About This Manual	11
Related Documentation From Texas Instruments	11
Glossary	11
Support Resources	11
Export Control Notice	11
Release History	12
<b>1 Introduction</b>	13
1.1 Overview	14
1.2 Module Allocation and Instances within Device Domains	14
1.3 Functional Block Diagram	15
1.4 Device MAIN Domain	17
1.4.1 Arm Cortex-A53 Subsystem (A53SS)	17
1.4.2 Arm Cortex-R5F Processor (R5FSS)	17
1.4.3 Deep Learning Accelerator (C7x256v)	18
1.4.4 Vision Pre-processing Accelerator	19
1.4.5 Depth and Motion Perception Accelerator	19
1.4.6 Mailbox (MAILBOX)	20
1.4.7 Spinlock (SPINLOCK)	20
1.4.8 DDR 32-bit Subsystem (DDR32)	20
1.4.9 Data Movement Subsystem (DMSS)	20
1.4.10 General Purpose Input/Output Interface (GPIO)	21
1.4.11 Inter-Integrated Circuit Interface (I2C)	21
1.4.12 Serial Peripheral Interface (SPI)	21
1.4.13 Universal Asynchronous Receiver/Transmitter (UART)	21
1.4.14 3-port Gigabit Ethernet Switch (CPSW3G)	22
1.4.15 Universal Serial Bus (USB) Subsystem 2.0	22
1.4.16 Universal Serial Bus 3.1 Subsystem (USBSS)	22
1.4.17 Serializer/Deserializer (SERDES)	23
1.4.18 Peripheral Component Interconnect Express Subsystem (PCIE)	23
1.4.19 Enhanced Pulse-Width Modulation Module (EPWM)	23
1.4.20 Enhanced Quadrature Encoder Pulse Module (EQEP)	24
1.4.21 Enhanced Capture Module (ECAP)	24
1.4.22 Controller Area Network (MCAN)	24
1.4.23 Flash Subsystem (FSS) with Octal Serial Peripheral Interface (OSPI)	24
1.4.24 General Purpose Memory Controller (GPMC)	25
1.4.25 Error Location Module (ELM)	25
1.4.26 Multi-Media Card/Secure Digital Interface (MMCSD)	25
1.4.27 Memory Cyclic Redundancy Check	26
1.4.28 Windowed Watchdog Timer/Real Time Interrupt	26
1.4.29 TIMER	26
1.4.30 Audio Tracking Logic	26
1.4.31 Camera Subsystem	26
1.4.32 Dual Clock Comparator	27
1.4.33 Error Signaling Module (ESM)	27
1.4.34 Multi-Channel Audio Serial Port (McASP)	27
1.4.35 Camera Streaming Interface Receiver (CSI-RX)	28
1.4.36 Display Subsystem (DSS)	29
1.4.37 Open LVDS Display Interface transmitter (OLDI-TX)	29

1.4.38 MIPI DPHY Receiver.....	29
1.4.39 MIPI DPHY Transmitter.....	30
1.4.40 Graphics Processing Unit.....	30
1.4.41 Video Accelerator (CODEC).....	31
1.5 Device MCU Domain.....	31
1.5.1 Arm Cortex-R5F Processor (R5FSS).....	32
1.5.2 MCU General Purpose Input/Output Interface (MCU_GPIO).....	32
1.5.3 MCU Inter-Integrated Circuit Interface (MCU_I2C).....	33
1.5.4 MCU Multi-channel Serial Peripheral Interface (MCU_SPI).....	33
1.5.5 MCU Universal Asynchronous Receiver/Transmitter (MCU_UART).....	33
1.5.6 MCU Windowed Watchdog Timer/Real Time Interrupt .....	33
1.5.7 MCU TIMER .....	33
1.5.8 MCU Dual Clock Comparator.....	34
1.5.9 Memory Cyclic Redundancy Check.....	34
1.5.10 Controller Area Network (MCAN).....	34
1.6 Device WKUP Domain.....	34
1.6.1 Arm Cortex-R5F Processor (R5FSS).....	34
1.6.2 Inter-Integrated Circuit Interface (I2C).....	35
1.6.3 Universal Asynchronous Receiver/Transmitter (UART).....	35
1.6.4 MCU Error Signaling Module.....	36
1.6.5 Global Time Counter.....	36
1.6.6 Windowed Watchdog Timer/Real Time Interrupt .....	36
1.6.7 WKUP_TIMER .....	36
1.7 Device Identification.....	38
<b>2 Memory Map.....</b>	<b>39</b>
2.1 MAIN Memory Map.....	40
2.2 MCU Memory Map.....	58
2.3 WKUP Memory Map.....	60
2.4 R5FSS0 Memory Map.....	61
2.5 MCU_R5FSS0 Memory Map.....	61
2.6 WKUP_R5FSS0 Memory Map.....	61
2.7 DMASS0 Memory Map.....	62
2.8 SMS0 Memory Map.....	62
2.9 SA3_SS0 Memory Map.....	62
<b>3 System Interconnect.....</b>	<b>63</b>
3.1 System Interconnect Overview.....	64
3.1.1 Terminology.....	64
3.2 Domain Partition.....	64
3.3 Initiator/Target Connectivity.....	65
3.4 Interrupt Condition for Interconnect.....	65
3.4.1 Register MMR for default_err_intr.....	66
3.4.2 Register MMR for default_exp.....	68
3.5 Coherency Features.....	70
3.5.1 IO Coherency Support.....	70
3.6 Performance Tuning.....	71
3.6.1 Latency Reduction.....	71
3.6.2 Using Quality of Service (QoS) MMR.....	71
3.7 Interconnect Debugging Feature.....	75
3.8 Quality of Service (QoS) Block.....	75
<b>4 Module Integration.....</b>	<b>77</b>
4.1 Memory Controllers.....	78
4.1.1 DDR32 Subsystem (DDR32SS).....	78
4.1.2 msram8kx256e.....	79
4.2 System Interconnect.....	80
4.2.1 CBASS.....	80
4.2.2 C7XV_RSWS_BS_LIMITER.....	83
4.2.3 JPGENC_RS_BW_LIMITER.....	84
4.2.4 JPGENC_WS_BW_LIMITER.....	84
4.2.5 GPU_RS_BW_LIMITER.....	84
4.2.6 GPU_WS_BW_LIMITER.....	85
4.2.7 VPAC_RSWS_BW_LIMITER.....	85

4.3 Processors and Accelerators.....	86
4.3.1 Arm Cortex A53 Subsystem (A53SS).....	86
4.3.2 Video Encoder/Decoder (CODEC).....	91
4.3.3 Arm Cortex R5F Subsystem (R5FSS).....	92
4.3.4 Vision Pre-processing Accelerator (VPAC).....	97
4.3.5 Depth and Motion Perception Accelerator (DMPAC).....	110
4.3.6 JPGENC.....	113
4.3.7 C7X256V.....	114
4.3.8 Graphics Processing Unit (GPU).....	353
4.4 Interprocessor Communication.....	359
4.4.1 Mailbox.....	359
4.4.2 Spinlock.....	375
4.5 Device Configuration.....	376
4.5.1 Control Module (CTRL_MMR).....	376
4.5.2 Voltage and Thermal Manager (VTM).....	379
4.5.3 Power Sleep Controller (PSC).....	382
4.5.4 Clocking.....	383
4.6 Interrupts.....	386
4.6.1 TIMESYNC_EVENT_INTROUTER.....	386
4.6.2 Generic Interrupt Controller Subsystem (GICSS).....	416
4.7 Data Movement Architecture.....	422
4.7.1 Data Movement Subsystem (DMSS).....	423
4.7.2 Block Copy DMA (BCDMA).....	424
4.7.3 Peripheral DMA (PDMA).....	425
4.7.4 Packet DMA (PKTDMA).....	426
4.8 Audio.....	427
4.8.1 Audio Tracking Logic (ATL).....	427
4.8.2 Multichannel Audio Serial Port (MCASP).....	429
4.9 General Connectivity.....	440
4.9.1 General Purpose Input/Output (GPIO).....	440
4.9.2 Inter-Integrated Circuit (I2C).....	442
4.9.3 Multichannel Serial Peripheral Interface (MCSPI).....	448
4.9.4 Universal Asynchronous Receiver/Transmitter (UART).....	457
4.10 High-speed Serial Interfaces.....	469
4.10.1 Peripheral Component Interconnect Express (PCIe) Subsystem.....	469
4.10.2 Gigabit Ethernet Switch (CPSW).....	475
4.10.3 Serializer/Deserializer (SerDes).....	480
4.10.4 Universal Serial Bus Subsystem (USB).....	484
4.11 Memory Interfaces.....	540
4.11.1 Flash Subsystem (FSS).....	540
4.11.2 Octal Serial Peripheral Interface (OSPI).....	541
4.11.3 General-Purpose Memory Controller (GPMC).....	543
4.11.4 Error Location Module (ELM).....	545
4.11.5 Multimedia Card Secure Digital (MMCSD).....	546
4.12 Industrial and Control Interfaces.....	550
4.12.1 Modular Controller Area Network (MCAN).....	550
4.12.2 Enhanced Capture (ECAP).....	577
4.12.3 Enhanced Pulse Width Modulation (EPWM).....	580
4.12.4 Enhanced Quadrature Encoder Pulse (EQEP).....	585
4.13 Camera Subsystem.....	588
4.13.1 Camera Serial Interface Receiver (CSI_RX_IF).....	588
4.13.2 MIPI D-PHY Receiver (DPHY_RX).....	595
4.13.3 MIPI D-PHY Transmitter (DPHY_TX).....	597
4.13.4 Camera Streaming Interface Transmitter (CSI_TX_IF).....	598
4.14 Timer Modules.....	600
4.14.1 Global Timebase Counter (GTC).....	600
4.14.2 Real Time Interrupt (RTI).....	602
4.14.3 Real-Time Clock (RTC).....	609
4.14.4 Timer.....	611
4.15 Internal Diagnostic Modules.....	639
4.15.1 Dual Clock Comparator (DCC).....	639

4.15.2 Error Signaling Module (ESM).....	653
4.15.3 Memory Cyclic Redundancy Check (MCRC64).....	656
4.15.4 Programmable Built-In Self-Test (PBIST).....	659
4.15.5 ECC Aggregator (ECC_AGGR).....	665
4.16 Display Subsystem (DSS).....	667
4.16.1 DSS_UL Unsupported Features.....	667
4.16.2 Module Allocations.....	667
4.16.3 Resets, Interrupts, and Clocks.....	667
4.16.4 oldi_tx_core.....	670
4.17 On-Chip Debug.....	670
4.17.1 CPT2_PROBE.....	670
4.17.2 CTI.....	674
<b>5 Initialization.....</b>	<b>675</b>
5.1 Initialization Overview.....	676
5.1.1 ROM Code Overview.....	676
5.1.2 Bootloader Modes.....	676
5.1.3 Terminology.....	677
5.2 Boot Process.....	679
5.2.1 Public ROM Code Architecture.....	679
5.2.2 M4 ROM Description.....	680
5.2.3 Boot Process Flow.....	680
5.3 Boot Mode Pins.....	684
5.3.1 BOOTMODE Pin Mapping.....	685
5.4 Boot Modes.....	686
5.4.1 OSPI/xSPI/QSPI/SPI Boot.....	687
5.4.2 I2C Boot.....	698
5.4.3 SD Card Boot.....	699
5.4.4 eMMC Boot.....	701
5.4.5 Ethernet Boot.....	702
5.4.6 USB Boot.....	706
5.4.7 UART Boot.....	707
5.4.8 GPMC NOR Boot.....	709
5.4.9 GPMC NAND Boot.....	711
5.4.10 Serial NAND Boot.....	712
5.4.11 No boot/Development boot .....	714
5.5 PLL Configuration.....	715
5.6 Boot Parameter Tables.....	717
5.6.1 Common Header.....	717
5.6.2 PLL Setup.....	718
5.6.3 OSPI/QSPI/SPI Boot Parameter Table.....	719
5.6.4 UART Boot Parameter Table.....	720
5.6.5 I2C Boot Parameter Table.....	720
5.6.6 MMCSD/eMMC Boot Parameter Table.....	721
5.6.7 Ethernet Boot Parameter Table.....	722
5.6.8 xSPI/Fast-xSPI Boot Parameter Table.....	723
5.6.9 USB DFU Boot Parameter Table.....	724
5.6.10 USB MSC Boot Parameter Table.....	724
5.6.11 GPMC NOR Boot Parameter Table.....	725
5.6.12 GPMC NAND Boot Parameter Table.....	725
5.7 Boot Image Format.....	727
5.7.1 Overall Structure.....	727
5.7.2 X.509 Certificate.....	727
5.7.3 Organizational Identifier (OID).....	727
5.7.4 X.509 Extensions Specific to Boot.....	728
5.7.5 Extended Boot Info Extension.....	728
5.7.6 Generating X.509 Certificates.....	731
5.8 Boot Memory Maps.....	734
5.8.1 Memory Layout/MPU.....	734
5.8.2 Global Memory Addresses Used by ROM Code.....	734
<b>6 Device Configuration.....</b>	<b>735</b>
6.1 Control Module.....	736

6.1.1 Memory Mapped Control Register Modules (CTRL_MMR).....	736
6.1.2 General Purpose Control Register Modules Overview.....	736
6.1.3 I/O Debounce Control Registers .....	738
6.1.4 Security Control Register Modules.....	740
6.2 Power.....	740
6.2.1 Power Management Overview.....	740
6.2.2 Power Control Modules.....	740
6.2.3 Power Management Techniques.....	751
6.2.4 Power Management Subsystems.....	752
6.3 Reset.....	773
6.3.1 Overview.....	773
6.3.2 Reset Sources.....	785
6.3.3 Reset Status.....	786
6.3.4 Reset Controls.....	789
6.3.5 Reset Details.....	791
6.4 Clocking.....	811
6.4.1 Overview.....	811
6.4.2 Clock Inputs.....	812
6.4.3 Clock Outputs.....	813
6.4.4 Device Oscillators.....	815
6.4.5 PLLs.....	818
<b>7 Processors and Accelerators.....</b>	<b>834</b>
7.1 Arm Cortex-A53 Subsystem (A53SS).....	835
7.1.1 A53SS Overview.....	836
7.1.2 A53SS Functional Description.....	838
7.2 Arm Cortex R5F Subsystem (R5FSS).....	844
7.2.1 R5FSS Overview.....	845
7.2.2 R5FSS Functional Description.....	847
7.3 Cortex R5F Subsystem (R5FSS).....	860
7.3.1 R5FSS Overview.....	860
7.3.2 R5FSS Functional Description.....	863
7.3.3 Vectored Interrupt Manager (VIM).....	882
7.4 Device Manager Cortex R5F Subsystem (WKUP_R5FSS).....	892
7.4.1 WKUP_R5FSS Overview.....	892
7.4.2 WKUP_R5FSS Functional Description.....	895
7.5 Vectored Interrupt Manager (VIM).....	914
7.5.1 VIM Overview.....	914
7.5.2 VIM Functional Description.....	914
7.5.3 Interrupt Conditions.....	917
7.5.4 Memory Map.....	921
7.5.5 VIM Registers.....	922
7.5.6 Module I/O.....	929
7.5.7 Programmer's Guide.....	931
7.6 Video Encoder/Decoder (VENC/VDEC).....	932
7.6.1 Introduction.....	932
7.6.2 Features.....	932
7.6.3 Block Diagram.....	936
7.7 Vision Pre-processing Accelerator (VPAC).....	939
7.7.1 VPAC Overview.....	939
7.7.2 VPAC Subsystem Level.....	944
7.7.3 VPAC Vision Imaging Subsystem (VISS).....	955
7.7.4 VPAC Lens Distortion Correction (LDC) Module.....	1031
7.7.5 VPAC Multi-Scaler (MSC).....	1055
7.8 Depth and Motion Perception Accelerator (DMPAC).....	1077
7.8.1 DMPAC Overview.....	1077
7.9 Graphics Accelerator (GPU).....	1078
7.9.1 GPU Overview.....	1078
<b>8 Inter-processor Communication Scheme (IPC).....</b>	<b>1080</b>
8.1 Mailbox.....	1081
8.1.1 Mailbox Overview.....	1081
8.1.2 Mailbox Functional Description.....	1082

8.1.3 Mailbox Programming Guide.....	1086
8.2 Spinlock.....	1088
8.2.1 Spinlock Overview.....	1088
8.2.2 Spinlock Functional Description.....	1088
8.2.3 Spinlock Programming Guide.....	1090
8.3 Secure Proxy (SEC_PROXY).....	1092
<b>9 Memory Controllers.....</b>	<b>1093</b>
9.1 DDR Subsystem (DDRSS).....	1094
9.1.1 DDRSS Overview.....	1094
9.1.2 DDRSS Environment.....	1096
9.1.3 DDRSS Functional Description.....	1098
<b>10 Interrupts.....</b>	<b>1109</b>
10.1 Interrupt Architecture.....	1110
10.1.1 ESM Connectivity.....	1110
10.1.2 PSIL Events.....	1112
10.1.3 GPIO Interrupt Handling.....	1113
10.1.4 Utilizing Miscellaneous Signals as Interrupt.....	1114
10.2 Interrupt Controllers.....	1117
10.2.1 Generic Interrupt Controller (GICSS).....	1117
10.3 Interrupt Router (INTROUTER).....	1122
10.3.1 INTROUTER Integration.....	1122
10.4 Interrupt Sources.....	1122
10.4.1 C7X256V0_CLEC_INTERRUPT_MAP.....	1122
10.4.2 C7X256V1_CLEC_INTERRUPT_MAP.....	1129
10.4.3 COMPUTE_CLUSTER0_INTERRUPT_MAP.....	1136
10.4.4 CPSW0_INTERRUPT_MAP.....	1136
10.4.5 DMASS0_INTAGGR_0_INTERRUPT_MAP.....	1136
10.4.6 EPWM0_INTERRUPT_MAP.....	1137
10.4.7 EPWM1_INTERRUPT_MAP.....	1138
10.4.8 EPWM2_INTERRUPT_MAP.....	1138
10.4.9 ESM0_INTERRUPT_MAP.....	1138
10.4.10 GICSS0_INTERRUPT_MAP.....	1145
10.4.11 GLUELOGIC_A53_EVENTI_GLUE_INTERRUPT_MAP.....	1152
10.4.12 GLUELOGIC_EPWM0_SYNC_MUXGLUE_INTERRUPT_MAP.....	1152
10.4.13 GLUELOGIC_GLUE_EXT_INTN_INTERRUPT_MAP.....	1152
10.4.14 GLUELOGIC_MAIN_DCC_DONE_GLUE_INTERRUPT_MAP.....	1152
10.4.15 GLUELOGIC_MCU_ACCESS_ERR_INTR_GLUE_INTERRUPT_MAP.....	1153
10.4.16 GLUELOGIC_MCU_CBASS_INTR_OR_GLUE_INTERRUPT_MAP.....	1153
10.4.17 GLUELOGIC_MGASKET_INTR_GLUE_INTERRUPT_MAP.....	1153
10.4.18 GLUELOGIC_PWM_TRIP_OR_GLUE_INTERRUPT_MAP.....	1153
10.4.19 GLUELOGIC_SGASKET_INTR_GLUE_INTERRUPT_MAP.....	1153
10.4.20 GLUELOGIC_SOC_ACCESS_ERR_INTR_GLUE_INTERRUPT_MAP.....	1154
10.4.21 GLUELOGIC_SOC_CBASS_ERR_INTR_GLUE_INTERRUPT_MAP.....	1154
10.4.22 GLUELOGIC_WKUP_PBIST_CPUINTR_INTERRUPT_MAP.....	1154
10.4.23 GLUELOGICN_LBIST_DONE_GLUE_INTERRUPT_MAP.....	1155
10.4.24 GLUELOGICN_MAIN_PBIST_CPU_GLUE_INTERRUPT_MAP.....	1155
10.4.25 HSM0_INTERRUPT_MAP.....	1155
10.4.26 MAIN_GPIOMUX_INTROUTER0_INTERRUPT_MAP.....	1159
10.4.27 MCU_R5FSS0_CORE0_INTERRUPT_MAP.....	1166
10.4.28 PCIE0_INTERRUPT_MAP.....	1175
10.4.29 PDMA0_INTERRUPT_MAP.....	1175
10.4.30 PDMA1_INTERRUPT_MAP.....	1176
10.4.31 PDMA2_INTERRUPT_MAP.....	1177
10.4.32 PDMA3_INTERRUPT_MAP.....	1177
10.4.33 PINFUNCTION_CP_GEMAC_CPTS0_TS_COMPOUT_INTERRUPT_MAP.....	1177
10.4.34 PINFUNCTION_CP_GEMAC_CPTS0_TS_SYNCOUT_INTERRUPT_MAP.....	1177
10.4.35 PINFUNCTION_SYNC0_OUTOUT_INTERRUPT_MAP.....	1177
10.4.36 PINFUNCTION_SYNC1_OUTOUT_INTERRUPT_MAP.....	1177
10.4.37 PINFUNCTION_SYNC2_OUTOUT_INTERRUPT_MAP.....	1178
10.4.38 PINFUNCTION_SYNC3_OUTOUT_INTERRUPT_MAP.....	1178
10.4.39 R5FSS0_CORE0_INTERRUPT_MAP.....	1178

10.4.40 SMS0_COMMON_0_INTERRUPT_MAP.....	1183
10.4.41 TIFS0_INTERRUPT_MAP.....	1184
10.4.42 TIMESYNC_EVENT_INTROUTER0_INTERRUPT_MAP.....	1187
10.4.43 USB0_INTERRUPT_MAP.....	1188
10.4.44 WKUP_DEEPSLEEP_SOURCES0_INTERRUPT_MAP.....	1188
10.4.45 WKUP_ESM0_INTERRUPT_MAP.....	1189
10.4.46 WKUP_MCU_GPIOMUX_INTROUTER0_INTERRUPT_MAP.....	1192
10.4.47 WKUP_R5FSS0_CORE0_INTERRUPT_MAP.....	1193
<b>11 Data Movement Architecture.....</b>	<b>1199</b>
11.1 Data Movement Architecture Overview.....	1200
11.1.1 Overview.....	1200
11.1.2 Definition of Terms.....	1214
11.1.3 DMSS Hardware/Software Interface.....	1216
11.1.4 Operational Description.....	1243
11.2 Data Movement Subsystem (DMSS).....	1261
11.2.1 Data Movement Subsystem (DMSS).....	1262
11.2.2 Ring Accelerator (RINGACC).....	1266
11.2.3 Secure Proxy (SEC_PROXY).....	1277
11.2.4 Interrupt Aggregator (INTAGGR).....	1283
11.2.5 Packet Streaming Interface Link (PSI-L).....	1288
11.3 Peripheral DMA (PDMA).....	1292
11.3.1 PDMA Controller.....	1292
<b>12 Peripherals.....</b>	<b>1356</b>
12.1 General Connectivity Peripherals.....	1357
12.1.1 General-Purpose Interface (GPIO).....	1358
12.1.2 Inter-Integrated Circuit (I2C) Interface.....	1367
12.1.3 Multichannel Serial Peripheral Interface (MCSPI).....	1394
12.1.4 Universal Asynchronous Receiver/Transmitter (UART).....	1443
12.2 High-speed Serial Interfaces.....	1503
12.2.1 Gigabit Ethernet Switch (CPSW3G).....	1504
12.2.2 Peripheral Component Interconnect Express (PCIe) Subsystem.....	1610
12.2.3 Serializer/Deserializer (SerDes).....	1634
12.2.4 Universal Serial Bus Subsystem (USBSS).....	1643
12.2.5 Universal Serial Bus Subsystem (USBSS).....	1647
12.3 Memory Interfaces.....	1653
12.3.1 Flash Subsystem (FSS).....	1654
12.3.2 Octal Serial Peripheral Interface (OSPI).....	1659
12.3.3 General-Purpose Memory Controller (GPMC).....	1688
12.3.4 Error Location Module (ELM).....	1797
12.3.5 Multi-Media Card Secure Digital (MMCSD) Interface.....	1807
12.4 Industrial and Communication Interfaces.....	1880
12.4.1 Modular Controller Area Network (MCAN).....	1881
12.4.2 Enhanced Capture (ECAP) Module.....	1918
12.4.3 Enhanced Pulse Width Modulation (EPWM) Module.....	1947
12.4.4 Enhanced Quadrature Encoder Pulse (EQEP) Module.....	2008
12.5 Audio Peripherals.....	2033
12.5.1 Audio Tracking Logic (ATL).....	2034
12.5.2 Multichannel Audio Serial Port (MCASP).....	2035
12.6 Camera Peripherals.....	2109
12.6.1 Camera Serial Interface Receiver (CSI_RX_IF).....	2110
12.6.2 MIPI D-PHY Receiver (DPHY_RX).....	2132
12.6.3 MIPI D-PHY Transmitter (DPHY_TX).....	2139
12.6.4 Camera Streaming Interface Transmitter (CSI_TX_IF).....	2141
12.7 Timer Modules.....	2157
12.7.1 Global Timebase Counter (GTC).....	2157
12.7.2 RTI-Windowed Watchdog Timer (WWDT).....	2159
12.7.3 Real-Time Clock (RTC).....	2166
12.7.4 Timers.....	2180
12.8 Internal Diagnostics Modules.....	2203
12.8.1 Dual Clock Comparator (DCC).....	2203
12.8.2 Error Signaling Module (ESM).....	2211

12.8.3 Memory Cyclic Redundancy Check (MCRC) Controller.....	2225
12.8.4 ECC Aggregator.....	2239

## About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

## Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for the device, visit the Texas Instruments website at [www.ti.com](http://www.ti.com).

## Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

## Export Control Notice

Recipient agrees to not knowingly export or re-export, directly or indirectly, any product or technical data (as defined by the U.S., EU, and other Export Administration Regulations) including software, or any controlled product restricted by other applicable national regulations, received from disclosing party under nondisclosure obligations (if any), or any direct product of such technology, to any destination to which such export or re-export is restricted or prohibited by U.S. or other applicable laws, without obtaining prior authorization from U.S. Department of Commerce and other competent Government authorities to the extent required by those laws.

## Release History

The following table summarizes the J722S, TDA4VEN, TDA4AEN, AM67 Silicon Revision 1.0 Technical Reference Manual versions.

Version	Literature Number	Date	Notes

This chapter introduces the features, subsystems, and architecture of the J722S Processor Platform high-performance System-on-Chip (SoC).

### Note

This document describes the Superset architecture, processors and peripherals of the J722S Family of SoCs, which are part of the K3 Multicore SoC architecture platform. Not all features are available on each family of devices. The superset J722S devices are available for preproduction software development. Software should constrain the features used to match the intended production device. For more information on the specific features, processors and peripherals available on a particular device, refer to the Device Comparison table in the corresponding device-specific Data sheet.

The J722S Processor Platforms are hereinafter commonly referred to as *J722Splatform*, *device*, or *SoC*.

TI limits support for this family of SoCs to features that are supported via Software Development Kits (SDK). The SDK “build sheet” is available for download as part of each SDK and should be referenced to understand the subset of SoC hardware functionality that is available in software.

This document describes the Superset features of the Modules integrated into this Device. See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

## 1.3 Functional Block Diagram

**Figure 1-1. Device Block Diagram**

## 1.4 Device MAIN Domain

This section describes the modules integrated in the device MAIN domain.

### 1.4.1 Arm Cortex-A53 Subsystem (A53SS)

The integrated 64-bit Arm Cortex-A53 subsystem (A53SS) supports the following main features:

- Full Arm®v8-A architecture compliancy
- Advanced Single Instruction Multiple Data (SIMD) and floating point extension (Arm® Neon™)
- Floating-Point Unit (FPU) VFPv4
- Armv8 Cryptography Extensions
- Arm General Interrupt Controller (GICv3) architecture
- In-order pipeline with symmetric dual-issue of most instructions
- 32KB program and 32KB data Level 1 (L1) Cache
- Support for up to four timers within each Cortex-A53 core
- Arm® CoreSight™ Debug and Trace Architecture
- ECC protection for L1 data cache and L2 Cache
- Parity protection for L1 Instruction Cache
- 128-bit wide, synchronous or asynchronous VBUSM initiator interface
- Dedicated RTI windowed watchdog timer per core
- Support for Big-Endian (BE) and Little-Endian (LE) at core level
- Interface with Arm GIC-500 Interrupt Controller (SoC level, not part of A53SS)
- Advanced power management for low power optimization

### 1.4.2 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x ways
    - SECDED ECC protected per 64 bits
  - Data Cache
    - 4x ways
    - SECDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts

- Synchronous clock domain crossing on all core interfaces

---

**Note**

CORE0 has 64KB of TCM.

---

**Note**

These details describe a superset of the R5FSS memory configuration. For additional details on device memory availability, please refer to the device-specific Datasheet.

---

### 1.4.3 Deep Learning Accelerator (C7x256v)

- Single Core C7x/MMA subsystem
  - C7x ISA and RISC-V G ISA extensions
    - Vector DSP, 40 GFLOPS
    - 256-bit vector width
    - Deep-learning Matrix Multiply Accelerator (MMA), up to 2 TOPS
  - L1 memory architecture
    - 32KB I-cache
    - 64KB D-cache
  - L2 memory architecture
    - Repurposing of its L2/EL2 embedded memory for use by SOC resources when C7x/MMA/DRU are disabled
    - 1.25MB L2 with ECC protection on L2 SRAM
    - Unified Memory Controller (UMC) facilitates L2 SRAM accesses from CPU and SOC (DMAs) as well as EMIF accesses from CPU.
    - DRU (DMA engine) integrated that facilitates data transfer between L2, VPAC and EMIF.
      - Data compression support
      - Event bus interface integrates with SOC DMSS
      - Tightly coupled with C7x/MMA (DRU is not available for use when the C7x/MMA is disabled)
  - Interrupts
    - Local event controller (CLEC) integrated within CorePac for routing and handling of DRU interrupts, CPU generated IPC events to SOC, interrupts coming from SOC
  - Security
    - Support for C7x Authenticated Boot. Security is in-context during boot to facilitate the authentication and loading of the C7x image.
    - The C7x L2 SRAM (UMC) should not be used for storing security content as there is no protection of UMC memory from C7x itself. In a threat scenario, the C7x can be activated if in reset to execute malicious code to access data in UMC thereby defeating a protection for security data in UMC.
    - No security should be inferred from DRU as this IP is out of scope for security.
    - TrustZone debug controls (DBGGEN, NIDEN, SPIDEN, SPNIDEN) are supported
  - Safety
    - Support for reporting safety errors to SOC via interrupt
  - Debug
    - Independent debug interface supporting access to embedded features
    - Debug features include: Core debug, Advanced Event Triggering, Trace, CTSETs, and an embedded CP Tracer Aggregator with bus probes on internal memory interfaces
  - Power Management
    - support for granular gated clock domains to support low power modes and to support memory interface utilization while IP disabled.
  - Advanced SOC Integration
    - Dedicated PLL for full flexibility in performance and power trade-offs
    - Dedicated windowed watchdog timer per core

#### 1.4.4 Vision Pre-processing Accelerator

The Vision Pre-processing Accelerator (VPAC) provides a set of common vision primitive functions, performing various pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation, and offloads these common tasks from the main SoC processors (ARM, DSP, etc.). The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS) which provides raw data image processing such as:
  - Wide Dynamic Range (WDR) merge
  - Defect Pixel Correction (DPC)
  - Lens Shading Correction (LSC)
  - Global/Local Brightness and Contrast Enhancement (GLBCE)
  - Advanced Spatial Noise Filter (NSF4V)
  - Edge Enhancement (EE)
  - Demosaicing
  - Color conversion
- Lens Distortion Correction (LDC) block, which provides data reading from memory (DDR or on-chip) and applies perspective transformation as well as correction of lens distortion (including fisheye lenses).
- Multi-Scalar (MSC) block reads data from memory (DDR or on-chip) to internal shared level 2 (SL2) memory and generates up to 10 scaled outputs from one or two inputs, with various scaling ratios.
- Noise Filter (NF) block reads data from memory (DDR or on-chip) to internal SL2 memory and does Bilateral filtering to remove noise.
- Hardware Thread Scheduler (HTS) provides inter-processor communication among various VPAC sub-modules (VISS, LDC, MSC and NF) as well as with the local DMA Engine (UTC).
- Internal Shared Level 2 (SL2) memory for data exchange across VPAC sub-modules (VISS, LDC, MSC and NF) and from DDR/MSMC, using the K3 Data Movement Architecture (DMA) mechanism
- Load/Store Engine (LSE) which performs data load and store tasks on a the SL2 memory for the hardware accelerator algorithm cores
- VISS to LDC direct OTF (On-the-Fly) for multi-camera
- YUV422 10 and 12 bit format support on all units except NF (e.g. LDC/MS)
- Simultaneous visual (HV) and analytics (MV) output to system memory including L3 flex connect, saving need for additional read from system memory for HV+MV processing.
- Chromatic Aberration Correction (CAC) to support lower cost lens
- RGBIR support

#### 1.4.5 Depth and Motion Perception Accelerator

The Depth and Motion Perception Accelerator (DMPAC) computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common local memory, DMA, external messaging and control infrastructure. The DMPAC provides the following main features, among others:

- Image resolution up to 2MPix (maximum horizontal resolution up to 2048 pixels; maximum vertical resolution up to 1024 pixels)
- Maximum throughput up to 220MPix/sec for DOF, and up to 84-100MPix/sec for SDE
- Simultaneous operation of Stereo (1MPix@30fps) and Optical flow (1MP@30fps)
- 12-bit fully packed luminance data input pixel data format (other formats supported through conversion)
- Packed 16-bit (disparity) or 32-bit (flow vector) output data formats
- Shared Level 2 (SL2) memory sub-system, which serves the data transfer of the DOF and SDE blocks
- Unified Transfer Controller (UTC), which serves as a DMA engine
- Hardware Thread Scheduler (HTS) block for messaging and control mechanism
- Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the Stereo and Optical Flow hardware threads

### 1.4.6 Mailbox (MAILBOX)

Integrated in MAIN domain: One Mailbox (MAILBOX) module to facilitate the communication between the various on-chip processor cores of the device by providing a queued mailbox-interrupt mechanism with the following main features:

- 1x clusters
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

### 1.4.7 Spinlock (SPINLOCK)

One Spinlock module with (256 hardware semaphores) for synchronizing the processes running on multiple cores in the device.

