any value. However, when set to 0, a HBP packet is generated with 0 payload.

**vid\_hsize2** - again the fields are specifying the payload of the corresponding packet (in byte).

- `hfp_length` can have any value. However, when set to 0, no HFP blanking packet is generated.
- `rgb_size` must match the number of pixel per line of the display multiplied by the number of byte per pixel.

**vid\_blksize1** - still specifying size of the payload in byte.

- `blkline_event_pck` defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when `reg_blkline_mode` = 0b01 or 0b00 and when `sync_pulse_active` = 0. It is also needed by the VSG when `reg_blkline_mode` = 0b1x. Its value depends on the `hbp`, `rgb`, `blkeol`, and `hfp` packet length.
- `blkline_event_pck` defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when `reg_blkline_mode` = 0b01 or 0b00 and when `sync_pulse_active` = 0. It is also needed by the VSG when `reg_blkline_mode` = 0b1x. Its value depends on the `hbp`, `rgb`, `blkeol`, and `hfp` packet length.

-- 32767 = 0x7FFF = max value on 15 bits and -100 to take

`margin blkeol_pck < 32767 - hfp_length - hbp_length - hsa_length - rgb_size - 100;`

The `blkeol_pck` (and `blkeol_duration`) must be adapted to the `reg_wakeup_time` in case VCA is authorized to go back in LP.

**vid\_blksize2** - still specifying size of the payload in byte.

- `blkline_pulse_pck` has almost the same definition than `blk_event_pck` but it concerns blanking lines with sync pulse.

**vid\_pck\_time** - specifies duration in clock cycles.

- `blkeol_duration`: `blkeol_duration` = `div_round_up` <sup>(1)</sup> ((`blkeol_pck` + 6), `lane_nb`);
- `vert_blanking_duration` is no longer used and can always be set to 0. It remains present in the design for legacy reason.

**Note 1:** The function `div_round_up` is a function that performs a division then round the result to the first entire number superior or equal to the division result.

**vid\_dphy\_time**: specifies duration in clock cycles. These are values that have external dependencies and thus need to be calculated first (and rest of VSG programming is calculated from these values).

**reg\_line\_duration**: depends on display type and size and of its programming (in some display, the blanking sizes can be adapted to provide a given number of frame per second with one of the D-PHY possible clock frequency (as PLL can only generate a given number of discrete frequencies).

**if (pulse mode) {**

```

line_length = (blkline_pulse_pck + 6);
}
else (event mode) {
line_length = (blkline_event_pck + 6);
if (burst_mode and burst_lp and lane_nb == 2 and
hsa_length[0:0] == 1 and hfp_length[0:0] == 1)
line_length = line_length - 1;
}
result = div_round_up(line_length, lane_nb);

```

**Note 1:** The function `div_round_up` is a function that performs a division then round the result to the first entire number superior or equal to the division result.

Additional Notes about the line duration:

- If line length (in bytes) is a multiple of the number of lanes enabled, DSI will never face any timing jitter except due to the resynchronization in SP/DCB.
- If line length (in bytes) is NOT a multiple of the number of lanes enabled For Non LP operation, there should not have any problem since the line is once longer, once shorter than the "normal" value. For example: if line length is 491 bytes, it will be 245 then 246 in clock cycles with 2 lanes for an average value of 245.5.

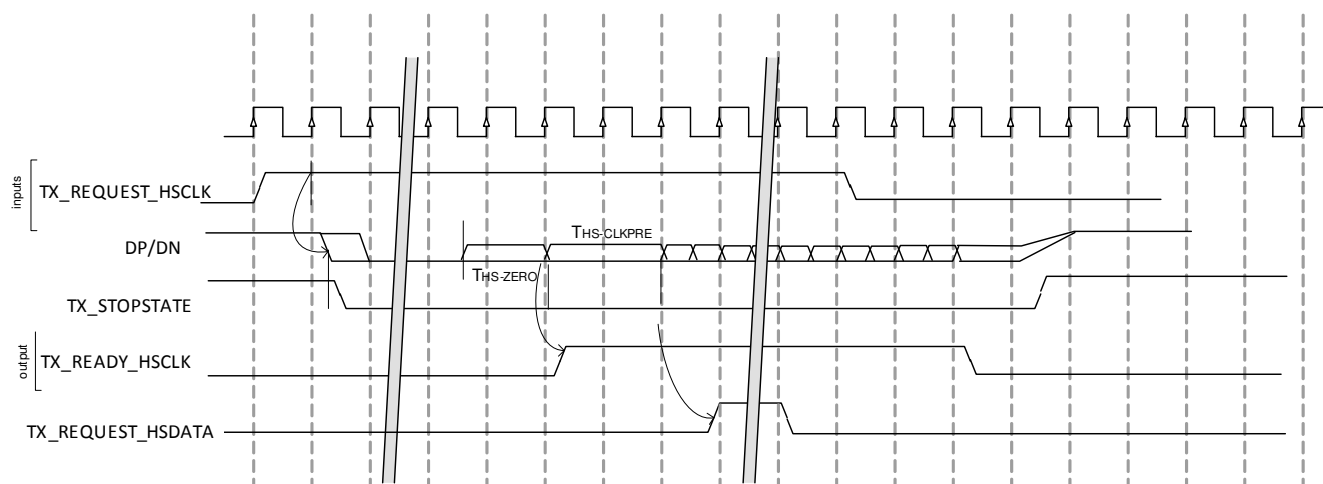

For LP enabled operation, the controller cannot allow underflow of the line and frame timing. With the previous example, the LP line length in clock cycles will be 246 since we cannot start the HS transmission in the middle of a clock cycle. And there is no mechanism to have one line in 245 and the next one in 246 cycles. For LP see section 0.

**reg\_wakeup\_time** must be shorter than line duration and depends on the D-PHY cell plus some pipelines delays inserted by the DSI link. This value strongly depends on the DPHY PLL programming and configuration, and is a mix of both internal and external analog and digital timing factors, therefore it is very difficult to provide an exact formula. The recommended approach to selecting a suitable value for this parameter is to characterize behaviour in at the system level environment using simulation, emulation (e.g. Palladium) or validation (e.g. FPGA).

The DPHY needs 100 ns + time for THXS-EXIT to go to Low Power mode.

The timing for the clock lane TXRequestHS going active to the TXReadyHS will be determined by the DPHY DDR bit rate clock frequency. The timing will be the total number of DDR bit clk cycles for the TXRequestHS to be detected and the clock lane to transition to High Speed, so  $TLPX + TCLK\_PREPARE + TCLK\_ZERO$ . Additional time is required between the clock lane driving HS clocks and the Data Lanes being activate,  $TCLK\_PRE$ . All of these parameters can be calculated from the DPHY datasheet.

Figure 12-578 shows timing diagram for clock lane activation/deactivation.

**Figure 12-578. Timing Diagram for Clock Lane Activation/Deactivation**

The data lane request follows a similar timing sequence from the TX\_Request\_HS to TX\_Ready\_HS, TLPX + THS-PREPARE + THS\_ZERO. The data lane requests will be activated once the clock lane is ready, i.e TX\_Ready\_HSCLK is high.

Figure 12-579 shows timing diagram for data lane activation/deactivation.

**Figure 12-579. Timing Diagram for Data Lane Activation/Deactivation**

**Table 12-488. Timing Parameters**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TLPX	Transmitted length of any Low- Power state period.	50 ns		50 ns
TCLK-PREPARE	Time that the transmitter drives the Clock Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	38 ns	95 ns	38-95 ns
TCLK-PREPARE + TCLK-ZERO	TCLK-PREPARE + time that the transmitter drives the HS-0 state prior to starting the Clock.	300 ns		300 ns
Wakeup Time CL				388-445 ns
TCLK-PRE	Time that the HS clock shall be driven by the transmitter prior to any associated Data Lane beginning the transition from LP to HS mode.	8 UI		12.3 ns

**Table 12-488. Timing Parameters (continued)**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
THS-PREPARE	Time that the transmitter drives the Data Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	40 ns + 4 × UI	85 ns + 6 × UI	~ 46-95 ns
THS-PREPARE + THS-ZERO	THS-PREPARE + time that the transmitter drives the HS-0 state prior to transmitting the Sync sequence.	145 ns + 10 × UI		160 ns
Wakeup Time DL				~ 270 ns

So the wakeup time values expressed as tx\_byte\_clk (12.3ns) cycles, CL = 36 and CLKPRE + DL = 22.

Figure 12-580 shows wakeup time timing diagram.

**Figure 12-580. Wakeup Time Timing Diagram**

Here is the example of the calculation done for the system running at **650 MHz**.

```

if (clk_continuous == TRUE) {
wakeup_time_cl = 0x1;
} else {
wakeup_time_cl = 0x24;
};

wakeup_time_dsi = 0xA; -- from request on VSG to request HS on DL1 (+ 1 for VSG internal cycle)
wakeup_time_dl = 0x14; -- from stop state falling edge to tx_ready rising edge
reg_wakeup_time = wakeup_time_dsi + wakeup_time_cl + wakeup_time_dl + (hs_host_eot × 4 / lane_nb)

```

**Note:** It is not necessary to program all the register values every time because some of them are used only in some modes. For instance, blkline\_event\_pck and blkline\_pulse\_pck are used depending on the way SYNC is generated, and then in pulse mode, there is no need to program blkline\_event\_pck and vice-versa.

### 12.9.2.7.7.3 VCA Configuration

The VCA setting done in two registers: vid\_vca\_setting\_1 and vid\_vca\_setting\_2. Their programming must respect the following rules:

- vid\_vca\_setting\_1:

- max\_burst\_limit specifies the size of the bigger packet that generates the following sequence RGB + packet + NULL packet + BLK packet; it must be linked with blkeol\_pck (same size minus the smaller NULL packet). It is equal to blkeol\_pck - 6.
  - burst\_lp can be set to 1'b1 if blkeol\_pck > 2 × reg\_wakeup\_time × lane\_number (reg\_wakeup\_time is only specifying the time to go from LP to HS thus need to consider the time to go from HS to LP too).
- vid\_vca\_setting\_2:
  - exact\_burst\_limit: as it specifies (in byte) the payload of the packet that generates a sequence RGB + packet + HFP, it must have the same value as of blkeol\_pck when the DSI link is in burst mode.
  - max\_line\_limit specifies the maximum size of a packet that generates HSS + (HSA + HSE) + packet + NULL packet. It then depends on line\_duration, hsa\_length regardless if the system is using pulse or event synchronizing. Its size is linked to vert\_blanking\_duration.

```
if (sync_pulse_active == 0) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = (blkline_event_pck-6);
};
if (sync_pulse_active == 1) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = gen_blkline_pulse_pck-6;
```

Another constraint to respect when using VCA is to ensure that only supported operations are sent from command side when video is active. For instance, no TE should be attempted, because it could break the video stream (TE completion time can be long). Command messages can be inserted into the LP states provided there is sufficient space for the message bytes and any associate bytes for the header and CRC, if a long packet type.

#### 12.9.2.7.7.4 TVG Configuration

The TVG has a single register: tvg\_img\_size that should complies with the following rules against VSG settings:

tvg\_line\_size: must be equal to rgb\_size set for VSG

tvg\_nblne: must be equal to vact\_length set for VSG

The TVG generates a data stream in the same format than the one specified at the output of the VRS. The content of that flow is specified by the following registers:

- Image size - TVG\_LINE\_SIZE[14:0] and TVG\_NBLINE[12:0] registers: Number of bytes per line and number of lines per frame.
- Image kind - TVG\_MODE[1:0] register: Single color, vertical stripes or horizontal stripes.
- Stripe width - TVG\_STRIPE\_SIZE[2:0] register: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128.
- Pixel kind VID\_PIXEL\_MODE[3:0] register: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB.
- Color one - COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered.
- Color two - COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered.
- Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

The Test Video Generator can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-581 presents TVG MODE patterns.

**Figure 12-581. TVG MODE Patterns**

An example of the sequence is as follows:

- Select TVG for video stream generation instead of DPI/SDI 1 interface.
  - IF1\_EN bit to 0 (SDI stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL.
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register.
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.
  - Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
  - Stripes size in TVG\_STRIPE\_SIZE field.
  - Image size in TVG\_IMG\_SIZE register.

**Note:** The TVG settings on active area for the number of lines per frame and number of bytes per line must match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL.
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register.
  - Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop the instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.9.2.7.8 DPI To DSI Programming

The DPI interface will normally be driven from a graphics driver that will be configured to match a frame geometry and refresh rate for a panel display. The DPI driver will use the expected refresh rate and geometry for the active and blanking parts of a frame to determine the pixel rate clock. The DSITX controller will then translate this to match the incoming byte information to send across the DSI DPHY link.

A system will always expect the bandwidth of the incoming pixels × BPP to match the transmission of bytes from the DSI DPHY based on the number of active lanes. The relationship of DPI clock to TX byte clock must ideally hold with the following formula:

$$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_clk}} \times \text{active\_lanes} \times 8 \div \text{bits\_per\_pixel};$$

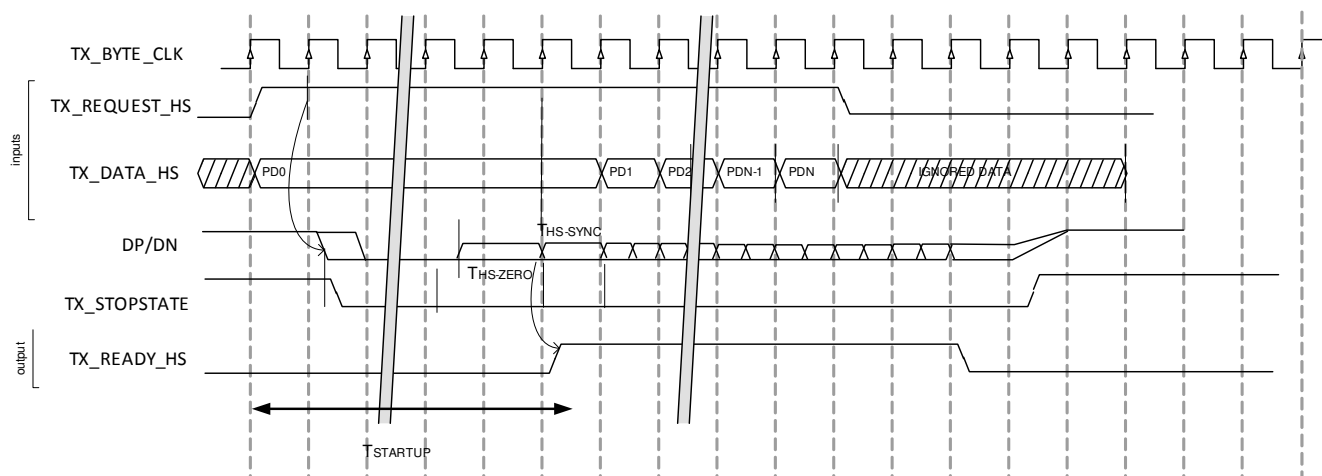

The DSI will supply packets to the DPHY interface using the internal sequencing and counters clocked from the tx\_byte clock. The normal system operation will mean that the DSI must always have the correct number of tx\_byte clock cycles to match the number of pixel clock cycles. This means that all the events used for the packet generation will be directly impacted by the delay that exists in the DPHY High Speed request to ready.

The DSITX controller relies upon the DPHY PLL being programmed and locked before starting the DPI video. The DSITX controller can then be configured and enabled (clock lane and data lanes) before starting the video transmission.

The DSITX controller will begin data transmission with a High Speed request after it receives the falling edge of the VSYNC on the DPI interface. The controller will then begin to build the bytes for the VSYNC packets (VSS, HSA, Blanking packets) during the delay period before the ready is returned from the DPHY. This delay will add an interval effect on all the packets that follow.

The DPI FIFO size must be sufficient to buffer all the incoming pixel data during the active line stage while the DSITX controller continues to send the previous lines packet information due to this interval effect.

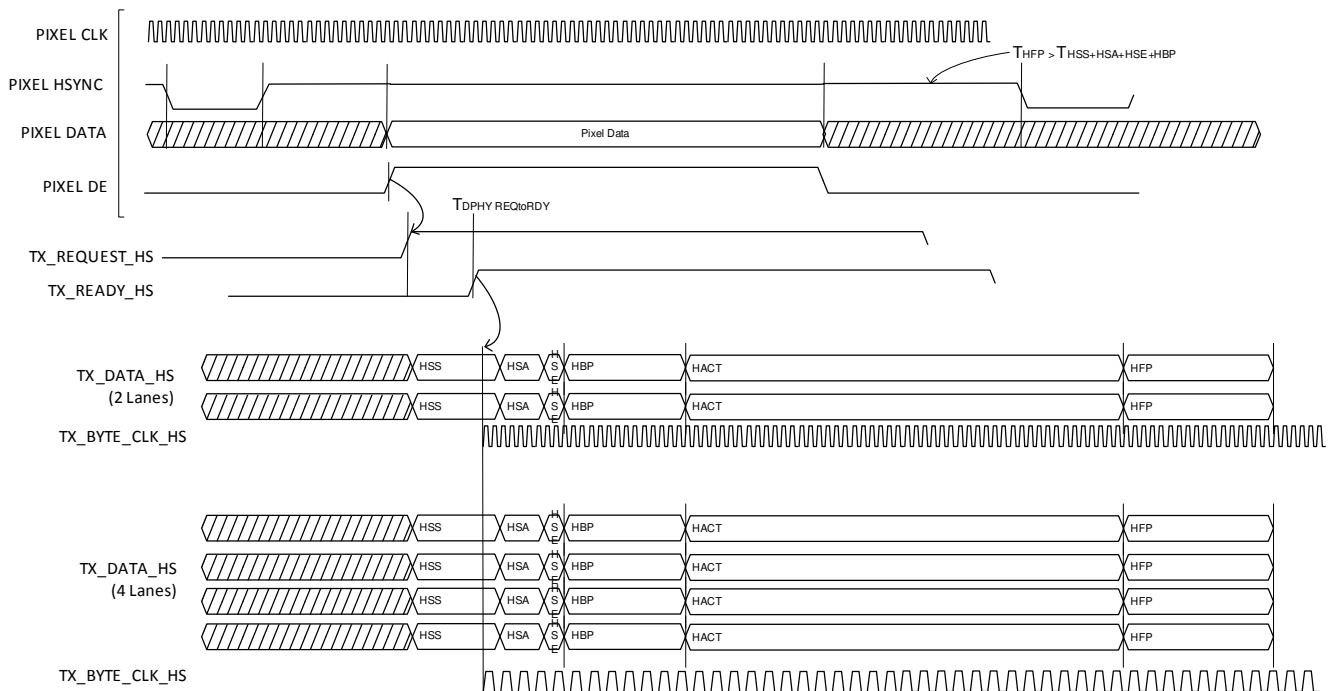

**Figure 12-582. Timing Diagram**

The DPI and DSI system may not be able to guarantee the exact frequency on the pixel clock input or tx\_byte clock from the DPHY. The DSI configuration can be adjusted to support a small deviation in frequencies using the size of the HFP packet so that it changes the alignment of packets on the active lanes to absorb the different pixel clock cycles during the line. More details are given in section 0.

#### 12.9.2.7.8.1 DSI and DPHY Operation

The DPI FIFO is used to buffer all the active pixel data from the DPI interface during the active line. The depth of the FIFO must be selected to allow the pixel to be stored after the DPHY request to ready delay is introduced at the start of every frame. The FIFO will fill to a depth based on the tx\_byte clock cycles used from the point where VSYNC is identified to the response from the DPHY link after it has exited Low Power and entered the zeroes state on the active data lanes.

Figure 12-583 presents DPI interface to DSI DPHY timing diagram.

**Figure 12-583. DPI Interface to DSI DPHY Timing Diagram**

The timing diagram above illustrates how the packets are generated for a DPHY with two and with four lanes activated. The diagram shows that the tx\_byte clock changes based on the number of lanes, and that the configuration register values for the number of bytes used for HSA, HBP and HFP will remain the same.

The register values calculated for each of the line synchronization stages needs to take the number of bytes used to form the packet into account so that the timing for each stage aligns to the timing of the DPI input and most importantly that the total number of bytes exactly matches the number of byte clock cycles. The values used for the Horizontal Front porch must be larger than the combined horizontal sync and back porch to allow the DPI FIFO to empty.

The basic rule is that the values used for the DSI will be based on the  $\text{DPI} \times \text{BPP}/8$ .

The DPI graphics driver must be configured with horizontal values that can be directly translated to DSI packet payloads.

- The minimum values for the DPI HSA must convert to be greater than:
  - Non-Burst Sync Pulses – 15 bytes
  - Non-Burst Sync Events – 11 bytes
- The minimum values for the DPI HBP must convert to be greater than:
  - Non-Burst Sync Pulses – 7 bytes
  - Non-Burst Sync Events – 7 bytes

These values will then form the number of tx\_byte\_clk cycles used to send the bytes over the number of active lanes. So, for an RGB888, DSI configuration the minimum values will be:

- $\text{HSA} = \text{roundup}(15/3) = 5$
- $\text{HBP} = \text{roundup}(11/3) = 4$

The diagram below, D-PHY Timings Control (see [Figure 12-584](#)), illustrates the byte mapping for a four lane DPHY link. In this example, the calculation for the horizontal sync stage aligns exactly across the four byte lanes.

- HSS – Four Bytes
- HSA – Blank Packet with Header (4) + HSA\_Count + CRC(2)
- HSE – Four Bytes

The next stage is the horizontal back porch:

- HBP – Blank Packet with Header (4) + HBP\_Count + CRC(2)

The value used in the HBP count can be used to account for the Header bytes used in the active data packet in next stage, although it is best to add this to the HFP stage calculation and allow time to empty the FIFO.

**Figure 12-584. Horizontal Line Packet Timing Diagram**

The Active part of the line will be a fixed size based on the line size and BPP, and include the six bytes for the packet header and CRC. The final stage is the horizontal front porch.

- HFP – Blank Packet with Header (4) + HFP\_Count + CRC(2)

The HFP value should be adjusted to ensure that the number of tx\_byte clock cycles for the horizontal line exactly matches the pixel clock cycles for the line times the BPP.

The timing diagram below, Control Block, illustrates the byte alignment changing when the HBP calculated is two bytes shorter than the previous case. This leads to the active and front porch packet headers beginning two bytes earlier, however the HFP count is adjusted to keep the end of the line on exactly the same tx\_byte\_clk cycle count.

**Figure 12-585. Horizontal Line Packet - Shorter HBP - Longer HFP Timing Diagram**

The recommendation is to ensure that the total bytes for each horizontal line results in an exact integer tx\_byte clock cycles (Total\_bytes MOD num\_of\_lanes = zero), except for the case where the clocks are not exactly matched.

#### 12.9.2.7.8.2 Pixel Clock to TX\_BYTE\_CLK Variation

The selection of the Pixel clock rate and DPHY Bit clock rate should ideally match based on the ratio of bpp on the pixel side compared to the tx\_byte\_clk. The timing for the horizontal sync, back and front porch will also be configured to allow the pixel data to be transferred without any over or underflow of the DPI FIFO.

The DPI FIFO fill level register (DPI\_CFG) can be used to track that the parameters are sufficient and that any clock variation can still be handled by the FIFO depth. This register will show the pixel data held in the buffer, so during the HSA and HBP packet generation stages DPI pixel data will be stored and this value will increment. Once the data packet is being generated, the DPI\_CFG level will remain constant, as the buffer is emptied at the same bandwidth as it is filled. Finally, the value will reduce to zero during the HFP stage.

The packet length of the HFP can be adjusted to help absorb small differences in the pixel\_clk to tx\_byte\_clk relationship. The DSITX controller will concatenate all of the packets during High Speed transmission, so for example adding to the byte value of the HFP will make the bytes at the end of the packet move to align on another lane.

The packets that follow will then be concatenated and aligned to the next available lane, so if the tx\_byte\_clk is faster than the expected pixel clock times bpp the extra byte will delay the start of the new line tx\_byte\_clk × extra\_byte/lanes.

Figure 12-586, Video coherency, illustrates the impact of increasing the HFP by one byte so that the next line begins ¼ tx\_byte clock later. This allows averaging out across the line length of small differences in the pixel to tx\_byte clocks when the tx\_byte clock is not ideally matched to the expected pixel clock multiplied by bpp.

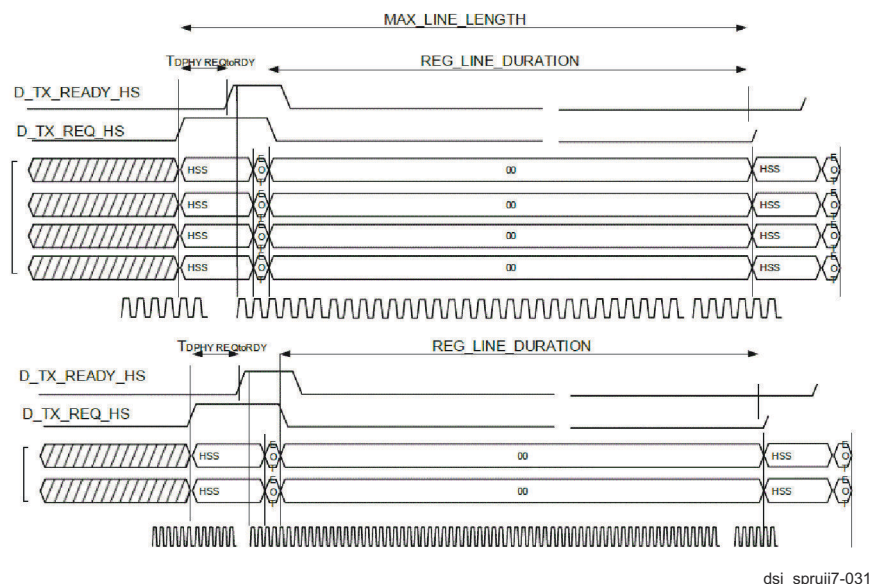

ds\_i\_spruij7-030

**Figure 12-586. Packet Alignment Control Using HFP Byte Increase - tx\_byte\_clk Faster than Ideal Rate**

The DPI\_CFG register will show any clock misalignment as an increasing/decreasing value for the FIFO fill level on each line of pixels (must be read mid-line for an accurate reading of the level). When the byte count adjustment is made, the DPI\_CFG register will return to the original fill level value every four lines.