### 1.4.8 DDR 32-bit Subsystem (DDR32)

Integrated in MAIN domain: One instance of DDR 32-bit Subsystem (DDR32) (also referred to as DDRSS) is used as an interface to external SDRAM devices which can be utilized for storing program or data. The DDRSS provides the following main features:

- Support of LPDDR4 memory type (up to 4000 MT/s)
- 32-bit memory bus interface with in-line ECC
- Up to 8 GB memory address range
- Support of dual rank configuration
- Support of automatic idle power saving mode when no or low activity is detected
- Class of Service (CoS) - three latency classes supported
- Dynamic change of refresh reach via SW for extended temperatures
- Prioritized refresh scheduling
- Statistical counters for performance management

### 1.4.9 Data Movement Subsystem (DMSS)

Integrated in the MAIN domain: One Data Movement subsystem named DMSS can be used for efficient transfer of data support between software, firmware and hardware in all combinations. It consists of the following main modules:

- Packet DMA Controller
- Block Copy DMA Controller
- Ring Accelerator provides hardware acceleration to enable straightforward passing of work between a producer and a consumer and has the following main features:
  - Supports independent memory-mapped ring structures
  - Supports various modes for each ring based on usage and compatibility
  - Provides single-word deep shared incoming Transfer Response FIFO
  - Provides bit-wide source VBUSM read/write target interface for accesses from DMA controller entities
- Secure proxy module is a modified version of the proxy module and in addition has the following main features:
  - Provides proxy function to store large data bursts that a host can only access in smaller amounts
  - Supports a configurable number of threads, where each has their own independent proxy function
  - Keeps the large data burst coherent until the complete data has been accessed
  - Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
  - Supports a configurable target resource. The target has a configurable number of channels, size of each channel and base address
  - Supports a programmable fixed queue for each proxy thread
  - Supports multiple producers all writing to the same queue
  - Supports programmable thresholds for when to generate events
  - Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce

- Optionally supports dynamic clock gating
- Interrupt Aggregator modules provide a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Main features are as follows:
  - 64-bit VBUSP target using 64-bit registers
  - Provide a set of TI Interrupt Architecture compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
  - Provides an optional set of Unmapped event (UNMAP) which can take an 'unmapped' event from the ingress ETL and generate a Global event on the egress Event Transport Lane (ETL) interface.
  - Provides an optional set of Global Event Input (GEVI) counters which can count events delivered via an ingress Event Transport Lane (ETL)
  - Provides an optional set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Provides an optional set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces

#### **1.4.10 General Purpose Input/Output Interface (GPIO)**

Integrated in MAIN domain: General Purpose Input/Output (GPIO) module that provide dedicated general-purpose pins that can be configured as either inputs or outputs. The GPIO module main features include:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

#### **1.4.11 Inter-Integrated Circuit Interface (I2C)**

Integrated in MAIN domain: Five instances of the multi-controller Inter-Integrated Circuit (I2C) interface module, each with the following main features:

- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- 8-bit-wide data access
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with fixed size of 32 bytes.

#### **1.4.12 Serial Peripheral Interface (SPI)**

Integrated in MAIN domain: Three instances of the Serial Peripheral Interface (SPI) module with the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to channels in controller mode, or single channel in receiver mode
- Support for various controller multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

#### **1.4.13 Universal Asynchronous Receiver/Transmitter (UART)**

Seven Instances of the configurable Universal Asynchronous Receiver/Transmitter (UART) interface module have the following main features:

- 16C750-compatible interface
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation

- Programmable sleep mode
- Baud-rate from 300 bits/s up to 3.6864 Mbps/s with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

#### Note

Only one UART instance has support for support full modem control functions. All other UART instances will support only the TX, RX, RTS, and CTS signals.

### 1.4.14 3-port Gigabit Ethernet Switch (CPSW3G)

Integrated in MAIN domain: One instance of the 3-port Gigabit Ethernet Switch (CPSW3G) subsystem provides Ethernet packet communication for the device. The CPSW3G subsystem provides the following main features:

- Two external Ethernet ports with selectable RGMII and RMII interfaces and one internal Communications Port Programming Interface (CPPI) port.
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Support of eight priority level Quality Of Service (QoS) - 802.1p
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- Differentiated Services Code Point (DSCP) Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Priority Based Flow Control (801.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Store and Forward Switching
- Non-Blocking switch fabric
- Support of Time Sensitive Network - IEEE P902.3br/D2.0 Interspersing Express Traffic and IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE) with 512 ALE table entries
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Maximum frame size of 2020 bytes
- Management Data Input/Output (MDIO) module for PHY Management
- Host port CPPI Streaming Packet Interface
- Emulation support

### 1.4.15 Universal Serial Bus (USB) Subsystem 2.0

Instantiated in MAIN domain: Two instances of the Universal Serial Bus (USB) subsystem with integrated USB2.0 PHY module has the following main features:

- Dual-Role Device (DRD) capability
- Support of Peripheral (aka Device) mode at High Speed (HS at 480 Mbps) and Full Speed (FS at 12 Mbps)
- Support of Host mode at High Speed (HS at 480 Mbps), Full Speed (FS at 12 Mbps), and Low Speed (LS at 1.5 Mbps)
- Support of Host Negotiation Protocol (HNP)
- Support of USB3 low power protocol states (U1, U2, and U3)
- USB instance contains a single xHCI compliant with xHCI 1.0 specification with internal DMA controller
- Embedded USB 2.0 PHY

### 1.4.16 Universal Serial Bus 3.1 Subsystem (USBSS)

Instantiated in MAIN domain: One instance of the Universal Serial Bus 3.1 subsystem (USBSS) with integrated USB2.0 PHY module has the following main features:

- Dual-Role Device (DRD) capability

- Compliant to the USB 3.1 Gen1 Specification
- Supports Peripheral/Device mode at High-Speed (HS at 480 Mbps), and Full-Speed (FS at 12 Mbps)
- Supports Host mode at Super-Speed (SS at 5 Gbps), High-Speed (HS at 480 Mbps), Full-Speed (FS at 12 Mbps), and Low-Speed (LS at 1.5 Mbps)
- Supports Host Negotiation Protocol (HNP)
- Supports USB3 low power protocol states (U1, U2, and U3)
- Single xHCI instance compliant to the xHCI 1.0 specification with internal DMA controller
- ECC on internal RAMs
- Embedded USB 2.0 PHY

#### **1.4.17 Serializer/Deserializer (SERDES)**

Integrated in MAIN domain: Two high-speed differential interfaces implemented with the Serializer/Deserializer (SERDES) Multi-protocol Multi-link module with the following main blocks:

- Quad lane PHY with common module for peripheral and Tx clocking handling
- PIPE Rev 4.2 Interface
- Physical coding sub-block for data translation from/to the parallel interface, as well as data encoding/decoding and symbol alignment
- MUX module for device interfaces multiplexing into a single SERDES lane (Tx and Rx)
- A wrapper for sending control and reporting status signals from the SerDes and muxes

#### **1.4.18 Peripheral Component Interconnect Express Subsystem (PCIE)**

Integrated in MAIN domain: One instance of the Peripheral Component Interconnect express (PCIe) subsystem module with shared SerDes lines, provides the following main features:

- Compliant to PCI-Express® Base Specification, Revision 4.0 (Version 0.7)
- 1-lane configuration with up to 8.0 Gbps/lane (Gen3).
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- Dual mode: Root Port (RP) or End Point (EP) operation modes, selectable via bootstrap pins
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Maximum payload size of 128 bytes
- Maximum remote read request size of 4KB
- Dual mode: Root Port (RP) or End Point (EP) operation modes
- Maximum number of non-posted outstanding transactions: 32
- Resizable Base Address Registers (BAR) capability
- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

#### **1.4.19 Enhanced Pulse-Width Modulation Module (EPWM)**

Integrated in MAIN domain: Three Enhanced Pulse-Width Modulation (EPWM) modules, each with the following main features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two independent PWM outputs that can be used in different configurations (with single-edge operation, with dual-edge symmetric operation or one independent PWM output with dual-edge asymmetric operation)
- Asynchronous override control of PWM signals during fault conditions
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both latched and un-latched fault conditions
- Events enabling to trigger both CPU interrupts and start of ADC conversions

### **1.4.20 Enhanced Quadrature Encoder Pulse Module (EQEP)**

Integrated in MAIN domain: Three 32-bit Enhanced Quadrature Encoder Pulse (EQEP) modules for position, speed, and frequency measurements support, each with the following main features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit
- Position counter and control unit for position measurement
- Quadrature edge capture unit for low speed measurement
- Unit time base for speed/frequency measurement
- Watchdog timer for detecting stalls

### **1.4.21 Enhanced Capture Module (ECAP)**

Integrated in MAIN domain: Three Enhanced Capture (ECAP) modules provide accurate timing for different events. When not being used for event capture, its resources can be used to generate a single channel of asymmetrical PWM waveforms (configurable as either one capture input, or as one auxiliary PWM output). Each ECAP module supports the following main features:

- 32-bit time base counter
- 4 x 32 bits event time-stamp capture registers
- 4 stage sequencer (Mod4 counter), synchronized to external events
- Independent edge polarity selection for up to four sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- Interrupt capabilities on any of the four capture events
- Support of different capture modes (single shot capture, continuous mode capture, absolute timestamp capture or delta mode time-stamp capture)

### **1.4.22 Controller Area Network (MCAN)**

Integrated in the domain: One Controller Area Network interfaces (MCAN) supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications and having the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

### **1.4.23 Flash Subsystem (FSS) with Octal Serial Peripheral Interface (OSPI)**

Integrated in MAIN domain: One instance of the Flash Subsystem (FSS) module provides access to external flash devices via Octal Serial Peripheral Interface (OSPI) along with encryption/decryption and in-line ECC protection. FSS supports the following main features:

- Provides one OSPI flash interfaces
- OSPI interface supports:
  - Execute in place (XIP) operation
  - 32-byte Block Copy (BC) operation
  - ECC
- OSPI supports up to 4 devices
- OSPI supports single, dual, quad, or octal SPI devices

- The OSPI interface has independent power management for low power operations

#### **1.4.24 General Purpose Memory Controller (GPMC)**

One instance of the General-Purpose Memory Controller (GPMC) module. The GPMC is dedicated to interfacing with external memory devices and has the following main features:

- Support of 8- or 16-bit-wide data path to external memory devices
- Supports up to 4 independent chip-select regions of programmable size and programmable base addresses on 16MB, 32MB, 64MB, or 128MB boundary in a total address space of
- Support of the following wide range of external memories/devices:
  - Asynchronous or synchronous 8-bit wide memory or device (non-burst device)
  - Asynchronous or synchronous 16-bit wide memory or device
  - 16-bit non-multiplexed NOR flash device
  - 16-bit address and data multiplexed NOR flash device
  - 8-bit and 16-bit NAND flash device
  - 16-bit pseudo-SRAM (pSRAM) device
- Supports various interface protocols when communicating with external memory or external devices:
  - Asynchronous read/write access
  - Asynchronous read page access (4, 8, and 16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4, 8, and 16 Word16)
  - Synchronous read burst access with wrap capability (4, 8, and 16 Word16)
- Supports up to 16-bit on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)

#### **1.4.25 Error Location Module (ELM)**

One instance of the Error Location Module (ELM). The ELM module works in conjunction with the GPMC and has the following main features:

- ECC calculations (up to 16-bit) for NAND support and ability to work in both page-based and continuous modes
  - 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
  - Eight simultaneous processing contexts
  - Page-based and continuous modes
  - Interrupt generation on error-location process completion

#### **1.4.26 Multi-Media Card/Secure Digital Interface (MMCSD)**

Integrated in MAIN domain: Three Multi-Media Card/Secure Digital (MMCSD) controller modules with the following main features:

- One controller with 8-bit wide data bus
- Two with 4-bit wide data bus
- Support of eMMC5.1 Host Specification (JESD84-B51)
- Support of SD Host Controller Standard Specification - SDIO 3.00
- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3
- eMMC Electrical Standard 5.1 (JESD84-B51)
- Multi-Media card features:
  - Backward compatible with earlier eMMC standards
  - Legacy MMC SDR: 3.3/1.8 V, 8/4/1-bit bus width, 0-25 MHz, 25/12.5/3.125 MB/s
  - High Speed SDR: 3.3/1.8 V, 8/4/1-bit bus width, 0-50 MHz, 50/25/6.25 MB/s
  - High Speed DDR: 3.3/1.8 V, 8/4-bit bus width, 0-50 MHz, 100/50 MB/s
  - HS200 SDR: 1.8 V, 0-200 MHz, 8/4-bit bus width, 200/100 MB/s
- SD card support: SDIO, SDR12, SDR25, SDR50, SDR104, DDR50

### 1.4.27 Memory Cyclic Redundancy Check

- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system. The MCRC module has the following main feature:
  - Four Channels of CRC Compression based Signature Generation
  - 8, 16, 32, or 64-bit Data Size
  - Maximum Length PSA based on 64-bit Polynomial
  - Programmable 20 bit pattern counter per channel
  - Three Operating Modes: Auto, Semi-CPU, Full CPU
  - MCRC or CPU can perform signature verification for each Channel
  - Timeout Interrupt if CRC is not performed within the time limit

### 1.4.28 Windowed Watchdog Timer/Real Time Interrupt

- Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Fast enabling/disabling of events

### 1.4.29 TIMER

- Dual mode Timer (TIMER) module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code

### 1.4.30 Audio Tracking Logic

The Audio Tracking Logic (ATL) module, which is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock, supports the following main features:

- Contains four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local Audio Word Select [AWS] and Baseband Word Select [BWS])
- Each instance selects between 8 mux choices for BWS and 8 mux choices for AWS
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing
- Selection between interface or functional clock to run error counting timers and to derive modulated clock outputs
- Clock and reset management: receives clock and reset signals from the device PSC module
- Hardware reset
- Local software reset

### 1.4.31 Camera Subsystem

Camera Subsystem unites three camera streaming interfaces – receiver and transmitter, allowing the device to stream video inputs from multiple cameras to the video processing accelerator (VPAC) or to internal memory and to output CSI-2 protocol image data to any device that supports MIPI CSI-2 protocol. Main modules are as follows:

- Camera Streaming Interface Receiver (CSI\_RX\_IF) with the following main features:
  - Compliant to MIPI CSI-2 v1.3+ and MIPI CSI-2 v2.0

- Supports up to 16 virtual channels per input
- Supports one 4MP camera or eight 2MP camera streams
- Supports data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Receiver (DPHY\_RX)
- Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
- Supports four independent (simultaneous) output streams:
  - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator
  - One (up to 4 channels) PPI 16-bit pixel retransmission interface to Camera Streaming Interface Transmitter (CSI\_TX\_IF)
  - One (up to 32 Channels) DMA interface through a 128-bit Packet Streaming Interface Link (PSI\_L) connection to NAVSS for transfers to memory:
- Functional and data path error interrupts
- ECC support
- MIPI D-PHY Receiver (DPHY\_RX) with the following main features:
  - Allows the device to input video streams from external sensor cameras and other CSI2 compliant sources
  - Compliant to MIPI D-PHY standard v1.2
  - Supports up to 4 data and 1 clock lanes
  - Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
  - Clock lane Control / Interface logic type: CIL-SCNN for HS and low power receiving
  - Data lane Control / Interface logic type: CIL-SFAN for HS and low power receiving
  - Data lanes can be independently operated in HS or ULP mode
  - Swapping of DP/DN signals within each clock/data pair
- Camera Streaming Interface Transmitter (CSI\_TX\_IF) with the following main features:
  - Compliant to MIPI CSI-2 v1.3+, MIPI CSI-2 v2.0, and MIPI D-PHY v1.2
  - Data rate up to 2.5 Gbps per lane (wire rate)
  - Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Transmitter (DPHY\_TX)
  - Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
  - Support of 16 virtual channels
  - Support of four configurable input streams

#### 1.4.32 Dual Clock Comparator

- Dual Clock Comparator (DCC) modules, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement

#### 1.4.33 Error Signaling Module (ESM)

Error Signaling Module (ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:

- Selectable low and high priority interrupt error pin prioritization of each error event
- Up to 1024 level or pulse error event inputs
- Error signal routed out of device through MCU\_ESM error signal
- Configurable time base for error signal
- Error forcing capability
- Internal redundant flops on safety critical fields

#### 1.4.34 Multi-Channel Audio Serial Port (McASP)

The McASP module supports the following features:

- Transmit control section consisting of:
  - Transmit state machine supporting IIS and DIT modes
  - Transmit formatter supporting IIS and DIT options
  - Transmit clock generation with auto-switch on bad clock detect
  - Transmit frame sync generation
  - Transmit TDM control
- Receive control section consisting of:
  - Receive state machine implementing supported protocols
  - Receive clock generation
  - Receive frame sync generation
  - Receive TDM control
  - Option to synchronize to transmit control section
- Multiple shift registers (2 to 16 specified at module generation):
  - Individual transmit / receive / off selection
  - Transmit in IIS or DIT mode
  - Flexible order in memory to ease DMA operation versus pinout
  - TDM mode function selection (Z, 0, 1)
- Single RX interrupt generation, with individual enables for:
  - Data Ready: all slots, last slot
  - Error: overrun, unexpected frame sync, bad clock
- Two DMA events (RX, TX)
- Slot counter exported with DMA request to enable per-slot DMA request (or left/right, at minimum)
- Automatic mute output pin option with programmable polarity on error detect

### 1.4.35 Camera Streaming Interface Receiver (CSI-RX)

The CSI\_RX module supports the following features:

- Fully Compliant to MIPI CSI v1.3 Specification
- Supports up to 16 virtual channels per input (partial support for MIPI CSI v2.0)
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to MIPI D-PHY
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported)
- Four Independent (Simultaneous) Output Streams:
  - Two VID32 streams to VISS inputs of VPAC Image Processing Accelerator (2x 16-bit Pixels Per Clock)
  - One (Up to 4 Channel) PPI 16-bit pixel Retransmission interface to CSI-TX (2x 16-bit Pixels Per Clock)
  - One (Up to 32 Channel) DMA interface through a 128 bit PSIL Connection to NavSS/DMSS for transfers to memory.
- TI Wrapper Interrupts:
  - PSIL fifo overflow
  - VP0 frame/line mismatch
  - VP1 frame/line mismatch
- CSI2-RX core functional (informational) interrupts:
  - Stream Abort Process Complete (x4)
  - Stream Stop Process Complete (x4)
  - Reception of Generic Short Packet
  - Reception of Short Packet
  - Reception of Long Packet
  - Deskew Entry
  - ECC Spares Error (protocol non-compliance)
  - D-PHY Sleep
  - D-PHY Wakeup
- For stream 0, stream monitor interrupts:
  - Line Count Error Interrupt

- Frame Mismatch Error Interrupt
- Frame Count Error Interrupt
- FCC Stop Interrupt
- FCC Start Interrupt
- Line/Byte Interrupt
- Timer / Timer Interrupt
- CSI Core / Datapath Error Interrupts:
  - Stream FIFO Overflow (x4)
  - Invalid Short Packet Received
  - Invalid Access to Configuration Register Space
  - Data ID Error in Packet Header
  - Header ECC Error (Correctable/Uncorrectable)
  - Payload CRC Error
  - Front (D-PHY to CSI-RX) FIFO Overflow

#### **1.4.36 Display Subsystem (DSS)**

The Display Subsystem IP module supports the following features:

- Two display outputs (for a single DSS7\_UL instance)2
  - Up to 24-bit per pixel parallel or embedded sync output
  - Up to 300MHz pixel clock
  - Support for RGB/YUV422 modes
  - Support for progressive/interlaced modes
- Two input display processing pipelines
  - One video pipeline supporting full RGB and 8/10-bit YUV data formats with 3/5-tap 16-phase scaler capable of 0.25x to 16x resizing.
  - One video\_lite pipeline supporting full RGB and 8/10-bit YUV data formats (no resizing support)
- Two Overlay Managers with multi layer alpha blending
- One DMA controller capable of supporting up to 2K input source width.
  - 48bit addressing (256 TB reach)
- On-the-fly X/Y-axis flip of the source (Flip/Mirror mode support)
- Safety check (freeze frame detection and data correctness check)

#### **1.4.37 Open LVDS Display Interface transmitter (OLDI-TX)**

The OLDI\_TX module integration (two instances) supports OLDI resolution up to:

- 1920x1440@60fps with a 200MHz pixel clock in single link mode (2x independent or duplicate displays)
- 3840x1080@60fps with a 300MHz pixel clock in dual link mode

The OLDI\_TX module features include:

- OLDI Mapping
  - 3 or 4 LVDS data channels
  - VESA or JEIDA bit mapping
- Multiple OLDI Link Modes
  - Single Link (Duplicate or non-duplicate mode)
  - Dual Link (odd or even data) – Link Off
- Clock Transmission
- ANSI/TIA/EIA644-A compliant VLVDs signaling

#### **1.4.38 MIPI DPHY Receiver**

The DPHY\_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane

- Clock Lane **C**ontrol / Interface **L**ogic type is **CIL-SCNN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **C**lock
  3. **N/A** forward, **N/A** reverse escape mode features
- Data Lane **C**ontrol / Interface **L**ogic type is **CIL-SFAN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **F**orward direction only for high speed mode
  3. **A**ll forward direction escape mode features are supported
  4. **N**o reverse direction escape mode features are supported
- Data lanes can be independently operated in HS or ULP mode
- Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI\_RX\_IF controller)

#### 1.4.39 MIPI DPHY Transmitter

The DPHY\_TX0 module supports the following main features:

- Compliance to MIPI D-PHY standard version 1.2.
- Supports up to 4 data lanes and 1 clock lane.
- Supports High Speed up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane.
- Supports Escape mode:
  - Remote triggers
  - LP-DT up to 10 Mbps
  - ULPS mode
- Clock Lane **C**ontrol / Interface **L**ogic type is **CIL-MCNN**: [HS-TX, LP-TX]
  1. **(M)** Controller
  2. **C**lock
  3. **N/A** forward, **N/A** reverse escape mode features.
- Data Lane **C**ontrol / Interface **L**ogic type is **CIL-MFAA**: [HS-TX, LP-TX, LP-RX, LP-CD]
  1. **(M)** Controller
  2. **F**orward direction only for High Speed mode
  3. **A**ll forward direction escape mode features are supported
  4. **A**ll reverse direction escape mode features are supported.
- Data Lanes can be independently operated in HS or ULP mode.
- Includes a CMN block with reference generators / resistor calibration and an integrated PLL.
- Fault detection:
  - Contention detection (for example, when RX and TX sides of same link drive opposite LP levels).
  - Sequence error detection (corruption on lanes).

#### 1.4.40 Graphics Processing Unit

The GPU module supports the following features:

- Base architecture, fully compliant with the following APIs:
  - OpenGL ES 3.2
  - OpenCL 1.2 EP
  - Vulkan 1.2
- Tile-based deferred rendering architecture for 3D graphics workloads, with concurrent processing of multiple tiles
- Support for DRM security
- Support for GPU virtualization
  - Up to 8 virtual GPUs
  - Separate IRQ for each OSID
- Multi-threaded Unified Shading Cluster (USC) engine incorporating pixel shader, vertex shader and GP-GPU (compute shader) functionality
- USC incorporates an ALU architecture with high SIMD efficiency
- Fully virtualized memory addressing (up to 64 GB address space), supporting unified memory architecture
- Fine-grained task switching, workload balancing and power management

- Advanced DMA driven operation for minimum host CPU interaction
- 256KB System Level Cache (SLC)
- Specialized Texture Cache Unit (TCU)
- Compressed Texture Decoding
- Lossless data compression (PVRGC) - The PowerVR's geometry compression, which is performed in the Geometry Processing phase of the 3D graphics workload.
- Dedicated RISC-V processor for firmware execution
- Separate power island for the firmware processor for low latency power domain transitions
- On-Chip Performance, Power and Statistics Registers.
- Resolution Support
  - Frame buffer max size = 8K × 8K
  - Texture max size = 8K × 8K
- Anti-aliasing
  - Maximum 4× multisampling
- Performance
  - Floating Point Operations (F32) - 64 operations per clock
  - Floating Point Operations (F16) - 128 operations per clock
  - Texture performance - 4 texels per clock (@32 BPP)
  - Pixel performance - 4 pixel(s) per clock (@32 BPP)
  - Geometry Performance - 0.25 triangles per clock
  - Max performance
    - ~50 GFLOPS, 4 GTex/s or 4 GPix/s @ 800MHz

#### 1.4.41 Video Accelerator (CODEC)

CODEC module supports the following features:

- HEVC (H.265) Encode Main profiles @ L5.1 High-tier
- H.264 Encode BaseLine/Main/High Profiles @ L.52
- YUV420/YUV422 format
- 8b bit-depth
- I and P frame encoding
- ¼ -pel precision Motion vector
- Search Range in HEVC (+/- 128H, +/-64V)
- Search Range in H.264(+/- 64J, +/-48V)
- 4K resolution at 60 fps
- 8 channel 1080p40 Encode
- Rotation in multiples of 90 degree & vertical and horizontal Mirroring
- 4K resolution at 60fps for decode for all
- 8-channel 1080p30 decode
- 2 VBUSM initiator interfaces for data traffic (Primary and Secondary)
- 48 bit address width
- 128 bit data width
- ChannelID based on Internal Data Requestor
- Data interface at wrap level is synchronous to SoC CBA clocks
- 1 VBUSP 32-bit target interface to access config registers
- Fuse Controllevel high interrupt
- All memories are non-repair memories

### 1.5 Device MCU Domain

This section describes the modules integrated in the device MCU domain.

#### Note

In TI documentation, the MCU Domain may be referred to as "MCU Island", "MCU Channel", or "MCU Subsystem".

The Microcontroller Unit Domain (MCU Domain) is a “chip-in-a-chip” concept and it operates using separate clock sources and resets. This allows the MCU Domain to function continuously regardless of the state of the rest of the device, including periods in which the rest of the device is held in reset or powered down. The MCU island integrates communication peripherals such as SPI, I2C, and UART which are expected to be used for safety critical communication, so if the main SoC goes down, the MCU island can communicate this information to the rest of the system.

### 1.5.1 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x ways
    - SECEDED ECC protected per 64 bits
  - Data Cache
    - 4x ways
    - SECEDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECEDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts
- Synchronous clock domain crossing on all core interfaces

---

#### Note

CORE0 has 64KB of TCM.

---

---

#### Note

These details describe a superset of the R5FSS memory configuration. For additional details on device memory availability, please refer to the device-specific Datasheet.

---

### 1.5.2 MCU General Purpose Input/Output Interface (MCU\_GPIO)

Integrated in MCU domain: One General Purpose Input/Output (MCU\_GPIO) module provides dedicated general-purpose pins that can be configured as either inputs or outputs. the MCU\_GPIO module includes these main features:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs

- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

### 1.5.3 MCU Inter-Integrated Circuit Interface (MCU\_I2C)

Integrated in MCU domain: One multi-controller Inter-Integrated Circuit (MCU\_I2C) interface with the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms
- Low power consumption

### 1.5.4 MCU Multi-channel Serial Peripheral Interface (MCU\_SPI)

Integrated in MCU domain: Two Multi-channel Serial Peripheral Interface (MCU\_SPI) modules where each have the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPI word lengths, ranging from 4 to 32 bits
- Up to four controller channels, or single channel in receiver mode
- Support of different controller multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

### 1.5.5 MCU Universal Asynchronous Receiver/Transmitter (MCU\_UART)

Integrated in MCU domain: One configurable Universal Asynchronous Receiver/Transmitter (MCU\_UART) interface with the following main features:

- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- 16C750 compatible interface
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

### 1.5.6 MCU Windowed Watchdog Timer/Real Time Interrupt

- Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWDT) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Windowed Watchdog Timer (WWDT) feature
  - Some RTI modules are pre-dedicated to specific processor cores

### 1.5.7 MCU TIMER

- Timer modules with support of the following main features:

- Free running 32-bit upward counter
- Generates a 1-ms tick with a 32.768-kHz functional clock
- Interrupts generated on overflow, compare and capture
- Supported modes of operation: compare and capture, auto-reload and start-stop
- Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting) for systems operation and benchmarking code
- Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer

### 1.5.8 MCU Dual Clock Comparator

- The Dual Clock Comparator (MCU\_DCC) module, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement

### 1.5.9 Memory Cyclic Redundancy Check

- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system. The MCRC module has the following main feature:
  - Four Channels of CRC Compression based Signature Generation
  - 8, 16, 32, or 64-bit Data Size
  - Maximum Length PSA based on 64-bit Polynomial
  - Programmable 20 bit pattern counter per channel
  - Three Operating Modes: Auto, Semi-CPU, Full CPU
  - MCRC or CPU can perform signature verification for each Channel
  - Timeout Interrupt if CRC is not performed within the time limit

### 1.5.10 Controller Area Network (MCAN)

Integrated in the domain: One Controller Area Network interfaces (MCAN) supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications and having the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

## 1.6 Device WKUP Domain

This section describes the modules integrated in the device WKUP domain.

### 1.6.1 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x ways
    - SECEDED ECC protected per 64 bits
  - Data Cache
    - 4x ways
    - SECEDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECEDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts
- Synchronous clock domain crossing on all core interfaces

---

#### Note

CORE0 has 64KB of TCM.

---

#### Note

These details describe a superset of the R5FSS memory configuration. For additional details on device memory availability, please refer to the device-specific Datasheet.

---

### 1.6.2 Inter-Integrated Circuit Interface (I2C)

Multi-controller Inter-Integrated Circuit (I2C) interface module, with the following main features:

- 1x Instances with open-drain voltage buffers in compliance with the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- 8-bit-wide data access
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with fixed size of 32 bytes.

### 1.6.3 Universal Asynchronous Receiver/Transmitter (UART)

Seven Instances of the configurable Universal Asynchronous Receiver/Transmitter (UART) interface module have the following main features:

- 16C750-compatible interface
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths

- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud-rate from 300 bits/s up to 3.6864 Mbits/s with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

#### Note

Only one UART instance has support for support full modem control functions. All other UART instances will support only the TX, RX, RTS, and CTS signals.

### 1.6.4 MCU Error Signaling Module

- Error Signaling Module (MCU\_ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
  - Up to 1024 level or pulse error event inputs
  - Selectable low and high priority interrupt error pin prioritization of each error event
  - Single Error Pin output to signal severe device failure to outside world
  - Configurable time base for error signal
  - Triple Redundant Pulse Inputs
  - Two Priority Levels
  - Error Forcing capability
  - Internal redundant flops on safety critical fields

### 1.6.5 Global Time Counter

- Global Time Counter (GTC) module that can be used for time synchronization and debug trace time stamping with the following main features:
  - 64-bit up counter
  - No rollover during the lifetime of the device
  - Compatible with Armv8 system counter requirements
  - Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
  - Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

### 1.6.6 Windowed Watchdog Timer/Real Time Interrupt

- Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Windowed Watchdog Timer (WWDT) feature
  - Some RTI modules are pre-dedicated to specific processor cores

### 1.6.7 WKUP\_TIMER

- Dual mode timer module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal

- On-the-fly read/write register (while counting) for systems operation and benchmarking code
- Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer
- On-the-fly read/write register (while counting) for systems operation and benchmarking code

## 1.7 Device Identification

The manufacturer identity, the boundary scan part number, and the silicon revision of the device can be read in the WKUP\_CTRL\_MMR\_CFG0\_JTAGID register. See [Table 1-1](#) and [Table 1-2](#) tables for more information.

**Table 1-1. Device JTAG ID**

WKUP_CTRL_MMR_CFG0_JTAGID Register Field	Value	Comment
[31-28] VARIANT	See <a href="#">Table 1-2</a>	Silicon Revision (SR) identifier.
[27-12] PARTNO	See <a href="#">Table 1-2</a>	Part number for boundary scan.
[11-1] MFG	0x17	Manufacturer identity (TI).
[0] LSB	0x1	Always reads 1.

**Table 1-2. Device JTAG ID Values**

Silicon Type	VARIANT	PARTNO	WKUP_CTRL_MMR_CFG0_JTAGID Register Value
TDA4VEN SR1.0 TDA4AEN SR1.0 AM67 SR1.0	0x0	0xBBA0	0x0BBA002F

The SoC level memory map is constructed using a 36b physical address and follows the guideline to put peripherals at 64KB aligned boundary. No virtual address is supported on the SoC level. However, A53 core can support virtual address internally. If software utilizes the address more than 36b, only the lower 36b is used for SoC level address decoding and the upper address bits will be ignored by the SoC. Not all the 36b memory regions are implemented. Any transactions hitting the unimplemented address range will be terminated and routed to null end point to avoid system hang. An interrupt will be asserted and the above transaction will be logged. All the SoC level peripherals and processors use the common SoC memory except the 32b only processors, such as the R5 core. For those processors and peripherals which natively only supports 32b physical address, the Region based Address Translation (RAT) module is used to remap the 32b address into the common 36b SoC address map.

## 3.1 System Interconnect Overview

### 3.1.1 Terminology

- **CBASS:** this is a crossbar module to provide physical connection among the initiators and targets
- **VBUSP interface:** a single-issue interface
- **VBUSM interface:** a multi-issue interface
- **Channel ID:** channel ID for interface indicates a logical flow. All the transactions with the same channel ID coming from the same initiator interface are consider orthogonal and independent flow.
- **OrderID:** a 4 bits value associated with each transaction. All the transactions from the same initiator to the same target end point with the same orderID needs to be executed in order. OrderID is also to be used to select real-time and non-real time path for the transaction. OrderID 8-15 reserved for real-time path.
- **Asel:** Address Selection. Asel can be either used for select a unique memory map or be used to indicate the IO coherent transactions.
- **PrivID:** indicates the security access group. PrivID is assigned by the ISC block.
- **ISC:** stands for Initiator Security Control.
- **Region based firewall:** this is firewall block based on address region.
- **Channelized firewall:** firewall block with finer granularity down to register level with fixed region size.
- **QoS:** Quality of Service block is a feature which can be enabled for each CBA initiator port. Each initiator can choose to enable the QoS feature in the CBA configuration file. If an initiator port supports channel ID, the QoS block provides priority and order ID for each channel, otherwise all the transactions from that initiator port share the same priority and order ID value.

#### CAUTION

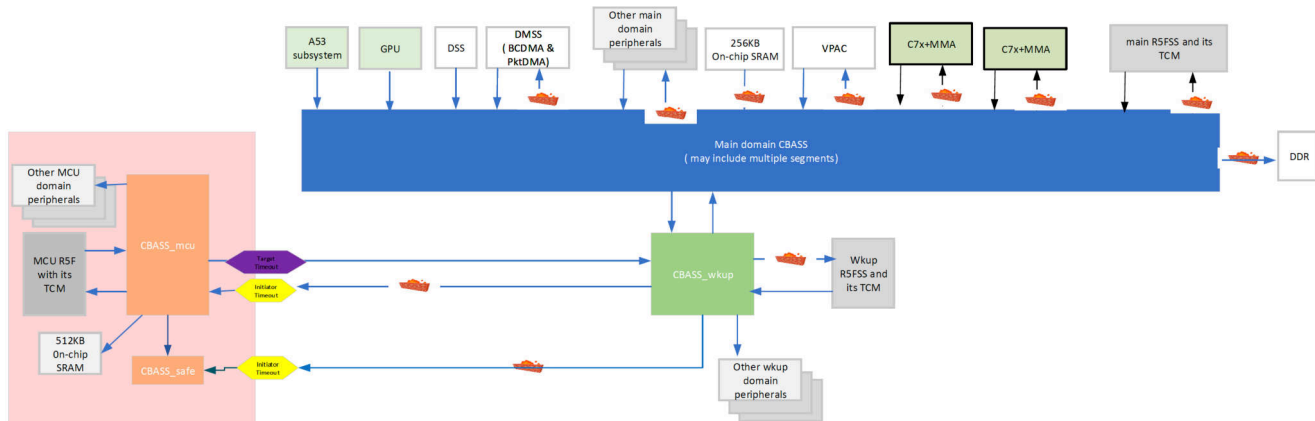

Since OrderID is used for ordering purpose in CBASS, changing the order ID when the system is running can cause system deadlock. Therefore, QoS configuration shall be part of the initialization steps, if the application wants to change the QoS setting from the default value.