#### 12.9.2.7.8.3 LP Operation

The DSITX controller can be configured to perform a transition between LP state and HS state during the horizontal lines which have long periods of blanking. The registers controlling the timing for the DPHY wakeup time and the reg\_line\_duration must be programmed to exactly match the DPI cycles of the horizontal line to the tx\_byte\_clk cycles required for the number of active lanes selected.

**Figure 12-587. Low Power Operation with Four and Two Active Lanes**

The LP operation for each vertical blanking line will require the `reg_line_duration` to be configured to match the following:

- `Max_line_length` (in `tx_byte_clk` cycles see 2.2.4) minus `Eot` (if enabled), also minus further 10 if `CLOCK` lane is non-continuous.

Note `REG_WAKEUP_TIME` is used internally to adjust the cycles for each vertical LP line.

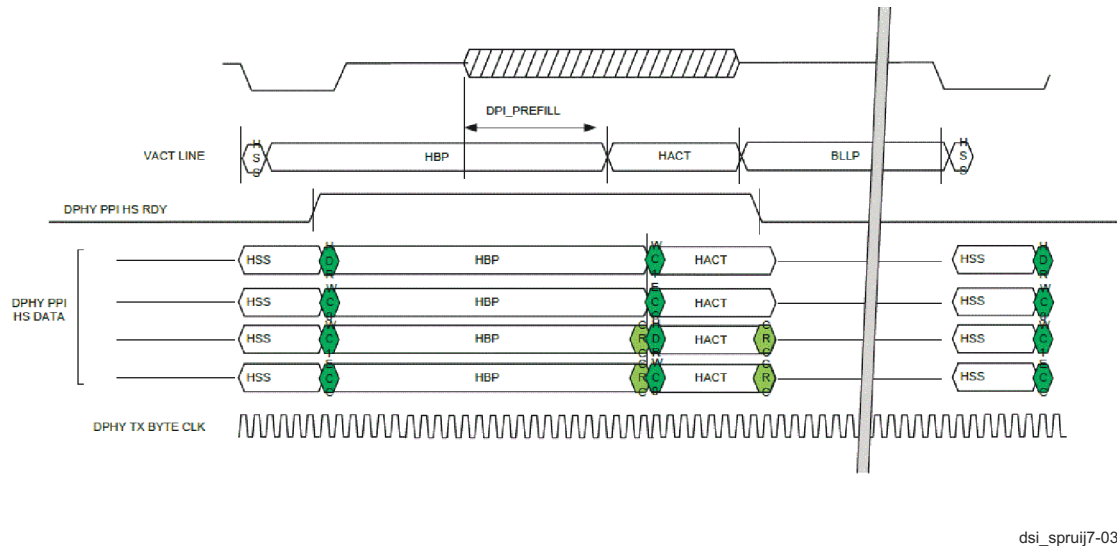

**Figure 12-588. REG\_LINE\_DURATION Timing Example for LP Operation**

#### 12.9.2.7.8.4 DPI Interface Burst Operation

The DSITX controller can support burst operation on the DPI interface provided the DPI FIFO size is large enough to store the line pixel data with enough data to not underflow. The burst operation will use a `tx_byte_clk` that is faster than normal event based operation, so the DPI FIFO size will be impacted by the ratio of the `pixel_clk` and `BPP` input to the `tx_byte_clk` and number of lanes on the output.

The recommended operation is to set the DSI HSA and DSI HFP registers to zero, and adjust the DSI HBP size to control the number of bytes prefilled in the DPI FIFO before the burst is sent.

Figure 12-589 shows DPI operation with event burst mode.

**Figure 12-589. DPI Operation with Event Burst Mode**

#### 12.9.2.7.9 Programming the DSITX Controller to Match the Incoming DPI Stream

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. Assuming that is the case, then the blanking and active data periods must be matched up.

For each frame of video the time will be:

$$(V_{\text{total}} * H_{\text{total}})_{\text{@pixel\_clk}} = (V_{\text{total}} * H_{\text{total}})_{\text{@tx\_byte\_clk}} \times \text{bits\_per\_pixel}/8;$$

So for example, the time for a full HD frame 1920x1080 with reduced blanking in RGB565 will be:

$$2200 \times 1200 \text{ pixels} = 2200 \times 1200 \text{ tx\_bytes} \times 16/8;$$

The DSITX controller will match its frame timing to the incoming DPI vsync, as long as it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered. The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

##### 12.9.2.7.9.1 Vertical Timing

The DSITX controller will generate vertical packets for each part of the frame beginning with the VSS and VSE combined with blanking packets to fill the VSA. The blanking packets for the pulse mode program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2 → VSS and VSE)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

DPI horizontal timing is measured in pixel clocks, whereas the DSITX controller uses byte clocks. The horizontal timing should also be matched per line; therefore the blanking and active periods of each line should match. The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. The timing for a horizontal line for the DPI driver side will be the number of pixel cycles for the **HLINE** = (HSA + HBP + HACT +

HFP) and this will form **HLINE** × bpp/8 bytes for the controller. These bytes will then be sent using 1, 2, 3 or 4 data lanes, so the DSITX controller will required 1, ½, 1/3, ¼ this number of tx\_byte\_clk cycles respectively.

e.g a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line.

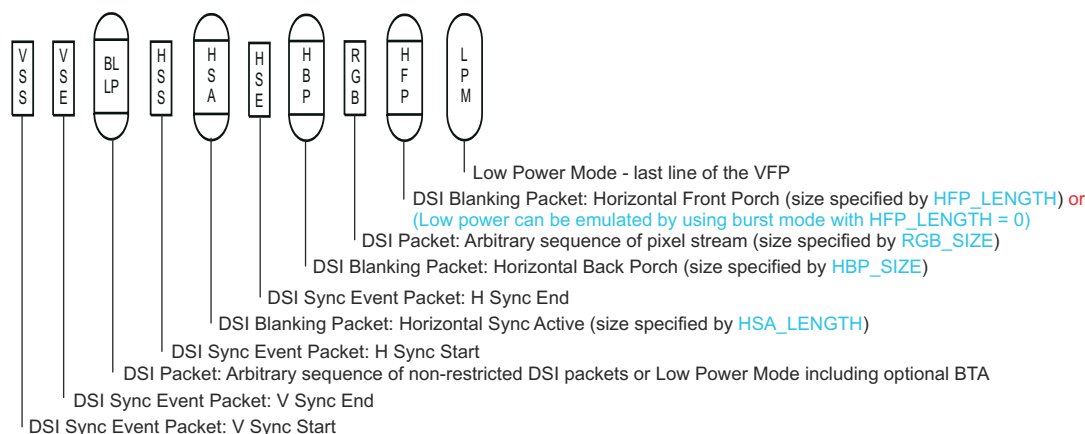

This gives the DSI horizontal lines 3936 bytes to transmit and would use 984 tx\_byte\_clks on a four lane system, or 1312 on a three lane system etc..

The horizontal configuration uses different registers depending on the Mode (Pulse or Event) and the control of the BLKLINE\_MODE register bit.

- Non-Burst Mode with Sync Pulses – enables the peripheral to accurately reconstruct original video timing, including sync pulse widths.

Note that for accurate reconstruction of timing, packet overhead including Data ID, ECC, and Checksum bytes should be taken into consideration.

- Non-Burst Mode with Sync Events – similar to above, but accurate reconstruction of sync pulse widths is not required, so a single Sync Event is substituted.
- Burst mode – RGB pixel packets (active video) portion are time-compressed, leaving more time during a scan line for LP mode (saving power) or for multiplexing other transmissions onto the DSI link.

ds1-034

**Figure 12-590. Vertical Timing**

#### 12.9.2.7.9.2 Horizontal Timing for Non-Burst Mode with Sync Pulses

Sync Pulse Mode uses the Short packet and Long packet structures to accurately track the DPI interface timing. Figure 12-591 illustrates the packet sequence for a single frame.

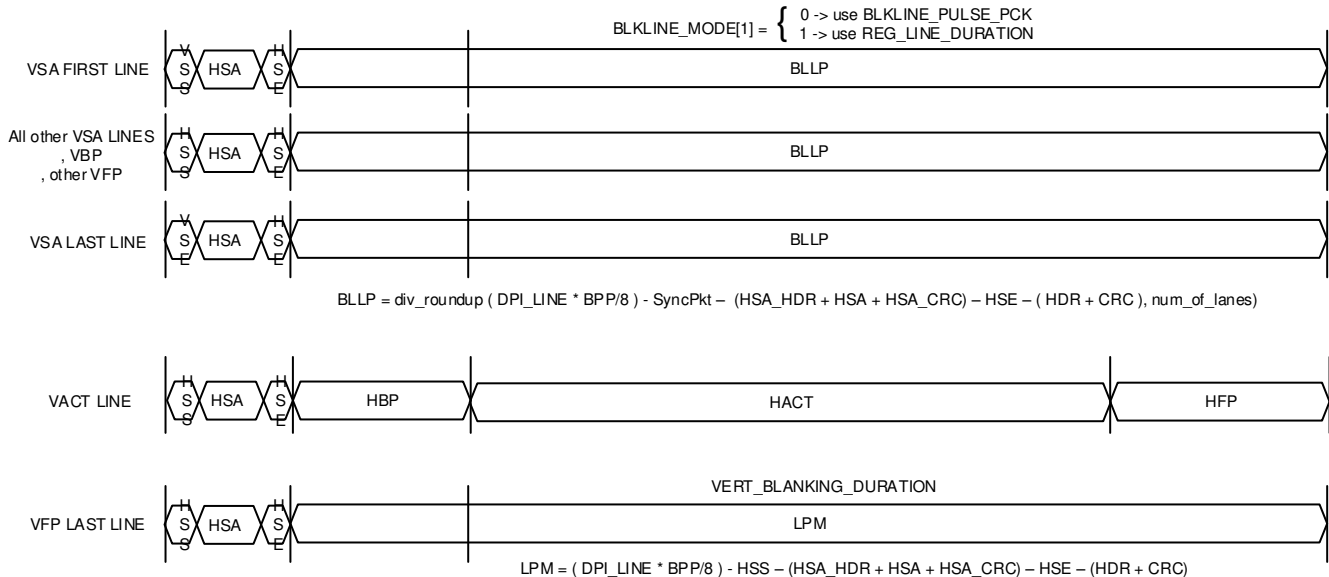

dsi-035

**Figure 12-591. Vertical Timing**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, Trigger Mapping Information. The calculation of the total number of bytes in any horizontal line must always be  $HLINE \times bpp/8$  bytes.

**Figure 12-592. Non-Burst Mode With Sync Pulse Line Structures**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and CRC footer (4 + 2 bytes) and the HSE short packet (4 bytes).
- HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes).
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.

Finally for lines with no active data, the controller will use either:

- **BLKLINE\_PULSE\_PCK**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in bytes minus the HSA 20 bytes (14 for HSA header and CRC, 6 for the remaining blanking which is all combined into a single packet).
- **REG\_LINE\_DURATION**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times \text{bpp}/8$  minus 14 bytes (14 for HSA header and CRC) minus the EOT packet (4 bytes) if required, divided by number of lanes). This should be aligned to the number of active lane so rounding the value so that  $REG\_LINE\_DURATION \bmod \text{Lanes}$  equals zero.
- **VERT\_BLANKING\_DURATION**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times \text{bpp}/8$  minus 14 bytes (14 for HSA header and CRC) divided by number of lanes).