## 3.2 Domain Partition

SoC is partitioned into several domains which are connected by interconnect modules.

- **MAIN Domain:** there are multiple interconnect components providing the connectivity among initiators and target interfaces for the processors and peripherals in the MAIN domain. The main application processors, such as A53SS, are located in the MAIN domain.
- **WKUP domain:** R5FSS is located in the WKUP domain. The WKUP domain is active during deepsleep mode.
- **MCU domain:** A microcontroller is located in the MCU domain. The MCU domain can be isolated from the rest of SoC during safety use case.

All modules connected to WKUP\_safe interconnect can belong to both MCU domain and WKUP domain depending on the use case. The deep sleep low power mode is controlled by the WKUP Domain. However, when the MCU domain is configured for a safety use case, all of the modules connected to WKUP\_safe interconnect will be part of the MCU domain.

**Figure 3-1. System Interconnect Overview**

### 3.3 Initiator/Target Connectivity

All processors and the DMA can communicate with all SoC memory mapped peripherals.

### 3.4 Interrupt Condition for Interconnect

Each CBASS crossbar IP may generate up to two interrupts:

- `default_err_intr`: the intent of this interrupt is for debug purposes. Any illegal transactions will trigger this interrupt and the illegal transaction information is logged by CBASS IP.
- `default_exp`: this interrupt is asserted whenever there is a firewall violation. Only the CBASS IP contains firewall module that can generate this interrupt.

The illegal transactions triggering `default_err_intr` can be caused by multiple reasons:

- The transaction is sent to a memory region not implemented in CBASS
- The target interface or target peripheral is in disabled state

When CBASS detects an illegal transaction, it terminates the transaction gracefully to avoid a system hang. In addition, the CBASS sends return status back to the initiator with error status. If this illegal transaction is a read transaction, the read data is returned with all zeros. If this illegal transaction is a write transaction, this write transaction is terminated and returns a write error back to initiator. The interrupt and illegal transaction logging can be found in the CBASS's `err_regs` region.

For any transaction blocked by the firewall, the transaction is terminated gracefully and the initiator will receive error status for the blocked transaction. If this blocked transaction is read, the read data is returned with all zeros. If this blocked transaction is a write transaction, this write transaction is terminated and returns a write error back to the initiator. The `default_exp` interrupt and the blocked transaction information can be found in the `glb_regs` region.

**Table 3-1. CBASS Interrupt**

CBASS Name	default_err_intr supported	default_exp Interrupt supported
CBASS0	Yes	Yes
MCU_CBASS0	Yes	No
CBASS_INFRA1	Yes	Yes
CBASS_FW0	Yes	No
CBASS_DBG0	Yes	No

### 3.4.1 Register MMR for default\_err\_intr

Each CBASS supports default\_err\_intr containing an err\_regs region, which includes the following registers:

Address Offset	Register Mnemonic	Register Name
0x0	PID	Revision Register
0x4	DESTINATION_ID	Destination ID Register
0x24	EXCEPTION_LOGGING_HEADER0	Exception Logging Header 0 Register
0x28	EXCEPTION_LOGGING_HEADER1	Exception Logging Header 1 Register
0x2c	EXCEPTION_LOGGING_DATA0	Exception Logging Data 0 Register
0x30	EXCEPTION_LOGGING_DATA1	Exception Logging Data 1 Register
0x34	EXCEPTION_LOGGING_DATA2	Exception Logging Data 2 Register
0x38	EXCEPTION_LOGGING_DATA3	Exception Logging Data 3 Register
0x50	ERR_INTR_RAW_STAT	Global Interrupt Raw Status Register
0x54	ERR_INTR_ENABLED_STAT	Global Interrupt Enabled Status Register
0x58	ERR_INTR_ENABLE_SET	Interrupt Enable Set Register
0x5c	ERR_INTR_ENABLE_CLR	Interrupt Enable Clear Register
0x60	ERR_EOI	EOI Register

PID (Revision Register) is located at offset 0x0. The following shows the definition of each field of this register.

The Revision Register contains the major and minor revisions for the module.

Bit	Name	Type	Reset	Description
31:30	scheme	r	0x1	PID register scheme
29:28	bu	r	0x2	Business Unit: 10 = Processors
27:16	func	r	0x600	Module ID
15:11	rtl	r	0x6	RTL revision. Will vary depending on release.
10:8	major	r	0x1	Major revision
7:6	custom	r	0x0	Custom
5:0	minor	r	0x2	Minor revision

DESTINATION\_ID (Destination ID Register) has offset 0x4.

The Destination ID Register defines the destination ID value for error messages.

Bit	Name	Type	Reset	Description
31:8	reserved	r	0x0	Reserved
7:0	dest_id	rw	0x0	The destination ID.

EXCEPTION\_LOGGING\_HEADER0 (Exception Logging Header 0 Register), (0x24)

The Exception Logging Header 0 Register contains the first word of the header.

Bit	Name	Type	Reset	Description
31:24	type_f	r	0x0	Type. 7 = CBASS.
23:8	src_id	r	0x0	Source ID. Always 0.
7:0	dest_id	r	0x0	Destination ID.

EXCEPTION\_LOGGING\_HEADER1 (Exception Logging Header 1 Register) has offset 0x28.

The Exception Logging Header 1 Register contains the second word of the header.

Bit	Name	Type	Reset	Description
31:24	group	r	0x0	Group. Always 0.
23:16	code	r	0x0	Code. 0 = CBASS decode error.
15:0	reserved	r	0x0	Reserved

EXCEPTION\_LOGGING\_DATA0 (Exception Logging Data 0 Register) has offset 0x2c.

The Exception Logging Data 0 Register contains the first word of the data.

Bit	Name	Type	Reset	Description
31:0	addr_l	r	0x0	Address lower 32 bits.

EXCEPTION\_LOGGING\_DATA1 (Exception Logging Data 1 Register), (0x30)

The Exception Logging Data 1 Register contains the second word of the data.

Bit	Name	Type	Reset	Description
31:16	reserved	r	0x0	Reserved
15:0	addr_h	r	0x0	Address upper 16 bits.

EXCEPTION\_LOGGING\_DATA2 (Exception Logging Data 2 Register) has offset 0x34.

The Exception Logging Data 2 Register contains the third word of the data.

Bit	Name	Type	Reset	Description
31:28	reserved	r	0x0	Reserved
27:16	routeid	r	0x0	Route ID.
15:14	reserved	r	0x0	Reserved
13	write	r	0x0	Write.
12	read	r	0x0	Read.
11	debug	r	0x0	Debug.
10	cacheable	r	0x0	Cacheable.
9	priv	r	0x0	Priv.
8	secure	r	0x0	Secure.
7:0	priv_id	r	0x0	Priv ID.

EXCEPTION\_LOGGING\_DATA3 (Exception Logging Data 3 Register) has offset 0x38.

The Exception Logging Data 3 Register contains the fourth word of the data.

Bit	Name	Type	Reset	Description
31:10	reserved	r	0x0	Reserved
9:0	bytecnt	r	0x0	Byte count.

### ERR\_INTR\_RAW\_STAT (Global Interrupt Raw Status Register), (0x50)

The interrupt raw status register indicates if there is null interrupt regardless of interrupt enable

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	intr	rw1ts	0x0	Level Interrupt status

### ERR\_INTR\_ENABLED\_STAT (Global Interrupt Enabled Status Register), (0x54)

The interrupt status register is gated by the interrupt enable

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	enabled_intr	rw1tc	0x0	Level Enabled Interrupt status

### ERR\_INTR\_ENABLE\_SET (Interrupt Enable Set Register), (0x58)

Only when this register is set, null access will cause interrupt to be generated.

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	intr_enable_set	rw1ts	0x0	Interrupt Enable Set Register

### ERR\_INTR\_ENABLE\_CLR (Interrupt Enable Clear Register), (0x5c)

Setting this register disables the null interrupt generation

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	intr_enable_clr	rw1tc	0x0	Interrupt Enable Clear Register

### ERR\_EOI (EOI Register), (0x60)

Writing to EOI Register indicates that current interrupt has been serviced which then allows next interrupt to be generated

Bit	Name	Type	Reset	Description
31:16	reserved	r	0x0	Reserved
15:0	eoi_wr	rw	0x0	End Of Interrupt Register

### 3.4.2 Register MMR for default\_exp

All of the registers for default\_exp\_intr are located in the glb\_regs region of the CBASS which supports this feature. For each glb\_reg region, the following registers are supported.

**Table 3-2. glb\_regs for default\_exp\_intr**

Address Offset	Register Mnemonic	Register Name
0x0	PID	Revision Register
0x4	DESTINATION_ID	Destination ID Register
0x20	EXCEPTION_LOGGING_CONTROL	Exception Logging Control Register
0x24	EXCEPTION_LOGGING_HEADER0	Exception Logging Header 0 Register
0x28	EXCEPTION_LOGGING_HEADER1	Exception Logging Header 1 Register
0x2c	EXCEPTION_LOGGING_DATA0	Exception Logging Data 0 Register
0x30	EXCEPTION_LOGGING_DATA1	Exception Logging Data 1 Register

**Table 3-2. glb\_regs for default\_exp\_intr (continued)**

Address Offset	Register Mnemonic	Register Name
0x34	EXCEPTION_LOGGING_DATA2	Exception Logging Data 2 Register
0x38	EXCEPTION_LOGGING_DATA3	Exception Logging Data 3 Register
0x40	EXCEPTION_PEND_SET	Exception Logging Pending Set Register
0x44	EXCEPTION_PEND_CLEAR	Exception Logging Pending Clear Register

The Revision Register contains the major and minor revisions for the module.

Bit	Name	Type	Reset	Description
31:30	scheme	r	0x1	PID register scheme
29:28	bu	r	0x2	Business Unit: 10 = Processors
27:16	func	r	0x600	Module ID
15:11	rtl	r	0x6	RTL revision. Will vary depending on release.
10:8	major	r	0x1	Major revision
7:6	custom	r	0x0	Custom
5:0	minor	r	0x2	Minor revision

The Destination ID Register defines the destination ID value for error messages.

Bit	Name	Type	Reset	Description
31:8	reserved	r	0x0	Reserved
7:0	dest_id	rw	0x0	The destination ID.

The Exception Logging Control Register controls the exception logging.

Bit	Name	Type	Reset	Description
31:2	reserved	r	0x0	Reserved
1	disable_pend	rw	0x0	Disables logging pending when set.
0	disable_f	rw	0x0	Disables logging when set.

The Exception Logging Header 0 Register contains the first word of the header.

Bit	Name	Type	Reset	Description
31:24	type_f	r	0x0	Type.
23:8	src_id	r	0x0	Source ID.
7:0	dest_id	r	0x0	Destination ID.

The Exception Logging Header 1 Register contains the second word of the header.

Bit	Name	Type	Reset	Description
31:24	group	r	0x0	Group.
23:16	code	r	0x0	Code.
15:0	reserved	r	0x0	Reserved

The Exception Logging Data 0 Register contains the first word of the data.

Bit	Name	Type	Reset	Description
31:0	addr_l	r	0x0	Address lower 32 bits.

The Exception Logging Data 1 Register contains the second word of the data.

Bit	Name	Type	Reset	Description
31:16	reserved	r	0x0	Reserved
15:0	addr_h	r	0x0	Address upper 16 bits.

The Exception Logging Data 2 Register contains the third word of the data.

Bit	Name	Type	Reset	Description
31:28	reserved	r	0x0	Reserved
27:16	routeid	r	0x0	Route ID.

9:0	bytecnt	r	0x0	Byte count.

The Exception Logging Pending Set Register allows to set the pend signal.

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	pend_set	rw1ts	0x0	Write a 1 to set the exception pend signal.

The Exception Logging Pending Clear Register allows to clear the pend signal.

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	pend_clr	rw1tc	0x0	Write a 1 to clear the exception pend signal.

## 3.5 Coherency Features

### 3.5.1 IO Coherency Support

There are 4 bits for ASEL sideband signals. These enable a single SoC to support up to 16 different memory maps. ASEL can be used for two different purposes: it can be used as an indicator of a different memory map (ASEL value 1-12) or indicate transactions requires IO coherency (ASEL value 13-14). ASEL value can be configured either through DMA configuration if the transaction is initiated by DMSS or UTC or DRU or configured through QoS MMR for the initiator who generates the transactions. Refer to [QoS Programming Guide](#).

#### ASEL value of 0

- Default for the SoC Memory Map

- Will use the transaction address for memory map decoding

### Non-zero ASEL values

- Assigned to a target end point, which can be used to bypass the normal address decoding
- Can be assigned to the transactions through either DMA configuration for both BCDMA and pktDMA transaction or through the QoS block inserted for each initiator interface
- ASEL value 1: Reserved for PCIe if supported by the device. Otherwise, transactions will be routed to the null end point for graceful termination.
- ASEL values 2-13: Transactions will be routed to the null end point for graceful termination.
- ASEL values 14-15: Dedicated routing to A53SS ACP Interface for transactions that require IO Coherency.
  - Write transactions with ASEL=14 cause A53SS L2 cache allocation: for cache warming feature
  - Write transactions with ASEL=15 do not cause A53SS L2 cache allocation
  - Read transactions with ASEL=14 and 15 do not cause L2 cache allocation
  - All the transactions to ACP port can be protected by firewall if firewall is inserted by the SoC level interconnect

The A53SS checks security on the transactions from the ACP port. However, it does not include supervisor or user mode checks. If different permissions are needed for the supervisor or user mode transactions, different access permissions can be granted using the region-based firewall.

The transactions initiated by the microcontroller do not support IO coherency.

## 3.6 Performance Tuning

### 3.6.1 Latency Reduction

The auto clock gating feature of WKUP domain peripherals is enabled by default.

The disabling of auto clock gating may result in improved performance.

The auto clock gating control can be modified during device initialization time through registers CLKGATE\_CTRL0 and CLKGATE\_CTRL1 in the WKUP\_CTRL\_MMR domain.

### 3.6.2 Using Quality of Service (QoS) MMR

The majority of the initiator has a dedicated QoS block to provide the configurability of the transaction characteristic, such as OrderID, priority/epriority, asel and etc. The user can utilize the OrderID and priority/epriority fields to fine tune the performance.

Each transaction in the system carries 3 bits priority information. The priority information is used for interconnect for arbitration decision, which implements typical priority based round robin. Priority value 0x0 is the highest priority, while 0x7 is the lowest priority. By default, QoS has priority value set to 0x7( lowest priority). The priority and epriority can be changed through the QoS block for each initiator.

Some of the modules such as DSS is able to adjust the priority of the transaction based on the system congestion condition. But majority of the transactions have static priority level set by the QoS block. But the priority setting through QoS block can be tuned to fit certain use case scenarios.

#### CAUTION

Priority, orderID and asel value from the QoS block shall only be modified as part of the initialization steps, when the SoC is idle. Changing the QoS block configuration during the run time is prohibited, and may cause system error or other undefined behavior.

#### 3.6.2.1 QoS MMR Programming Guide

The QoS MMR is integrated as part of data plane interconnect to provide programmability of priority, orderID and QoS sideband signals for each initiator port in the data plane. Currently the QoS sideband signal is not used for any routing or schedule purpose. For most of the initiator ports, it has only one setting of the orderID and QoS field. For the initiator port supports with multiple channels, the transactions in each channel can be programmed

to have different sets of priority, orderID and QoS. The orderID is a four-bit field value. All the transactions coming from the same initiator ports with the same orderID expect to receive the read data in order.

In the previous generation of the interconnect, how the traffic is split among parallel paths to the same end points was hard coded. The traffic from a certain initiator port was hard coded to choose one of the parallel paths. Due to the nature of hard coded, the system could not load balance based on the use case. The current generation of interconnect removes this limitation by splitting traffic using the OrderID value. Since the orderID value for the traffic from each initiator port is programmable, the user can load balance based on the use case scenario.

Each target port in each SCR has its own arbiter. The SoC interconnect arbitration is based on priority. For the ports with equal priority, the arbiter uses round robin to break the tie.

DDR EMIF (External Memory Interface) also uses orderID to maintain transaction ordering. All transactions with the same orderID sent to the EMIF will be executed in order. In order to maximize the EMIF performance, the user shall carefully use the full range of 16 orderID values. Therefore, the EMIF can utilize its re-ordering mechanism to improve the EMIF utilization.

Inside the EMIF controller, registers map CBA priority to AXI priority. The EMIF controller schedules transactions using a strict priority scheme based on AXI priority. In order to maximize the DDR utilization to reduce the memory page open/close and read and write turn around penalty, it is suggested to map to a single AXI priority.

### 3.6.2.2 QoS Summary Tables

#### 3.6.2.2.1 CODEC0\_QoS\_Map

**Table 3-3. CODEC0 QoS Map**

Initiator	MMR Base Address	Channel Count	QOS Capable	Virtual Id Capable	Order ID Capable	Transaction Priority Capable	Address Type Capable	Asel Capable

## 3.7 Interconnect Debugging Feature

Interconnect routes the transaction to null end point for graceful termination under the following situation:

- There is no physical connection between initiator and target end points
- Or target interface is in disabled state
- Or the transaction is sent to an unpopulated address

The null end point returns the error status back to the initiator to prevent the interconnect hang. At the same time, the interconnect module logs this transaction information in err\_reg region and issues an error interrupt (default\_err\_intr). This default\_err\_intr is sent to all of the application processors for debug purposes.

If the transaction is sent to a valid target interface, however the firewall in front of the target interface can prohibit the transaction, the transaction will be logged in the glb\_regs region and the interconnect will assert a default\_exp interrupt.

## 3.8 Quality of Service (QoS) Block

CBASS arbitrates the transaction based on priority from high to low. If the transactions going to the same end point have the same priority, then the CBASS uses round robin method for these transactions.

In the CBASS with parallel paths, orderID is used to determine how the transactions are forwarded to those parallel paths. The parallel paths are defined as two target interfaces with the exact same memory map assignment.

By default, all the target interfaces have a certain address assigned and CBASS routes the transactions based on this address. However, some of the special target interfaces can be routed through a different mechanism using the ASEL signal, such as MPU A53SS's ACP interface and PCIe target interfaces.

By default, the majority of the transactions default to the lowest priority level, ASEL value to zero and orderID to zero. The transactions from BCDMA and pktDMA have those attributes as part of the DMA configuration. ASEL value is part of the address information passed to the DMA engine. It is normally specified in descriptors such as host packet descriptor and host buffer descriptor for pktDMA, and Transfer Request (TR) packet descriptor for BCDMA. The priority and orderID information can be configured through each DMA channel's priority control register.

For the rest of the initiators, the CBASS IP provides QoS block to allow the user to program the transaction's attributes such as priority level, ASEL coding and orderID.

The QoS block programming is through CBASS's qos\_regs region. Each initiator, except the BCDMA, pktDMA, and debugss, has an MMR to allow the user to set the priority, ASEL, and orderID value. There is another exception on priority setting. The display IP implements dynamic priority schedule based on the FIFO threshold. The QoS block inside CBASS does not have the ability to overwrite the priority value coming from the display IP.

Each QoS block has one 4B MAP register per channel that allows the user to program ASEL, orderID, and priority. The first MAP register is at offset 0x100 and the MAP register for channel X is located at offset 0x100+400x. See *QoS Block MMR*.

For any write to address range 0x4500\_0000 to 0x45FF\_FFFF, it is recommended to read back the value after the write to make sure the write landed. The registers in this regions are mainly for firewall configuration, ISC/DMA credential configuration, QoS MMR configuration.

On QoS MMR configuration, in order to configure certain transaction to be the highest priority, the priority field needs to be set to zero for that transaction. In order to make sure that priority field is indeed to set to zero, the following sequence should be followed:

1. Read the priority field, if it is non-zero value, follow a write to overwrite priority field to be 0x0.
2. If read back priority field is zero, write to QoS MMR register to set priority field to be 0x7. Read back the same priority field. If the read back value is 0x7, write to QoS MMR register to set priority field to be 0x0. If the read back value is 0x0, it means this register is not implemented and priority setting is not working.

## 4.1 Memory Controllers

### 4.1.1 DDR32 Subsystem (DDR32SS)

This section contains the integration details for the 32-bit DDR module on this device. For Further information, see the DDR32 Subsystem (DDR32SS) section of the Memory Controllers chapter

#### 4.1.1.1 DDR32SS Not Supported Features

The following features are not supported on this family of devices:

- DDR3, DDR3L, DDR3U, and LPDDR4x Devices
- Two independent 16-bit channels for LPDDR4
- DIMMS
- Data bus obfuscation / data encryption
- Fail-safe reset I/O to maintain reset state during SoC power OFF
- Automatic periodic scrubbing of SDRAM for ECC
- Coherence of transactions arriving across the RT and NRT bus interfaces
- Maximum of 17 row bits are supported for LPDDR4. LPDDR4 with 18 row bits are not supported
- LPDDR4 devices with byte mode die configurations
- The ECC engine of the DDR controller
- 1T command timing (only 2T timing is supported)

### 4.3.2 Video Encoder/Decoder (CODEC)

This section contains the integration details for the CODEC module on this device. For Further information, see the Video Encoder/Decoder (CODEC) section of the Processors and Accelerators chapter

#### 4.3.2.1 CODEC Unsupported Features

The following features are not supported on this family of devices:

- YUV422 format output in Decode
- YUV422 10-bit Support
- Slice Level Processing/Synchronization

#### 4.3.2.2 Module Allocations

**Table 4-49. WAVE521CL CODEC Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
CODEC0			✓

#### 4.3.2.3 Resets, Interrupts, and Clocks

#### 4.3.3.3 Arm Cortex R5F Subsystem (MCU\_R5FSS)

This section contains the integration details for the MCU\_R5FSS module on this device. For Further information, see the Arm Cortex R5F Subsystem (MCU\_R5FSS) section of the Processors and Accelerators chapter

##### 4.3.3.3.1 MCU\_R5FSS Unsupported Features

The following features are not supported on this family of devices:

- Non-Maskable Interrupts (NMI) - All interrupts are maskable

##### 4.3.3.3.2 Module Allocations

**Table 4-57. MCU\_R5FSS Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main

### 4.3.8 Graphics Processing Unit (GPU)

This section contains the integration details for the GPU module on this device. For Further information, see the Graphics Processing Unit (GPU) section of the Processors and Accelerators chapter.

#### 4.3.8.1 GPU Unsupported Features

The following features are not supported on this family of devices:

- Multi-GPU Support

#### 4.3.8.2 Module Allocations

**Table 4-100. GPU Modules Allocation Within Device Domains**

Instance	Domain

## 4.4 Interprocessor Communication

### 4.4.1 Mailbox

This section contains the integration details for the Mailbox module on this device. For Further information, see the Deep Mailbox section of the Interprocessor Communications chapter

#### 4.4.1.1 Mailbox Unsupported Features

The following features are not supported on this family of devices:

- 'User' protection of mailbox in hardware - Must be implemented by software if required

#### 4.4.1.2 Module Allocations

**Table 4-104. Mailbox Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
MAILBOX0_MAILBOX_CLUSTER_0			✓
MAILBOX0_MAILBOX_CLUSTER_1			✓
MAILBOX0_MAILBOX_CLUSTER_2			✓
MAILBOX0_MAILBOX_CLUSTER_3			✓
MAILBOX0_MAILBOX_CLUSTER_4			✓
MAILBOX0_MAILBOX_CLUSTER_5			✓
MAILBOX0_MAILBOX_CLUSTER_6			✓
MAILBOX0_MAILBOX_CLUSTER_7			✓

#### 4.4.1.3 Resets, Interrupts, and Clocks

**Table 4-105. Mailbox Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
MAILBOX0_MAILBOX_CLUSTER_0	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_1	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_2	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_3	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_4	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_5	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_6	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON
MAILBOX0_MAILBOX_CLUSTER_7	PSC0	GP_CORE	LPSC_MAIN_SMS_COMMON	27	ON	YES	LPSC_MAIN_ALWAYSON

**Table 4-106. Mailbox Resets**

Module Instance	Source	Description
MAILBOX0_MAILBOX_CLUSTER_0	PSC0	MAILBOX0_MAILBOX_CLUSTER_0 reset
MAILBOX0_MAILBOX_CLUSTER_1	PSC0	MAILBOX0_MAILBOX_CLUSTER_1 reset
MAILBOX0_MAILBOX_CLUSTER_2	PSC0	MAILBOX0_MAILBOX_CLUSTER_2 reset
MAILBOX0_MAILBOX_CLUSTER_3	PSC0	MAILBOX0_MAILBOX_CLUSTER_3 reset
MAILBOX0_MAILBOX_CLUSTER_4	PSC0	MAILBOX0_MAILBOX_CLUSTER_4 reset
MAILBOX0_MAILBOX_CLUSTER_5	PSC0	MAILBOX0_MAILBOX_CLUSTER_5 reset
MAILBOX0_MAILBOX_CLUSTER_6	PSC0	MAILBOX0_MAILBOX_CLUSTER_6 reset
MAILBOX0_MAILBOX_CLUSTER_7	PSC0	MAILBOX0_MAILBOX_CLUSTER_7 reset

**Table 4-107. Mailbox Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type

## 4.4.2 Spinlock

This section contains the integration details for the Spinlock module on this device. For Further information, see the Spinlock section of the Peripherals chapter

### 4.4.2.1 SPINLOCK Unsupported Features

The following features are not supported on this family of devices:

- ARM Architectural Spinlock Instructions (LDREX,STREX)
- Any use model other than binary mutex (ex. counting semaphore, lockless programming) - Spinlock MMR is a single binary 0,1 implemented by a state machine
- 64 bit accesses - Spinlock MMRs are aligned on 32-bit boundaries meaning a 64 bit access affects the state of 2 spinlocks

### 4.4.2.2 Module Allocations

**Table 4-109. Spinlock Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
SPINLOCK0			✓

### 4.4.2.3 Resets, Interrupts, and Clocks

**Table 4-110. Spinlock Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
SPINLOCK0	PSC0	GP_CORE	LPSC_MAIN_S MS_COMMON	27	ON	YES	LPSC_MAIN_A LWAYSON

**Table 4-111. Spinlock Resets**

Module Instance	Source	Description
SPINLOCK0	0	NONE

## 4.6.2 Generic Interrupt Controller Subsystem (GICSS)

This section contains the integration details for the GICSS modules on this device. For Further information, see the GICSS section of the Interrupts chapter

### 4.6.2.1 GICSS Unsupported Features

The following features are not supported on this family of devices:

- GICv2 backwards compatibility
- AWID-based LPI mapping

#### 4.6.2.2 Module Allocation

**Table 4-142. GICSS Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
GICSS0			✓

#### 4.6.2.3 Resets, Interrupts, and Clocks

**Table 4-143. GICSS Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
GICSS0	PSC0	GP_CORE	LPSC_MAIN_GIC	36	ON	YES	LPSC_MAIN_IP

**Table 4-144. GICSS Resets**

Module Instance	Source	Description
GICSS0	PSC0	GICSS0 reset

**Table 4-145. GICSS Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type

**Table 4-145. GICSS Hardware Requests (continued)**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
GICSS0	GICSS0_gic_pwr0_wake_req_uest_2	TIFS0_nvic_IN_223	TIFS0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_2	HSM0_nvic_IN_203	HSM0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_2	HSM0_nvic_IN_204	HSM0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_2	HSM0_nvic_IN_222	HSM0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_2	HSM0_nvic_IN_223	HSM0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	WKUP_R5FSS0_CORE0_intr_I N_154	WKUP_R5FSS0_CO RE0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	WKUP_R5FSS0_CORE0_intr_I N_155	WKUP_R5FSS0_CO RE0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	WKUP_R5FSS0_CORE0_intr_I N_156	WKUP_R5FSS0_CO RE0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	WKUP_R5FSS0_CORE0_intr_I N_157	WKUP_R5FSS0_CO RE0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	TIFS0_nvic_IN_203	TIFS0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	TIFS0_nvic_IN_204	TIFS0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	TIFS0_nvic_IN_222	TIFS0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	TIFS0_nvic_IN_223	TIFS0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	HSM0_nvic_IN_203	HSM0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_req_uest_3	HSM0_nvic_IN_204	HSM0	GICSS0 interrupt request	level

**Table 4-145. GICSS Hardware Requests (continued)**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
GICSS0	GICSS0_gic_pwr0_wake_request_3	HSM0_nvic_IN_222	HSM0	GICSS0 interrupt request	level
GICSS0	GICSS0_gic_pwr0_wake_request_3	HSM0_nvic_IN_223	HSM0	GICSS0 interrupt request	level

**Table 4-146. GICSS Clocks**

Module Instance	Module Clock Input	Source Clock Signal	Source Control Register	Description
GICSS0	VCLK_CLK	MAIN_SYSCLK0/2		

## 4.7 Data Movement Architecture

#### 4.7.1 Data Movement Subsystem (DMSS)

This section contains the integration details for the DMSS module on this device. For Further information, see the Data Movement Subsystem (DMSS) section of the Data Movement Architecture chapter

##### 4.7.1.1 DMSS Unsupported Features

The following features are not supported on this family of devices:

- Ring Accelerator QM and CREDENTIAL Modes

##### 4.7.1.2 Module Allocations

**Table 4-147. DMSS Module Allocations within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
DMSS	-	-	✓
DMSS_CSI	-	-	✓

##### 4.7.1.3 Global Event Map

The global event map for all DMSS events is shown in [Table 4-148](#).

**Table 4-148. Global Event Map**

Destination		Offset	PSIL Routed Slots	Actual Slots
DMSS Instance or External	Port			
DMSS	DMSS INTAGGR SEVI	0 (0k)	8192 (8k)	1536
DMSS	DMSS INTAGGR MEVI	8192 (8k)	2048 (2k)	128
DMSS	DMSS INTAGGR GEVI	10240 (10k)	2048 (2k)	256
External	DMSC IA SEVI	18432 (18k)	2048 (2k)	-
DMSS	DMSS INTAGGR LEVI	32768 (32k)	32 (0.03k)	32
External	PDMA_MAIN0 LEVI	41984 (41.000k)	128	-
External	PDMA_MAIN1 LEVI	42112 (41.125k)	128	-
DMSS	DMSS BCDMA Triggers	50176 (49k)	1024 (1k)	156
External	UTC0	62464	128	-
External	UTC1	62720	128	-
External	DRU0	62976	64	-
External	DRU1	63232	64	-

##### 4.7.1.4 PSI-L System Thread Map

**Table 4-149. DMSS PSILSS Thread Map**

Thread Number	NAV Instance	Endpoint
0x0000	DMSS	PSILCFG CFGSTRM
0x0020	DMSS	PKTDMA CFGSTRM
0x0021	DMSS	BCDMA CFGSTRM
0x1000-0x1FFF	DMSS	PKTDMA Threads
0x2000-0x2FFF	DMSS	BCDMA Threads
0x3000-0x42FF	DMSS	Reserved
0x4300-0x43FF	DMSS	PDMA_MAIN0
0x4400-0x44FF	DMSS	PDMA_MAIN1
0x4500-0x457F	DMSS	PDMA_MCASP
0x4580-0x45FF	DMSS	PDMA_MCASP1

**Table 4-149. DMSS PSILSS Thread Map (continued)**

Thread Number	NAV Instance	Endpoint
0x4600-0x46FF	DMSS	CPSW2
0x4700-0x74FF	DMSS	Reserved
0x7500-0x7506	DMSS	SAUL0

## 4.7.2 Block Copy DMA (BCDMA)

### 4.7.2.1 Block Copy DMA (BCDMA)

**Table 4-150. BCDMA Allocation within Device Domains**

	Domain		
	WKUP	MCU	Main
DMSS_BCDMA	-	-	✓ (DMSS)
DMSS_CSI_BCDMA	-	-	✓ (DMSS_CSI)

### 4.7.3 Peripheral DMA (PDMA)

This section contains the integration details for the PDMA module on this device. For Further information, see the Peripheral DMA (PDMA) section of the Data Movement Architecture chapter

#### 4.7.3.1 PDMA Unsupported Features

The following features are not supported on this family of devices:

- Dynamic Transfer Requests
- Cross-Channel Triggering

#### 4.7.3.2 Module Allocations

**Table 4-151. PDMA Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
PDMA0			✓
PDMA1			✓
PDMA2			✓
PDMA3			✓

#### 4.7.3.3 Resets, Interrupts, and Clocks

**Table 4-152. PDMA Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
PDMA3	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_DM2MAIN_INFRA_ISO
PDMA2	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_DM2MAIN_INFRA_ISO
PDMA1	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_DM2MAIN_INFRA_ISO
PDMA0	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_DM2MAIN_INFRA_ISO

**Table 4-153. PDMA Resets**

Module Instance	Source	Description
PDMA3	0	NONE
PDMA2	PSC0	PDMA2 reset
PDMA1	PSC0	PDMA1 reset
PDMA0	PSC0	PDMA0 reset

**Table 4-154. PDMA Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
0	NONE	NONE	NONE	NONE	NONE
PDMA1	PDMA1_ecc_ded_pend_0	ESM0_esm_lvi_event_IN_89	ESM0	PDMA1 interrupt request	level
PDMA1	PDMA1_ecc_sec_pend_0	ESM0_esm_lvi_event_IN_28	ESM0	PDMA1 interrupt request	level
PDMA0	PDMA0_ecc_ded_pend_0	ESM0_esm_lvi_event_IN_88	ESM0	PDMA0 interrupt request	level
PDMA0	PDMA0_ecc_sec_pend_0	ESM0_esm_lvi_event_IN_15	ESM0	PDMA0 interrupt request	level

**Table 4-155. PDMA Clocks**

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
PDMA3	VCLK	MAIN_SYSCLK0/2		
PDMA2	VCLK	MAIN_SYSCLK0/2		
PDMA1	VCLK	MAIN_SYSCLK0/4		
PDMA0	VCLK	MAIN_SYSCLK0/4		

#### 4.7.4 Packet DMA (PKTDMA)

##### 4.7.4.1 Packet DMA (PKTDMA)

**Table 4-156. PKTDMA Allocation Within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DMASS0_PKTDMA_0	-	-	✓ (DMSS)

##### 4.7.4.2 Resets, Interrupts, and Clocks

**Table 4-157. Packet DMA Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
DMASS0_PKTDMA_0	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_DM2MAIN_INFRA_IS0

**Table 4-158. Packet DMA Clocks**

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
DMASS0_PKTDMA_0	CLK	MAIN_SYSCLK0		

## 4.8 Audio

### 4.8.1 Audio Tracking Logic (ATL)

This section contains the integration details for the ATL module on this device. For further information, see the Audio Tracking Logic (ATL) section of the Peripherals chapter.

#### 4.8.1.1 ATL Module Allocations

**Table 4-159. ATL Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
ATL0			✓

#### 4.8.1.2 Resets, Interrupts, and Clocks

**Table 4-160. ATL Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
ATL0	PSC0	GP_CORE	LPSC_MAIN_GPCORE_RSVD 2	43	OFF	YES	LPSC_MAIN_IP

**Table 4-161. ATL Resets**

Module Instance	Source	Description
atl0	0	NONE

### Table 4-162. ATL Clocks

Table 1-102: ATL Clocks				
Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
atl0	ATL_CLK	MAIN_PLL2_HSDIV8_CLKOUT	ATL_CLKSEL[2:0]

## 4.8.2 Multichannel Audio Serial Port (MCASP)

This section contains the integration details for the McASP module on this device. For Further information, see the Multichannel Audio Serial Port (MCASP) section of the Peripherals chapter

### 4.8.2.1 MCASP Unsupported Features

The following features are not supported on this family of devices:

- Muting output (AMUTE)
- Muting input (AMUTEIN)
- Instances may not support all pin options. See device specific datasheet for details on which McASP instance support which pins

### 4.8.2.2 Module Allocations

**Table 4-163. MCASP Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
MCASP0			✓
MCASP1			✓
MCASP2			✓
MCASP3			✓
MCASP4			✓

### 4.8.2.3 Resets, Interrupts, and Clocks

**Table 4-164. MCASP Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
MCASP0	PSC0	GP_CORE	LPSC_MAIN_M CASP0	17	OFF	YES	LPSC_MAIN_IP
MCASP1	PSC0	GP_CORE	LPSC_MAIN_M CASP1	18	OFF	YES	LPSC_MAIN_IP
MCASP2	PSC0	GP_CORE	LPSC_MAIN_M CASP2	19	OFF	YES	LPSC_MAIN_IP
MCASP3	PSC0	GP_CORE	LPSC_MAIN_G PCORE_RSVD 3	50	OFF	YES	LPSC_MAIN_IP
MCASP4	PSC0	GP_CORE	LPSC_MAIN_G PCORE_RSVD 3	50	OFF	YES	LPSC_MAIN_IP

**Table 4-165. MCASP Resets**

Module Instance	Source	Description
MCASP0	PSC0	MCASP0 reset
MCASP1	PSC0	MCASP1 reset
MCASP2	PSC0	MCASP2 reset
MCASP3	0	NONE
MCASP4	0	NONE

**Table 4-166. MCASP Hardware Requests**

## 4.9 General Connectivity

### 4.9.1 General Purpose Input/Output (GPIO)

This section contains the integration details for the GPIO modules on this device. For Further information, see the General Purpose Interface section of the Peripherals chapter

#### 4.9.1.1 GPIO Unsupported Features

The following features are not supported on this family of devices:

- The following apply to MCU\_GPIO0:
  - MCU\_GPIO0\_[143:24] are not pinned out.
  - Interrupts [143:24] are not pinned out.
  - Bank Interrupts [8:2] are not pinned out.
- The following apply to GPIO0:
  - GPIO0\_[143:92] are not pinned out.
  - Interrupts [143:92] are not pinned out.
  - Bank Interrupts [8:6] are not pinned out.
- The following apply to GPIO1:
  - GPIO1\_[143:52] are not pinned out.
  - Interrupts [143:52] are not pinned out.
  - Bank Interrupts [8:4] are not pinned out.

#### 4.9.1.2 Module Allocation

**Table 4-168. GPIO Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
GPIO0			✓
GPIO1			✓
MCU_GPIO0		✓	

#### 4.9.1.3 Resets, Interrupts, and Clocks

**Table 4-169. GPIO Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
GPIO0	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
GPIO1	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
MCU_GPIO0	WKUP_PSC0	GP_CORE_CT L_MCU	LPSC_MCU_AL WAYSON	0	ON	NO	NONE

## 4.9.2 Inter-Integrated Circuit (I2C)

This section contains the integration details for the I2C module on this device. For Further information, see the Inter-Integrated Circuit (I2C) section of the Peripherals chapter

### 4.9.2.1 I2C Unsupported Features

The following features are not supported on this family of devices:

- Serial Camera Control Bus (SCCB) Protocol
- DMA Mode
- Full I<sup>2</sup>C electrical compliance for I2C modules using device pins with LVCMOS voltage buffers (Refer to chapter 4 of the device-specific Datasheet for details related to device *Terminal Configuration and Functions*)
- High-speed (3.4-Mbps) operation for I2C modules using device pins with LVCMOS voltage buffers (Refer to chapter 4 of the device-specific Datasheet for details related to device *Terminal Configuration and Functions*)
- Debug suspend mode
- Asynchronous wakeup (via IO Daisy Chain) not supported by Main domain instances.

### 4.9.2.2 Module Allocations

**Table 4-173. I2C Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
I2C0			✓
I2C1			✓
I2C2			✓
I2C3			✓
I2C4			✓
MCU_I2C0		✓	
WKUP_I2C0	✓		

### 4.9.2.3 Resets, Interrupts, and Clocks

**Table 4-174. I2C Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
I2C0	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
I2C1	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
I2C2	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
I2C3	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO

#### 4.9.4 Universal Asynchronous Receiver/Transmitter (UART)

This section contains the integration details for the UART module on this device. For Further information, see the Universal Asynchronous Receiver/Transmitter (UART) section of the Processors and Accelerators chapter

##### 4.9.4.1 UART Unsupported Features

The following features are not supported on this family of devices:

- 12Mbps not supported for MCU and WKUP domains.
- Full modem handshaking is not available on all instances. See device datasheet for instances supporting full modem handshaking.
- Synchronous mode - SCLK not pinned out
- ISO7816 Mode
- SCR DMA Mode 2
- Multi-drop Transmission
- 9-bit Mode

##### 4.9.4.2 Module Allocations

**Table 4-183. UART Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
UART0			✓
UART1			✓
UART2			✓
UART3			✓
UART4			✓
UART5			✓
UART6			✓
MCU_UART0		✓	
WKUP_UART0	✓		

##### 4.9.4.3 Resets, Interrupts, and Clocks

**Table 4-184. UART Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
UART0	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
UART1	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
UART2	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
UART3	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO

**Table 4-184. UART Integration Attributes (continued)**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
UART4	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
UART5	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
UART6	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
MCU_UART0	WKUP_PSC0	PD_MCUSS	LPSC_MCU_C OMMON	9	ON	YES	LPSC_DM2SAF E_ISO
WKUP_UART0	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE

**Table 4-185. UART Resets**

Module Instance	Source	Description
UART0	PSC0	UART0 reset
UART1	PSC0	UART1 reset
UART2	PSC0	UART2 reset
UART3	PSC0	UART3 reset
UART4	PSC0	UART4 reset
UART5	PSC0	UART5 reset
UART6	PSC0	UART6 reset
MCU_UART0	WKUP_PSC0	MCU_UART0 reset
WKUP_UART0	PSC0	WKUP_UART0 reset

**Table 4-186. UART Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
UART0	UART0_usart_dma_0	PDMA1_usart_main_0_rx_IN_0	PDMA1	UART0 interrupt request	level

## 4.10 High-speed Serial Interfaces

### 4.10.1 Peripheral Component Interconnect Express (PCIe) Subsystem

This section contains the integration details for the PCIe module on this device. For further information, see the Peripheral Component Interconnect Express (PCIe) section of the Peripherals chapter.

#### 4.10.1.1 Module Allocations

**Table 4-188. PCIe Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
PCIE0			✓

#### 4.10.1.2 Resets, Interrupts, and Clocks

**Table 4-189. PCIe Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
PCIE0	PSC0	PD_PCIE	LPSC_MAIN_PCIE0	75	OFF	YES	LPSC_MAIN_SERDES1

**Table 4-190. PCIe Resets**

Module Instance	Source	Description
PCIE0	PSC0	PCIE0 reset

**Table 4-191. PCIe Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
PCIE0	PCIE0_pcie_cpts_comp_0	EPWM0_epwm_syncin_IN_0	EPWM0	PCIE0 interrupt request	level
PCIE0	PCIE0_pcie_cpts_comp_0	DMASS0_INTAGGR_0_intaggr_level_pend_IN_1	DMASS0_INTAGGR_0	PCIE0 interrupt request	level

### 4.10.2 Gigabit Ethernet Switch (CPSW)

This section contains the integration details for the CPSW module on this device. For Further information, see the Gigabit Ethernet Switch (CPSW) section of the Peripherals chapter

#### 4.10.2.1 CPSW Unsupported Features

The following features are not supported by the CPSW switch:

- Maximum frame size of 9600 bytes
- MII
- GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet

#### 4.10.2.2 Module Allocations

**Table 4-193. CPSW Modules Allocation within Device Domains**

Instance	Domain

#### 4.10.4 Universal Serial Bus Subsystem (USB)

This section contains the integration details for the USB module on this device. For Further information, see the Universal Serial Bus Subsystem (USB) section of the Peripherals chapter

##### 4.10.4.1 USB2SS Unsupported Features

The following features are not supported on this family of devices:

- Battery Charger Support
- Accessory Charger Adaptor Support
- On-The-Go (OTG)
- No Virtualization Support
- SuperSpeed (5Gb/s) operation
- USB 2.0 ECN: Link Power Management (LPM)
- Low Speed operation in device mode
- Charger Detection

##### 4.10.4.2 Module Allocations

**Table 4-203. USB Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
USB0			✓
USB1			✓

##### 4.10.4.3 Resets, Interrupts, and Clocks

**Table 4-204. USB Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
USB0	PSC0	GP_CORE	LPSC_MAIN_U SB0	23	OFF	YES	LPSC_MAIN_IP
USB1	PSC0	GP_CORE	LPSC_MAIN_U SB1	47	OFF	YES	LPSC_MAIN_IP

**Table 4-205. USB Resets**

Module Instance	Source	Description
USB0	0	NONE
USB1	0	NONE

**Table 4-206. USB Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
USB0	USB0_a_ecc_aggr_corrected_err_level_0	ESM0_esm_lvl_event_IN_35	ESM0	USB0 interrupt request	level
USB0	USB0_a_ecc_aggr_uncorrected_err_level_0	ESM0_esm_lvl_event_IN_111	ESM0	USB0 interrupt request	level
USB0	USB0_host_system_error_0	ESM0_esm_lvl_event_IN_32	ESM0	USB0 interrupt request	level

**Table 4-206. USB Hardware Requests (continued)**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
USB0	USB0_irq_0	GICSS0_spi_IN_220	GICSS0	USB0 interrupt request	level

## 4.11 Memory Interfaces

### 4.11.1 Flash Subsystem (FSS)

This section contains the integration details for the Flash Subsystem on this device. For Further information, see the Flash Subsystem (FSS) section of the Peripherals chapter

#### 4.11.1.1 FSS Unsupported Features

For more information, see [Section 4.11.2.1, OSPI Unsupported Features](#).

#### 4.11.1.2 Module Allocations

**Table 4-208. FSS Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
FSS0			✓

#### 4.11.1.3 Resets, Interrupts, and Clocks

**Table 4-209. FSS Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
FSS0_FSAS_0	PSC0	GP_CORE	LPSC_MAIN_FSS_OSPI	28	ON	YES	LPSC_MAIN_IP

**Table 4-210. FSS Resets**

Module Instance	Source	Description
FSS0	PSC0	FSS0 reset

**Table 4-211. FSS Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
FSS0_FSAS_0	FSS0_FSAS_0_ecc_intr_err_pend_0	ESM0_esm_lvl_event_IN_141	ESM0	FSS0_FSAS_0 interrupt request	level

**Table 4-212. FSS Clocks**

Module Instance	Module Clock Input	Source Clock Signal	Source Control Register	Description
FSS0_FSAS_0	ICLK	MAIN_SYSCLK0		FSS0_FSAS_0 Interface Clock

#### 4.11.2 Octal Serial Peripheral Interface (OSPI)

This section contains the integration details for the OSPI module on this device. For Further information, see the Octal Serial Peripheral Interface (OSPI) section of the Peripherals chapter

##### 4.11.2.1 OSPI Unsupported Features

The following features are not supported on this family of devices:

- OSPI PDMA. Use CPU-triggered block DMA
- OSPI Clock Phase/Polarity Modes 1,2,3
- Reset Pins OSPI0\_RESET\_OUT2, OSPI0\_RESET\_OUT3

##### 4.11.2.2 Module Allocations

**Table 4-213. OSPI Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
FSS0_OSPI_0			✓

##### 4.11.2.3 Resets, Interrupts, and Clocks

**Table 4-214. OSPI Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
FSS0_OSPI_0	PSC0	GP_CORE	LPSC_MAIN_FSS_OSPI	28	ON	YES	LPSC_MAIN_IP

**Table 4-215. OSPI Resets**

Module Instance	Source	Description
FSS0	PSC0	FSS0 reset

**Table 4-216. OSPI Hardware Requests**

### 4.11.3 General-Purpose Memory Controller (GPMC)

This section contains the integration details for the GPMC module on this device. For Further information, see the General-Purpose Memory Controller (GPMC) section of the Peripherals chapter

#### 4.11.3.1 GPMC Unsupported Features

The following features are not supported on this family of devices:

- Pins GPMC\_CS[7:4]n are not pinned out
- Pins GPMC\_A[27:23] are not pinned out
- Pins GPMC\_AD[31:16] are not pinned out
- Pins GPMC\_WAIT[3:2] are not pinned out
- Pins GPMC\_BE[3:2]n are not pinned out

#### 4.11.3.2 Module Allocations

**Table 4-218. GPMC Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
GPMC0			✓

#### 4.11.3.3 Resets, Interrupts, and Clocks

**Table 4-219. GPMC Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies

Module Instance	Module Clock Input	Source Clock Signal	Source Control Register	Description
GPMC0	FCLK	GPMC_FCLK	GPMC_CLKSEL[0:0]	GPMC0 Functional Clock
	ICLK	MAIN_SYSCLK0/2		GPMC0 Interface clock

#### 4.11.4 Error Location Module (ELM)

This section contains the integration details for the ELM module on this device. For Further information, see the Error Location Module (ELM) section of the Peripherals chapter

##### 4.11.4.1 ELM Unsupported Features

The following features are not supported on this family of devices:

- There are no unsupported features

##### 4.11.4.2 Module Allocations

**Table 4-223. ELM Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
ELM0			✓

##### 4.11.4.3 Resets, Interrupts, and Clocks

**Table 4-224. ELM Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
ELM0	PSC0	GP_CORE	LPSC_MAIN_G PMC	15	OFF	YES	LPSC_MAIN_IP

ELM0	ELM0_elm_porocpsinterrupt_lvl_0	C7X256V1_CLEC_gic_spi_IN_164	C7X256V1_CLEC	ELM0 interrupt request	level

**Table 4-227. ELM Clocks**

Module Instance	Module Clock Input	Source Clock Signal	Source Control Register	Description
ELM0	FICLK	MAIN_SYSCCLK0/4		ELM0 Functional and Interface Clock

#### 4.11.5 Multimedia Card Secure Digital (MMCSD)

This section contains the integration details for the MMCSD module on this device. For Further information, see the Multimedia Card Secure Digital (MMCSD) section of the Peripherals chapter

##### 4.11.5.1 MMCSD Unsupported Features

The following features are not supported on this family of devices:

- The following apply to 4-bit MMCSD instances:
  - SD Card busy LED - Not pinned out
  - High Speed DDR
- The following apply to 8-bit MMCSD instances:
  - SD Card busy LED - Not pinned out
  - SD/SDIO/MMC Cards (Removable) - no support for 4-pin/8-pin muxing
  - SD Card Detect Pin - Not pinned out
  - SD Card Write Protect Pin - Not pinned out
  - Enhanced Strobe

##### 4.11.5.2 Module Allocations

**Table 4-228. MMCSD Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
MMCSD0 (8-bit)			✓
MMCSD1 (4-bit)			✓
MMCSD2 (4-bit)			✓

##### 4.11.5.3 Resets, Interrupts, and Clocks

**Table 4-229. MMCSD Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
MMCSD0	PSC0	GP_CORE	LPSC_MAIN_E MMC8B	20	OFF	YES	LPSC_MAIN_IP
MMCSD1	PSC0	GP_CORE	LPSC_MAIN_E MMC4B0	21	OFF	YES	LPSC_MAIN_IP

## 4.12 Industrial and Control Interfaces

### 4.12.1 Modular Controller Area Network (MCAN)

This section contains the integration details for the MCAN module on this device. For Further information, see the Modular Controller Area Network (MCAN) section of the Peripherals chapter

#### 4.12.1.1 MCAN Unsupported Features

- Debug DMAs - DMA Ack not supported by PDMA architecture. Debug messages can be traced through the RX FIFO.
- TX DMA channels 3-31 are not supported by the Main domain instance (MCAN0)- Only TX\_DMA[2:0] have associated PDMA channels
- DMA is not supported on the MCU domain instances, MCU\_MCAN0 and MCU\_MCAN1

#### 4.12.1.2 Module Allocations

**Table 4-233. MCAN Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
MCAN0			✓
MCAN1			✓
MCU_MCAN0		✓	
MCU_MCAN1		✓	

#### 4.12.1.3 Resets, Interrupts, and Clocks

**Table 4-234. MCAN Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
MCAN0	PSC0	GP_CORE	LPSC_MAIN_M CANSS0	35	OFF	YES	LPSC_MAIN_IP
MCAN1	PSC0	GP_CORE	LPSC_MAIN_M CANSS1	16	OFF	YES	LPSC_MAIN_IP
MCU_MCAN0	WKUP_PSC0	PD_MCUSS	LPSC_MCU_M CANSS_0	7	OFF	YES	LPSC_MCU_C OMMON
MCU_MCAN1	WKUP_PSC0	PD_MCUSS	LPSC_MCU_M CANSS_1	8	OFF	YES	LPSC_MCU_C OMMON

**Table 4-235. MCAN Resets**

Module Instance	Source	Description
MCAN0	PSC0	MCAN0 reset
MCAN1	PSC0	MCAN1 reset
MCU_MCAN0	WKUP_PSC0	MCU_MCAN0 reset
MCU_MCAN1	WKUP_PSC0	MCU_MCAN1 reset

### 4.12.2 Enhanced Capture (ECAP)

This section contains the integration details for the ECAP module on this device. For Further information, see the Enhanced Capture (ECAP) section of the Peripherals chapter

#### 4.12.2.1 ECAP Unsupported Features

The following features are not supported on this family of devices:

- There are no unsupported features

#### 4.12.2.2 Module Allocations

**Table 4-238. ECAP Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
ECAP0			✓
ECAP1			✓
ECAP2			✓

#### 4.12.2.3 Resets, Interrupts, and Clocks

**Table 4-239. ECAP Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
ECAP0	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
ECAP1	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
ECAP2	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO

**Table 4-240. ECAP Resets**

Module Instance	Source	Description
ECAP0	PSC0	ECAP0 reset
ECAP1	PSC0	ECAP1 reset
ECAP2	PSC0	ECAP2 reset

**Table 4-241. ECAP Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
ECAP0	ECAP0_ecap_int_0	GICSS0_spi_IN_145	GICSS0	ECAP0 interrupt request	pulse
ECAP0	ECAP0_ecap_int_0	R5FSS0_CORE0_intr_IN_83	R5FSS0_CORE0	ECAP0 interrupt request	pulse

### 4.12.3 Enhanced Pulse Width Modulation (EPWM)

This section contains the integration details for the EPWM module on this device. For Further information, see the Enhanced Pulse Width Modulation (EPWM) section of the Peripherals chapter

#### 4.12.3.1 EPWM Unsupported Features

The following features are not supported on this family of devices:

- EPWM digital comparators
- Hi Res Extension (Delay Line Based)

#### 4.12.3.2 Module Allocations

**Table 4-243. EPWM Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
EPWM0			✓
EPWM1			✓
EPWM2			✓

#### 4.12.3.3 Resets, Interrupts, and Clocks

**Table 4-244. EPWM Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
EPWM0	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
EPWM1	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO
EPWM2	PSC0	GP_CORE	LPSC_MAIN_IP	34	ON	YES	LPSC_MAIN_D M2MAIN_INFR A_ISO

**Table 4-245. EPWM Resets**

Module Instance	Source	Description
EPWM0	PSC0	EPWM0 reset
EPWM1	PSC0	EPWM1 reset
EPWM2	PSC0	EPWM2 reset

**Table 4-246. EPWM Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
EPWM0	EPWM0_epwm_etint_0	GICSS0_spi_IN_229	GICSS0	EPWM0 interrupt request	pulse
EPWM0	EPWM0_epwm_etint_0	R5FSS0_CORE0_intr_IN_36	R5FSS0_CORE0	EPWM0 interrupt request	pulse

## 4.13 Camera Subsystem

### 4.13.1 Camera Serial Interface Receiver (CSI\_RX\_IF)

This section contains the integration details for the CSI\_RX\_IF module on this device. For Further information, see the Camera Serial Interface Receiver (CSI\_RX\_IF) section of the Peripherals chapter

#### 4.13.1.1 CSI\_RX\_IF Unsupported Features

The following features are not supported on this family of devices:

- Line Count Error Interrupt (Streams 1-3)
- Frame Mismatch Error Interrupt (Streams 1-3)
- Frame Count Error Interrupt (Streams 1-3)
- FCC Stop Interrupt (Streams 1-3)
- FCC Start Interrupt (Streams 1-3)
- Line/Byte Interrupt (Streams 1-3)
- Timer / Timer Interrupt (Streams 1-3)

#### 4.13.1.2 Module Allocations

**Table 4-253. CSI\_RX\_IF Modules Allocation within Device Domains**

Instance	Domain

### 4.13.2 MIPI D-PHY Receiver (DPHY\_RX)

This section contains the integration details for the DPHY\_RX module on this device. For Further information, see the MIPI D-PHY Receiver (DPHY\_RX) section of the Peripherals chapter

#### 4.13.2.1 DPHY\_RX Unsupported Features

The following features are not supported on this family of devices:

- Swapping of Clock & Data Lanes

#### 4.13.2.2 Module Allocations

**Table 4-258. DPHY\_RX Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
DPHY_RX0			✓

#### 4.13.2.3 Resets, Interrupts, and Clocks

**Table 4-259. DPHY\_RX Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Deault	Controllable	Dependencies
DPHY_RX0	PSC0	GP_CORE	LPSC_MAIN_D PHY_RX0	26	OFF	YES	LPSC_MAIN_IP
DPHY_RX1	PSC0	GP_CORE	LPSC_MAIN_D PHY_RX1	10	OFF	YES	LPSC_MAIN_IP

## 4.14 Timer Modules

### 4.14.1 Global Timebase Counter (GTC)

This section contains the integration details for the GTC module on this device. For Further information, see the Global Timebase Counter (GTC) section of the Peripherals chapter

#### 4.14.1.1 GTC Unsupported Features

The following features are not supported on this family of devices:

- There are no unsupported features

#### 4.14.1.2 Module Allocations

**Table 4-273. GTC Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
WKUP_GTC0	✓		

#### 4.14.1.3 Resets, Interrupts, and Clocks

**Table 4-274. GTC Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies

#### 4.14.2 Real Time Interrupt (RTI)

This section contains the integration details for the RTI module on this device. For Further information, see the Real Time Interrupt (RTI) section of the Peripherals chapter

##### 4.14.2.1 RTI Unsupported Features

The following features are not supported on this family of devices:

- Analog watchdog timer
- External clock supervision
- Periodic Interrupt
- Timestamp (Capture Registers)

##### 4.14.2.2 Module Allocations

**Table 4-278. RTI Modules Allocation within Device Domains**

### 4.14.3 Real-Time Clock (RTC)

This section contains the integration details for the RTC module on this device. For Further information, see the Real-Time Clock (RTC) section of the Peripherals chapter

#### 4.14.3.1 RTC Unsupported Features

The following features are not supported on this family of devices:

- PMIC enable support

#### 4.14.3.2 Module Allocations

**Table 4-283. RTC Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
WKUP_rtcss0	✓		

#### 4.14.3.3 Resets, Interrupts, and Clocks

**Table 4-284. RTC Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
WKUP_RTCSS0	PSC0	GP_CORE	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE

**Table 4-285. RTC Resets**

Module Instance	Source	Description
WKUP_rtcss0	PSC0	WKUP_rtcss0 reset

**Table 4-286. RTC Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
WKUP_rtcss0	WKUP_rtcss0_rtc_event_pend_0	GICSS0_spi_IN_132	GICSS0	WKUP_rtcss0 interrupt request	level
WKUP_rtcss0	WKUP_rtcss0_rtc_event_pend_0	WKUP_R5FSS0_CO_RE0_intr_IN_97	WKUP_R5FSS0_CO_RE0	WKUP_rtcss0 interrupt request	level
WKUP_rtcss0	WKUP_rtcss0_rtc_event_pend_0	MCU_R5FSS0_COR_E0_cpu0_intr_IN_97	MCU_R5FSS0_COR_E0	WKUP_rtcss0 interrupt request	level
WKUP_rtcss0	WKUP_rtcss0_rtc_event_pend_0	WKUP_DEEPSLEEP_SOURCES0_Isam62_dm_wakeup_deepsleep_sources_IN_7	WKUP_DEEPSLEEP_SOURCES0	WKUP_rtcss0 interrupt request	level
WKUP_rtcss0	WKUP_rtcss0_rtc_event_pend_0	C7X256V0_CLEC_gic_spi_IN_132	C7X256V0_CLEC	WKUP_rtcss0 interrupt request	level
WKUP_rtcss0	WKUP_rtcss0_rtc_event_pend_0	C7X256V1_CLEC_gic_spi_IN_132	C7X256V1_CLEC	WKUP_rtcss0 interrupt request	level

**Table 4-287. RTC Clocks**

Module Instance	Module Clock Input	Source Clock Signal	Source Control Register	Description
WKUP_rtcss0	ANA_OSC32K_CLK	DEVICE_CLKOUT_32K	WKUP_RTC_CLKSEL[0:0]

		CLK_32K_RC	WKUP_RTC_CLKSEL[0:0]	
	VCLK_CLK	DM_CLK/8	WKUP_CLKSEL[0:0]	

#### 4.14.4 Timer

This section contains the integration details for the Timer module on this device. For Further information, see the Timer section of the Peripherals chapter

##### 4.14.4.1 Timer Unsupported Features

The following features are not supported on this family of devices:

- Cascading of timer instances is not supported.

##### 4.14.4.2 Module Allocations

**Table 4-288. Timer Modules Allocation within Device Domains**

Instance	Domain

## 4.15 Internal Diagnostic Modules

### 4.15.1 Dual Clock Comparator (DCC)

This section contains the integration details for the DCC module on this device. For Further information, see the Dual Clock Comparator (DCC) section of the Peripherals chapter

#### 4.15.1.1 DCC Unsupported Features

The following features are not supported on this family of devices:

- There are no unsupported features

#### 4.15.1.2 Module Allocations

**Table 4-293. DCC Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
DCC0			✓
DCC1			✓
DCC2			✓
DCC3			✓
DCC4			✓
DCC5			✓
DCC6			✓
DCC7			✓
DCC8			✓
MCU_DCC0		✓	
MCU_DCC1		✓	

#### 4.15.1.3 Resets, Interrupts, and Clocks

**Table 4-294. DCC Integration Attributes**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
DCC0	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC1	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC2	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC3	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC4	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC5	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC6	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE

**Table 4-294. DCC Integration Attributes (continued)**

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
DCC7	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
DCC8	PSC0	GP_CORE	LPSC_MAIN_A LWAYSON	0	ON	NO	NONE
MCU_DCC0	WKUP_PSC0	GP_CORE_CT L_MCU	LPSC_MCU_AL WAYSON	0	ON	NO	NONE
MCU_DCC1	WKUP_PSC0	GP_CORE_CT L_MCU	LPSC_MCU_AL WAYSON	0	ON	NO	NONE

**Table 4-295. DCC Resets**

Module Instance	Source	Description
DCC0	PSC0	DCC0 reset
DCC1	PSC0	DCC1 reset
DCC2	PSC0	DCC2 reset
DCC3	PSC0	DCC3 reset
DCC4	PSC0	DCC4 reset
DCC5	PSC0	DCC5 reset
DCC6	PSC0	DCC6 reset
DCC7	PSC0	DCC7 reset
DCC8	PSC0	DCC8 reset
MCU_DCC0	WKUP_PSC0	MCU_DCC0 reset
MCU_DCC1	WKUP_PSC0	MCU_DCC1 reset

**Table 4-296. DCC Hardware Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
DCC0	DCC0_intr_done_level_0	GICSS0_spi_IN_128	GICSS0	DCC0 interrupt request	level

#### 4.15.2 Error Signaling Module (ESM)

This section contains the integration details for the ESM module on this device. For Further information, see the Error Signaling Module (ESM) section of the Peripherals chapter

##### 4.15.2.1 ESM Unsupported Features

The following features are not supported on this family of devices:

- No Dedicated ERROR Pin for MAIN domain ESM. MAIN ESM error interrupts are routed to the MCU ESM - the MCU ESM drives the MCU\_ERROR pin and can factor in errors from MAIN ESM if programmed to do so.

##### 4.15.2.2 Module Allocations

**Table 4-309. ESM Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
ESM0			✓
WKUP_ESM0	✓		

##### 4.15.2.3 Resets, Interrupts, and Clocks

**Table 4-310. ESM Integration Attributes**

### 4.15.3 Memory Cyclic Redundancy Check (MCRC64)

This section contains the integration details for the MCRC64 module on this device. For Further information, see the Memory Cyclic Redundancy Check (MCRC64) section of the Peripherals chapter

#### 4.15.3.1 MCRC64 Unsupported Features

The following features are not supported on this family of devices:

- Data Trace Mode (Automatic PSA on CPU Instruction and Data TCM busses) - Wrapper only supports VBUSM Signature Analysis. ITCM, DTCM designed for Cortex R5F
- DMA is not supported by the MCU instances

#### 4.15.3.2 Module Allocations

**Table 4-314. MCRC64 Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
MCRC64_0			✓
MCU_MCRC64_0		✓	

#### 4.15.3.3 Resets, Interrupts, and Clocks

## 4.16 Display Subsystem (DSS)

This section contains the integration details for the DSS module on this device. For Further information, see the Display Subsystem (DSS) section of the Peripherals chapter

### 4.16.1 DSS\_UL Unsupported Features

The following features are not supported on this family of devices:

- Simultaneous output to both DPI Pipe and either OLDI or DSI from the same DSS Pipeline
- Fragmented frame buffers

### 4.16.2 Module Allocations

**Table 4-329. DSS\_UL Modules Allocation within Device Domains**

Instance	Domain		
	WKUP	MCU	Main
DSS0			✓

<b>5.8 Boot Memory Maps.....</b>	<b>734</b>

## 5.1 Initialization Overview

Figure 5-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip(s)
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software (SBL)
- **Initial software:** Software that loads, prepares, and passes control to application software or to the high-level operating system (HLOS)
- **High-Level Operating System** or bare-metal application which runs on main processor(s)

init-003

**Figure 5-1. Initialization Process**

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

### 5.1.1 ROM Code Overview

ROM bootloader (or ROM Code) is a software that resides in a on-chip read-only memory (ROM) to assist the customer in transferring and executing their application code. The device has two ROM codes operating in tandem – the Public ROM code, and the M4 ROM code.

In order to accommodate various system scenarios, the ROM Code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host via the selected interface. Either the host writes the application code directly into internal memory or the ROM Code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

1. Hardware initialization phase
2. Boot process.

During initialization, the ROM Code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements.

During the boot process the boot image can be loaded into device memory and executed, or executed in place, depending on the boot peripheral. M4 will perform code verification and allow, or forbid, the image execution.

Main configuration source for boot after power-up are the BOOTMODE pins sampled automatically after reset release and stored in device status registers. At ROM Code startup, these pin values are read from the registers to create the boot peripheral list and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

### 5.1.2 Bootloader Modes

Table 5-1 shows the boot modes supported by ROM code.

**Table 5-1. ROM Code Boot Modes**

Boot Mode	Boot Media/Host	SoC Peripheral	Can be a Backup Mode? <sup>(1)</sup>	Notes
No-boot/Dev-boot	No media or host	None	N	No boot or development boot – debug modes
OSPI	OSPI flash	FSS0_OSPI0	N	On OSPI port
QSPI	QSPI flash	FSS0_OSPI0	N	On OSPI port
SPI	SPI flash	FSS0_OSPI0	Y	On OSPI port
Ethernet	External host	CPSW0	Y	In BOOTP mode. RGMII or RMII PHY
I2C	I <sup>2</sup> C EEPROM	I2C0	Y	I2C target boot is not supported
UART	External host	UART0	Y	XMODEM protocol
MMCSD	MMCSD card	MMCSD0 (8bit) or MMCSD1 (4bit)	Y	Boot from User Data Area (UDA) or file system
eMMC	eMMC flash	MMCSD0 (8bit)	N	Boot from boot partition
USB - target	USB boot from external host	USB0	Y	USB device mode boot using DFU (device firmware upgrade), Boot is running on USB2.0 speeds.
USB - host	USB mass storage	USB0	Y	USB2.0 host mode, boot from FAT32 filesystem
Serial Flash	Serial Flash	FSS0_OSPI0	N	On OSPI port
xSPI	xSPI flash	FSS0_OSPI0	N	On OSPI port
Fast-xSPI	Fast-xSPI	FSS0_OSPI0	N	On OSPI port
GPMC	NOR flash, NAND flash	GPMC0	N	CSn0 connected, 8 bit NAND flash only, 16-bit non-mux NOR flash only

(1) The peripheral can be selected also as a backup boot mode. A backup mode is tried if primary boot mode fails.

#### Note

Because different devices support different sets of peripherals, see the *device-specific Datasheet* to obtain the list of peripherals supported in your device.

### 5.1.3 Terminology

- **Boot Mode Pins:** Boot mode pins provide vital information to ROM code for boot. These pins must be properly set up before power ramp.
- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase.
- **Boot Header:** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into on-chip RAM by the ROM code during the peripheral booting phase.
- **eFuse:** A one-time programmable memory location usually set at the factory.
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device (SoC) or a non-secure device.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software. This can be the SBL (secondary bootloader) responsible for loading an OS.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory.
- **Controller CPU:** The Arm® Cortex® CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.