Program the DSI horizontal size registers as follows:

$\text{burst\_mode} = 0$  and  $\text{sync\_pulse\_active} = \text{sync\_pulse\_horizontal} = 1$ ;

$HSA = (DPI\_HSA \times \text{bpp}/8) - 14$  – DPI HSA min value 5 for RGB888

$HBP = (DPI\_HBP \times \text{bpp}/8) - 12$  – DPI HBP min value 5 for RGB888

$HACT = (DPI\_HACT \times \text{bpp}/8)$

$HFP = (DPI\_HFP \times \text{bpp}/8) - 6$  – DPI HFP min value 10 for RGB888

**Note:**  $(DPI\_HACT \times \text{bpp}/32)$  must be an integer. Total Line Length =  $\text{div\_roundup}((H_{LINE} \times \text{bpp}/8), \text{num of lanes})$ ;

$(BLKLINE\_PULSE\_PCK) \text{ bytes} = (H_{LINE} \times \text{bpp}/8) - 20 - HSA$ ;

$(REG\_LINE\_DURATION)_{\text{tx\_byte\_clks}} = \text{Total Line Length} - \text{div\_roundup}((HSA \times \text{bpp}/8) - 14, \text{number of lanes})$ ;

$(VERT\_BLANKING\_DURATION)_{\text{tx\_byte\_clks}} = \text{Total Line Length} - \text{div\_roundup}((HSA \times \text{bpp}/8) - 14, \text{number of lanes})$ ;

For example; a DPI with  $HSA = 12$ ,  $HBP = 12$ ,  $HACT = 1920$ ,  $HFP = 24$  and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI  $H_{LINE}$  of 3936 bytes. So for 4 lanes, 984 tx\_byte\_clk cycles;

$HSA = (12 \times 16/8) - 14 = 10$

$HBP = (12 \times 16/8) - 12 = 12$

$HACT = (1920 \times 16/8) = 3840$

$HFP = (24 \times 16/8) - 6 = 42$

Total Line =  $\text{div\_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984 \text{ tx\_byte\_clk cycles} = 3936 \text{ bytes}$ ;

$BLKLINE\_PULSE\_PCK = (3936) - 20 - 10 = 3906$

$REG\_LINE\_DURATION = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$

$VERT\_BLANKING\_DURATION = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$

Confirming the calculation for each line with  $BLKLINE\_MODE = 0$ ;

$VSS = VSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VSA_{Line} = HSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VSE = VSEPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VACT = HSSPkt + HSAPkt + HSEPkt + HBPPkt + HACTPkt + HFPPkt = 4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936$ ;

$VFP = HSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$

$VFPLast = HSSPkt + HSAPkt + HSEPkt + VERT\_BLANKING\_DURATION = 4 + (4 + 10 + 2) + 4 + (978 \times 4) = 3936;$

Confirming the calculation for each line with  $BLKLINE\_MODE = 1$  matches the tx\_byte cycles;

$VSS = VSSPkt + HSAPkt + HSEPkt + REG\_LINE\_DURATION = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$

$VSALine = HSSPkt + HSAPkt + HSEPkt + REG\_LINE\_DURATION = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$

$VSE = VSEPkt + HSAPkt + HSEPkt + REG\_LINE\_DURATION = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$

$VACT = HSSPkt + HSAPkt + HSEPkt + HBPPkt + HACTPkt + HFPPkt = \text{div\_roundup}((4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2)), 4) = 984;$

$VFP = HSSPkt + HSAPkt + HSEPkt + REG\_LINE\_DURATION = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$

$VFPLast = HSSPkt + HSAPkt + HSEPkt + VERT\_BLANKING\_DURATION = \text{div\_roundup}((4 + (4 + 10 + 2) + 4 + (3912), 4) = 984;$

#### 12.9.2.7.9.3 Event Mode Horizontal Timing

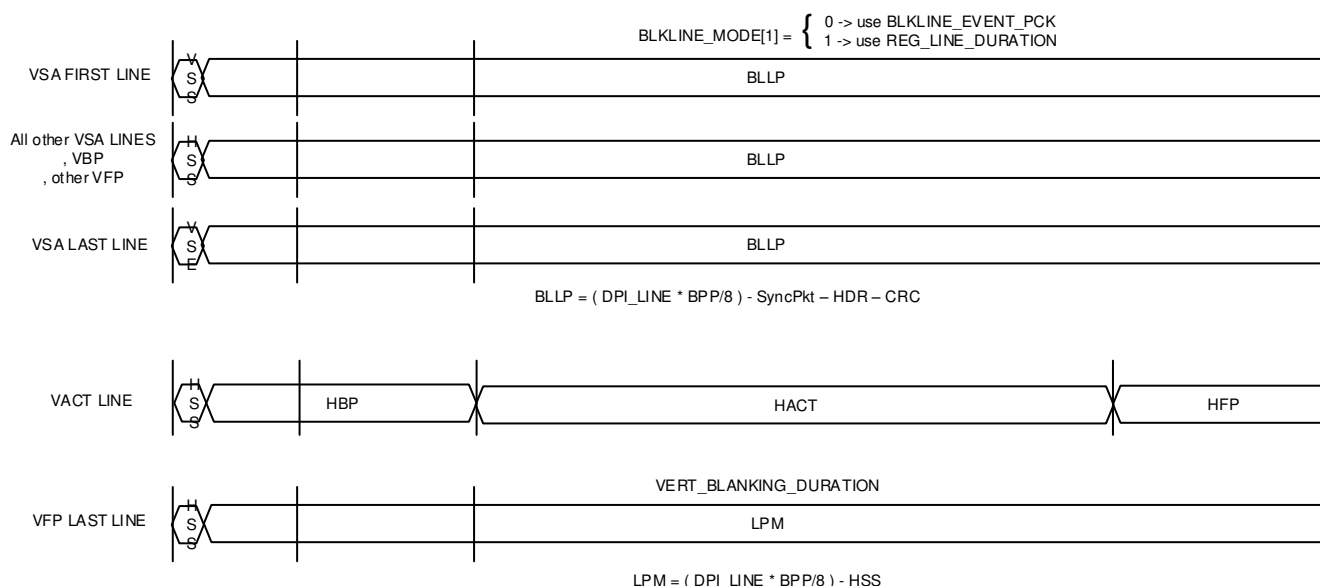

Non Burst Event Mode uses the Short packet and Long packet structures to track the DPI interface timing without accurate reconstruction of sync pulse widths, so a single Sync Event is substituted. [Figure 12-593](#) illustrates the packet sequence for a single frame.

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal.

**Figure 12-593. Horizontal Timing - 1**

line based on the DPI line configuration and the BPP for the colour pixel data. The packet structure for each of line during the frame is shown in [Figure 12-594](#):

**Figure 12-594. Horizontal Timing - 1**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (2 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet.
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer and footer of the active data.

Finally, for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK: Total line size (HLINE × bpp/8) in bytes minus 10 bytes (4 for VSS/VSE/HSS, 6 for the remaining blanking header/footer which is all combined into a single packet).
- REG\_LINE\_DURATION: Total line size div\_roundup(HLINE × bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 8 bytes (4 for VSS/VSE/HSS, and 4 for EOT). This should be aligned to the number of active lane so round the value so that REG\_LINE\_DURATION MOD Lanes equals zero.
- VERT\_BLANKING\_DURATION: Total line size div\_roundup(HLINE × bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 4 bytes (4 for HSS).

Program the DSI horizontal size registers as follows:

burst\_mode = 0 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = ((DPI\_HSA + DPI\_HBP) × bpp/8) - 12 - DPI HSA + HBP min value 5 for RGB888
- HACT = (DPI\_HACT × bpp/8)
- HFP = (DPI\_HFP × bpp/8) - 6 - DPI HFP min value 10 for RGB888

**Note:** (DPI\_HACT × bpp/32) must be an integer. Total Line Length = div\_roundup((HLINE × bpp/8), num of lanes).

(BLKLINE\_EVENT\_PCK) bytes} = (HLINE × bpp/8) - 10

(REG\_LINE\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(8, number of lanes)

(VERT\_BLANKING\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(4, number of lanes)

For example: a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes.

HSA = 0

$$HBP = ((12 + 12) \times 16/8) - 12 = 24$$

$$HACT = (1920 \times 16/8) = 3840$$

$$HFP = (24 \times 16/8) - 6 = 42$$

$$\text{Total Line} = \text{div\_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984$$

$$\text{BLKLINE\_EVENT\_PCK} = (\text{HLIN} \times \text{bpp}/8) - 10 = 981$$

$$\text{REG\_LINE\_DURATION} = 984 - \text{div\_roundup}(8, 4) = 982$$

$$\text{VERT\_BLANKING\_DURATION} = 984 - \text{div\_roundup}(4, 4) = 983$$

Confirming the calculation for each line:

$$VSS = \text{VSSPkt} + \text{BLK\_LINE\_EVENT\_PCKPkt} = 4 + (4 + 3926 + 2) = 3936$$

$$\text{VSALine} = \text{HSSPkt} + \text{BLK\_LINE\_EVENT\_PCKPkt} = 4 + (4 + 3926 + 2) = 3936$$

$$VSE = \text{VSEPkt} + \text{BLK\_LINE\_EVENT\_PCKPkt} = 4 + (4 + 3926 + 2) = 3936$$

$$\text{VACT} = \text{HSSPkt} + \text{HBPPkt} + \text{HACTPkt} + \text{HFPPkt} = 4 + (4 + 24 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936$$

$$\text{VFP} = \text{HSSPkt} + \text{BLK\_LINE\_EVENT\_PCKPkt} = 4 + (4 + 3926 + 2) = 3936$$

$$\text{VFPLast} = \text{HSSPkt} + \text{VERT\_BLANKING\_DURATION} = 4 + (983 \times 4) = 3936$$

#### 12.9.2.7.9.4 Burst Event Mode Horizontal Timing

Burst Event Mode uses the Short packet and Long packet structures to transmit the video information in short bursts and allow the system to use the Low Power states to save active power. This can only be supported with DSITX controllers able to store a horizontal line in the DPI FIFO. The burst mode will expect the tx\_byte\_clk to be twice the rate of the non burst event mode, and the register calculation will expect the total bytes for each line to double. Figure 12-595 illustrates the packet sequence for a single frame.

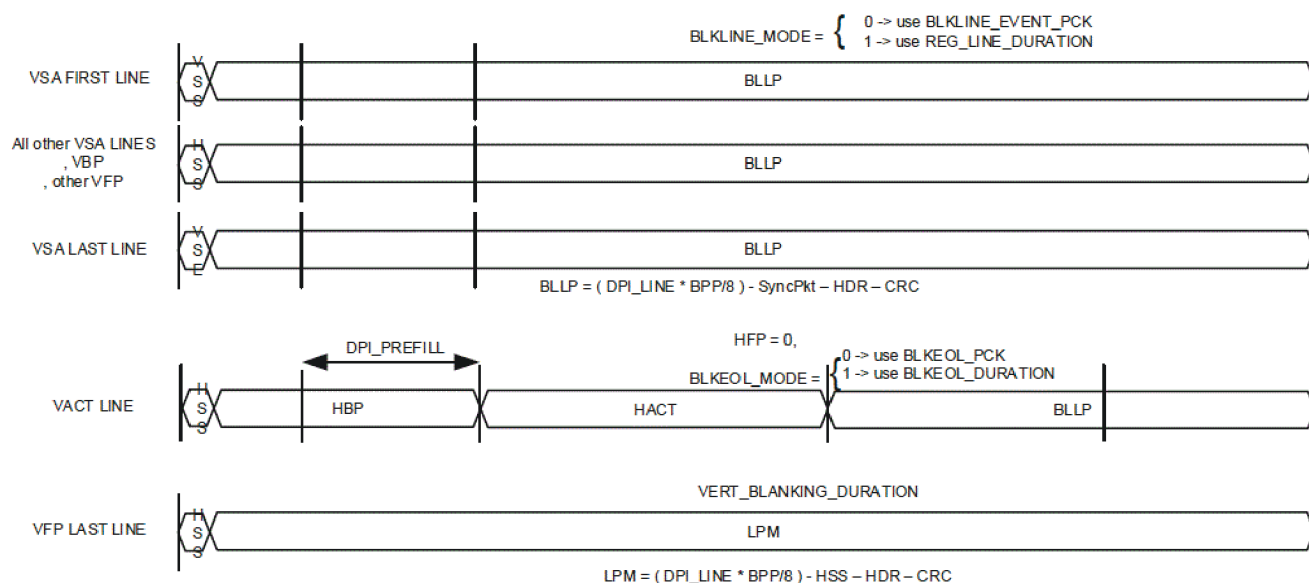

dsi-039

**Figure 12-595. Burst Event Mode Horizontal Timing - 1**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, with the DSI HFP = 0 to select BLLP operation.

dsi\_spruij7-040

**Figure 12-596. Burst Event Mode Horizontal Timing - 2**

The DSI short packets and packet headers that are inserted by the controller for active lines must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet. In this case the DPI must also reduce the HSA and HFP timing.
- BLLP uses BLKEOL\_PCK or BLKEOL\_DURATION and will change depending on the HFP use case:
  - HFP can be zero to extend the BLKEOL\_x values(recommended).
  - or a non-zero value to transmit a Blanking Packet instead of LP state. The Blanking Packet HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.
  - The host\_eot state will cause the BLLP to either add and EOT cycle or not. The BLKEOL\_PCK or BLKEOL\_DURATION value will need to be adjusted to include this extra cycle if host\_eot is disabled.

Finally for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK in bytes, excluding the header and crc.
- REG\_LINE\_DURATION or VERT\_BLANKING\_DURATION.
- Both are the total expected tx\_byte\_clk cycle for the line minus the number of cycles required to send the header packet bytes (4 for VSS/VSE/HSS) over the active lanes.

Program the DSI horizontal size registers as follows:

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = (2 \* (DPI\_HSA + DPI\_HBP) \* bpp/8) - 12 + DPI FIFO Prefill
- HACT = (DPI\_HACT \* bpp/8) NOTE: (DPI\_HACT \* bpp/32) must be an integer.
- HFP = Zero

Total Line Length = div\_roundup((HLINE \* bpp/8), num of lanes);

(BLKLINE\_EVENT\_PCK)} = (HLINE \* bpp/8) \* 2 - 4

$(\text{REG\_LINE\_DURATION})\} = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{VERT\_BLANKING\_DURATION})\} = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{BLKEOL\_DURATION})\} = \text{Total Line Length} \times 2 - \text{TX\_BYTE\_CYCLES}$

$(\text{BLKEOL\_PCK}) \text{ bytes} = \text{Total Line Length} \times 2 - (\text{HACT} + \text{HBP} + \text{HSS})$

**Note:**  $\text{TX\_BYTE\_CYCLES} = \text{TX Byte clock cycles to send Active Line bytes on the number of active lanes} = \text{div\_roundup}(\text{HBP} + \text{HACT}, \text{number of lanes})$ .