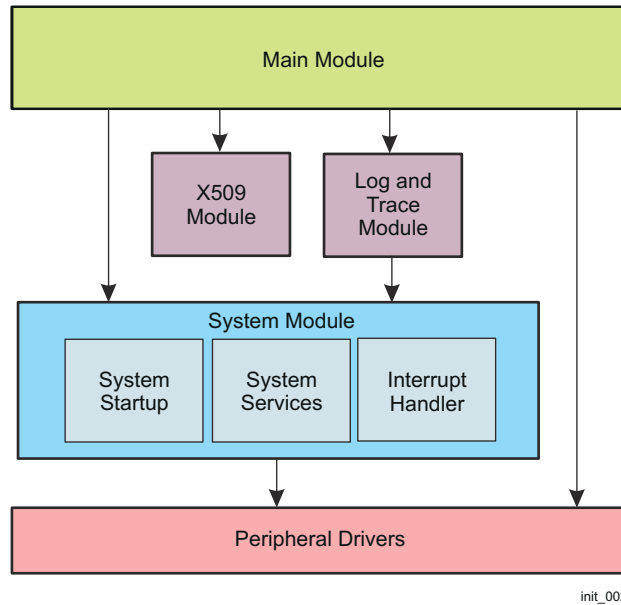

- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory.
- **ROM Code:** or ROM bootloader (RBL), the on-chip software in device ROM that executes first and implements booting.
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **Booting Parameter Table:** A logical structure stored in the on-chip RAM memory and contains information for the boot, such as the boot file name or an address to boot from.

## 5.2 Boot Process

### 5.2.1 Public ROM Code Architecture

The Public ROM code has the following components (see also [Public ROM Code Architecture](#)):

- Main
- Buffer manager
- X.509
- Log and Trace
- System
- Protocol
- Driver

**Figure 5-2. Public ROM Code Architecture**

#### 5.2.1.1 Main Module

The Main module contains the top level execution loop. This loop repeats until a boot image has been received or directed to sleep by the M4. The main loop has three different execution sub-paths based on the boot peripheral.

- **Image Path** This path is used by the OSPI, QSPI, SPI, and xSPI boot modes. In these cases the image data can be directly read by both the R5 and the M4 in place.
- **Block Path** This path is used by the I2C, USB-DFU, UART, eMMC, Ethernet, eMMC/SD cards in raw mode. In this mode data is received from the peripheral in blocks. Blocks are accumulated in the boot buffer until a full X.509 certificate header has been received, at which point this full certificate and any subsequent blocks are passed to the M4 as they arrive.
- **Filesystem Path** This path is used by the USB host (MSC) mode and eMMC/SD cards in filesystem mode. This mode executes exactly like in the block path, except that the boot image location is defined by a filesystem.

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images. In some cases, detection of an invalid image is done after the initial data buffer has been sent to the M4. In that case the R5 must inform the M4 that the image was in fact invalid and it will be looking for the next image and try again.

#### 5.2.1.2 X509 Module

The X509 module parses the boot header. The boot header is an X.509 certificate as defined in [RFC5280](#). Extensions specific to boot are described in [Section 5.7.2, X.509 Certificate](#).

This module also includes an OID decoder as well as defines OID values as C #define constants for any values that can be used during boot.

#### 5.2.1.3 Buffer Manager Module

The buffer manager module is used to allocate buffers to hold boot data. The R5 code allocates a buffer when it is ready to read a block of data from the boot peripheral. Once the data is read the buffer ownership is passed to the M4. When the M4 has completed processing the data in the buffer ownership is returned to the R5, which then frees the buffer.

#### 5.2.1.4 Log and Trace Module

The Log and Trace modules are not integral to the boot process. Instead, they provide ability to record operation of the ROM code and track unexpected occurrences.

Log and trace function is currently TI internal.

#### 5.2.1.5 System Module

The system module provides services to other modules. These services are not directly related to boot drivers. The system module is the only module that operates in the supervisor mode of the R5 (a few services will run in user). The system module supports the following functions:

- Interrupt enable, disable, and service
- IPC
- Power
- Pinmux
- Clock
- Task switch

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

#### 5.2.1.6 Protocol Module

The protocol modules provide implementation of high-level data transfer protocols. The BOOTP/TFTP and XMODEM protocols reside in this layer. These modules provide services as defined in well-known standards.

#### 5.2.1.7 Driver Module

The driver module implements the low level peripheral drivers.

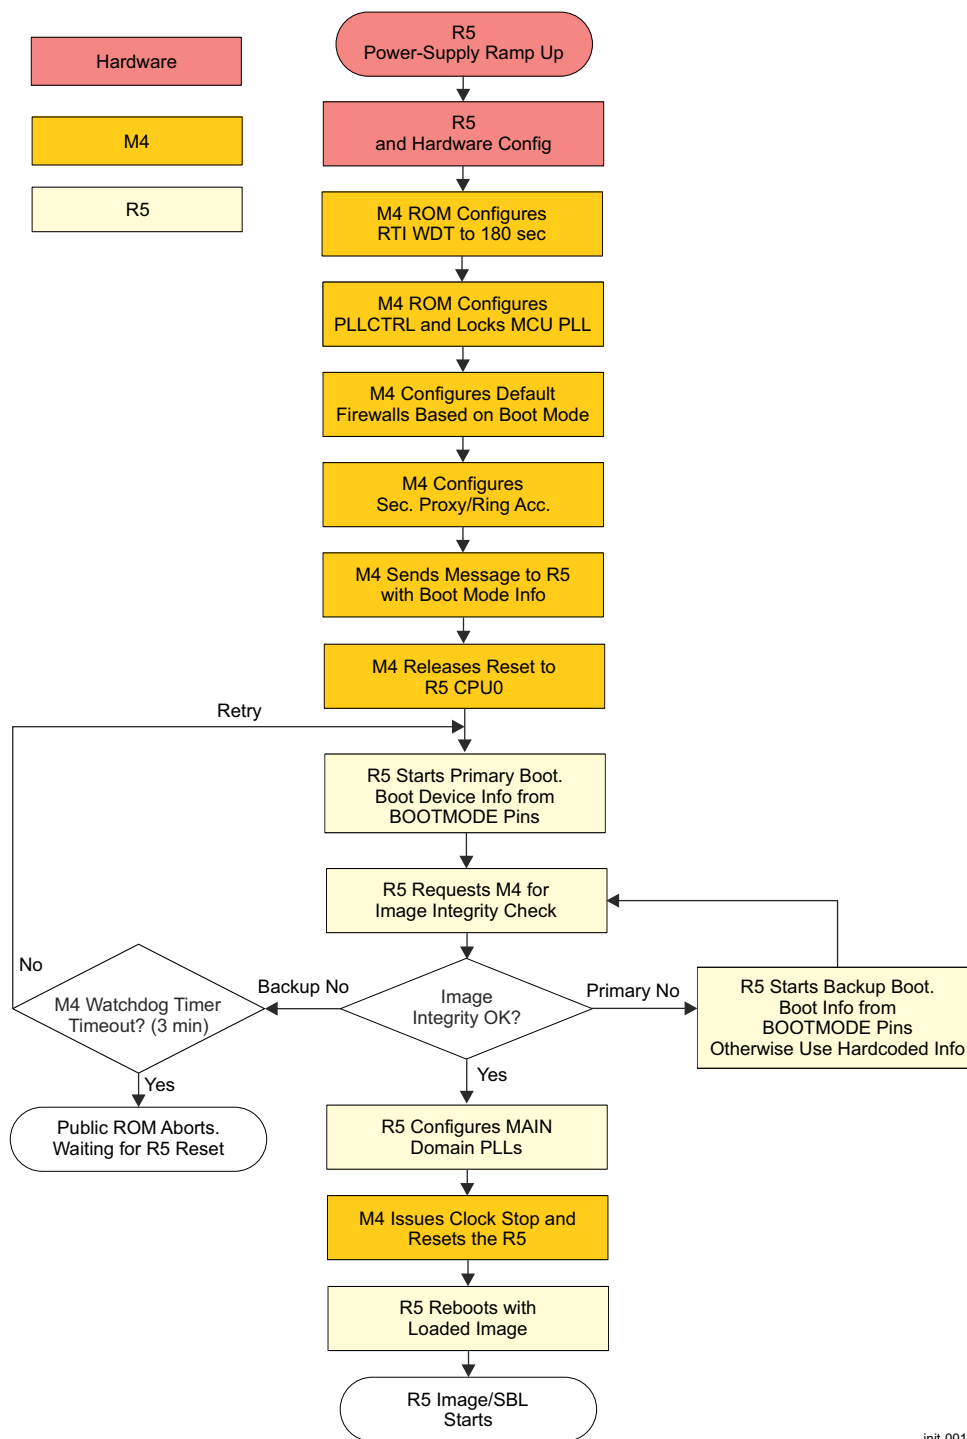

### 5.2.2 M4 ROM Description

In a general-purpose (GP) device, M4 ROM performs the following functions:

- Device management
- Configures the boot vectors (in BOOT\_CFG) and controls reset release of R5 core. That is, M4 is the boot controller of R5 core.
- IPC configuration via Main DMSS rings and Secure Proxy
- PLL configuration (R5 and SA2UL)
- X509 certificate parsing
- SA2UL configuration to SHA512 for image integrity checks
- M4 firmware loading

### 5.2.3 Boot Process Flow

The R5 boot process flow is shown in [Figure 5-3](#).

init-001

**Figure 5-3. Boot Process**

The values of BOOTMODE[15:0] pins are latched into the Device Status register CTRLMMR\_MAIN\_DEVSTAT[15:0] by hardware as the device comes out of global cold reset, sampled after MCU\_PORz deassertion. For more information how to set BOOTMODE pins, see [Section 5.3, Boot Mode Pins](#).

The M4 is the boot controller for the Public ROM. M4 performs the necessary configurations and releases R5's reset for CPU0.

The R5 checks the boot mode pins and then configures the appropriate peripheral interface to get access to a boot image. A cursory check of the image is made, and the image is passed to M4. M4 ROM then will perform code verification and route the boot image to the on-chip RAM. Once the image has been received, R5 enters a clean state and idles. M4 ROM code will assert reset to the R5, redirect the boot vector to the newly loaded image, and release the reset. This restarts the R5 with the Public ROM code fully disconnected.

The Public ROM code executes after a cold or warm reset.

---

#### Note

M4 ROM sets up a 3-minute watchdog timer (RTI0) timeout. During this time, the R5 boot needs to get completed, otherwise a WDT reset will occur. Once the R5 image is loaded (SBL/SPL), M4 ROM will restart the watchdog timer for additional 3 minutes upon entering the R5 SBL. The customer-provided R5 image needs to load and install the TI-provided SYSFW image into the M4, which will manage the watchdog timer during run time.

---

---

#### Note

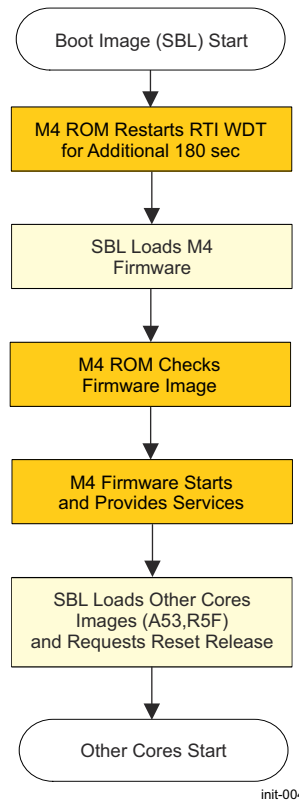

The following system conditions must be met at POR to perform device boot:

- USB cable plug must be inserted
- Ethernet PHY is powered up and out of reset
- The SD card cage must be powered before entering the SD card boot mode. A SD/MMC card with pre-loaded image must be inserted
- Memory devices must be up and ready (power ramped up and reset completed) at device startup:
  - eMMC
  - xSPI/OSPI/QSPI/SPI and Serial flash
  - I2C EEPROM
  - NOR/NAND flash

Failing to meet these requirements may result in boot fail and performing a backup boot (if available for that mode).

---

Figure 5-4 describes the external bootloader (SBL) typical tasks.

**Figure 5-4. External Bootloader Tasks**

Upon R5 reset and SBL execution start, M4 ROM restarts the RTI watchdog timer for additional 180 seconds of timeout. During that time, SBL must load the M4 firmware provided by TI otherwise an R5 reset will occur as a preventive measure against software misbehavior.

One of the SBL's main tasks is to load the M4 firmware. Only after this task is performed, SBL can load the other processors' image and request a reset release from M4 firmware for those cores.

### 5.3 Boot Mode Pins

Boot Mode pins provide means to select the boot mode and options before the device is powered up. After every POR, they are the main source to populate the Boot Parameter Tables. See [Section 5.6, Boot Parameter Tables](#) for table list and description.

Boot mode pins can be divided into the following categories:

- **BOOTMODE[02:00]** – Denote system clock frequency (MCU\_OSC0\_XI/XO) to ROM code for PLL configuration.
- **BOOTMODE[06:03]** – Select the requested boot (primary) mode after POR, that is, the peripheral/memory to boot from.
- **BOOTMODE[09:07]** – These pins provide optional configurations for primary boot and are used in conjunction with the boot mode selected.
- **BOOTMODE[12:10]** – Select the backup boot mode, that is, the peripheral/memory to boot from, if primary boot device failed.
- **BOOTMODE[13]** – This pin provides optional configurations for the backup boot devices.
- **BOOTMODE[15:14]** – Reserved pins.

---

#### Note

It is user's responsibility to set the boot mode pins (via pullups or pulldowns, and jumpers/switches) depending on the desired boot scenario.

---

### 5.3.1 BOOTMODE Pin Mapping

The ROM execution is directed through the main boot mode pins. This provides more flexibility and more booting peripherals to boot from. The Main domain must be powered and functional.

Main boot mode pins are shown in [Table 5-2](#).

Any Bootmode pins marked as Reserved or not used must be tied high or low with pull resistors. They should not be left floating.

**Table 5-2. BOOTMODE Pin Mapping**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Reserved	Backup Boot Mode Config	Backup Boot Mode			Primary Boot Mode Config			Primary Boot Mode				PLL Config		

[Table 5-3](#) describes the BOOTMODE pins that need to be set according to the system clock provided to the device.

The ROM Code will configure any PLLs required during the boot process.

#### Note

Reference clock selections may be limited by the device. Please consult the device specific datasheet to determine which system clock frequencies are valid.

**Table 5-3. PLL Reference Clock Selection**

PLL Config Pins			Ref Clock (MHz)
B2	B1	B0	
0	1	0	Reserved
0	1	1	25
1	0	0	Reserved

#### 5.3.1.1 Primary Boot Mode Selection and Configuration

The primary boot mode is the first mode attempted after reset. [Table 5-4](#) lists all possible primary boot modes. All pins marked as reserved can be either 0 or 1. All boot mode signals must be pulled low or high through a pull resistor on the board, they must not be left floating

#### Note

All BOOTMODE[15:00] signals must be pulled high through a resistor to VDDSHV3, or pulled low to ground, including Reserved signals. Reserved BOOTMODE signals must not be left floating.

**Table 5-4. Primary Boot Mode Selection**

Primary Boot Mode Config							Primary Boot Mode
B9	B8	B7	B6	B5	B4	B3	
Reserved	Read Mode 2	Read Mode 1	0	0	0	0	Serial NAND
Reserved	Reserved	Csel	0	0	0	1	OSPI
Reserved	Reserved	Csel	0	0	1	0	QSPI
Reserved	Mode	Csel	0	0	1	1	SPI
0	0	Link Info	0	1	0	0	Ethernet RGMII
Clkout	Clk src	0	0	1	0	1	Ethernet RMII
Bus reset	Reserved	Addr	0	1	1	0	I2C
Reserved	Reserved	Reserved	0	1	1	1	UART
1	Reserved	Fs/raw	1	0	0	0	MMCSDBoot (SD Card Boot or eMMC Boot using UDA)

**Table 5-4. Primary Boot Mode Selection (continued)**

Primary Boot Mode Config							Primary Boot Mode
B9	B8	B7	B6	B5	B4	B3	
Reserved	Reserved	Reserved	1	0	0	1	eMMC Boot
0	Mode	Lane Swap	1	0	1	0	USB
Reserved	Reserved	Reserved	1	0	1	1	GPMC NAND
Reserved	Reserved	Reserved	1	1	0	0	GPMC NOR
Reserved	Reserved	Reserved	1	1	0	1	Fast-xSPI
SFPD	Read Cmd	Mode	1	1	1	0	xSPI
Reserved	ARM/Thumb	No/Dev	1	1	1	1	No-boot/Dev boot

### 5.3.1.2 Backup Boot Mode Selection and Configuration

The backup boot mode is selected via pins within the main BOOTMODE map. [Table 5-5](#) lists all possible backup boot modes.

**Table 5-5. Backup Mode Selection**

Backup Boot Config	Backup Boot Mode Selection			Backup Boot Mode Selected
B13	B12	B11	B10	
Reserved	0	0	0	None
Mode	0	0	1	USB
Reserved	0	1	0	Reserved
Reserved	0	1	1	UART
IF	1	0	0	Ethernet
Port	1	0	1	MMCSD Boot (SD Card Boot or eMMC Boot )
Reserved	1	1	0	SPI
Reserved	1	1	1	I2C

## 5.4 Boot Modes

### 5.4.1 OSPI\xSPI\QSPI\SPI Boot

The following apply to all or multiple boot modes that are SPI related.

- Octal SPI flash memories support various protocols, however, the OSPI boot mode of the device will only support a specific protocol defined in OSPI Bootloader Operation. If the flash memory is compliant with JEDEC xSPI standards JESD251 and JESD216D, then xSPI boot mode is additionally supported. Please refer to xSPI boot mode description for further details.
- Command protocols follow the JEDEC spec definition and indicate the number of active pins used for the instruction, address, and data, and also the data rate used for each (S = Single Data Rate, D= Double Data Rate). For example, 1S-1S-8S describes a protocol which uses 1 signal (D0) for command in SDR mode, 1 signal (D0) for address in SDR mode, and 8 signals (D7:D0) for data in SDR mode
- When using a OSPI\xSPI\QSPI\SPI flash device greater than 128Mb, a flash device package with a RESET signal must be used. The reason is that the ROM only uses 3 byte addressing mode (address is 24bits). To address the full memory address range, software will typically switch to 4-byte addressing mode. If a reset to the processor occurs (eg, due to a warm reset), the ROM will execute expecting 3-byte addressing mode, but the flash will have been left in 4-byte addressing mode. In order for the flash device to return to 3-byte addressing mode, it must be reset using this signal. This typically can be achieved by using the RESET signal on the flash memory device. The ROM does not issue a software reset command.

### 5.4.1.1 OSPI Boot

Table 5-6 shows configuration pins assignment to functions when boot mode is the Octal SPI using the OSPI module.

**Table 5-6. OSPI Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-7 summarizes the OSPI pin configuration done by ROM code for OSPI boot device.

**Table 5-7. OSPI Boot Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CS <sub>n</sub> 0	OSPI0_CS <sub>n</sub> 0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CS <sub>n</sub> 1	OSPI0_CS <sub>n</sub> 1	Disable	NA	0	Disable	0	PADCONFIG12

#### Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

#### 5.4.1.1.1 OSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to OSPI boot mode

The OSPI boot mode supports 1S-1S-8S mode only. The ROM will issue a Read Command (0x8B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The flash device should then respond with 8-bit data. The frequency of operation during the read portion is 50 MHz.

##### 5.4.1.1.1.1 OSPI Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the OSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.1, *OSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI Boot Parameter Table*.

##### 5.4.1.1.1.2 OSPI Loading Process

OSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

#### 5.4.1.2 xSPI Boot

Table 5-8 shows configuration pins assignment to functions when boot mode is xSPI using the OSPI module.

**Table 5-8. xSPI Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description
9	SFDP	0	SFDP disabled
		1	SFDP enabled
8	Read cmd	0	0x0B Read Command
		1	0xEE Read Command
7	Mode	0	1S-1S-1S mode @ 50MHz
		1	8D-8D-8D mode @ 25MHz

Table 5-9 summarizes the OSPI pin configuration done by ROM code for xSPI boot device on port 0.

**Table 5-9. xSPI Boot Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

#### Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

##### 5.4.1.2.1 xSPI Bootloader Operation

Please refer to [Section 5.4.1](#) for more information that applies to xSPI boot mode

The xSPI protocol defines 1S-1S-1S mode for general backwards compatibility, and 8D-8D-8D for maximum throughput.

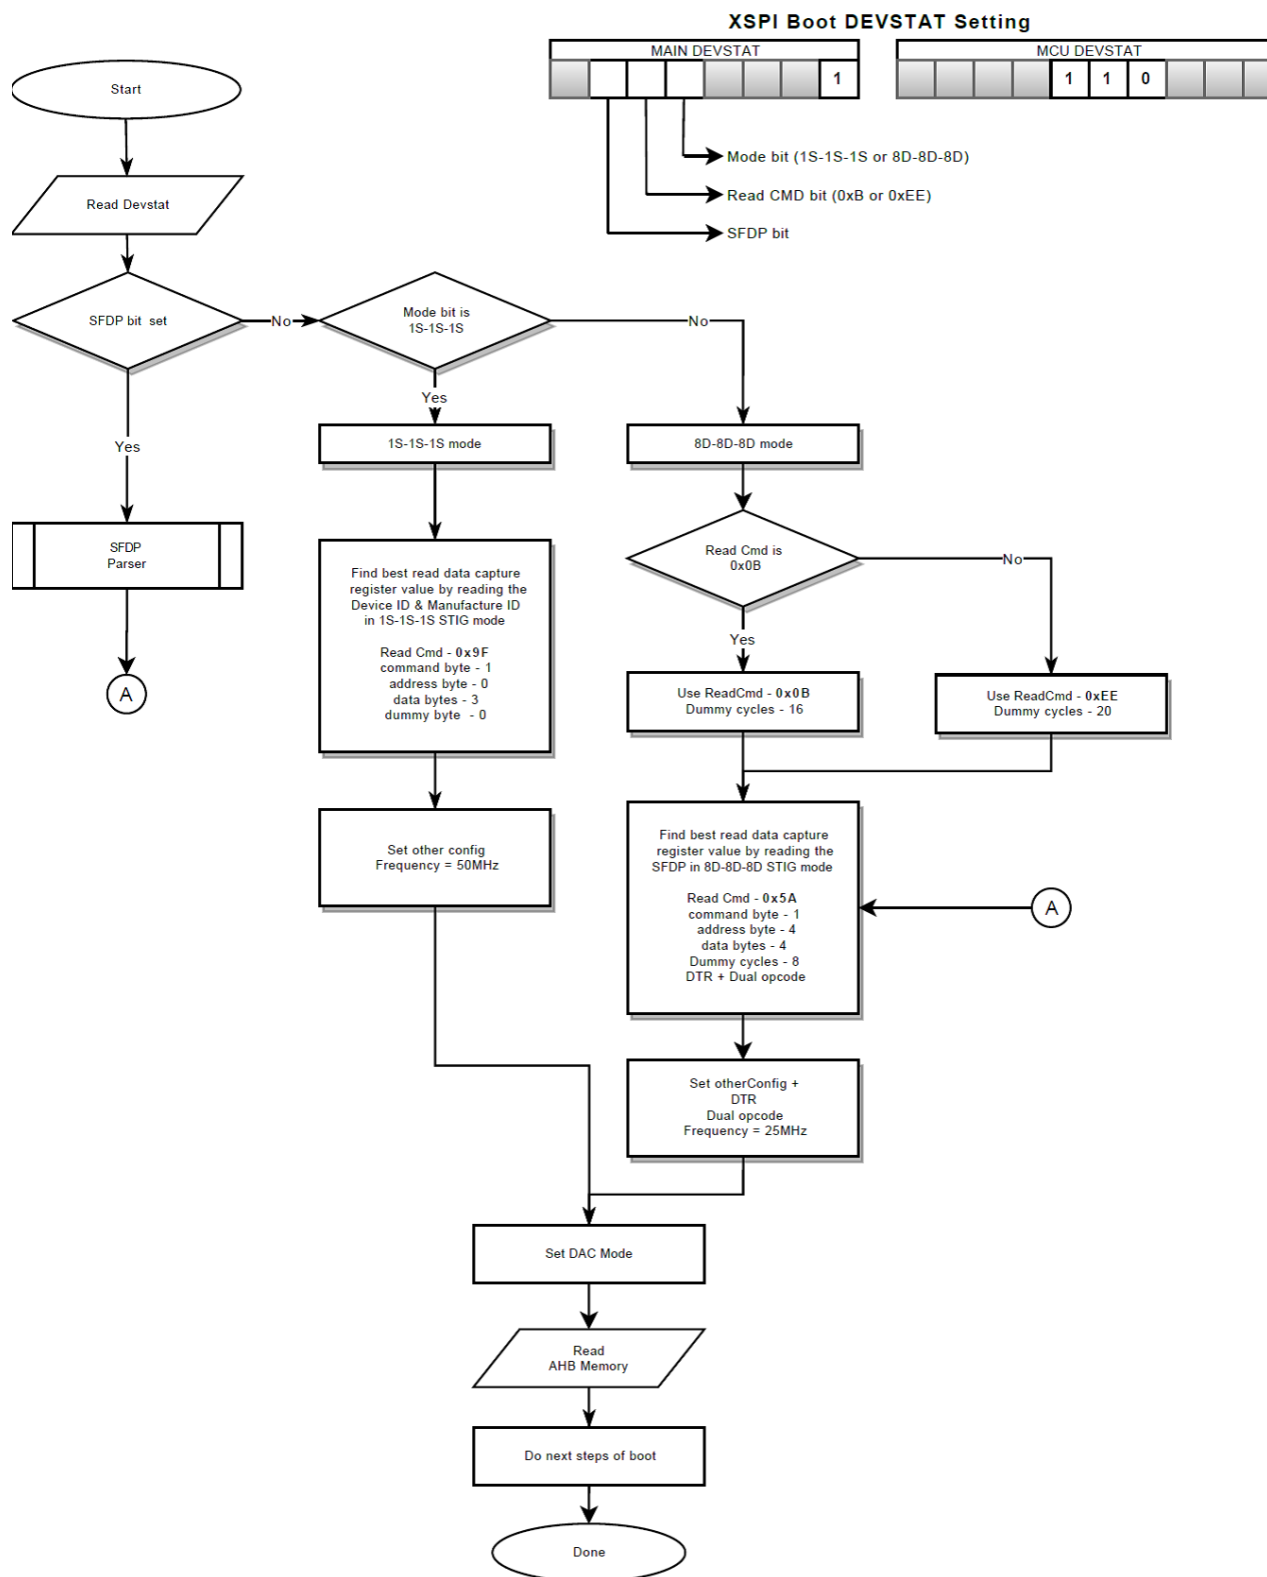

For 1S-1S-1S mode of operation, the ROM will issue a Fast Read Output command (0x0B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The frequency of operation is 50 MHz.

For 8D-8D-8D mode of operation, the ROM will issue a Fast Read command (0x0B or 0xEE, depending on BOOTMODE signal), followed by a 32 bit (4 byte) address (the starting address is all zeros). The frequency of operation is 25 MHz.

When SFDP is enabled using a BOOTMODE signal, the ROM starts operation in 1S-1S-1S mode reads SFDP header from flash memory to get 8D-8D-8D switching sequence, Read Command, CMD Extension and Byte Order. SFDP parsing of ROM is described below and on successful parsing ROM will issue 8D-8D-8D command

switching sequence and then will read the boot image in 8D-8D-8D mode with read command specified in SFDP header

**Figure 5-5. xSPI Flow Chart**

**Figure 5-6. ROM SFDP Parser Flow**

#### 5.4.1.3 Fast-xSPI Boot Mode Configuration

The Fast-xSPI boot mode is an extension of the xSPI boot mode where the OSPI PHY will be tuned in order to set the frequency of operation to 100MHz for 8D-8D-8D mode. Flash needs to support SFDP.

To support Fast-xSPI boot, ROM expects the tuning configuration in the last sector of flash which is determined by the flash device configuration. Absence of the configuration will cause ROM to switch the non-PHY based/standard xSPI boot.

ROM will get the flash memory density (flash memory size **S**) and largest erase sector size (**E** bytes) from the BFPT table and calculates the beginning of last sector as E bytes from the end of flash. We call this location as start of the configuration data (**C0 = S - E**)

#### Supported Configurations:

1. ROM will support online PHY tuning as specified by the search bounds in the configuration data
2. ROM will support offline PHY tuning as specified by the delays in the configuration data

Selection between the two configurations is through magic words defined by ROM.

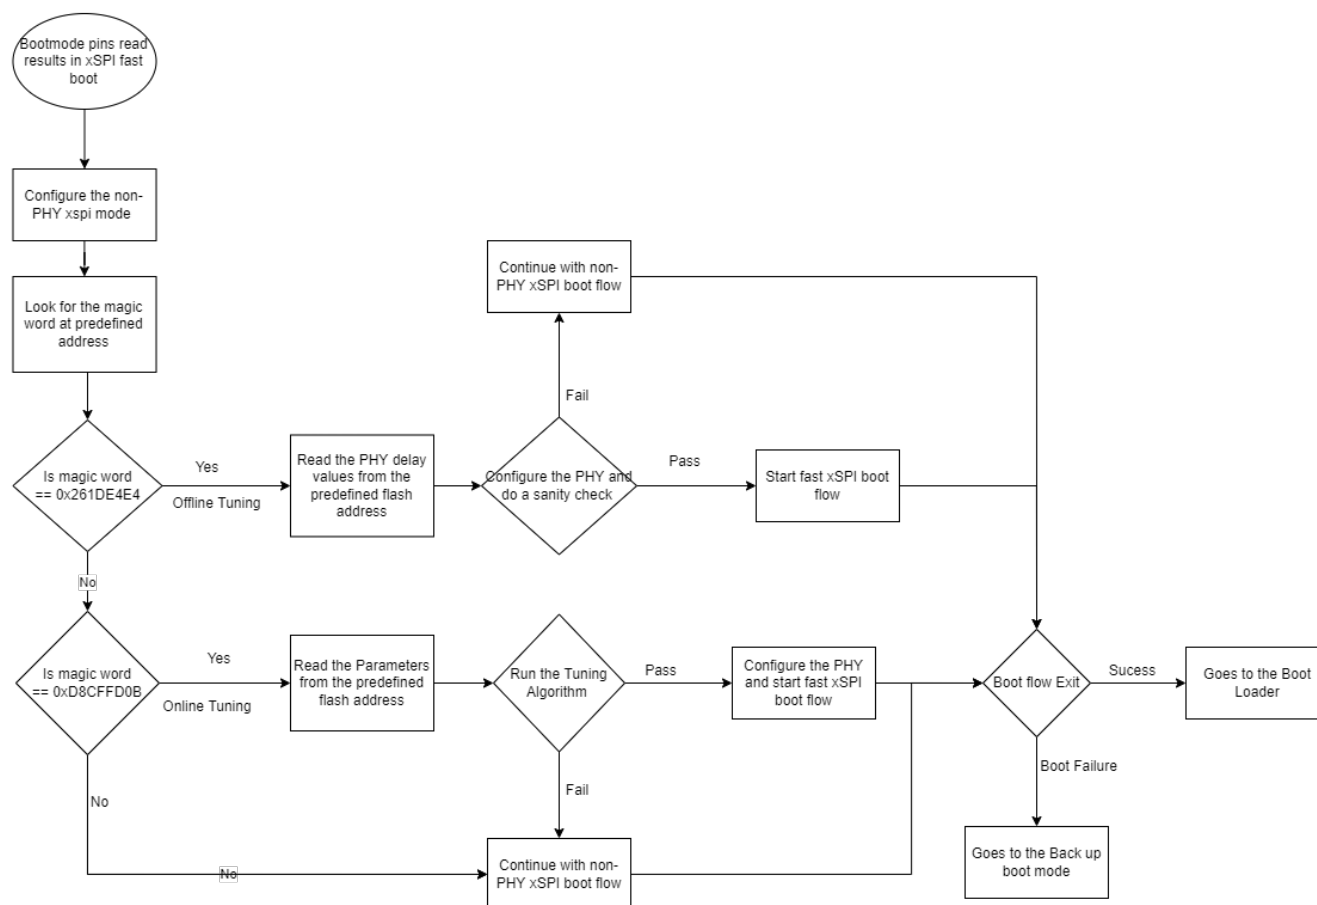

Figure 5-7. Fast-xSPI Control Flow

Table 5-10. Configuration Data for Fast-xSPI Boot

Offset from C0	Bitfields	Description
0 to 127	All	128 byte calibration pattern
128 to 131	All	4 byte Magic Word (defined by ROM). There are two distinct magic words to indicate <ul style="list-style-type: none"> <li>Offline tuning - 0x261DE4E4               <ul style="list-style-type: none"> <li>byte 128 - E4, 129 - E4, 130 - 1D, 131 - 26</li> </ul> </li> <li>Online tuning - 0xD8CFFD0B               <ul style="list-style-type: none"> <li>byte 128 - 0B, 129 - FD, 130 - CF, 131 - D8</li> </ul> </li> </ul> The magic word is stored in little endian format. Absence of the magic word leads the ROM use the non-PHY mode.
132 to 135	All	4 byte unsigned int for clock frequency. Only 100Mhz is currently supported. ROM operates at 20 dummy cycles, so the flash should support the chosen frequency at 20 dummy cycles. The clock frequency is stored in little endian format. Any unknown clk freq leads ROM to the non-PHY mode. eg: <ul style="list-style-type: none"> <li>100Mhz - 100000000 - 0x5F5E100</li> </ul> byte 132 - 00, 133 - E1, 134 - F5, 135 - 05

**Table 5-10. Configuration Data for Fast-xSPI Boot (continued)**

Offset from C0	Bitfields	Description
136	7:0	Flash Parameter Table version 0x00 or 0xFF - Parameter Table version 0 ( Not supported for Fast-xSPI boot) 0x01 - Parameter Table version 1 ( Latest version supported for Fast-xSPI boot)
137 to 139	All	3 bytes are reserved must be set to 0xFF
140 to 143		3 bytes for Tx_delay, Rx_delay, Rd_delay and one byte for padding. (Only used in case of offline tuning) Byte 143 - Padding must be set to 0xFF.
144 to 158		15 parameters (one byte each) (Only used in case of online tuning)
159	0	Determines if the master delay line locks on a full cycle or half cycle of delay. 0 - Full cycle of Delay 1 - Half cycle of Delay
159	1	DLL bypass mode control Controls the bypass mode of the master and slave DLLs 0 - Master Operation mode 1 - Bypass mode
159	4:2	DLL Phase Detect Selector for sampling clock generation to handle the clock domain crossing between the reference clock and sampling clock. Selects the number of delay elements to be inserted between the phase detect flip-flops: 3'b000 = One delay element 3'b001 = Two delay element 3'b010 = Three delay element 3'b011 = Four delay element 3'b100 = Five delay element 3'b101 = Six delay element 3'b110 = Seven delay element 3'b111 = Eight delay element
159	7:5	Reserved
160	7:0	Secondary search offset: To ensure the search point is valid, we try to do a secondary search. Value provided in this field will be used as an offset which is added to the primary search point TxDLL and then Secondary search is performed from offsetted TxDLL point. Supports value from 0 to 127
161		DLL Lock Timeout flag For non-zero flag value, calculated values of DllLockErrCnt and LoopbackLockErrCnt are ignored and 0 is returned instead.
162 to 163		DLL Lock Timeout value in $\mu$ s.