### Burst Operation Frame Configuration

Burst mode operation can be used to save power provided the system configuration can support the higher tx\_byte clock rate. The user should consider if the power saving during LP states is more than reducing the number of active lanes and running in non-burst mode.

The burst mode can only be used if the controller configuration can support it; either using SDI video interface, of DPI interface with a buffer size large enough to prefill the data. The video driver timing from the DPI side will also need to be changed.

ds\_i\_spruij7-041

**Figure 12-597. DSITX Controller Video Frames for Burst Mode Compared with DPI Driver Side**

For example:

The VESA configuration for a 1920x1200 frame at 60-frames per second with normal blanking would have a pixel clock at 193.25 MHz, HSA 200 pixels, HBP 336 pixels, HFP 136 pixels and total line 2592 pixels. This would need to be reconfigured to move the active area earlier in the horizontal line for the DSITX controller, so could be changed to; HSA 20 pixels, HBP 30 pixels, HFP 622 pixels. This would allow the HFP LP state to be almost  $\frac{1}{4}$  of the line ( $622/2592$ ).

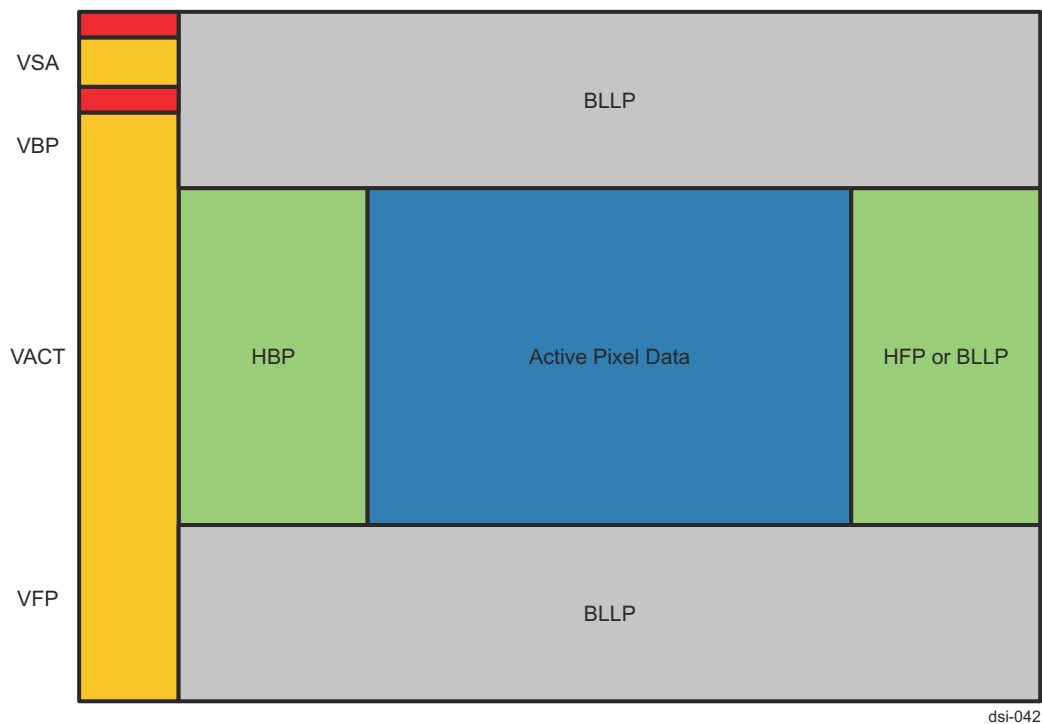

#### 12.9.2.7.9.5 Burst Mode Operation

The DSI IP offers different options for behavior in the BLLP areas:

- Insertion of blanking or null packets.
- Switch to LP (power saving).
- Insertion of commands (if any) + blanking or null packet.

Figure 12-598 shows burst mode operation.

**Figure 12-598. Burst Mode Operation**

The user should balance the increase in the clock frequencies for transmission of the active display, against the power saving by using BLLP(Null) or LP state.

For Burst with the LP state the register fields must be programmed for `burst_lp = 1` and `reg_blkeol_mode = 2'b2`.

### Command Insertion Operation

The DSITX can use the burst operation to allow the blanking/LP stages to be used for DCS/GEN command insertion by programming the size of the space available after the sync of each line.

Only one command packet can be passed within each video line. The decision to insert a command in a video line is done at the beginning of the slot just after the previous video packet. If a command arrives in the middle of the slot, it is not processed in that line, the decision to accept the command will be taken in the next line.

If the packet does not fit in a short slot (size bigger than `reg_max_burst_limit` and not equal to `reg_exact_burst_limit`), it is delayed up to next long slot. The signal `reg_err_burstwrite` is flagged (it is only an information that can help application software control). If its length is longer than `reg_max_line_limit`, it is discarded and the error `reg_err_linewrite` is generated.

Read commands and BTA requests are only passed during long slots, as there is no way to calculate their duration exactly. In the case where their duration takes longer time than the vertical blanking period, the error `reg_err_longread` is flagged.

**Figure 12-599. Burst Mode Command Locations During Video Frame**

### Command Insertion Registers in Burst Operation

The burst operation requires the configuraton of the registers to control the size of the packets that will fit in the space available on each type of horizontal line.

In VSA, VBP or VFP: Insertion of short and long command packets, read or BTA are allowed.

dsi-045

- In VACT: Only short packets can be inserted.
- Command, if inserted, is inserted right after the HSA or HSE or the video packet.
- Only one command can be inserted by line.

- When a command is inserted on a video line, no switch to LP but Null packet insertion.
- Trigger and TE insertion not supported.

VID\_VCA\_SETTING1 register:

[16] BURST\_LP: After an active line, in burst mode, the system can switch in LP (1) or should complete the line with NULL packet (0).

VID\_VCA\_SETTING1 register:

[15:0] MAX\_BURST\_LIMIT: Maximum length of a packet (number of bytes) that can be passed during the blanking period at the end of an active line (in burst mode) followed by a NULL packet with no data (6 bytes).

VID\_VCA\_SETTING2 register:

[15:0] EXACT\_BURST\_LIMIT: Exact maximum size of the burst packet (packet that fits after pixel data in burst mode), that is with no Null packet insertion afterwards.

VID\_VCA\_SETTING2 register:

[31:16] MAX\_LINE\_LIMIT: The "maximum" packet (number of bytes) that can be passed during the vertical blanking period.

If the packet does not fit in a short slot (size bigger than MAX\_BURST\_LIMIT and not equal to EXACT\_BURST\_LIMIT), it is delayed up to next long slot.

- If the packet length is longer than MAX\_LINE\_LIMIT, it is thrown away (an error is asserted).

Table 12-489 outlines the expected behaviour of each packet type during the video frame.

**Table 12-489. Behavior of the DSITX Transmission when Both Video and Command are Running**

Packet type	Packet Size	Behavior	Error Flagged
VACT Active Line - Read and BTA do not pass			
No packet	-	LP mode null packet sent	
Short packet		Packet passed followed by a null packet	
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	

**Table 12-489. Behavior of the DSITX Transmission when Both Video and Command are Running  
(continued)**

Packet type	Packet Size	Behavior	Error Flagged
Long packet	size = reg_exact_burst_limit	Packet passed	
Long packet	reg_max_burst_limit < size < reg_exact_burst_limit	Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Long packet	reg_exact_burst_limit < size <= reg_max_line_limit	packet is delayed to non-active part of frame: Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Packet type	Packet Size	Behavior	Error Flagged
Long packet	size > reg_max_line_limit	Packet thrown, LP mode packet thrown, null packet sent	Linewrite Linewrite
Read packet	-	Packet delayed, LP mode Packet delayed, null packet sent	-
BTA request	-	Packet delayed, LP mode Packet delayed, null packet sent	-
VSA, VBP, VFP - Long packet, read and BTA can be passed			
No packet	-	LP mode	-
Short packet	-	Packet passed followed by a null packet	-
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size > reg_exact_burst_limit	packet thrown, LP mode	Linewrite
Read packet	read completed (direction) before end of slot	Packet passed	
Read packet	read not completed (direction) before end of slot	Packet passed	Longread If operation lasts too long
BTA request	-	Packet passed	Longread If operation lasts too long

Note that for burst operation with Low Power, the command will be sent as a high-speed packet even if the request is made to send as Low Power. Also, the next active line will return to using LP during the HFP phase if no other commands are requested.

#### 12.9.2.7.9.6 Example Configurations

1. Here is an example for a VGA frame with 24bpp @60fps using non burst pulse sync mode: With blanking, total size 500 lines, each line is 800 pixels.

400000 DPI cycles/frame @ 24 MHz pixel clock <=> 300000 DSI cycles/frame @ 18 MHz byte clock;

800 DPI cycles/line @ 24 MHz <=> 600 DSI cycles/line @ 18 MHz;

**Table 12-490. DPI and DSI Parameters - 1**

Parameter	DPI	DSI
VSA	5	5
VBP	5	5
VACT	480	480

**Table 12-490. DPI and DSI Parameters - 1 (continued)**

Parameter	DPI	DSI
VFP	10	5
HSA	40	106 (120-14)
HBP	40	108 (120-12)
HACT	640	1920
HFP	80	234 (240-6)
HTOTAL	800 pixel cycles	2400 bytes

burst\_mode = 0

sync\_pulse\_active = 1

sync\_pulse\_horizontal = 1

BLKLINE\_PULSE\_PCK = 2380 (2400-20)

REG\_LINE\_DURATION = 2380

VERT\_BLANKING\_DURATION = 2384

**Note:** The controller will send 4 VFP lines then transition to LP for the duration equivalent to 6 lines.

2. Here are some example values for a 24fps UHD frame size with 24bpp using non-burst event mode: With blanking, total size 2250 lines, each line is 4000 pixels.

9000000 DPI cycles/frame @ 216 MHz pixel clock <-> 6750000 DSI cycles/frame @ 162 MHz byte clock

4000 DPI cycles/line @ 216 MHz <-> 3000 DSI cycles/line @ 162 MHz

**Table 12-491. DPI and DSI Parameters - 2**

Parameter	DPI	DSI
VSA	2	2
VBP	0	0
VACT	2160	2160
VFP	40	1
HSA	40	0
HBP	40	228 (120 + 120 - 12)
HACT	3840	11520
HFP	80	234 (240 - 6)
HTOTAL	4000	12000

burst\_mode = 0

sync\_pulse\_active = 0

sync\_pulse\_horizontal = 0

BLKLINE\_EVENT\_PCK = 11990 (12000-10)

REG\_LINE\_DURATION = 11990

VERT\_BLANKING\_DURATION = 11996

**Note:** After the active data the controller will transition immediately to LP for the duration equivalent to 88 lines, giving the maximum power saving between lines.

If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure.

#### 12.9.2.7.9.7 Stereoscopic Video Support

The DSI controller can support stereoscopic display format (SDF) using both command and video modes.

- Command Mode
  - APB Direct Command 3D Commands – Use get\_3D\_control with Read
  - SDI Command Mode – DCS Writes
- Video Mode – Single Link Operation
  - VSYNC Parameter1 Definition (L/R, Mode, Format)
  - SDI Video Mode
  - DPI Video Mode – Video stream will expect to follow expected format; frame, line, pixel
    - 3DVSNC = 0 not currently supported.

The DSI must be configured to enable the 3D operation and identify the format that is being used using the register control to enable the 3D features and the configuration that matches the video stream from the system.

The SDF format requires the system to provide frame and synchronisation information using the two parameter fields within the vertical sync short packet (VSS).

Configured the DSI mctl\_3dvideo\_ctl register to match format – L/R Pixel, L/R Line, L/R Frame Drive video stream based on orientation and format.

**Note:** DSI Controller will not perform any on-the-fly pixel manipulation for L-R ordering.

#### Example Video Operation

For a 3D video stream where the DSI video is given the combined images as one continuous large frame, the VSYNC packet would identify that the left image is sent first, it is a line based format and in landscape mode (see [Table 12-492](#)).

**Table 12-492. Example Video Operation**

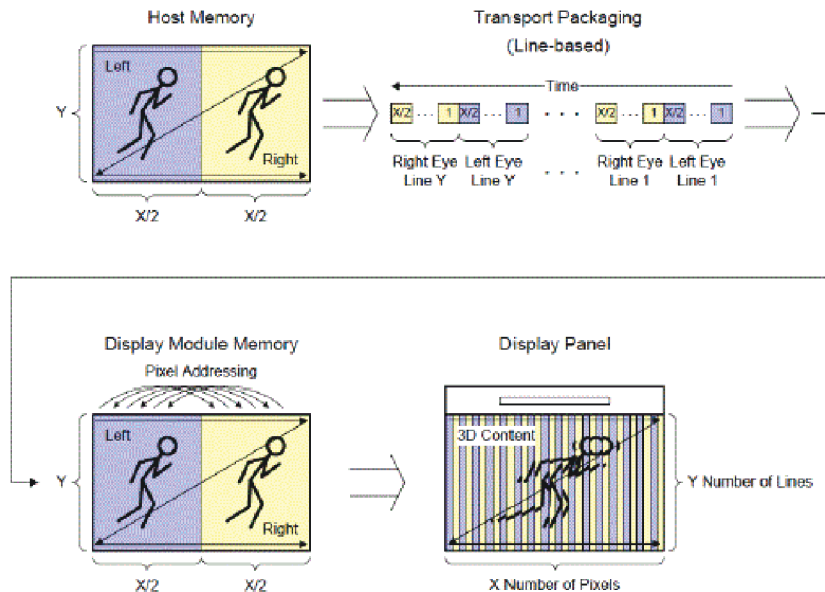

Position	D7	D6	D5	D4	D3	D2	D1	D0
Value	0	0	0	0	0	0	1	0
Description	Rsvd	Rsvd	Left First	No Sync	Line-based		Landscape	

mctl\_3dvideo\_ctl (0x20)

**Table 12-493. VSYNC Parameter 1**

[7]	vid_vsync_3d_en	1
[5]	vid_vsync_3d_lr	0
[4]	vid_vsync_3d_second_en	1
[3:2]	vid_vsync_3dformat	00
[1:0]	vid_vsync_3dmode	10

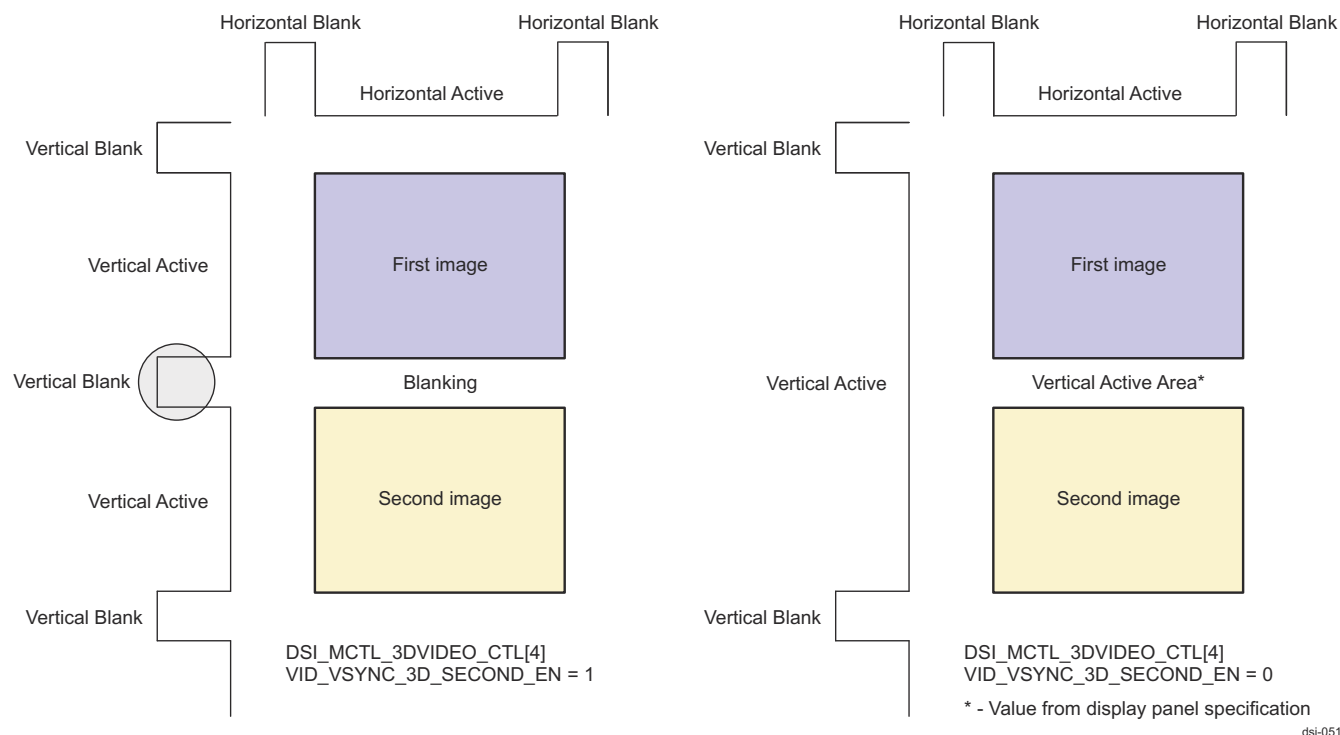

The video stream would then be configured in the DSI to be twice the line length of the normal image.

dsi\_spruij7-050

**Figure 12-600. Example DPI Image Format for SDF Combining Left And Right Pixels**

**Note:** The vertical operation DSI controller will expect the system to provide the left and right as two individual frames with SYNC to allow the blanking to be generated. The DSI does not insert the vertical blanking area when VSYNC = 0.

dsi-051

**Figure 12-601. 3D Image format for 3DVSYNCSplitting first and second images**

### 12.9.2.7.10 DSITX Video Stream Variable Refresh

The DSITX Controller can be programmed to allow the video stream sequence from a video source to halt between frames and enter Low Power state. The DPI video stream can halt before the new VSYNC is sent and remain in this state until the host video system wants to begin transmitting the new frame.

The DSITX will not perform the normal frame recovery mechanism when this is enabled, however it will continue to recover from line errors until the end of the frame.

**Table 12-494. DSITX Video Stream Variable Refresh**

Variable refresh rate operation enable control	Configures how the video generation timing is controlled.0, 1 DPI mode operation supports = 1 (enabled). For SDI operation, this parameter can optionally be set to FALSE (= 0) when the system clock and tx_byte_clk are generated from the same reference clock source, or TRUE to allow variable refresh rate control.

This chapter describes the on-chip debug support.

<b>13.1 On-Chip Debug Overview.....</b>	<b>2658</b>
<b>13.2 On-Chip Debug Features.....</b>	<b>2658</b>
<b>13.3 On-Chip Debug Functional Description.....</b>	<b>2659</b>

## 13.1 On-Chip Debug Overview

This chapter describes the properties and capabilities of the various features available through the On-Chip Debug framework deployed on this device.

The On-Chip Debug framework enables various Debug and Trace use-cases, including:

- **JTAG Tooling** – Access to on-chip debug resources is supported by an IEEE 1149.1 (JTAG) compliant interface that is supported by an Arm® CoreSight™ DAP JTAG-DP.
- **Self-Hosted Tooling** – code running on programmable cores within the device is able to use on-chip debug resources to enable embedded tooling solutions.
- **PCB-level interconnect testing** – IEEE 1149.1 and IEEE 1149.6 compliant Boundary Scan supports product level integration testing
- **Low Power Operation** – When on-chip JTAG and debug management logic is in a low power state, activity sensed on the JTAG interface will cause this logic to be placed in a functional state.
- **Stop Mode debugging** – Debug of embedded processors is supported using various mechanisms that can halt the pipeline of a CPU. Breakpoints (Software and Hardware), Watchpoints, Cross-Triggering, and On-demand (e.g. user requested) halt request mechanisms may be supported based on the capabilities of a given processor.
- **Debug-aware Peripherals** – Peripheral awareness of processor execution state allows safe suspension of peripheral operation. Supported by select peripherals.
- **Synchronized Debug** – Wide deployment of Cross-Triggering allows multiple processors and/or debug elements to be grouped together to process various actions based on a common event occurrence.
- **Processor Trace** – Support for the generation of a trace stream with the encoding of processor state that may include some combination of program flow, timing details (execution and stall), and memory references (address and/or data) with the goal of facilitating processor state reconstruction for debug purposes.
- **Software Messaging Trace** – Support for software messaging trace where embedded code running within the device can be instrumented to use memory writes to send important debug information to a trace stream.
- **System Traffic Trace** – Strategically selected points in the SoC topology are instrumented with trace-capable bus probes that support transaction trace, read-latency monitoring, and throughput computation.
- **Trace Correlation (through timestamping)** – Support for the correlation of different trace streams is enabled through the use of a common global timestamp that is distributed to supported trace sources.
- **Trace data movement** – Trace data movement on chip is supported using standard Arm ATB trace infrastructure components. Concurrent use of the trace bus by multiple trace sources is supported, with each trace source identifiable through a unique ID. An Arm® CoreSight™ Trace Router supports sending a trace stream off-chip (TPIU), to dedicated memory on-chip (TBR), or broadcasted to both (TPIU + TBR).
- **On-Chip trace collection via dedicated buffer** – An on-chip trace buffer is supported by logic that implements capturing trace data until either the memory fills (stop-on-full, system-bridge) or continuously until a request to stop is received (circular buffer). Interleaving of multiple trace streams is made possible through the use of a standardized encoding that embeds trace data along with the corresponding trace source ID.
- **Trace export over TPIU** – Trace data is exported over device LVCMOS pins using a standard protocol that embeds trace data along with the corresponding trace source ID.

### CAUTION

Debug features that are intrusive in nature may affect the ability of the system to meet critical real-time deadlines and should be used with caution.

## 13.2 On-Chip Debug Features

The On-Chip Debug framework provides a comprehensive hardware platform for a rich debug and development experience. The On-Chip Debug framework supports these features:

- An IEEE 1149.1 (JTAG and Boundary Scan) compliant device interface
- Cross-triggering and Debug boot mode device interface
- Trace port device interface
- Advanced power, reset, and clock management to facilitate debug across complex low power modes

- Breakpoint-based debug
- Cross-triggering
- Program flow trace
- System traffic monitoring trace
- Software instrumentation trace
- Trace export via trace port device interface
- Trace capture on-chip via dedicated buffer with options to support stop-on-full, circular-buffer, or data hand-off to various peripherals
- Arm® CoreSight™ compliant debug components deployed to streamline 3rd party tooling support

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

## 13.3 On-Chip Debug Functional Description

### 13.3.1 On-Chip Debug Block Diagram

A logical partitioning of the On-Chip Debug features deployed on this device is illustrated in [Figure 13-1](#).

**Figure 13-1. On-Chip Debug Block Diagram**

### 13.3.2 Device Interfaces

On-Chip Debug features are supported through three device interfaces:

- **JTAG:** IEEE 1149.1 compliant interface that provides access to Boundary Scan and acts as the primary interface for off-chip access to On-Chip debug resources (See [Section 13.3.2.1](#))
- **Trigger and Debug Boot Mode:** Multi-functional interface that supports product level cross-triggering and debug-related boot modes (See [Section 13.3.6](#), [Section 13.3.4](#))

- **Trace Port:** Arm TPIU compliant Trace Port interface is used to facilitate export of trace (See [Section 13.3.12](#))

Texas Instruments supports a variety of eXtended Development System (XDS™) JTAG controllers with various debug capabilities beyond only JTAG support. The following document is a good reference for guidelines: [Emulation and Trace Headers](#). More information can also be found here: [XDS Target Connection Guide](#).

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see [TI's Terms of Use](#).

### 13.3.2.1 JTAG Interface

**Table 13-1. JTAG Interface Signals**

SignalName	I/OType <sup>(1)</sup>	Description
TRSTn	I	<i>Test Reset.</i> Initializes and disables the test interface.
TCK	I	<i>Test Clock.</i> Controls the timing of the test interface independently from any system clocks. TCK is pulsed by the equipment controlling the test and not by the tested device.
TMS	I	<i>Test Mode Select.</i> Controls the transitions of the test interface state machine.
TDI	I	<i>Test Data Input.</i> Supplies the data to the JTAG registers.
TDO	O/Z	<i>Test Data Output.</i> Used to serially output the data from the JTAG registers to the equipment controlling the test.

(1) I = Input; I/O = Input or output; O = Output; O/Z = Output or three-state

### 13.3.2.2 Trigger and Debug Boot Mode Interface

**Table 13-2. Trigger and Debug Boot Mode Interface Signals**

Signal Name	I/O Type <sup>(1)</sup>	Description
EMU0	I/O	Channel 0 trigger or boot mode select
EMU1	I/O	Channel 1 trigger or boot mode select

(1) I = Input; I/O = Input or output; O = Output; O/Z = Output or three-state

### 13.3.2.3 Trace Port Interface

**Table 13-3. Trace Port Signals**

Pin Name	TPIU Signal Name	I/O Type <sup>(1)</sup>	Description
TRC_CLK	TRACECLK	O	TraceClock
TRC_CTL	TRACECTL	O	TraceControl
TRC_DATA[n:0]	TRACEDATA[n:0]	O	TraceData [n:0]

(1) I = Input; I/O = Input or output; O = Output; O/Z = Output or three-state

#### Note

The Trace Port interface signals are associated with device pins that are multiplexed with other signal functions.