**Table 5-11. Offline Tuning Parameters**

Parameters	Offset from C0
Tx_delay	byte 140
Rx_delay	byte 141
Rd_delay	byte 142

**Table 5-11. Offline Tuning Parameters (continued)**

Parameters	Offset from C0
0xFF (Padding)	byte 143
DLL Config parameter	byte 159
DLL lock timeout flag	byte 161
DLL lock timeout value in $\mu$ s	byte 162 and 163

**Table 5-12. Online Tuning Parameters**

Parameters	Offset from C0
Tx_Low_window_start	byte 144
Tx_Low_window_end	byte 145
Tx_High_window_start	byte 146
Tx_High_window_end	byte 147

OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

#### Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

##### 5.4.1.4.1 QSPI Bootloader Operation

Please refer to [Section 5.4.1](#) for more information that applies to QSPI boot mode

The QSPI boot mode supports the 1S-1S-4S mode only. The ROM will issue a Fast Read Quad Output command (0x6B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The flash device should then respond with 4-bit data. The frequency of operation during the quad read portion is 50 MHz.

##### 5.4.1.4.1.1 QSPI Initialization Process

In the QSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the QSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See [Section 5.4.1.4, QSPI Boot Device Configuration](#) for OSPI port settings.

A detailed summary of the QSPI boot parameter table and the boot configuration definitions are listed in [Section 5.6.3, QSPI Boot Parameter Table](#).

##### 5.4.1.4.1.2 QSPI Loading Process

QSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

#### 5.4.1.5 SPI Boot

Table 5-18 shows configuration pins assignment to functions when boot mode is SPI using the OSPI module.

**Table 5-18. SPI Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description
8	Mode	0	SPI Mode 0
		1	SPI Mode 3
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-19 summarizes the OSPI pin configuration done by ROM code for SPI boot device on port 0.

**Table 5-19. SPI Boot Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

#### Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

#### 5.4.1.5.1 SPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to SPI boot mode

The SPI boot mode supports the 1S-1S-1S mode only. The Read Command is 8-bits (0x03) followed by a 24 bit (3 byte) address. There are no dummy cycles issued after the read command. The frequency of operation supported is 6.250 MHz. OSPI0\_D0 will have data transfers **FROM** the processor **TO** the flash device, and OSPI0\_D1 will have data transfers **TO** the processor **FROM** the flash device

##### 5.4.1.5.1.1 SPI Initialization Process

In the SPI boot mode, the ROM Code initializes the OSPI peripheral to SPI mode and the image is read from the flash memory connected to the corresponding OSPI port and chip-select. A detailed summary of the SPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI/QSPI/SPI Boot Parameter Table*. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM.

##### 5.4.1.5.1.2 SPI Loading Process

SPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

## 5.4.2 I2C Boot

[Table 5-20](#) shows configuration pins assignment to functions when boot mode is the I2C mode.

**Table 5-20. I2C Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description
9	Bus reset	0	Hung bus reset attempt after 1 ms
		1	No hung bus reset attempted
7	Address	0	EEPROM's address is 0x50
		1	EEPROM's address is 0x51

The I<sup>2</sup>C bus is considered inactive if the data line is low and clock remains high for the specified timeout time. Recovery consists of driving the clock a stop condition is detected. A stop condition is a transition on the data line from 0 to 1 while the clock line is high. If the clock line is stuck low there is no way to take control of the bus.

[Table 5-21](#) summarizes the I2C pin configuration done by ROM code for I<sup>2</sup>C boot device.

**Table 5-21. I2C Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
I2C0_SCL	I2C0_SCL	Disable	NA	0	Enable	0	PADCONFIG120
I2C0_SDA	I2C0_SDA	Disable	NA	0	Enable	0	PADCONFIG121

### 5.4.2.1 I2C Bootloader Operation

#### 5.4.2.1.1 I2C Initialization Process

In the I2C boot mode, the ROM Code configures the Main Domain I2C0 in controller mode.

The boot controller drives the I<sup>2</sup>C target device where the image is stored. The image is copied to internal RAM, and is executed from there. If the image is not recognized, the ROM will attempt to read the image at offset 0x8000. This is the only redundant image supported by the ROM.

A detailed summary of the I<sup>2</sup>C boot parameter table and the BOOTMODE pins definitions are listed in [Section 5.6.5, I2C Boot Parameter Table](#) and [Section 5.4.2, I2C Boot Device Configuration](#).

##### 5.4.2.1.1.1 Block Size

ROM code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros.

##### 5.4.2.1.1.2 Addressing

The boot code does not support byte address to bus address wrapping. So the maximum image size that can be access is 64 kbytes. For example, if the read address is 0xFF00, the read size is 0x200 and the I<sup>2</sup>C bus address is 0x50, then 0x100 bytes will be read from 0xFF00 at bus address 0x50, followed by 0x100 bytes from 0x0000 at bus address 0x50. The bus address does not increment when the address rolls over.

##### 5.4.2.1.2 I2C Loading Process

#### 5.4.2.1.2.1 Loading a Boot Image From EEPROM

In this mode, the Main Domain I2C0 peripheral is configured as I<sup>2</sup>C controller.

ROM Code will start reading from the I<sup>2</sup>C EEPROM at the specified I<sup>2</sup>C bus address. This read will be done beginning at the specified base address offset. Data will be read in 2-KB chunks. The data will be stored at the address specified in the boot header. It will continue reading image data until a complete image has been read. When the complete image has been read, the ROM Code will branch to the start address of the image.

### 5.4.3 SD Card Boot

Table 5-22 shows configuration pins assignment to functions when boot mode is the SD card boot mode.

**Table 5-22. SD Card Boot Configuration Fields**

SD Card Boot Configuration Fields			
BOOTMODE Pins	Field	Value	Description
9 (13 <sup>(1)</sup> )	Port	0	Reserved
		1	MMC Port 1 (4 bit width). This bit must be set to 1
7	FS/Raw	0	Filesystem mode
		1	Raw Mode

(1) When MMCSD is the backup mode.

Table 5-23 summarizes the MMCSD pin configuration done by ROM code for SD Card boot on port1 (MMCSD1). SD Card boot on Port 0 (MMCSD0) is not supported.

**Table 5-23. SD Card (MMCSD1) Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
MMC1_DAT3	MMC1_DAT3	Disable	NA	0	Enable	0	PADCONFIG137
MMC1_DAT2	MMC1_DAT2	Disable	NA	0	Enable	0	PADCONFIG138
MMC1_DAT1	MMC1_DAT1	Disable	NA	0	Enable	0	PADCONFIG139
MMC1_DAT0	MMC1_DAT0	Disable	NA	0	Enable	0	PADCONFIG140
MMC1_CLK	MMC1_CLK	Disable	NA	0	Enable	0	PADCONFIG141
MMC1_CLKLB	MMC1_CLKLB	Disable	NA	0	Enable	0	PADCONFIG142
MMC1_CMD	MMC1_CMD	Disable	NA	0	Enable	0	PADCONFIG143
MMC1_SDCD	MMC1_SDCD	Disable	NA	0	Enable	0	PADCONFIG144

#### Note

MMC1\_CLKLB signal is not pinned out on the device. The pinmux configuration enables the input buffer of the internal loopback clock.

#### Note

MMC1\_SDWP is not configured by ROM since the ROM never writes to the SD card.

#### 5.4.3.1 SD Card Bootloader Operation

SD Card boot is only available on Port 1 of the MMCSD controller (MMCSD1). The ROM will boot from SD cards using one of these methods:

- User Data Area (UDA) in raw mode
- User Data Area (UDA) in filesystem mode

The ROM is capable of booting from any size SD card because the MMCSD controller is responsible for addressing. Only single data rate with backward compatible interface timing is supported.

The MMCSD module depends on proper voltage level on the SD card detect signal (SDCD). If SDCD=1, the ROM will assume the card is not present and will fail the boot mode. The SDCD must be 0 for the ROM to continue to attempt to boot. Card detect using DAT3 is not supported. If the card is detected, the initial discovery phase is performed:

1. Send CMD 0. (GO IDLE, both for MMC and SD)
2. Send CMD 55. If the card responds then the card type is assumed to be SD. On timeout the code sends CMD 1. If there is a response then the card type is MMC.

The ROM Code will start reading from the MMCSD memory boot sector, or filesystem, as specified by the BOOTMODE pin (FS/Raw). Only FAT32 and FAT16 formats are supported in filesystem mode. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. In RAW mode, the ROM supports a redundant image at offset 0x400000 in case the initial image fails to be recognized. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

When SD Card boot is used as a backup boot option, only User Data Area (UDA) in filesystem mode is supported. Raw mode is not supported. Additionally, boot will only occur in 1-bit mode during backup booting.

#### 5.4.4 eMMC Boot

[Table 5-24](#) shows configuration pins assignment to functions when boot mode is the eMMC Boot using a UDA boot mode (BOOTMODE[6:3]=1000b). Note that eMMC Boot using alternate eMMC Boot (BOOTMODE[6:3]=1001b) does not have any extra bootmode configuration fields. See [Section 5.4.4.1](#) for more information.

**Table 5-24. eMMC Boot Configuration Fields (UDA mode)**

eMMC Boot Configuration Fields			
BOOTMODE Pins	Field	Value	Description
9 (13 <sup>(1)</sup> )	Port	0	MMCSDB Port 0 (8 bit width). This bit must be set to 0
		1	Reserved
7	FS/Raw	0	Filesystem mode
		1	Raw Mode

(1) When MMCSDB Boot is the backup mode.

MMC Port 0 has no pin mux because the pins are dedicated.

##### 5.4.4.1 eMMC Bootloader Operation

Booting from an eMMC device is only available on Port 0 of the MMCSDB controller (MMCSDB0). Booting from an eMMC device is not available on Port1 (MMCSDB1)

The ROM will boot from eMMC devices using one of these methods:

- User Data Area (UDA) in raw mode
- User Data Area (UDA) in filesystem mode
- eMMC bootmode (alternate)

To boot from UDA in either raw or filesystem mode, choose bootmode "MMCSDB Boot" (see [Table 5-4](#)).

A special alternate boot mode is available with eMMC devices which allows the ROM to boot from an image that is in a separate boot partition in the eMMC. To boot from this mode, choose "eMMC Boot" (see [Table 5-4](#)).

The ROM Code will start reading from the memory boot sector, or filesystem, as specified by the BOOTMODE pin (FS/Raw). Only FAT32 and FAT16 formats are supported in filesystem mode. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. In RAW mode, the ROM supports a redundant image at offset 0x400000 in case the initial image fails to be recognized. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

When eMMC boot is used as a backup boot option, only User Data Area (UDA) in filesystem mode is supported. Raw mode is not supported. Additionally, boot will only occur in 1-bit mode during backup booting.

### 5.4.5 Ethernet Boot

Table 5-25 shows configuration pins assignment to functions when boot mode is the Ethernet RGMII mode.

**Table 5-25. Ethernet RGMII Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description
9	Clkout	0	Must be set to 0 to choose external clock
		1	Reserved
8	Delay	0	Must be set to 0 for RGMII with internal Tx delay
		1	Reserved
7	Link info	0	MDIO PHY scan used for link parameters.
		1	Link parameters programmed by the ROM

Table 5-26 shows configuration pins assignment to functions when boot mode is the Ethernet RMII mode.

**Table 5-26. Ethernet RMII Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description
9	Clkout	0	50 MHz clock not generated on CLKOUT0
		1	50 MHz clock generated on CLKOUT0
8	Clk src	0	External clock source for RMII1_REF_CLK
		1	Internal clock source for RMII1_REF_CLK
7	RMII	0	This bit must be set to 0
		1	Reserved

**Table 5-27. Ethernet RMII Clocking**

BOOTMODE Pin 9 (Clk out)	BOOTMODE Pin 8 (Clk src)	Description
0	0	50MHz external source to RMII_REF_CLK and to external Ethernet PHY input clock (CLKOUT0 is unused) These are the recommended settings
0	1	Not a valid configuration
1	0	CLKOUT0 is configured to 50MHz and connect to both RMII1_REF_CLK and to external Ethernet PHY input clock
1	1	Not a valid configuration

Table 5-28 shows configuration pins assignment to functions when the backup boot mode Ethernet. The Interface configuration field chooses which interface will be used (RGMII or RMII)

**Table 5-28. Ethernet Backup Boot Configuration Field**

BOOTMODE Pins	Field	Value	Description
13	Interface	0	RGMII with internal TX delay
		1	RMII with external clock source

Table 5-29 summarizes the RGMII pin configuration done by ROM code for Ethernet boot device on RGMII port.

**Table 5-29. RGMII Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
RGMII1_TX_CTL	RGMII1_TX_CTL	Disable	NA	0	Disable	0	PADCONFIG7 5
RGMII1_TXC	RGMII1_TXC	Disable	NA	0	Disable	0	PADCONFIG7 6
RGMII1_TD0	RGMII1_TD0	Disable	NA	0	Disable	0	PADCONFIG7 7

**Table 5-29. RGMII Pin Usage (continued)**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
RGMII1_TD1	RGMII1_TD1	Disable	NA	0	Disable	0	PADCONFIG78
RGMII1_TD2	RGMII1_TD2	Disable	NA	0	Disable	0	PADCONFIG79
RGMII1_TD3	RGMII1_TD3	Disable	NA	0	Disable	0	PADCONFIG80
RGMII1_RX_CTL	RGMII1_RX_CTL	Disable	NA	0	Enable	0	PADCONFIG81
RGMII1_RXC	RGMII1_RXC	Disable	NA	0	Enable	0	PADCONFIG82
RGMII1_RD0	RGMII1_RD0	Disable	NA	0	Enable	0	PADCONFIG83
RGMII1_RD1	RGMII1_RD1	Disable	NA	0	Enable	0	PADCONFIG84
RGMII1_RD2	RGMII1_RD2	Disable	NA	0	Enable	0	PADCONFIG85
RGMII1_RD3	RGMII1_RD3	Disable	NA	0	Enable	0	PADCONFIG86
MDIO0_MDIO	MDIO0_MDIO	Disable	NA	0	Enable	0	PADCONFIG87
MDIO0_MDC	MDIO0_MDC	Disable	NA	0	Disable	0	PADCONFIG88

Table 5-30 summarizes the RMII pin configuration done by ROM code for Ethernet boot device on RMII port.

**Table 5-30. RMII Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
RGMII1_RX_CTL	RMII1_RX_ER	Disable	NA	0	Enable	1	PADCONFIG81
RGMII1_RXC	RMII1_REF_CLK	Disable	NA	0	Enable	1	PADCONFIG82
RGMII1_RD0	RMII1_RXD0	Disable	NA	0	Enable	1	PADCONFIG83
RGMII1_RD1	RMII1_RXD1	Disable	NA	0	Enable	1	PADCONFIG84
RGMII1_TD0	RMII1_TXD0	Disable	NA	0	Disable	1	PADCONFIG77
RGMII1_TD1	RMII1_TXD1	Disable	NA	0	Disable	1	PADCONFIG78
RGMII1_TX_CTL	RMII1_TX_EN	Disable	NA	0	Disable	1	PADCONFIG75
RGMII1_TXC	RMII1_CRS_DV	Disable	NA	0	Enable	1	PADCONFIG76
RGMII1_TD3	CLKOUT0	Disable	NA	0	Disable	1	PADCONFIG_80
MDIO0_MDIO	MDIO0_MDIO	Disable	NA	0	Enable	0	PADCONFIG87
MDIO0_MDC	MDIO0_MDC	Disable	NA	0	Disable	0	PADCONFIG88

#### 5.4.5.1 Ethernet Bootloader Operation

##### 5.4.5.1.1 Ethernet Initialization Process

When the device is set to boot through the Ethernet mode, the ROM Code configures the Ethernet module and the interface mode (RMII, RGMII) according to the BOOTMODE pin settings, see [Section 5.4.5, Ethernet Boot Device Configuration](#). Also consult the boot parameter table for the Ethernet boot, see [Section 5.6.7, Ethernet Boot Parameter Table](#).

When Link Info = 0, the link parameters are read using MDIO scan. This is the typical setting when using an external PHY. With these parameters, the ROM identifies the PHY and establishes link with the supported speed and duplex mode.

When Link Info = 1, no MDIO scan is performed, and the link parameters are programmed by the ROM based on the RGMII status register. This is the typical setting when configured as a MAC to MAC RGMII interface whereby RGMII pins of two devices can be connected directly and establish link in force mode. The chosen configuration will be Gigabit, full duplex mode.

Note that booting from RGMII requires that an attached PHY be configured for RGMII-ID Mode immediately upon exiting reset. The ROM will not make this configuration change to the PHY.

The ROM will setup RGMII mode enabling internal delay mode.

#### **5.4.5.1.2 Ethernet Loading Process**

After device configuration, the bootloader performs a standard BOOTP/TFTP boot. The device sends a BOOTP request with its MAC address to a host TFTP server to be assigned an IP from a pool of addresses. The timeout for each BOOTP packet is 4 seconds, and the ROM will attempt 10 BOOTP retries, after which the boot mode will fail. If the connection is established, the device initiates a TFTP download and is able to receive image data encapsulated in Ethernet packets, see [Section 5.4.5.1.2.1](#). There is a timeout of 1 second to receive a response for the READ request, and the ROM will retry the READ request 10 times, after which the boot mode will fail. If TFTP download is successful, data received is stripped of its network headers and the boot data is stored in internal RAM. When the transfer completes and the image is found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

##### **5.4.5.1.2.1 Ethernet Boot Data Formats**

Ethernet boot uses the BOOTP/TFTP protocol for downloads. Only IPv4 is supported.

##### **5.4.5.1.2.1.1 Limitations**

- Received packets cannot be IP fragmented (should not be a problem in most systems since the BOOTP/TFTP packets have fixed lengths of small size)
- Only DIX Ethernet headers are supported.
  - 802.3 with SNAP/LLC not supported
  - DIX Ethernet with VLAN not supported
  - 802.3 with VLAN and SNAP/LLC not supported

##### **5.4.5.1.2.1.2 BOOTP Request**

##### **5.4.5.1.2.1.2.1 MAC Header (DIX)**

- Destination MAC = value from parameter table (default is broadcast)
- Source MAC = value from parameter table (default is e-fuse value)
- Type = IPv4 (0x0800)

##### **5.4.5.1.2.1.2.2 IPv4 Header**

- Version = 4
- Header length = 0
- TOS = 0
- Len = computed during operation
- ID = 0x0001
- Flags + Fragment offset = 0
- TTL = 0x10
- Protocol = UDP (17)
- Header checksum = Computed during operation
- SRC IP = 0.0.0.0
- Dest IP = 255.255.255.255

##### **5.4.5.1.2.1.2.3 UDP Header**

- Source port = BOOTP client (68 decimal)
- Destination Port = BOOTP server (67 decimal)
- Length = computed during operation

- Checksum = computed during operation

#### **5.4.5.1.2.1.2.4 BOOTP Payload**

- Opcode = Request (1)
- HW Type = Ethernet (1)
- HW Addr Len = 6
- Hop Count = 0
- Transaction ID = 1
- Number of seconds = 0
- Client IP = 0.0.0.0
- Your IP = 0.0.0.0
- Server IP = 0.0.0.0
- Gateway IP = 0.0.0.0
- Client HW Address = Device MAC address (from parameter table)
- Server hostname = NULL
- Filename = NULL
- Option 60, Vendor ID string, from parameter table
- Option 61, Client ID string, from parameter table

#### **5.4.5.1.2.1.2.5 TFTP**

There are no ROM code specific TFTP configurations.

#### **5.4.5.1.3 Ethernet Hand Over Process**

Once the ROM Code receives the valid packet, it decodes it to get the image sections and loads them in the appropriate memory location. After the image is loaded and validated, the ROM Code starts the boot image execution.

### 5.4.6 USB Boot

Table 5-31 shows configuration pins assignment to functions when boot mode is the USB mode.

**Table 5-31. USB Boot Configuration Fields**

USB Configuration Fields for Primary Boot Mode			
BOOTMODE Pins	Field	Value	Description
9	CoreVoltage	0	Must be set
		1	Reserved
8 (13 <sup>(1)</sup> )	Mode	0	DFU (USB device firmware upgrade)
		1	Host (MSC boot)
7	Lane Swap	0	D+/D- lines are not swapped
		1	D+/D- lines are swapped

(1) When USB is the backup mode.

Table 5-32 summarizes the USB pin configuration done by ROM code for USB boot device on port 0.

**Table 5-32. USB Port 0 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
USB0_DRVVBUS	USB0_DRVVBUS	Disable	NA	0	Disable	0	PADCONFIG149

#### Note

Note that other USB pins do not have pin mux options. USB\_DRVVBUS is configured in DFU mode even though it is not used.

Note on USB backup boot:

- Lane Swap (D+/D- lines) are not allowed

Configurability (pins) of these options do not exist in the USB backup boot mode.

#### CAUTION

A USB Type-AB connector should not be connected to another host when the device is booting as a USB Host. This will prevent two USB power sources from being connected together.

#### 5.4.6.1 USB Bootloader Operation

The USB boot mode is used to read the boot image from external USB host.

See Section 5.4.6, *USB Boot Device Configuration* and Section 5.6.10, *USB Boot Parameter Table* for the available configuration options.

More information about USB DFU protocol can be found at [http://www.usb.org/sites/default/files/DFU\\_1.1.pdf](http://www.usb.org/sites/default/files/DFU_1.1.pdf).

In DFU mode, the ROM will attempt an enumeration for 60 seconds, after which the boot mode will fail. If a successful enumeration is achieved, the ROM Code will start reading from the external host as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

##### 5.4.6.1.1 USB-Specific Attributes

##### 5.4.6.1.1.1 DFU Device Mode

- Vendor ID = 0x451
- Product ID = 0x6165
- Device ID = 0

### 5.4.7 UART Boot

ROM Code always configures the UART port to 115200 kbaud, 8-n-1 mode, and the XMODEM protocol is used to transfer the boot data.

[Table 5-33](#) summarizes the UART pin configuration done by ROM code for UART host on port 0.

**Table 5-33. UART Port 0 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
UART0_TXD	UART0_TXD	Disable	NA	0	Disable	0	PADCONFIG115
UART0_RXD	UART0_RXD	Disable	NA	0	Enable	0	PADCONFIG114

#### 5.4.7.1 UART Bootloader Operation

##### 5.4.7.1.1 Initialization Process

In the UART boot mode, the selected UART module (port) is the only peripheral configured. The baud rate, data, parity, and stop bits are configured based on the information in the UART boot parameter table. The boot parameter table definitions and the boot configuration values that can be set are in [Section 5.4.7, UART Boot Device Configuration](#) and [Section 5.6.4, UART Boot Parameter Table](#).

Once the ROM Code configures the UART, it sends the UART pings for few seconds, which can be seen in the host. The pings consist of an ASCII capital C character. The UART boot mode supports only the CRC mode of XMODEM and does not support CHECKSUM mode. Both 128 and 1024 byte block sizes are supported.

##### 5.4.7.1.2 UART Loading Process

Before the ping from the device stops, load the boot image from the host using the XMODEM protocol. Until UART boot data is sent from the host, the ROM code will continue to send pings for 120 seconds before aborting and moving to the secondary boot mode (if applicable).

#### Note

The device also implements a separate 180 watchdog timer. If UART boot is the primary boot mode, and no secondary boot mode is selected, the subsequent UART boot will timeout after 60sec due to the watchdog timer.

##### 5.4.7.1.2.1 UART XMODEM

The XMODEM protocol is used to transfer boot data. Only CRC mode is supported (not checksum), with both 128- and 1024-byte block sizes. The general, format of received frames is shown in [Table 5-34](#) and [Table 5-35](#).

**Table 5-34. XMODEM 1024- and 128-byte Data Frames**

STX	Block Num	Inv Block Num	1024 data bytes			CRC	CRC
SOH	Block Num	Inv Block Num	128 data bytes	CRC	CRC		

**Table 5-35. XMODEM Data Frame Fields**

Field	Value	Description
STX	0x02	The start character for 1024-byte CRC data blocks
SOH	0x01	The start character for 128-byte CRC data block
Block Num	0x01-0xFF – 0x00	The block number. The first block has value 1, and the block number wraps around 0xFF to 0
Inv Block Num	0xFE-0x00	The inverse block number (bit inverse of the block number)
CRC	Calculated	The 16-bit CRC generated from the polynomial 0x1021

The XMODEM protocol is implemented as a half-duplex protocol as shown in [Table 5-36](#).

**Table 5-36. Example of XMODEM Transfer protocol**

Transmitter Sends		Receiver Sends
	←	Ping ('C')
Frame 1	→	
	←	ACK (or NACK)
Frame 2	→	
	←	ACK (or NACK)
EOT	→	
	←	ACK (or NACK)

#### 5.4.7.1.3 UART Hand-Over Process

Once the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

### 5.4.8 GPMC NOR Boot

There are no configuration fields for this boot mode. GPMC NOR boot only supports 16-bit non-mux memory.

[Table 5-37](#) summarizes the GPMC pin configuration done by ROM code for GPMC NOR boot.

**Table 5-37. GPMC NOR Boot Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_AD0	GPMC0_AD0	Disable	NA	0	Enable	0	PADCONFIG15
GPMC0_AD1	GPMC0_AD1	Disable	NA	0	Enable	0	PADCONFIG16
GPMC0_AD2	GPMC0_AD2	Disable	NA	0	Enable	0	PADCONFIG17
GPMC0_AD3	GPMC0_AD3	Disable	NA	0	Enable	0	PADCONFIG18

GPMC0_OE <sub>n</sub> _REN	GPMC0_OE <sub>n</sub> _Ren	Disable	NA	0	Disable	0	PADCONFIG34
GPMC0_WEN	GPMC0_WEN	Disable	NA	0	Disable	0	PADCONFIG35

**Table 5-37. GPMC NOR Boot Pin Usage (continued)**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_BE0n_CLE	GPMC0_BE0n_CLE	Disable	NA	0	Disable	0	PADCONFIG36
GPMC0_BE1n	GPMC0_BE1n	Disable	NA	0	Disable	0	PADCONFIG37
GPMC0_CSn0	GPMC0_CSn0	Disable	NA	0	Disable	0	PADCONFIG42

**Note**

Only 21 address lines (GPMC0\_A0 – GPMC0\_A20) are used because the GPMC0\_A21 and GPMC0\_A22 lines are muxed with GPMC0\_WAIT1 and GPMC0\_WPn respectively.

GPMC0\_A20 is muxed with GPMC0\_CSn3, and ROM uses GPMC0\_A20 for this address line. Thus, no CSn3 support when using GPMC NOR boot.

All signals in the table will be configured even though some may not be used by this particular boot mode.

**5.4.8.1 GPMC NOR Bootloader Operation**

In this mode, the ROM Code configures the GPMC interface based on the configuration parameters specified in the boot parameter table for the GPMC NOR boot mode [Section 5.6.11](#), see *GPMC NOR Boot Parameter Table*.

Timing registers are programmed as follows for NOR flash boot:

**Table 5-38. GPMC NOR Timing Configuration**

GPMC register	Value
GPMC_CONFIG1	0x00001010
GPMC_CONFIG2	0x00101c01
GPMC_CONFIG3	0x23060917
GPMC_CONFIG4	0x1005bc1a
GPMC_CONFIG5	0x011b111e
GPMC_CONFIG6	0x8f070000
GPMC_CONFIG7	0x00000c50

GPMC NOR boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it. Only non-muxed memory is supported. If the initial image at offset 0x0 is not recognized, the ROM will attempt to read a redundant image from offset 0x100000. This is the only redundant image supported by the ROM.

### 5.4.9 GPMC NAND Boot

Table 5-39 summarizes the GPMC pin configuration done by ROM code for NAND boot.

**Table 5-39. GPMC NAND Boot Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_AD0	GPMC0_AD0	Disable	NA	0	Enable	0	PADCONFIG15
GPMC0_AD1	GPMC0_AD1	Disable	NA	0	Enable	0	PADCONFIG16
GPMC0_AD2	GPMC0_AD2	Disable	NA	0	Enable	0	PADCONFIG17
GPMC0_AD3	GPMC0_AD3	Disable	NA	0	Enable	0	PADCONFIG18
GPMC0_AD4	GPMC0_AD4	Disable	NA	0	Enable	0	PADCONFIG19
GPMC0_AD5	GPMC0_AD5	Disable	NA	0	Enable	0	PADCONFIG20
GPMC0_AD6	GPMC0_AD6	Disable	NA	0	Enable	0	PADCONFIG21
GPMC0_AD7	GPMC0_AD7	Disable	NA	0	Enable	0	PADCONFIG22
GPMC0_ADVn_ALE	GPMC0_ADVn_ALE	Disable	NA	0	Disable	0	PADCONFIG33
GPMC0_OEn_Ren	GPMC0_OEn_Ren	Disable	NA	0	Disable	0	PADCONFIG34
GPMC0_Wen	GPMC0_Wen	Disable	NA	0	Disable	0	PADCONFIG35
GPMC0_BEOn_CLE	GPMC0_BEOn_CLE	Disable	NA	0	Disable	0	PADCONFIG36
GPMC0_WAIT0	GPMC0_WAIT0	Disable	NA	0	Enable	0	PADCONFIG38
GPMC0_CSn0	GPMC0_CSn0	Disable	NA	0	Disable	0	PADCONFIG42

#### 5.4.9.1 GPMC NAND Bootloader Operation

Timing registers are programmed as follows for NAND flash boot:

**Table 5-40. GPMC NAND Timing Configuration**

GPMC register	Value
GPMC_CONFIG1	0x00000812
GPMC_CONFIG2	0x00080b00
GPMC_CONFIG3	0x22080810
GPMC_CONFIG4	0x05006890
GPMC_CONFIG5	0x0107080b
GPMC_CONFIG6	0x80000180
GPMC_CONFIG7	0x00000f50

GPMC NAND boot only supports boot from ONFI 1.0 compatible 8 bit parallel NAND memory up to 2Gbytes in size connected to GPMC CS0 with the following geometries:

- 2Kbyte page and spare area of at least 64 bytes or
- 4Kbyte page size and spare area of at least 128 bytes.
- Non-ECC part only:
  - ROM uses ELM to handle ECC
  - ECC is BCH8 using D[7:0] for data
  - The param page CRC is checked and in case of failure the redundant page is used

GPMC is setup to comply with mode 0 timing for NAND flash.

### 5.4.10 Serial NAND Boot

Serial NAND Configuration Fields table shows configuration pins assignment to functions when boot mode is Serial NAND.

**Table 5-41. Serial NAND Configuration Fields**

BOOTMODE Pins	Field	Value	Description
8	Read Mode 2	0	Reserved (Read mode is taken from Read Mode 1
		1	SPI/ 1-1-1 mode (Read mode is taken from Read Mode 2 and Read Mode 1 is ignored)
7	Read Mode 1	0	OSPI/ 1-1-8 Mode (valid only when Read Mode 2 is 0)
		1	OSPI/ 1-1-4 Mode (valid only when Read Mode 2 is 0)

Serial NAND Pin Usage table summarizes the pin configuration done by ROM code for the Serial NAND device.

**Table 5-42. Serial NAND Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

#### Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

#### 5.4.10.1 Serial NAND Bootloader Operation

Serial NAND defines 1S-1S-1S mode for general backwards compatibility, and 1S-1S-8S for maximum throughput (S here means \*S\*ingle Data rate). Serial NAND memory array is organized into pages of size 2KB/4KB. Read is a two-step process where a complete page is first read into flash's internal buffer/cache using Page read command and then the host controller reads from internal buffer in 1- or 4- or 8-bit mode using the read commands. Page read command that is issued is 0x13, followed by 24 address bits. The frequency of operation supported is 50 MHz.

For 1S-1S-1S mode of operation (Bit-width =1, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x0B, followed by address bits and 8 dummy cycles.

For 1S-1S-8S mode of operation (Bit-width =8, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x8B, followed by address bits and 8 dummy cycles. Additionally, flash is configured in 8-bit mode after POR through volatile configuration register if the manufacturer is Winbond.

For 1S-1S-4S mode of operation (Bit-width =4, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x6B, followed by address bits and 8 dummy cycles. Note that in 8-bit mode pin mux is done for all 8 OSPI data lines and in 4-bit/1-bit mode pin mux is done for 4 OSPI data lines. This is done to disable the HOLD functionality feature in 1-bit mode.

Serial NAND boot expects ECC to be auto-managed by the flash. Most of the flashes have the ECC enabled by default and can do 1-bit correction and 2-bit detection for ECC errors. ROM checks for 2-bit ECC error via status register 3 (address 0xC0) bit 5 after every page load. In case of 2-bit ECC error the boot will fail and ROM will take the fallback option.

Serial NAND boot also manages bad blocks that can be present in the flash at time of shipment or develop during the lifetime. Bad block marker is a non-FFh data byte stored at Byte 0 of spare area of Page 0 for each bad block and ROM checks for the same while reading the first page of a memory block. ROM will skip the particular block if it is marked as bad and move to the next one.

The Serial NAND driver in ROM does not support devices that have multiple planes as they require special handling to read even numbered blocks

#### **5.4.10.2 Serial NAND Initialization Process**

In the OSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the OSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See [Section 5.4.1.1, OSPI Boot Device Configuration](#) for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in [Section 5.6.3, OSPI Boot Parameter Table](#).

#### **5.4.10.3 Serial NAND Loading Process**

OSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

### 5.4.11 No boot/Development boot

Table 5-43 shows configuration pins assignment to functions when boot mode is the No-boot mode.

**Table 5-43. No-boot/Dev-boot Configuration Fields**

Field	Value	Description
No/Dev	0	Development Boot
	1	No boot
ARM/Thumb	0	ARM mode
	1	Thumb mode

These boot modes are useful for debugging purposes to preclude the execution of the ROM.

During the Development boot (BOOTMODE[7] = 0), the SMS M4F ROM code will act as if boot of the primary image has completed, and the SMS M4F ROM then will be waiting for a firmware load message from DM R5. Thus the user can load a standard u-boot/SPL image to the DM R5 RAM. U-boot/SPL will then load the SMS firmware and complete the full boot.

In No-boot (BOOTMODE[7] = 1), both the SMS M4F and DM R5 ROMs are bypassed and both CPUs are held in a dummy branch-to-self loop. No-boot is the most minimal device touch state by the ROM - only minimal hardware configurations are done and none of the PLLs is locked/configured. No-boot is suitable if user wants to load his own PLL, Pad config, and other basic settings.