### 13.3.3 Debug and Boundary Scan Access and Control

On-Chip debug resources are made available through three mechanisms:

- JTAG access via DAP and related APs
- JTAG access via Boundary Scan TAP
- Embedded access to debug resources via SoC address space

#### DAP

Off-chip debug tools are able to access On-Chip debug resources via the JTAG interface when not in Boundary Scan mode (see below). A CoreSight™ Compliant DAP architecture provides access via a DP and a collection of APs:

- SWJ-DP: Arm® CoreSight™ compliant SWJ Debug Port provides support for a JTAG interface with a 4-bit IR

#### Note

Even though an SWJ-DP is implemented on-chip, only JTAG is supported. This device does not support SWD.

- APB-AP: Arm® CoreSight™ APB Access Port provides access to the Debug-APB address space which is the primary configuration space for On-Chip Debug resources.
- AXI-AP: Arm® CoreSight™ AXI Access Port provides access to the SoC address space, allowing visibility and control over system resources.
- Config-AP: TI Configuration AP supports access to SoC debug management registers
- Power-AP: TI Configuration AP supports advanced power, reset, and clock management. (See *Power, Reset, Clock Management*)
- SEC-AP: TI AP supports debug authentication

Table 13-4 describes the APSEL assignment for this device.

**Table 13-4. DAP APSEL Assignment**

APSEL	AP	Description
0	Config-AP	TI AP - Reserved
1	APB-AP	Provides access to Debug Config Plane
2	AXI-AP	Provides access to SoC Address Space
3	Power-AP	TI AP - Extended Power/Reset/Clock Control
4-5	Reserved	Reserved for future use
6	SEC-AP	TI AP - Authentication Interface
7	SMS TIFS M4F	
8	Reserved	Reserved for future use
9	SMS HSM M4F	
10-31	Reserved	Reserved for future use

## Boundary Scan

This device supports boundary scan using an IEEE 1149.1 compliant JTAG TAP that is made visible through the use of a compliance-enable mode (see *Debug Boot Modes and Boundary Scan Compliance*). IEEE 1149.1 and 1149.6 Boundary Scan support are defined in device-specific BSDL files that can be found in the respective device's product folder on ti.com.

## SoC Address Space

The device architecture provides access to On-Chip debug resources through the SoC Address Space. This includes access to all DAP Access Ports (APs) as well as the Debug-APB address space.

### 13.3.4 Debug Boot Modes and Boundary Scan Compliance

The EMU1 and EMU0 device pins are used to convey debug boot mode behavior and can also be used as part of a boundary scan compliance sequence to enable boundary scan features.

## Debug Boot Mode

EMU1 and EMU0 are sampled when MCU\_PORz is de-asserted and the decoded value determines the debug boot mode behavior as detailed in Table 13-5.

**Table 13-5. Debug Boot Modes**

Sample Time	EMU1	EMU0	Boot Mode	Behavior
MCU_PORz deassertion	0	0	Reserved	Reserved for future use
	0	1	Reserved	Reserved for future use
	1	0	Wait-In-Reset (WIR)	Device will remain quiescent until a debug connection is established and the debugger releases WIR. This mode is useful for debugging boot sequences.
	1	1	Normal	Device boots normally. Debug can connect at any time but the context will be post-boot.

## Boundary Scan Compliance

EMU1 and EMU0 are sampled when TRSTz is de-asserted and the decoded value determines the debug boot mode behavior as detailed in [Table 13-6](#).

**Table 13-6. Boundary Scan Compliance**

Sample Time	EMU1	EMU0	Boundary Scan Compliance	Behavior
TRSTn deassertion	0	1	Boundary Scan Enabled	The device's Boundary Scan TAP is connected to the device's JTAG interface.
	0	0		
	1	0	Boundary Scan Disabled	The device's SWJ-DP is connected to the device's JTAG interface.
	1	1		

### 13.3.5 Power, Reset, Clock Management

This device includes advanced power, reset, and clock management debug capabilities, including:

- **Wakeup support for debug logic:** logic within the device is able to sense JTAG activity and ensure that debug logic is on and able to service JTAG requests.
- **Reset isolation:** critical configuration and trace datapaths and logic are not sensitive to warm reset
- **Configuration independence:** debug configuration occurs over a debug-only interconnect, separate from SoC traffic to ensure debug logic remains available even during deadlock scenarios.
- **Power-AP:** a CoreSight™ compliant Access Port (AP) developed by TI that provides a standard interface for debug tooling to access status and control over power, reset, and clocking for the system and various LPSC-defined sub-domains.

### 13.3.6 Debug Cross Triggering

This device supports an Arm® CoreSight™ compliant four-channel programmable on-chip Cross Triggering network. In addition to the four-channel on-chip network, this device implements two channels of product level triggering via the EMU0 and EMU1 device pins.

Conceptually, each channel of Cross Triggering can be viewed as mapping of a user-defined set of events to a user-defined set of actions, where the occurrence of any event in the set-of-events results in the generation of the set-of-actions. [Table 13-7](#) provides a domain-level summary of the supported events and actions.

**Table 13-7. Domain-Level Summary of Triggering Capability**

Domain	Events	Actions
Product-Level	Zero detected on EMU0 input pin	EMU0 output pin driven to Zero
	Zero detected on EMU1 input pin	EMU1 output pin driven to Zero
SoC Debug	TBR Acquisition Complete	TPIU insert trigger packet
	TBR Embedded buffer is full	TPIU start flush process
	System reset asserted	TBR insert trigger packet
	Bus Probe-n match	TBR start flush process
	STM write to a TRIG location	Bus Probe-n Start
	STM write to a trigger-enabled stimulus port	Bus Probe-n Stop

**Table 13-7. Domain-Level Summary of Triggering Capability (continued)**

Domain	Events	Actions
R5FSS0	R5FSS0 has halted	R5FSS0 – halt request
	PMU generated interrupt	R5FSS0 – resume request
	ETM Trigger outputs	ETM Trigger inputs
	has halted	– halt request
	PMU generated interrupt	– resume request
	ETM External Out (EXTOUT) trigger	ETM External In (EXTIN) trigger
A53SS0	A53SS0 core-n has halted	A53SS0 core-n – halt request
	PMU generated interrupt	A53SS0 core-n – resume request
	ETM trigger	CTI interrupt
	--	ETM External In (EXTIN) trigger

### 13.3.7 Peripheral Suspend

Some peripherals on the device include support for a debug suspend capability that allows the peripheral's behavior to alter when an assigned CPU enters the debug suspend state. To use this feature, it must be enabled within the peripheral and a connection made between the desired suspend source (CPU) and the suspend destination (peripheral) of interest.

Details on the debug suspend feature for a specific peripheral, including how to enable it, is covered in the associated peripheral section.

On this device, there is a dedicated interrupt router (INTR), DBGSUSPENDROUTER0, that supports the routing of a suspend source to a suspend destination. Details on the assignment of DBGSUSPENDROUTER0 inputs and outputs are provided in the following tables.

**Figure 13-2. Peripheral Suspend Support**
**Table 13-8. Suspend Source Assignment**

Index	Suspend Source	Description
1	A53SS0_0	A53SS0 Core 0
2	A53SS0_1	A53SS0 Core 1
3	A53SS0_2	A53SS0 Core 2
4	A53SS0_3	A53SS0 Core 3
9	C7X256V0	C7X256V0 Core 0
10	C7X256V1	C7X256V1 Core 0
22	R5FSS0	R5FSS0 CPU
23	WKUP_R5FSS	Device Management Cortex R5F
24	MCU_M4FSS	MCU M4F
25	SMS0_HSM	SMS HSM

**Table 13-9. Suspend Destination Assignment**

Index	Suspend Destination	Description
0	WKUP_GTC0	Global Time Counter
1	CPSW0	Ethernet Switch (SoC)
2	DMSS	DMA SS (SoC)
3	DMSS_HSM	SA3SS DMSS_HSM
4	DMSS_CSI	DMA SS (CSI-RX)

### 13.3.8 R5FSS0, WKUP\_R5FSS0 Debug

The R5FSS0, WKUP\_R5FSS0 includes an Arm Cortex R5F with embedded debug capability, including:

- Independent debug configuration
- ROM Table
- Basic debug functionality
- Cross Triggering
- PMU: Performance Monitor Unit
- ETM: Embedded Trace Macrocell

A summary of the R5FSS0, WKUP\_R5FSS0 debug capabilities is detailed in [Table 13-10](#).

**Table 13-10. R5FSS0, WKUP\_R5FSS0 Debug Capabilities**

Capability	Feature	Notes
Basic Debug	Independent debug configuration	Debug resource configuration is performed over a configuration interface that is isolated from functional traffic
	ROM table	Facilitates discovery of debug resources within debug configuration address space
	Processor halt	Support user-requested entry into the suspended state
	Single step	Execution of a single instruction before entering the suspended state
	Software breakpoints	Software breakpoints are supported via opcode replacement
	Hardware breakpoints	Eight Debug Breakpoint resources support hardware breakpoints
	Hardware watchpoints	Eight Debug Watchpoint resources support data address breakpoints
	Core register access	Access to processor core registers
	System memory access	Access to memory from perspective of CPU
	Vector catch	Halting in response to an exception
	Arm® TrustZone® debug authentication	Provisioning for DBGEN and NIDEN

**Table 13-10. R5FSS0, WKUP\_R5FSS0 Debug Capabilities (continued)**

Capability	Feature	Notes
Cross Triggering	Debug state	Support for controlling execution state (run, halt) via triggers and creating triggers upon entry into debug state
	PMU	PMU interrupt trigger
	ETM	Five ETM external triggers (one ETM Trigger, two external out event triggers, two external in event triggers)
PMU	Profile Counters	Three counters can be used to count different events available for gathering statistics on the operation of the processor and memory system
	Cycle Counter	One dedicated counter available for counting CPU clock cycles
ETM	Triggering Infrastructure	Comprehensive triggering infrastructure supports use of comparators (address, data value, context ID), counters, sequencer state, an external inputs and outputs to control the enabling of trace.
	Instruction trace	Supports tracing of instruction flow
	Cycle-accurate tracing	Supports inclusion of a precise cycle count of executed instructions.
	Branch broadcast tracing	Support for tracing branch address details even in circumstances where that information might be discoverable from object code
	Data tracing	Support for data address and data value tracing

### 13.3.9 A53SS0 Debug

The A53SS0 is a multi-core Arm Cortex-A53 subsystem with embedded debug capability and features, including:

- Independent debug configuration
- ROM Table
- Basic debug functionality
- Cross Triggering
- PMU: Performance Monitor Unit
- ETM: Embedded Trace Macrocell

A summary of the A53SS0 debug capabilities and features is detailed in [Table 13-11](#).

**Table 13-11. A53SS0 Debug Capabilities**

Capability	Feature	Notes
Basic Debug	Independent debug configuration	Debug resource configuration is performed over a configuration interface that is isolated from functional traffic
	ROM table	Facilitates discovery of debug resources within debug configuration address space
	Processor halt	Support user-requested entry into the suspended state
	Single step	Execution of a single instruction before entering the suspended state
	Software breakpoints	Software breakpoints are supported via opcode replacement
	Hardware breakpoints	Six Debug Breakpoint resources support hardware breakpoints
	Hardware watchpoints	Four Debug Watchpoint resources support data address breakpoints
	Core register access	Access to processor core registers
	System memory access	Access to memory from perspective of CPU
	Vector catch	Halting in response to an exception
	Arm® TrustZone® debug authentication	Provisioning for DBGEN, NIDEN, SPIDEN, SPNIDEN, SUIDEN, and SUNIDEN
Cross Triggering	Debug state	Support for controlling execution state (run, halt) via triggers and creating triggers upon entry into debug state
	PMU	PMU interrupt trigger
	ETM	Four ETM external triggers
	CPU	CTI interrupt into CPU

**Table 13-11. A53SS0 Debug Capabilities (continued)**

Capability	Feature	Notes
PMU	Profile Counters	Six counters can be used to count different events available for gathering statistics on the operation of the processor and memory system
	Cycle Counter	One dedicated counter available for counting CPU clock cycles
ETM	Instruction trace with cycle counting	Support for tracing instruction execution with timing information
	Branch broadcast tracing	Support for tracing branch address details even in circumstances where that information might be discoverable from object code
	Return stack tracing	Support for tracing of the return stack
	Stall Control	Support for stalling the A53 processor to avoid ETM overflows
	Global timestamping	Support for attaching a global timestamp to trace traffic

### 13.3.10 C7XSS0 and C7XSS1 Debug

The C7XSS0 and C7XSS1 are a single-core C7xV-256 subsystem with embedded debug capability and features, including:

- Independent debug configuration
- Basic debug functionality
- Cross Triggering
- AET: Advanced Event Triggering
- Processor Trace
- Traffic Monitoring Trace

A summary of the C7XSS0 and C7XSS1 debug capabilities and features is detailed in the following table.