## 5.5 PLL Configuration

ROM code must be aware of the reference clock provided to PLLs. That is, the speed of the quartz crystal, or the clock supplied by an external clock oscillator. On how to indicate the PLL reference clock, see [PLL Reference Clock Selection](#)

ROM code configures only PLLs which are required during boot. Therefore, if a PLL is required for the backup boot mode but not the primary boot mode, and if the backup boot mode never executes, then the PLLs required for backup boot are not enabled.

The following tables show the HSDIV values that are programmed by the R5 ROM if a boot mode uses it. A value of NA means that the ROM does not program that HSDIV

**Table 5-44. MAIN\_PLL0 (MAIN PLL) (2000MHz)**

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	4	500	MAIN SYSCLK0
0	HSDIV1	10	200	OSPI
0	HSDIV2	0	NA	WKUP_CLKOUT
0	HSDIV3	15	133	GPMC NOR/GPMC NAND
0	HSDIV4	0	NA	MCAN
1	HSDIV5	5	200	eMMC0
1	HSDIV6	0	NA	CPTS
1	HSDIV7	4	250	TIMER
1	HSDIV8	0	NA	USB0
1	HSDIV9	0	NA	PRUSS-M

**Table 5-45. MAIN\_PLL1 (PER0 PLL) (1920MHz)**

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	10	192	UART
0	HSDIV1	12	160	UART
0	HSDIV2	0	NA	WKUP_CLKOUT
0	HSDIV3	0	NA	TIMER
0	HSDIV4	0	NA	Reserved
1	HSDIV5	0	NA	OSPI
1	HSDIV6	0	NA	McASP

**Table 5-46. MAIN\_PLL2 (PER1 PLL) (2000MHz)**

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	0	NA	PRUSS-M core
0	HSDIV1	8	250	CP_GEMAC
0	HSDIV2	10	200	eMMC1
0	HSDIV3	0	NA	DebugSS
0	HSDIV4	0	NA	GPU
1	HSDIV5	0	NA	PRUSS-M IEP
1	HSDIV6	0	NA	TIMER
1	HSDIV7	0	NA	GPMC
1	HSDIV8	0	NA	McASP
1	HSDIV9	0	NA	WKUP_CLKOUT

**Table 5-47. MAIN\_PLL15 (2400MHz)**

HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
HSDIV0	5	400	HSM/SMS
HSDIV1	5	400	SA3_UL PKA
HSDIV5	3	800	DM

---

**Note**

All other PLLs are not used or programmed by the ROM

---

---

**Note**

The bringup and configuration of bootmode-specific PLLs by ROM code will result in a bootmode-specific device clocking setup which for example has an impact on which peripheral modules can readily be clocked and used by SBL/SPL prior to loading and bringing up System Firmware (SYSFW)

---

## 5.6 Boot Parameter Tables

The boot parameter tables direct the main module boot process. On cold boot the tables are created based on pin strapped values (see [Section 5.3, Boot Mode Pins](#)) and built-in data. The ROM Code supports two parameter tables stored as an array in a fixed memory address in the MSRAM, each of size 512 bytes. The ROM will attempt to boot using the primary table. On boot failure, ROM Code will retry using the second table.

Using two tables handles two cases.

- The first is in initial board manufacture where the primary boot table specifies boot from a flash device, and the flash is blank. ROM Code would then switch to the secondary boot mode which would receive the image externally (Ethernet, USB, UART) and this image would flash the boot image.
- The second case is failure due to total flash corruption. In all flash parameter tables there exist backup addresses within the primary boot mode. This covers the problem of a flash update failure with a backup image present on the same flash device.

The boot tables reside at a fixed location in memory which is described in [Section 5.8.2, Global Memory Addresses Used by ROM Code](#).

### 5.6.1 Common Header

These boot parameter tables have certain parameters common across all the boot modes, while the rest of the parameters are unique to the boot modes. The common entries in the boot parameter table are shown in [Table 5-48](#).

**Table 5-48. Boot Parameter Table Common Header**

Byte Offset	Size (bytes)	Name	Description
0	2	Length	The length of the table
2	2	Checksum	Ones complement checksum over length bytes in the table. If 0 the checksum is not validated.
4	2	Peripheral	Identifies the boot peripheral and format of the table after the common header. See <a href="#">Table 5-49</a>
6	2	Reserved	Reserved
8	4	Timeout	Timeout for this boot mode, in milliseconds
12	4	Magic	Magic value 0x01AD0911
16	40	PLL Config 0	PLL Configuration 0. See <a href="#">Table 5-50</a>
56	40	PLL Config 1	PLL Configuration 1
96	40	PLL Config 2	PLL Configuration 2
136	40	PLL Config 3	PLL Configuration 3
176	40	PLL Config 4	PLL Configuration 4
216	40	PLL Config 5	PLL Configuration 5

[Table 5-49](#) lists the possible boot modes used in the boot parameter tables.

**Table 5-49. Boot Peripheral Selection**

Peripheral Field Value	Description
0	Sleep (No boot)
10	Ethernet Reserved
20	Ethernet BOOTP/TFTP (general)
21	Ethernet RGMII specific
22	Ethernet RMII specific
30	Reserved
31	Reserved
32	Reserved
40	I2C

**Table 5-49. Boot Peripheral Selection (continued)**

Peripheral Field Value	Description
50	SPI
60	UART
70	USB DFU
71	USB Reserved
72	USB Host MSC
80	QSPI
85	OSPI
90	Reserved
100	MMCSD Card (general)
101	eMMC (general)
102	MMC 1-bit
103	MMC 4-bit
104	MMC 8-bit
110	GPMC NOR
120	Reserved
130	xSPI
140	GPMC NAND
150	Serial NAND
160	Fast-xSPI

### 5.6.2 PLL Setup

Table 5-50 through Table 5-54 describe the PLL configuration fields.

**Table 5-50. Boot Parameter Table PLL Configuration**

Byte Offset	Size (bytes)	Name	Description
0	1	Domain/cfg	See Table 5-51
1	1	PLL number	PLL number indexed from 0.
2	1	Input source	See Table 5-53
3	1	PLL Type	This field must be 1 to indicate an SCPLL
4	4	Input Ref Clock	The PLL input clock, in Q16.16 format
8	4	Feed back divider, integer part	Integer value of feedback divider
12	4	Feed back divider, fractional part	Fractional portion of feedback divider. Total divider is the Integer part + (Fractional part / 2 <sup>24</sup> )
16	1	Ref divider	Input clock pre-divider
17	1	Post divider 1	Output post divider 1
18	1	Post divider 2	Output post divider 2
19	1	Reserved	Reserved
20	2	Hsdiv Enable	Bit map. A set bit indicates that the corresponding hsdiv is enabled.
22	2	Reserved	Reserved
24	16	Hsdiv[16]	Array of hs divider values.

**Table 5-51. PLL Domain and Enable Configuration**

7	6	5	4	3	2	1	0
Reserved		Enable		Reserved			Domain

**Table 5-52. PLL Domain and Enable Field Description**

Field	Value	Description
Enable	0	PLL not configured
	1	PLL enabled only if currently disabled or in bypass
	2	PLL is unconditionally enabled. If currently enabled with a different configuration the PLL is first disabled
	3	PLL is unconditionally disabled
Domain	0	PLL is in the MCU domain
	1	PLL is in the MAIN domain

**Table 5-53. PLL Reference Source Bit Fields**

7	6	5	4	3	2	1	0
Source Type				Source Index			

**Table 5-54. PLL Reference Source Field Description**

Field	Value	Description
Source Type	0	Source is HFOSC
	1	Source is external pin
	2	Reserved
	3-7	Reserved
Source Index	0-31	Source index (HFOSC[0-31] or pin[0-31], depending on Source Type) HFOSC[0] – WKUP_HFOSC0 HFOSC[1] – HFOSC1 (in MAIN domain) PIN[1] – EXT_REFCLK1 pin (not all PLLs, see <i>Clocking</i> )

### 5.6.3 OSPI/QSPI/SPI Boot Parameter Table

Table 5-55 shows the boot parameter table for OSPI, QSPI, or SPI boot. Must be preceded with the common boot parameters described in Table 5-48.

**Table 5-55. OSPI/QSPI/SPI Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 2, 4, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 2, 4, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 2, 4, 8)
261	1	Address Size	24	24, and 32 bits are the valid address sizes
262	1	Mode	0	OSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	Reserved	0	Reserved
270	2	Module Freq	0	The OSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The OSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command

**Table 5-55. OSPI/QSPI/SPI Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
280	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
284	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
288	4	notDAC	From pins	When 0, DAC mode is used
292	4	Read Index	0	Index to the active read address (0-1)
296	4	Read Addr 0	0x000000	The initial flash read address
300	4	Read Addr 1	0x400000 (0x4000 SPI)	Backup read address
304	4	Reserved	0	Reserved
308	4	Reserved	0	Reserved

#### 5.6.4 UART Boot Parameter Table

Table 5-56 shows the boot parameter table for UART boot. Must be preceded with the common boot parameters described in Table 5-48.

**Table 5-56. UART Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Magic	0x49	Required Magic value
257	1	Protocol	63 (0x3F)	Specifies the transfer protocol = XMODEM
258	2	Reserved	0	Reserved
260	1	Max error Count	10	Error count resulting in boot abort
261	1	Ack timeout	3	Timeout in seconds on ack
262	1	Char timeout	20	Inter-character timeout in milliseconds
263	1	Reserved	0	Reserved
264	4	Port	From Pins	Physical port number
268	4	Mod Ref Clk	48000	Module reference clock, in kHz
272	4	Data Rate	115200	Baud rate (bps)
276	1	Parity	0	0=none, 1=odd, 2=even
277	1	Data bits	8	Only 8 data bit width is supported
278	1	Stop bits	2	Stop bits in Q7.1 format (2 = 1 stop bit)
279	1	Flow Control	0	0=none, 1= RTS/CTS
280	1	Over sample	16	Only 16× and 13× oversample are supported
281	1	Magic 2	0xB7	Required magic value

#### 5.6.5 I2C Boot Parameter Table

Table 5-57 shows the boot parameter table for I2C boot. Must be preceded with the common boot parameters described in Table 5-48.

**Table 5-57. I2C Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode	From Pins	0x4E = I2C Controller, 0x72 = I2C target
258	1	Dev Addr	From Pins	I2C address when target mode (0x10 or 0x11)
259	1	Reserved	0	Reserved

**Table 5-57. I2C Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
260	4	Mod Clock	0	I2C Module input clock. If 0, it is computed by ROM code.
264	2	Bus Freq	400	I2C Controller mode bus frequency, in kHz
266	2	Bus Addr	From Pins	I2C Controller mode storage device's address (0x50 or 0x51)
268	2	Read Index	0	Index to the active read offset (0 or 1)
270	2	Read Offset 0	0x0000	I2C Controller mode read offset
272	2	Read Offset 1	0x8000	I2C Controller mode backup read offset
274	2	Reserved	0	Reserved
276	2	Reserved	0	Reserved
280	2	Busy Timeout	From pins	Number of $\mu$ s before a bus recovery is attempted. In units of microseconds in Q3 number format. Value of 0 disables bus recovery attempts.

### 5.6.6 MMCSD/eMMC Boot Parameter Table

MMCSD/eMMC Boot Parameter Table shows the boot parameter table for eMMC, MMC or SD card boot. Must be preceded with the common boot parameters described in [Table 5-48](#).

**Table 5-58. MMCSD/eMMC Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	From Pins	Physical port number
257	1	eMMC	From Pins	0 = SD/MMC, else eMMC
258	1	bootAck	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode the controller expects a boot ack from the eMMC
259	1	Media	1 for eMMC 0 for SD/MMC	0 = auto detect card type 1 = MMC 2 = SD
260	1	busWidth	8 for eMMC From Pins for SD/MMC	Number of data pins (1, 4, or 8). If 0, max supported pins of the port are used.
261	1	bootAlt	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode, the controller uses the alt boot method (CMD1 with arg 0xFFFF_FFFA) to initiate data transfer
262	1	sigVolt	0x18 for port0 0x33 for port1	Sets the signal voltage for the controller. 0x18 = 1.8V 0x33 = 3.3V
263	1	Reserved	0	Reserved
264	4	Max Bus Freq	0	Max bus frequency in kHz. If 0, the value is determined by reading the CSD register from the card (still maxes out at 25 MHz)
268	4	refClkkHz	0	Module reference clock frequency, in kHz. If 0, the ROM code computes the value.
272	4	respTimeout	40000	The timeout period on initial card read, in milli-seconds, Q3 number format
276	128	Filename	"tboot3.bin"	For SD/MMC, boot filename in 16-bit Unicode characters (max 64)
404	4	Mode	0x1144D091	0x1144D091 = file system boot 0x1144C180 = raw image boot
408	4	CardIsInit	0	0 = card not yet initialized 1 = card has been initialized
412	4	Rsvd	0	Reserved
416	4	RawIndex	0	Current active read offset (0 or 1)

**Table 5-58. MMCSD/eMMC Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
420	4	Rsvd	0	Reserved
424	4	Raw Offset 0	0x000000	Raw read offset
428	4	Raw Offset 1	0x400000	Backup raw read offset
432	4	Rsvd	0	Reserved
436	4	Rsvd	0	Reserved

### 5.6.7 Ethernet Boot Parameter Table

Table 5-59 is shown segmented into four sections:

1. The first section contains information required to configure the device hardware
2. The second section contains information used by the top level Ethernet module to execute the boot
3. The third section contains information for the Ethernet stack code.
4. The fourth section contains information for creating the BOOTP packet (vendor string, ID string and debug string), and holds information returned in the BOOTP response (Default route and file name)

Table 5-59 shows the boot parameter table for Ethernet boot. Must be preceded with the common boot parameters described in Table 5-48.

**Table 5-59. Ethernet Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
Hardware Configuration Options				
256	2	Mod Freq	0	Module clock frequency, kHz. If 0, ROM code computes the value.
258	1	Port Num	0	Physical port number
259	1	Interface	From Pins	0 = RGMII with internal delay 1 = RGMII with external delay 2 = RMII
260	1	Init Level	0	0 = Initialize only not enabled modules 1 = Full ethernet sub-system initialization
261	1	Clock out enable	From pins	0x10 = CLKOUT0 enable 0x11 = CLKOUT0 disable
262	1	Clk out freq	From pins	0x20 = CLKOUT0 25 MHz (RGMII) 0x21 = CLKOUT0 50 MHz (RMII)
263	1	RMII Clk In	From pins	0x60 = RMII internal (SoC) clock 0x61 = RMII external clock
264	1	Port Enable	0x01	Bit map. A set bit indicates that the corresponding physical port will be enabled
265	1	Phy Query	From pins	0x30 = speed/duplex determined from RGMII status register 0x31 = MDIO used to query PHY 0x32 = Use fixed speed/duplex values from offset 266/267.
266	1	Speed		0x40 = full speed (1Gbit for RGMII, 100Mbit for RMII) 0x41 = slow speed (100Mbit for RGMII, 10Mbit for RMII)
267	1	Duplex		0x50 = full duplex 0x51 = half duplex
Main Level Boot Control				
268	1	Bootp enable	1	0 = Image information already in this structure 1 = Use BOOTP to get boot image information
269	1	Reserved	0	Reserved
270	2	Bootp Timeout	4000	BOOTP timeout in milli-seconds
272	2	TFTP timeout	1000	TFTP timeout in milli-seconds
274	2	Bootp retries	10	Number of BOOTP retries before fail

**Table 5-59. Ethernet Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
276	2	TFTP retries	10	Number of TFTP retries before fail
278	2	Reserved	0	Reserved
Network Stack Configuration (plus TFTP server ID)				
280	6	MAC Address	From E-fuse	MAC address of the device
286	2	Reserved	0	Reserved
288	4	Device IP	0	IP address of the device. Valid only if BOOTP not enabled
292	4	Net Mask	0	Net mask. Valid only if BOOTP not enabled
296	4	Tftp server IP	0	TFTP server IP. Valid only if BOOTP not enabled
BOOTP send and receive Information				
300	20	Vendor String	"TI K3 Bootp Boot"	BOOTP request vendor string. Valid only if BOOTP not enabled
320	9	Client ID	1-mac-address-0	Client ID. See <a href="#">RFC1700</a>
329	1	ID len	7	Client ID length
330	45	Debug array	SOC ID up to size available	Debug array output
375	1	Debug len	Varies	The number of valid bytes in debug array
376	4	Next hop	0	Next hop IP address. Valid only if bootp not enabled
380	4	Default Route	0	IP default route IP address. Valid only if bootp not enabled
384	128	Boot filename	0	Boot filename. Valid only if bootp not enabled

### 5.6.8 xSPI/Fast-xSPI Boot Parameter Table

Table 5-60 shows the boot parameter table for xSPI boot. Must be preceded with the common boot parameters described in Table 5-48.

**Table 5-60. xSPI/Fast-xSPI Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 8)
261	1	Address Size	24	24 and 32 bits are the valid address sizes
262	1	Mode	0	QSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	ddrEnable	From pins	OSPI DDR mode operation
270	2	Module Freq	0	The QSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The QSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	1	SFDP	From Pins	Enables SFDP parser for 1S-1S-1S to 8D-8D-8D switching

**Table 5-60. xSPI/Fast-xSPI Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
282	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
286	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
290	4	inDAC	From pins	When 0, XIP mode is used
294	4	Read Index	0	Index to the active read address
298	4	Read Addr 0	0x000000	The initial flash read address
302	4	Read Addr 1	0x400000	Backup read address

### 5.6.9 USB DFU Boot Parameter Table

[USB DFU Boot Parameter Table](#) shows the boot parameter table for USB DFU boot. Must be preceded with the common boot parameters described in [Table 5-48](#).

**Table 5-61. USB DFU Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
264	4	Base address 1	From pins (port)	Base address of controller
268	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
272	4	modRefClkKHz	varies	Module reference clock, in kHz
276	2	Vendor ID	0x0451	USB vendor ID. Read from control registers.
278	2	Product ID	0x6165	USB product ID. Read from control registers.
280	2	BCD Device	0x200	Binary Coded Decimal device release number
284	4	String Table addr	0x4182A76C	Pointer to the string table in RAM
288	2	Vendor String offset	0	Offset to vendor string in string table
290	2	Prod string offset	32	Offset to product string in string table
292	2	Serial num string offset	64	Offset to serial number string in string table
294	2	Timeout	5000	USB timeout in milliseconds
296	2	Mode	1	1 = DFU #1 = MSC Mode 1 = backup DFU, 2 = backup MSC
298	1	Lane reverse	From pins	Set to non-zero for lane reverse
299	1	CoreVoltage	From pins	USB Core Voltage 0 = 0.85V, 1 = 0.75V
300	4	Block Size	4096	DFU Block Size

### 5.6.10 USB MSC Boot Parameter Table

[USB MSC Boot Parameter Table](#) shows the boot parameter table for USB boot. Must be preceded with the common boot parameters described in [Table 5-48](#).

**Table 5-62. USB MSC Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
264	4	Base address 1	From pins (port)	Base address of controller
268	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
272	4	modRefClkKHz	varies	Module reference clock, in kHz

**Table 5-62. USB MSC Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
276	2	Vendor ID	0x0451	USB vendor ID. Read from control registers.
278	2	Product ID	0x6164	USB product ID. Read from control registers.
280	2	BCD Device	0	Binary Coded Decimal device release number
284	4	String Table addr	0x4182BCA8	Pointer to the string table in RAM
288	2	Vendor String offset	0	Offset to vendor string in string table
290	2	Prod string offset	0	Offset to product string in string table
292	2	Serial num string offset	0	Offset to serial number string in string table
294	2	Timeout	5000	USB timeout in milliseconds
296	2	Mode	1	1 = DFU ≠1 = MSC Mode 1 = backup DFU, 2 = backup MSC
298	1	Lane reverse	From pins	Set to non-zero for lane reverse
299	1	CoreVoltage	From pins	USB Core Voltage 0 = 0.85V, 1 = 0.75V
300	64	FileName	tiboot3.bin	Boot file name

### 5.6.11 GPMC NOR Boot Parameter Table

[Table 5-63](#) shows the boot parameter table for GPMC NOR boot. Must be preceded with the common boot parameters described in [Table 5-48](#).

**Table 5-63. GPMC NOR Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	refClkKHz	0	The module functional clock frequency, in kHz. 0 = ROM code computes the value.
260	4	csSizeMb	64	The size of each chip-select, in MB
264	1	Csel	From pins	The chip-select to use (0-3)
265	1	adMux	From pins	The address/data multiplexing used. 0 = A/D parallel, 1 = A/A/D mux, 2 = A/D mux
266	1	Width	16	Data bus width
267	1	Reserved	0	Reserved
268	4	Read index	0	The currently active read offset (0-1)
272	4	Read offset 0	0x000000	Read address offset 0
276	4	Read offset 1	0x400000	Backup read address offset 1
280	4	Reserved	0	Reserved
284	4	Reserved	0	Reserved

### 5.6.12 GPMC NAND Boot Parameter Table

[GPMC NAND Boot Parameter Table](#) shows the boot parameter table for GPMC NAND boot. Must be preceded with the common boot parameters described in [Table 5-48](#).

**Table 5-64. GPMC NAND Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Ref Clk kHz	From pins	Specifies the module ref clock.
260	4	Page Size	0	Page size in bytes 2048 or 4096
264	1	Chip Select	0	Chip Select
265	1	Ad Mux	0	Address/data multiplexing

**Table 5-64. GPMC NAND Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
266	1	Data Bus Width	8	Data bus width. Valid values are 8 and 16
267	1	AD rows	0	Number of Row address
268	1	AD columns	0	Number of Column address cycles
269	1	ECC Nibbles	0	Size of BCH remainder in nibbles. 0 if no ECC, 26 for BCH8
270	2	Current Valid Block	0xFFFF	Block number of last known good block
272	2	Pages per Block	0	Number of pages in a block
274	2	Reserved	0	Reserved
276	4	Current Read Index	0	Active read index
280	4	Read Offset[0]	0	Offsets from base of GPMC NAND memory
284	4	Read Offset[1]	0x400000	Offsets from base of GPMC NAND memory

## 5.7 Boot Image Format

### 5.7.1 Overall Structure

The boot image consists of an X.509 Certificate, followed immediately by a boot image blob.

X.509 Certificate (Variable Size) (Optional)
Boot Image Blob (Variable Size)

### 5.7.2 X.509 Certificate

The X.509 certificate is described in [RFC5280](#). Section 4.1 of the specification describes the format.

The X.509 fields relevant to the public boot (taken from RFC5280) are shown below.

```

Certificate ::= SEQUENCE {
    tbsCertificate      TBSCertificate,
    signatureAlgorithm  AlgorithmIdentifier,
    signatureValue       BIT STRING }
TBSCertificate ::= SEQUENCE {
    version             [0] EXPLICIT Version DEFAULT v1,
    serialNumber        CertificateSerialNumber,
    signature            AlgorithmIdentifier,
    issuer               Name,
    validity             Validity,
    subject              Name,
    subjectPublicKeyInfo SubjectPublicKeyInfo,
    issuerUniqueID      [1] IMPLICIT UniqueIdentifier OPTIONAL,
                        -- If present, version MUST be v2 or v3
    subjectUniqueID     [2] IMPLICIT UniqueIdentifier OPTIONAL,
                        -- If present, version MUST be v2 or v3
    extensions          [3] EXPLICIT Extensions OPTIONAL
                        -- If present, version MUST be v3
}
Extensions ::= SEQUENCE SIZE (1..MAX) OF Extension
Extension ::= SEQUENCE {
    extnID              OBJECT IDENTIFIER,
    critical             BOOLEAN DEFAULT FALSE,
    extnValue            OCTET STRING
                        -- contains the DER encoding of an ASN.1 value
                        -- corresponding to the extension type identified
                        -- by extnID
}

```

In general, an X.509 certificate contains a public key which has been signed by a private key. The public ROM code does not directly use the keys. In non-secure devices, the public key value is in general a don't care condition. The exception is certificates containing a degenerate RSA public key. GP devices with a degenerate RSA key allow for integrity checking of most (but not all) of the certificate.

The public ROM only needs to extract some of information from the X.509 formatted structure:

- The total size of the X.509 Certificate
- The total size of the boot image

The total size of the X.509 Certificate is determined by reading the length of the sequence containing the certificate. The length of the image is determined by parsing the certificate to find the extension field which holds the image length.

The ROM defines several extensions that are used only by TI for boot. These are placed in the extensions field of the TBS certificate.

### 5.7.3 Organizational Identifier (OID)

OID (organizational identifier) values are represented as a tree structure. TI has the following node registered:

1.3.6.1.4.1.294: iso(1), identified-organization(3), dod(6), internet(1), private(4), enterprise(1), Texas Instruments(294)

ROM code adds the following branch after *Texas Instruments: device-boot(1)*. The OID values shown in this section are leaves off the device boot branch.

#### 5.7.4 X.509 Extensions Specific to Boot

These values are not defined in any standard, but created by TI for boot.

##### 5.7.4.1 Boot Info (OID 1.3.6.1.4.1.294.1.1)

This extension must be present on all boot images. It is from this extension that the image length is extracted.

```
bootInfo ::= SEQUENCE {
    cert_type: INTEGER,-- identifies the certificate type
    boot_core:INTEGER,-- identifies the boot core
    core_opts:INTEGER,-- 32 or 64 bit boot core target
    load_addr:OCTET STRING,-- Global address image destination
    image_size:INTEGER,-- Image size in bytes
}
```

**Table 5-65. Certificate Type Values**

Value	Description
0x0000_0001	Primary boot image
0x0000_0002	Firmware image

**Table 5-66. Boot Core Values**

Value	Description
0x00	Firmware (M4) image
0x08	M4 certificate
0x10	R5 image
0x20	Reserved

**Table 5-67. Core Options Bit Fields**

31	2	1	0
Reserved		Split	Mode

**Table 5-68. Core Options Field Description**

Bits	Field	Value	Description
1	Split	0	Dual MCU set to lockstep (two cores in lockstep)
		1	Dual MCU set to split mode (two independent cores)
0	Mode	0	MCU starts execution in Arm® mode
		1	MCU starts execution in Thumb® mode

##### 5.7.4.2 Image Integrity (OID 1.3.6.1.4.1.294.1.2)

```
imageIntegrity ::= SEQUENCE {
    sha_type:OID,-- Identifies the SHA type
    hash:OCTET STRING-- The SHA of the boot image
}
```

#### 5.7.5 Extended Boot Info Extension

The ROM supports a combined boot image boot flow. In this flow, a boot binary blob has both Secondary bootloader (SBL) and System Firmware (SYS-FW) embedded in the boot image with a single X509 certificate. This method helps with the following situations:

- Allows ROM to load and run both the bootloader and SYS-FW in parallel without any dependency.
- Optimizes ROM boot time by minimizing different x509 certificate parsing and authentication.

To support this combined boot format, ROM employs a new X509 extension called: `ext_boot_info`. It supports multiple boot components with a single certificate. It allows up to 5 components as part of this extension:

- Component1: Mandatory and should point to info about SBL binary
- Component2: Optional and if present should point to SYS-FW binary in all device types
- Component3: Optional (Load section to SBL, new certType)
- Component4: Optional (Load section to SYS-FW, new certType)
- Component5:
  - HS-FS and HS-SE non Prime devices. Mandatory and should point to SYS-FW Inner certificate
  - GP and HS-SE Prime devices. Optional (Load Section to SBL or SYS-FW)

This extended boot info extension replaces `boot_seq` (`boot_info`) and `image_integrity` extensions from the previous sections, and these should be exclusive in any given certificate.

ROM supports other extensions, such as `sw_rev` and `debug_info`, in both formats.

ROM selects the combined image flow based on the presence of `ext_boot_info` extension in the certificate and skips `boot_seq` (`boot_info`) and `image_integrity` extensions boot flow.

Having one component in `ext_boot_info` is same as legacy flow (that is, flow using `boot_seq` and `image_integrity`); for two or more components, ROM starts both SBL and SYS-SW, the third and fourth components are loaded by ROM to the allowed loading memory range of SBL and SYS-FW if there is no overlap in load address with executable binary info.

Each of the components can independently specify hash value of the binary, and ROM validates the hash on HS and GP if RSA degenerate key is used for signing.

Additionally, ROM rejects the full image if hash of any single component mismatches.

#### 5.7.5.1 Impact on HS Device

For HS devices, ROM supports encryption of images optionally when specified with the Encryption extension.

Encryption - Encryption of the components must be specified with a new extension called `ext_boot_enc`. This is an optional extension that must be specified only if any of the components are encrypted with a customer key set. Specify a component number followed by encryption extension details for ROM to decrypt the given components. This extension is used only with combined boot image format (that is, using Extended Boot Info Extension).

Prime vs Non-Prime - The main difference between HS prime and non-prime devices is the presence of the SYS-FW Inner certificate. Extended boot info extension supports both prime and non-prime devices. ROM supports SYS-FW binary as Comp#2 in all device types; for HS-SE non-prime and HS-FS devices, the SYS-FW inner certificate is expected as another optional component in #3, 4, or 5.

#### 5.7.5.2 Extended Boot Info Details

```

### 5.7.5.3 Certificate / Component Types

ROM supports only the following component types; all other component types will be rejected.

- CompType 0x1 for SBL binary - compType = INTEGER:1
- CompType 0x2 for SYS\_FW binary - compType = INTEGER:2
- CompType 0x3 for SYS\_FW Inner Certificate - compType = INTEGER:3
- CompType 0x11 for SBL Memory load section - compType = INTEGER:17

Primary Image load section, that can be loaded in to SBL allowed memory range:

- CompType 0x12 for SYS\_FW Memory load section - compType = INTEGER:18

SYS-FW load section, that can be loaded in to SYS-FW allowed memory range

### 5.7.5.4 Extended Boot Encryption Info

Extended Boot Encryption Info specifies the imageEncryption extension per component basis. This extension is not applicable for GP or HS-FS devices, and is optional for HS-SE devices if any components in the image are encrypted. In HS-FS and HS-SE non-prime devices, the SYS-FW binary encryption details are part of SYS-FW Inner certificate. This extension is applicable if either SBL, SYS-FW binary in HS-SE prime, or any binary blobs are encrypted in HS-SE devices.

salt = FORMAT:HEX,OCT:cccccccccccccccccaa84f29d6b68d0

```

#### 5.7.5.5 Component Ordering

ROM supports fixed Component ordering for SBL- Binary and SYS-FW Cert and Binary.

For GP and HS-SE Prime devices, Comp#1 should be SBL binary, and Comp#2 should be SYS-FW binary.

For HS-FS and HS-SE non-Prime devices, Comp#1 should be SBL binary, Comp#2 should be SYS-FW Inner Certificate, and Comp#3 should be SYS-FW binary.

#### 5.7.5.6 Memory Load Sections Overlap with Executable Components

Memory load sections for SBL and SYS-FW (CompType 0x11 and 0x12) the destination address and size should not overlap with the corresponding load and execute sections, and should also fall in the allowed memory range by ROM.

#### 5.7.5.7 Device Type and Extended Boot Extension

X509 Extension	Component	GP Device	HS-FS	HS-SE non-prime	HS-SE Prime Device
ext_boot_info	Comp#1	SBL Binary	SBL Binary	SBL Binary	SBL Binary
	Comp#2	SYS-FW binary	SYS-FW binary	SYS-FW binary	SYS-FW binary
	Comp#3	SBL mem load section	SBL mem load section	SBL mem load section	SBL mem load section
	Comp#4	SysFW mem load section	SysFW mem load section	SysFW mem load section	SysFW mem load section
	Comp#5	N/A	SysFW inner certificate	SysFW inner certificate	N/A
ext_enc_info	Comp#1	N/A	N/A <sup>1</sup>	SBL encryption	SBL encryption
	Comp#2			N/A	SYS FW encryption
	Comp#3			SBL memory load Encryption	SBL memory load encryption
	Comp#4			Sys-FW memory load encryption	Sys-FW memory load encryption
	Comp#5			N/A <sup>1</sup>	NA

1. SYS-FW encryption in HS-FS and HS-SE (non Prime) are handled in SYS-FW Inner certificate and they are not part of the extended boot info extensions.

#### 5.7.6 Generating X.509 Certificates

X.509 Certificates are generated using OpenSSL and a configuration script to supply values in the extension fields.

##### 5.7.6.1 Key Generation

The SBL must always be signed with a given OpenSSL key - Secure and GP devices. Secure must have encryption and authentication, GP device must only have authentication. The key used for authentication can be random or specific. If a random key is generated and SBL is signed with this, the ROM will copy the SBL image for authentication using memcpy. With this key, ROM code will be directed to use DMA to load the SBL for authentication which saves boot time.

##### 5.7.6.1.1 Degenerate RSA Keys

Degenerate RSA keys are valid RSA keys with the private exponent set to 1. This results in the signature field being equal to the digest, since in RSA:

$$\text{Signature} = \text{digest}^{\text{privExp}} \bmod n^{\text{privExp}} \bmod n^{\text{privExp}} \quad (1)$$

Where  $n$  is the key size. Since the hash used is SHA-512 and the signature is an ASN.1 sequence containing the OID defining which has was used as well as the hash value, the degenerate RSA must have a value of  $n$  greater than the maximum digest size. Typically 1024-bit is chosen.

The following sequence is used to generate degenerate RSA keys:

1. Create a random RSA key:

```
openssl genrsa -out key.pm 1024
```

2. Convert to text:

```
openssl rsa -in key.pem -text -noout > key.txt
```

3. Create an asn1 template for the degenerate key called degenerateKey.txt. Simply copy the values for modulus, prime (listed as  $p$  in key.txt), prime 2 (listed as  $q$ ), and coefficient (listed as  $\text{coeff}$ ). Set the public and private key exponents to 1, as well as the values for  $e_1$  and  $e_2$ . See the example below.

4. Convert the template to DER:

```
openssl asn1parse -genconf degenerateKey.txt -out degenerateKey.der
```

5. Sanity check the key:

```
openssl rsa -in degenerateKey.der -inform der -text -check
```

6. If there are no errors create the degenerate key pem file:

```
openssl rsa -in degenerateKey.der -inform der -outform pem -out degenerateKey.pem
```

An example degenerateKey.txt file is shown.

```
asn1=SEQUENCE:rsa_key
[rsa_key]
version=INTEGER:0
modulus=INTEGER<copied from key.txt>
pubExp=INTEGER:1
privExp=INTEGER:1
p=INTEGER:<copied from key.txt>
q=INTEGER:<copied from key.txt>
e1=INTEGER:1
e2=INTEGER:1
coeff=INTEGER<copied from key.txt>
```

Note that when copying the multi-byte fields from key.txt it is necessary to remove the colons, concatenate the lines and add a preceding 0x.