**Table 13-12. C7XSS0 and C7XSS1 Debug Capabilities**

Capability	Feature	Notes
Basic Debug	Independent debug configuration	Debug resource configuration is performed over a configuration interface that is isolated from functional traffic
	ROM table	Facilitates discovery of debug resources within debug configuration address space
	Processor halt	Support user-requested entry into the suspended state
	Single step	Execution of a single instruction before entering the suspended state
	Software breakpoints	Software breakpoints are supported via opcode replacement
	Hardware breakpoints	Four Debug Breakpoint resources support hardware breakpoints
	Core register access	Access to processor core registers
	System memory access	Access to memory from perspective of CPU
	Arm TrustZone debug authentication	Provisioning for DBGEN, NIDEN, SPIDEN, SPNIDEN, SUIDEN, and SUNIDEN
Cross Triggering	Debug state	Support for controlling execution state (run, halt) via triggers and creating triggers upon entry into debug state
	AET	Two channels of AET external triggers (input and output)

**Table 13-12. C7XSS0 and C7XSS1 Debug Capabilities (continued)**

Capability	Feature	Notes
AET	Profile Counters	Two counters can be used to count different events available for gathering statistics on the operation of the processor and memory system. Includes watermark support.
	Application Context Sensitive Triggering	Supports generation of events based on the context of application execution (e.g. Thread-ID, Virtual Machine ID, Program bus activity, Memory bus activity)
	Visibility and detection of events	provided by CPU, Subsystem, and SOC
	Range detection	of Program and Memory bus activity
	Programmable State Machine	supports complex, state-based event detection
	Trace Stream Filtering / Windowing	supports the management of trace windows
Trace	Historical Record	Creates a customized (based on trace stream filtering/ windowing) historical account of the CPU's behavior through the use of different types of trace streams
	Program Flow Trace	records program flow execution, including discontinuities resulting from branches, interrupts, or exceptions
	Cycle Accurate Trace	records cycle-accurate timing information
	Memory Reference Trace	records data log activity (address, data, address and data)
	Event Trace	records information about the occurrence, duration, or relationship of one or more events
	Stream Buffer Parameter Trace	records the parameters used to start a stream buffer operation allowing off-line reconstruction
	Application Context Trace	records changes in the context of the application (virtual machine ID, thread-ID)
	Stall Control	Support for stalling the C7X processor to avoid Trace overflows
	Global timestamping	Support for attaching a global timestamp to trace traffic
	Traffic Monitoring	Traffic monitoring bus probes are deployed within C7XSS0 memory subsystem

### 13.3.11 SoC Debug and Trace

This device includes debug capabilities deployed at the system level, including:

- Software messaging trace
- Debug-aware peripherals
- Traffic monitoring with bus probes
- Global timestamping for trace

More details for each of these capability areas can be found in the corresponding sections below.

#### 13.3.11.1 Software Messaging Trace

Software messaging trace is supported on this device by an MIPI STP-V2 compliant Arm® CoreSight™ STM with supporting logic that maps initiator IDs to specific STP Major Source IDs. The following device initiators support software messaging:

- A53SS0 cores
- C7XSS1
- R5FSS0
- MCU
- SMS0\_TIFS
- DAP AXI-AP

### 13.3.11.2 Debug-Aware Peripherals

Select peripherals support a debug feature that allows them to react to the debug state of a controlling processor. For instance, a timer peripheral that is allocated to a particular processor could be configured to stop counting when the associated processor is in the halted state.

This device includes programmable support for shared peripherals that allows the developer to select the processor whose debug state a given peripheral should receive. Peripherals that are debug aware include programmable support to enable or disable sensitivity to debug.

A list of the processors and peripherals that support this debug model can be found in [Table 13-13](#).

**Table 13-13. Debug-Aware Peripheral Support**

Supported Processors	Supported Peripherals
A53SS0 cores	GTC
C7XSS1	DMSS
R5FSS0	SA3SS
	TIMER instances
	EPWM instances
	MCAN instances
SMS0_TIFS	I2C instances
--	MCRC64 instances
--	ECAP instances
--	EQEP instances
--	PDMA_SPI
--	PDMA_UART
--	PDMA_MCASP
--	RTI/WWDT instances <sup>(1)</sup>

(1) RTI/WWDT suspend is associated with the processor that it is allocated to

### 13.3.11.3 Traffic Monitoring With Bus Probes

Traffic monitoring bus probes are deployed at strategic points in the system interconnect and support the following capabilities:

- MIPI STP-V2 compliant trace messaging support with global timestamping support
- Latency Statistics Collection: Statistics on the timeliness of responses to read requests are collected during a sampling window and then read by a profiling entity (application thread or encoded into a trace message)
- Throughput Statistics Collection: Statistics on the amount of data moving across an interface are collected during a sampling window and then read by a profiling entity (application thread or encoded into a trace message)
- Transaction Trace: Information about specific transactions occurring at a probed location are captured and encoded into a trace message
- Complex filtering support allows discrimination of traffic being monitored
- Cross-Trigger support for enabling and disabling probe monitoring

[Table 13-14](#) details the locations in the system interconnect that are probed:

**Table 13-14. Bus Probe Points**

Probe Point	Bus Monitoring Details
A53SS0 Write Initiator	Provides visibility to all write requests initiated by A53SS0
A53SS0 Read Initiator	Provides visibility to all read requests initiated by A53SS0
A53SS0 ACP Target	Monitors traffic to the A53SS0 ACP port
C7XSS0 Deep Learning Accelerator MDMA Initiator	Monitors traffic initiated by DLA MDMA

**Table 13-14. Bus Probe Points (continued)**

Probe Point	Bus Monitoring Details
C7XSS0 Deep Learning Accelerator SDMA Target	Monitors traffic to DLA SDMA port
C7XSS1 Deep Learning Accelerator MDMA Initiator	Monitors traffic initiated by DLA MDMA
C7XSS1 Deep Learning Accelerator SDMA Target	Monitors traffic to DLA SDMA port
DDR Target	Monitors traffic to DDR
GMPC Target	Monitors traffic to GMPC
FSS Target	Monitors traffic to FSS0
JPEG Encoder Read Initiator	Provides visibility to all read requests initiated by JPEG Encoder
JPEG Encoder Write Initiator	Provides visibility to all write requests initiated by JPEG Encoder
OCSRAM 2 Bank 1 – future use	Monitors traffic to OCSRAM Bank 1 (future use)
OCSRAM 2 Bank 2 – future use	Monitors traffic to OCSRAM Bank 2 (future use)
VPAC LDC Initiator	Monitors requests initiated by VPAC LDC initiator
VPAC Real-Time Initiator	Monitors requests initiated by VPAC RT initiator
VPAC Non-Real-Time Initiator	Monitors requests initiated by VPAC NRT initiator
VPAC Target	Monitors traffic to VPAC

#### 13.3.11.4 Global Timestamping for Trace

Support for a global timestamp for use by debug is enabled by a 48-bit continuous timestamp managed by the device's GTC. This 48-bit global timestamp is readable by embedded software, via the GTC, and distributed across the device to various trace sources where it is used as a time reference when timestamping trace streams. Trace sources that support global timestamping, include:

- A53SS0 cores: ETM
- C7XSS1: Trace
- SMS0\_TIFS: ITM and ETM
- STM
- Bus Probes

#### 13.3.12 Trace Traffic

Trace traffic originates from a trace source, is distributed across the device using Arm® CoreSight™ compliant trace infrastructure components, and reaches one of two possible trace sinks.

##### 13.3.12.1 Trace Sources

A summary of the trace sources present on this device is included in [Table 13-15](#).

**Table 13-15. Trace Sources**

Domain	Trace Source
SoC Debug	Bus Probes
	STM
R5FSS0	ETM
SMS0_TIFS	ETM, ITM / DWT
A53SS0	ETM (each core)
C7XSS1	Processor Trace

##### 13.3.12.2 Trace Infrastructure

Trace distribution is accomplished using standard Arm® CoreSight™ compliant trace infrastructure components:

- CoreSight™ Trace Funnels (CSTF): Non-programmable CSTFs are used at points of interleaving where multiple trace sources converge and form a single stream of trace traffic. This device includes one instance of a programmable CSTF that is deployed immediately before the TPIU.
- CoreSight™ Trace Replicator (CSREP): A programmable CSREP is used as a routing device, that can be used to forward trace traffic, based on its ID, to one, both, or none of the device trace sinks.

### 13.3.12.3 Trace Sinks

Two trace sinks are supported on this device:

- Arm® CoreSight™ TPIU: TPIU supports export of trace off-chip via LVCMOS device pins (See 1.3.3.3) for capture by an external receiver.
- TI Trace Buffer Router (TBR) with 64KB of storage: the TBR can function as a trace buffer or as a system bridge. As a trace buffer, the TBR can be setup to capture trace data until the internal buffer fills or it can operate as a circular buffer that will capture continuously. When configured as a system bridge the TBR's storage becomes an elastic buffer that supports the concurrent queueing and dequeuing of trace traffic. The system bridge mode supports interrupt and event notification capabilities that support integration with device level CPUs and/or DMAs to support a variety of use cases, including, for e.g., relocation of trace data to DDR and off-chip export over USB.

### 13.3.13 Application Support

TI includes a set of system level debug facilities in the Debug Subsystem of devices known as Chip Tools (CTools). For easy integration of A53 processor trace and system trace into applications, a set of libraries commonly referred to as CToolsLib are provided. CToolsLib is a collection of embedded target APIs/libraries focused on enabling easy access to the CTools. CToolsLib encompasses the following libraries to assist in trace integration:

- STM Library
- CP Tracer Library
- TBR Library
- ETM Library

For more information about these libraries, downloadable files, and other useful links, please visit the [CToolsLib Wiki site](#).

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

# Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

## Changes from March 22, 2024 to October 31, 2024 (from Revision \* (March 2024) to Revision A (October 2024))

	Page
• Added Interrupt Condition for Interconnect section.....	65
• Added Quality of Service (QoS) Block section.....	75
• Add MII to CPSW Unsupported Features list.....	475
• Add Enhanced Strobe to MMCSD Unsupported Features.....	546
• Only 25MHz PLL Reference Clock is supported.....	685
• Added note that MMC Port0 has no pin mux options.....	701
• Updated X.509 Certificate information from 'Optional.'.....	727
• Rename WKUP_CTRL_MMR1 to MCU_CTRL_MMR.....	736
• Added General Purpose Control Register Modules Overview section.....	736
• Add Register Partitions section.....	736
• Add Pad Configuration Registers section.....	737
• Add Kick Protection Registers section.....	737
• Add Proxy Addressing Registers section.....	738
• Added POK Module Overview table.....	752
• Added Configuration Registers section.....	753
• Updated Power OK (POK) Modules section.....	766
• Added High Level Reset Control diagram.....	773
• Added High Level Reset Flow diagram.....	775
• Added Reset Architecture Block Diagram.....	779
• Added SoC Reset Hardware Logic Diagram.....	780
• Added MCU Domain Reset Hardware Logic Diagram.....	782
• Added MAIN Domain Reset Hardware Logic Diagram and MAIN Domain PORz Hardware Logic Diagram.....	784
• Add additional details about VTM hardware alert signal.....	804
• Added Top-Level Clock Diagram.....	811
• Updated Clock Outputs section.....	813
• Updated MAIN Domain PLLs Overview section.....	818
• Update figure so that FOUTPOSTDIV is routed to HSDIV[5-9] and FOUTP is routed to HSDIV[0-4].....	820
• Updated Basic Information of MAIN Domain PLLs table.....	825
• Updated Initiator Interfaces section.....	850
• Updated R5FSS Interrupts section.....	858
• Update register names in Chapter.....	939
• Registers names updated within SPI chapter.....	1394
• Updated the UART Baud Rate Settings table for baud rate up to 12Mbps.....	1482
• Register name updates within CPSW3G Chapter.....	1504
• Added SGMII information to Functional Block Diagram section.....	1511
• Added SGMII information in CPSW Ports section.....	1512
• Add PCIe Differential Reference Clocks.....	1613
• Updated SERDES0 Overview diagram.....	1635

• Added SERDES1 Overview diagram.....	1635
• Updated SerDes Features section.....	1636
• Updated SerDes Supported Standards table.....	1637
• Updated Industry Standards Compatibility section.....	1637
• Updated SERDES0/1 Input/Output Description table, SerDes Environment diagram.....	1638
• Updated SerDes Integration section.....	1639
• Updated Interface Selection section.....	1641
• Updated SerDes Internal Reference Clock Selection table.....	1641
• Update register names in OSPI Chapter.....	1659
• Update register names (GPMC_BCH_RESULT_*). .....	1754
• Update register names in ELM Chapter.....	1797
• Update register names in GTC Chapter.....	2157
• Update register names in chapter.....	2159
• Update register names in chapter.....	2180
• Register names updated within Chapter.....	2203
• Change bit name DSS_IDLE_STATUS to DISPC_IDLE_STATUS.....	2520
• Updated On-Chip Debug Block Diagram.....	2659
• Updated DAP APSEL Assignment table.....	2661
• Updated Domain-Level Summary of Triggering Capability table.....	2663
• Added Peripheral Suspend section.....	2664
• Added C7XSS0 and C7XSS1 Debug section.....	2668
• Updated Software Messaging Trace section.....	2669
• Updated Debug-Aware Peripheral Support table.....	2670
• Updated Bus Probe Points table.....	2670
• Updated Global Timestamping for Trace section.....	2671
• Updated Trace Sources table.....	2671