### 5.7.6.2 Configuration Script

An example openssl configuration script is shown below. Not all extensions are required, but all possible are shown.

```
[ req ]
distinguished_name = req_distinguished_name
x509_extensions = v3_ca
prompt = no
dirstring_type = nobmp
[ req_distinguished_name ]
C = GB
ST = HI
L = Boston
O = Texas Instruments., Inc.
OU = DSP
CN = Bob
emailAddress = Bob@hou.ti.com
[ v3_ca ]
```

```
basicConstraints = CA:true
1.3.6.1.4.1.294.1.1 = ASN1:SEQUENCE:boot_seq
1.3.6.1.4.1.294.1.2 = ASN1:SEQUENCE:image_integrity
1.3.6.1.4.1.294.1.3 = ASN1:SEQUENCE:swrv
1.3.6.1.4.1.294.1.4 = ASN1:SEQUENCE:encryption
1.3.6.1.4.1.294.1.5 = ASN1:SEQUENCE:key_derivation
1.3.6.1.4.1.294.1.7 = ANSI:SEQUENCE:p11Control
1.3.6.1.4.1.294.1.8 = ANSI:SEQUENCE:debug
[ boot_seq ]
certType = INTEGER:1
bootCore = INTEGER:16
bootArchWidth = INTEGER:32
destAddr = FORMAT:HEX,OCT:bc934b00
imageSize = INTEGER:0x00004860
[ image_integrity ]
shaType = OID:1.3.14.3.2.26
shaValue = FORMAT:HEX,OCT:4cf4d59ef77b5d9ab28d2ceb3c9fe83cb52ae6d2
[ swrv ]

[ encryption ]
Iv =FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
Rstring = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff101112131415161718191a1b1c1d1e1f
Icount = INTEGER:1
Salt = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
[ p11Control ]
p110_num = INTEGER:0
p110_cfg = FORMAT:HEX,OCT:00345678900
p111_num = INTEGER:1
p110_cfg = FORMAT:HEX,OCT:00345678900
[ debug ]
uid = FORMAT:HEX,OCT:00345678900
type = INTEGER:1
dbgE = INTEGER:0
secDbgEn = INTEGER:0
```

The certificate is then generated using the following openssl command:

```
openssl req -new -x509 -key <private_key_pem_file> -nodes -out <output_x.509_pem_file> -config
<config_file> -sha512
```

If a delegate key is being signed, then add the option -signkey <sign\_key\_pem\_file> to the command above.

### 5.7.6.3 Image Data

The image data (blob) is considered simply as a byte stream. On devices that are multiple bytes wide the image must be formatted so that all multi-byte fields match the endianness of the device. The R5 will always run in little endian mode.

## 5.8 Boot Memory Maps

### 5.8.1 Memory Layout/MPU

Memory Layout/MPU shows an overview of the MPU configuration. In the R5 MPU, higher numbered regions have priority, therefore in the table, where two regions overlap, the region on the right defines the memory attributes.

### 5.8.2 Global Memory Addresses Used by ROM Code

The ROM code uses several global memory addresses that are useful for debugging. They are shown in [Global Memory Addresses](#).

**Table 5-69. Global Memory Addresses**

Group	Address	Size (bytes)	Content
SMS0_HSM_SRAM0_0	0x43c00000	0x7e000	Loadable memory space for SBL
Warning/Error logs	0x43c7e480	0x200	Warning Entries
Warning/Error logs	0x43c7e680	0x200	Severe Entries
Warning/Error logs	0x43c7e880	0x100	Critical Entries
Warning/Error logs	0x43c7eb80	0x14	Circular message buffer
Warning/Error logs	0x43c7eb98	0x50	Boot log context
Trace	0x43c7ebe8	0x18	Boot trace context
Trace	0x43c7ec00	0x400	Boot trace entry buffers
Parameter tables	0x43c7f290	0x4	Parameter tables index for R5 bootloader
Parameter tables	0x43c7f298	0x400	Boot Parameter table for R5 bootloader
Parameter tables	0x43c7f1e0	0xb0	Extended boot data for R5 bootloader

The ROM code version information is a structure shown in [Table 5-70](#)

**Table 5-70. ROM Code Version**

Field	Address	Size (bytes)	Value for PG1
Version Number	0x4182_FF80	0x4	TBD
Version Date	0x4182_FF84	0x8	"TBD"
Device Name	0x4182_FF8C	0xC	"TBD"
Commit ID	0x4182_FF98	0x28	"TBD"

6.1 Control Module.....	736
6.2 Power.....	740
6.3 Reset.....	773
6.4 Clocking.....	811

## 6.1 Control Module

### Note

Some features may not be available. See *Module Integration* for more information.

### 6.1.1 Memory Mapped Control Register Modules (CTRL\_MMR)

This chapter covers three categories of device level control register modules:

- General-Purpose Control Register Modules
- Pad Configuration Register Modules
- Security Control Register Modules

Each category of module is described in its own section, along with detailed register descriptions for each module.

### 6.1.2 General Purpose Control Register Modules Overview

There are three General Purpose Control Register Modules on the Device:

- CTRL\_MMR0 for the MAIN domain
- WKUP\_CTRL\_MMR0 for the WKUP domain
- MCU\_CTRL\_MMR0 shared between the WKUP and MCU domains, with Parity Protection.

#### 6.1.2.1 Description for General Purpose Control Register Module Register Types

The following sub-sections provide summary and description for most of the registers which are part of the CTRL\_MMR0, WKUP\_CTRL\_MMR0 and MCU\_CTRL\_MMR0 modules memory spaces. The rest of the registers are described in the corresponding chapters where the functionality associated with particular register is covered in more detail.

##### 6.1.2.1.1 Register Partitions

The CTRL\_MMR0 memory space is divided into the partitions shown in [Table 6-1](#).

**Table 6-1. CTRL\_MMR0 Register Partitions**

Partition <sup>(1)</sup>	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 6	Power and reset control and status	1 8000h to 1 9FFFh	1 A000h to 1 BFFFh

(1) Not listed partitions are reserved and not used.

The MCU\_CTRL\_MMR0 memory space is divided into the partitions shown in [Table 6-2](#).

**Table 6-2. MCU\_CTRL\_MMR0 Register Partitions**

Partition <sup>(1)</sup>	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	BIST control/status regs	C000h to DFFFh	E000h to FFFFh
Partition 4	Verification and test/control status regs	1 0000h to 1 1FFFh	1 2000h to 1 3FFFh
Partition 6	Power and reset control and status	1 8000h to 1 9FFFh	1 A000h to 1 BFFFh

(1) Not listed partitions are reserved and not used.

The WKUP\_CTRL\_MMR0 memory space is divided into the partitions shown in [Table 6-3](#).

**Table 6-3. WKUP\_CTRL\_MMR0 Register Partitions**

Partition <sup>(1)</sup>	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	EFUSE CRC status regs	C000h to DFFFh	E000h to FFFFh
Partition 4	Verification and test control/status regs	1 0000h to 1 1FFFh	1 2000h to 1 3FFFh
Partition 5	DDR frequency Control	1 4000h to 1 5FFFh	1 6000h to 1 7FFFh
Partition 6	Power and reset control and status	1 8000h to 1 9FFFh	1 A000h to 1 BFFFh
Partition 7	Backup Data for Deep Sleep	1 C000h to 1 DFFFh	1 E000h to 1 FFFFh

(1) Not listed partitions are reserved and not used.

#### 6.1.2.1.2 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is associated with one pad and has bits as described in [Pad Configuration Register Functional Description](#).

Many of the device pads support pad multiplexing. This means that their function can be independently chosen from two or more options. The selection of functions available on each pad is enumerated in table “Pin Multiplexing” of the device-specific Datasheet. The desired function is selected via the MUXMODE field of the associated pad configuration register.

The PADCFG\_CTRL0\_CFG0\_PADCONFIGx registers control the signal multiplexing of modules in the device MAIN domain.

#### Note

It is recommended to first configure the PADCONFIG and debounce, as well as the debounce counter values in the SoC MMR, prior to enabling the IP.

#### 6.1.2.1.3 Kick Protection Registers

There are Kick and Proxy registers associated with each CTRL\_MMR register partition. This section describes the Kick registers. For information about the Proxy registers see [Proxy Addressing Registers](#).

The Kick registers provide a protection mechanism which prevents spurious writes from changing the values of its registers. The LOCKi\_KICK0 and LOCKi\_KICK1 registers are used for this purpose. A write is required first to the LOCKi\_KICK0[31-1] KEY field and then to the LOCKi\_KICK1[31-0] KEY field with exact data values to unlock the protection mechanism. Once released then all registers within Partition "i" having write permissions can be written to. The read only registers are still read only. An indication for unlocked Partition "i" is when the LOCKi\_KICK0[0] UNLOCKED bit is set to 1h. When the protection mechanism is locked (indicated by LOCKi\_KICK0[0] UNLOCKED = 0h) none of the registers within Partition "i" can be written to. They can only be read..

The key values for all partitions are:

- LOCKi\_KICK0 Key: 68EF 3490h
- LOCKi\_KICK1 Key: D172 BC5Ah

See for Partition Unlock Values.

Writing any other data value to either of these registers locks the protection mechanism and blocks any writes to the registers that reside in Partition "i".

#### Note

In order to ensure that all registers from all partitions are write protected, software must always re-lock the protection mechanism after completing the register writes.

#### 6.1.2.1.4 Proxy Addressing Registers

There are Kick and Proxy registers associated with each CTRL\_MMR partition. This section describes the Proxy registers. For information about the Kick registers see [Kick Protection Registers](#).

The Proxy registers provide proxy addressing, allowing each of the CTRL\_MMR registers to be accessed through two different addresses - Proxy0 and Proxy1. Each partition is 16KB. The first 8KB are for Proxy0 addresses, and the second 8KB are for Proxy1 addresses. The Proxy0 address is intended as the normal read and write access address. The Proxy1 address provides exclusive register write control.

When a bit from the Px\_CLAIMy[31-0] PROXY1\_CLAIMED field is set to 1h, a register becomes read-only at its Proxy0 address and may only be written through its Proxy1 address. The Proxy registers themselves may always be read through their Proxy0 address but may only be written through their Proxy1 address.

The **x** (representing the partition) and **y** indices can be calculated through the following equations:

- $x = \text{INT}(\text{HEX2DEC}(\text{address\_offset})/16384)$
- $y = \text{INT}(\text{MOD}(\text{HEX2DEC}(\text{address\_offset}), 16384)/128)$

where:

- INT() rounds down to the nearest integer
- HEX2DEC() converts from hexadecimal to decimal
- MOD() returns the remainder of HEX2DEC(address\_offset)/16384

#### 6.1.3 I/O Debounce Control Registers

Some device pads have debounce logic. The following MCU\_CTRL\_MMR0 registers are used to configure the debounce period as shown in [Table 6-4](#).

**Table 6-4. Debounce period**

MCU_CTRL_MMR Debounce Register	PADCONFIGx[13-11] DEBOUNCE_SEL setting
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG1	1h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG2	2h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG3	3h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG4	4h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG5	5h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG6	6h

#### Note

The debounce logic is not associated with all signals that can be multiplexed on a pad. Only certain signals can use it.

For information about each signal that has associated debounce logic, see Signal Descriptions in the device Datasheet.

#### Note

It is recommended to first configure the PADCONFIG and debounce, as well as the debounce counter values in the SoC MMR, prior to enabling the IP.

For information about the PADCONFIGx registers, see [Pad Configuration Registers](#).

[Table 6-5](#) shows the debounce period values to load in the MCU\_CTRL\_MMR\_CFG0\_DBOUNCE\_CFGx[5-0] DB\_CFG field.

### Note

The debounce clock selection should happen before the consumer of the debounced signals is enabled as the clock multiplexers for the debounce logic are NOT glitch-free.

**Table 6-5. Debounce Period Values**

MCU_CTRL_MMR_CFG0_DBOUN CE_CFGx[5:0] DB_CFG Decimal Value	Slow Inputs (32.768kHz (1))	Fast Inputs (25MHz <sup>(1)</sup> )	MCU_CTRL_MMR_CFG0_DBOUN CE_CFGx[5:0] DB_CFG Decimal Value	Slow Inputs (25MHz <sup>(1)</sup> )	Fast Inputs (250MHz <sup>(1)</sup> )
	Delay[ms]	Delay[μs]		Delay[μs]	Delay[ns]
0	bypassed	n/a	32	0.04	4
1	1.95	2.56	33	0.08	8
2	2.93	3.84	34	0.12	12
3	3.91	5.12	35	0.16	16
4	4.88	6.40	36	0.20	20
5	5.86	7.68	37	0.24	24

31	156.25	204.80	63	204.80	20.48

(1) These are the debounce logic clock frequencies.

### 6.1.4 Security Control Register Modules

The following sections describe the CTRL\_MMR0 and PADCFG\_CTRL0\_CFG0 modules.

#### 6.1.4.1 Security Control Register Modules Overview

There are three Security Control Register Modules on the Device:

- MAIN\_SEC\_MMR0 for the MAIN domain
- MCU\_SEC\_MMR0 for the MCU domain
- WKUP\_SEC\_MMR0 for the WKUP domain

## 6.2 Power

This chapter describes the power-management architecture implemented in the device.

### 6.2.1 Power Management Overview

To provide a versatile architecture that supports multiple power-management techniques, the power management framework is built with three levels of resource management: clock, power, and voltage.

These management levels are enforced by defining the managed entities or building blocks of the power management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch).

To minimize device power consumption, the clocks can be gated (turned off), or the power to the modules can be switched off, when they are not in use. Independent power and clock control of sections of the device allows for turning on and off specific sections of the device without affecting other sections.

### 6.2.2 Power Control Modules

The Power Control Modules are divided into two sections, dependent on their functionality - Power Sleep Controller section and Device Manager section.

#### 6.2.2.1 Power Sleep Controller (PSC)

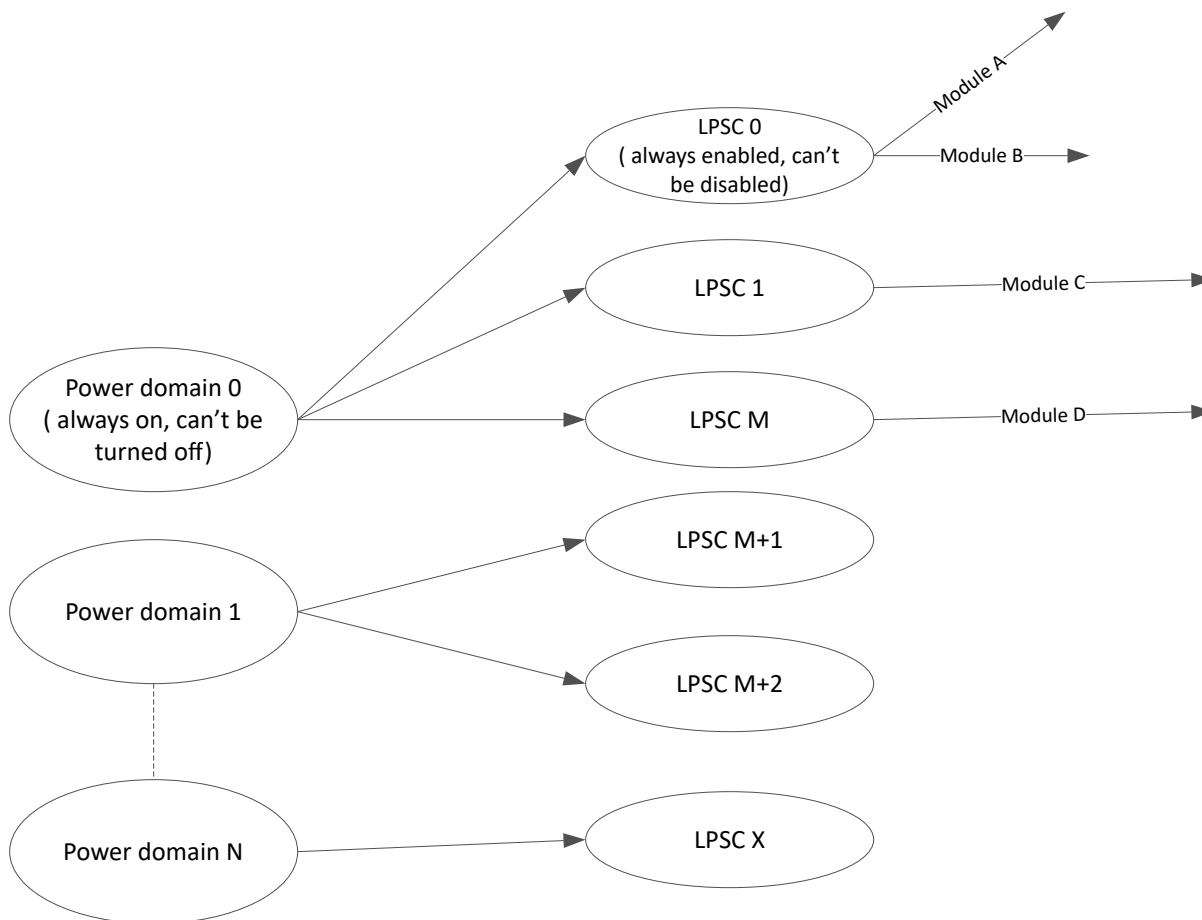

##### 6.2.2.1.1 PSC Architecture

Power Sleep Controller (PSC) is a control component to manage the power domain and module's clock and reset transition. Each PSC module contains multiple power domains, within each power domain, it can contain multiple LPSC. Each LPSC can be used to manage the one or multiple module's reset and clock stop status, see [Figure 6-1](#).

Each power domain has a unique index, starting from number 0. The power domain 0 is a special power domain, which is always on. The status of power domain 0 can't be changed after the device is out of reset.

Each power domain can have one or more Local Power Sleep Control (LPSC). Each LPSC in the same PSC has a unique index value as well. LPSC 0 is special, which user can't change its status. LPSC 0 is always set to be enabled after the device is out of reset.

One LPSC can be used to control the reset and clock status for one or more modules. Some of the LPSC can be used to provide local reset function for the processors, such as A53 and R5 core. LPSC can also be used to manage the clock stop interface for the interfaces between two interconnect IPs. This is mainly used for providing isolation features required by some special features such as security isolation, functional safety isolation or reset isolation between different parts of the SoC.

**Figure 6-1. PSC Architecture**

**Note**

PSC functions are controlled via Device Manager. For more information how to use Device Manager, see [TISCI API](#) available at ti.com.

### 6.2.2.1.2 LPSC Features

**Table 6-6. LPSC Features**

PSC	Power Domain Name	LPSC Name	LPSC Index	Default State	Software controllable	Modules

#### 6.2.2.1.4 Software Sequence to enable an IP through PSC

In order to enable a module, user needs to program the PSC to put LPSC into enable state. There is dependence between power domain and LPSC and among different LPSC controls.

First of all, in order to enable any LPSC, the power domain which that LPSC belongs needs to be enabled first. The LPSC can't put into any state other than disable if the power domain is not enabled.

Among different LPSC, there is also a special sequence needs to be followed to make sure the device is not getting into undefined state.

Similarly, a special sequence shall be followed to disable the LPSC to prevent device getting into undefined states. Before a power domain can be turned off, all the LPSCs within that power domain shall be disabled first. Normally, user can turn off the power domain to save power. However, it is not necessary to turn off the power domain when all the LPSCs inside that power domain are disabled.

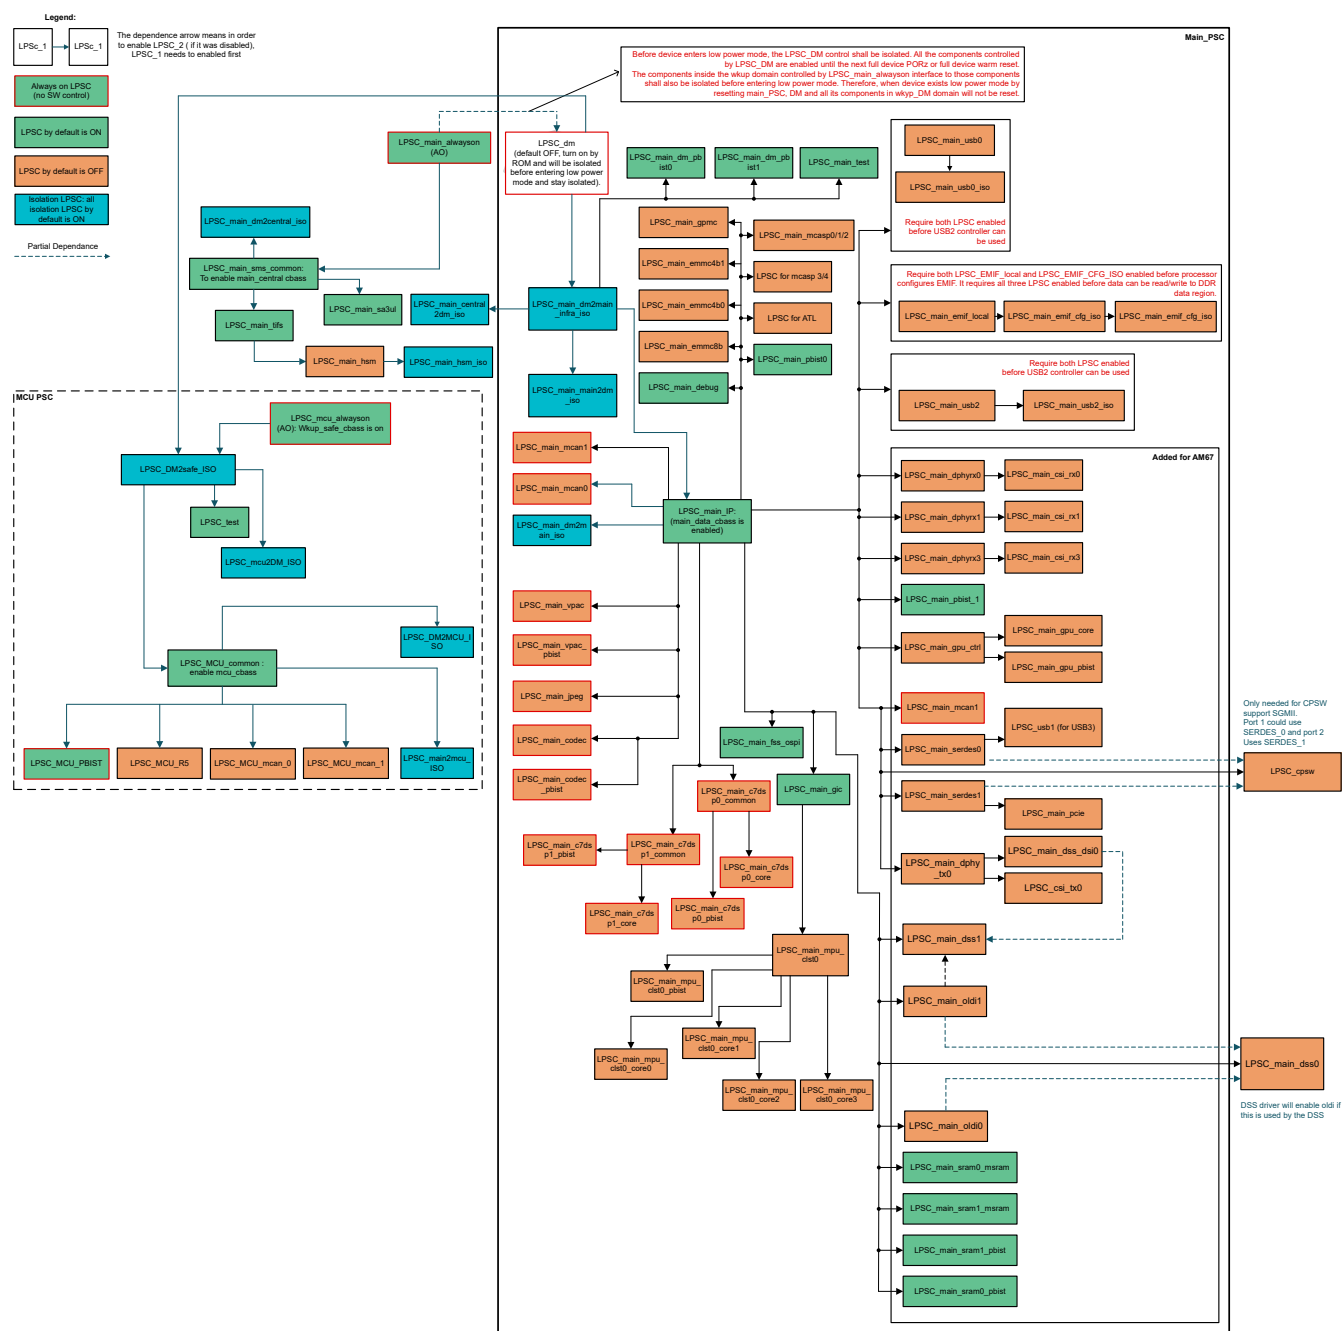

[Figure 6-2](#) shows how to understand the dependent relationship between two LPSCs. In order to enable LPSC\_2, LPSC\_1 shall be enabled first.

If user wants to disable LPSC\_1, LPSC\_2 shall be disabled first.

**Figure 6-2. LPSC Dependence**

[Figure 6-3](#) shows the dependent relationship among all the LPSCs in the device.

### 6.2.2.2 Device Manager

The device has one Device Manager located in WKUP domain. Device Manager is responsible for entry/exit to low power modes. Also, Device Manager hosts RM/PM (Resource Manager/Power Manager) SYSFW code for providing RM/PM services to HLOS. As part of boot, public ROM is executed over Device Manager.

#### Device Manager Features

- Single Core Cortex-R5 subsystem
  - ARMv7-R architecture with following extensions

- Advanced SIMD extension for integer and floating-point vector operations
- Vector Floating Point Version 3 (VFPv3)
- L1 memory architecture
  - 32KB I-cache with 64-bit ECC error checking
  - 32KB D-cache with 64-bit ECC error checking
- 64Kbyte TCM(L2) with 32-bit ECC error checking
- 32-bit AXI3 initiator interface for accessing local peripherals
- 1x RTI/WWDT
- 2x Timer
- 1x UART
- 1x I2C
- Wake-up logic
- Public ROM
- RTC digital
- VTM
- LFOSC

#### Note

PSC functions are controlled via Device Manager. For more information how to use Device Manager, see [TISCI API](#) available at ti.com.

### 6.2.3 Power Management Techniques

The following section describes the power management techniques supported by the device

#### 6.2.3.1 Dynamic Frequency Scaling (DFS)

DFS is a power management technique where the operating frequency is dynamically scaled across device Operating Performance Points (OPP). An OPP is a voltage/frequency pair that defines a specific power state. For each OPP, software controls clock frequency in order to adjust the performance and power to the optimum point. The Device supports DFS for Cortex-A53 only.

#### 6.2.3.2 OPP Low

The device supports lower bus frequency operation as OPP Low. The OPP Low must be configured at boot time. In OPP Low, the main CBASS clock frequency is reduced in half in order to lower active power consumption with reduced performance. The performance of some peripheral modules is limited or not available in this operating condition.

Refer to the device datasheet to determine the supported features and the clock frequency of cores, modules, and peripheral I/Os in OPP Low.

## 6.2.4 Power Management Subsystems

This section provides an overview of how three Power blocks work together; the three blocks are: Power On Reset module (POR), Power OK module (POK), and the POK Reset Generator – Ping-Pong module (PRG\_PP) and a PRG without Ping-Pong (PRG).

### 6.2.4.1 Power Subsystems Overview

#### 6.2.4.1.1 POK Overview

POK modules are responsible for accurately detecting average voltage levels.

Two types of POK modules are implemented in this family of devices - POK and POK\_SA.

POK module is capable of monitoring a range of supplies and indicating a failure within the programmable upper and lower threshold limits for the supply being monitored. POKs are used to monitor 3.3 V, 1.8 V and core supply levels with programmable threshold levels.

Figure 6-4 shows the concept of the POK. It is a comparator with a fixed 0.45V and the voltage to be monitored. The voltage-to-be-monitored is defined based upon a CTRL register (see *POK Related Registers*) and the silicon hook-up of the POK. The POK has three possible input voltage ports – VDD\_MON3P3, VDD\_MON1P8, and VDD\_MON. The effect of the CTRL register depends upon which of these three ports is selected; for example, a threshold value of 0x28 in the threshold register would create a different threshold voltage depending upon:

- How the POK was hooked-up (i.e. VDD\_MON3P3, VDD\_MON1P8, or VDD\_MON) see *POK Modules and Monitored Voltages*.
- Whether the POK is selected for undervoltage detection or overvoltage detection as determined by bit 7 in the POK CTRL register (e.g. \_POR\_VDDR\_MCU\_UV\_CTRL)

The POK output triggers high (i.e. indicating a fail condition) when:

- Under-voltage: the monitored voltage (divided based upon CTRL registers) is less than 0.45V. The CTRL register tables translate the input voltage back to a monitored voltage level. If the monitored voltage falls below the trip point, the POK outputs HIGH, (i.e. FAIL).
- Over-voltage: the monitored voltage (divided based upon CTRL registers) is greater than 0.45V. The CTRL register tables translate the input voltage back to a monitored voltage level. If the monitored voltage rises above the trip point, the POK outputs HIGH, (i.e. FAIL).

When the monitored voltage threshold is changed, the new threshold settles within us.

Figure 6-4 also shows a mux on the output of the comparator. The mux is configured based upon the selection of under-voltage or over-voltage and is used to maintain the proper polarity of the fail signature.

---

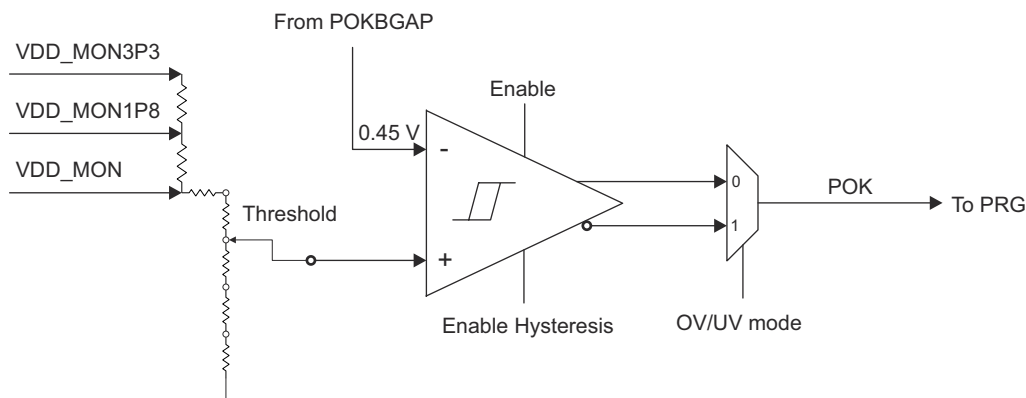

#### Note

POK\_SA (used only on VMON1\_ER\_VSYS) directly compares the monitored voltage to 0.45V.

---

Two other features of the POK diagram (i.e. Figure 6-4) need some explanation:

- The comparator can be enabled or disabled individually; note, that once enabled, the comparator output is continuous (though as shown below in is sampled and filtered). The comparator enable settling time is 15us.
- Hysteresis is applied to the comparator input. In general, it is expected that the monitored voltage is far away from the reference and that the hysteresis is moot.

pok-001

**Figure 6-4. POK Block Diagram**

### Note

POK configuration is not designed to find and report an instantaneous dip / rise in the voltage.

**Table 6-8. POK Module Overview**

POK Module Instance Name	PRG Index (3)	POK Index (1)	Voltage Monitored	Module Type	OV/UV <sup>(2)</sup>	Description
IPOK_VDD_CORE_OV	PRG0	4	VDD_CORE	POK_CORE	OV	Voltage Monitor for VDD_CORE
IPOK_VDDA_PMIC_IN_UV	PRG0	3	VMON_ER_VSYS	POK_SA	UV	Voltage Monitor for PMIC_IN
IPOK_VDDS_DDRIO	PRG1	4	VDDS_DDR	POK_CORE	UV/OV	Voltage Monitors for DDRIO
IPOK_VDDR_CORE	PRG1	3	VDDR_CORE	POK_CORE	UV/OV	Voltage Monitors for VDDR_CORE
IPOK_VDDS_CAP_MCU	PRG1	2	CAP_VDDS_MCU	POK_CORE	UV/OV	Voltage Monitors for MCU mid-rail
IPOK_VDDS_MCU_1P8	PRG1	1	VMON_1P8_SOC	POK_1P8	UV/OV	Voltage Monitors for 1.8-V I/O supply in MCU
IPOK_VDDSHV_MCU_3P3	PRG1	0	VMON_3P3_SOC	POK_3P3	UV/OV	Voltage Monitors for 3.3-V I/O supply in MCU

(1) The POK Index also represents the mapping index for relevant under and overvoltage status and interrupts where applicable.

(2) UV: POK is set for undervoltage detection. OV: POK is set for overvoltage detection. UV/OV: POK monitors both OV and UV through a Ping-Pong mechanism.

(3) Ping-pong mechanism is only applicable to PRG1.

#### 6.2.4.1.1 Configuration Registers

Configuration registers needed for POK (Supervisor Module) are given in [Table 6-9](#). For each POK there is one comparator that is controlled through the registers. These registers decide the functionality of the POK Comparator. It decides if it is UV/OV mode and also the threshold voltages.

Comparator threshold levels and corresponding configuration register settings are given in the following tables:

- POK\_CORE: [Table 6-10](#)
- POK\_1P8: [Table 6-11](#)
- POK\_3P3: [Table 6-12](#)

**Table 6-9. POK Configuration Registers**

Register Name	POK Type

**6.2.4.1.2 PRG / PRG\_PP Overview**

The POKs are both controlled by and send their output back through the PRG(\_PP) module; the PRG(\_PP) module.

1. Controls the POKs – enable / disable, over-volt / under-volt / ping-pong
2. Samples the continuous output
3. Filters the output

Each POK is controlled, sampled, and filtered by a specific PRG(\_PP) (see *POK Modules and Monitored Voltages*) and the control register within that PRG(\_PP) is where the POKs are controlled (e.g. \_PRG\_POR\_CTRL).

1. Control of the POKs: The POK threshold voltage and hysteresis enable are set in CTRL registers defined in *POK Related Registers*. The PRG(\_PP) controls how these POKs are enabled / disabled and how the threshold are applied:
  - Enable / Disable has both;
    - a. A global control –POK\_EN\_SEL (e.g. \_PRG\_PP\_MCU\_CTRL[15]). POK\_EN\_SEL
    - b. A per-POK enable (e.g. \_PRG\_PP\_MCU\_CTRL[1]. POK\_VDDR\_MCU\_EN)

To enable a given POK, both levels of enable are required to be set.

- The options on how thresholds are applied to the POK is the key difference between the PRG\_PP and PRG modules. The PRG\_PP module will be described in this bullet and then the restriction imposed by the PRG module will be addressed. The PRG\_PP can be configured in any of three modes, shown in [Table 6-13](#).
- Sampling the POKs: The POKs are sampled by a divided-down CLK\_12M\_RC (WKUP\_RC\_OSC\_12M from the internal RC oscillator). The sampling clock is nominally 12.5MHz (though because it is an RC-generated clock, the frequency is not precise). This input clock is divided by 16 so that sampling records the POK output on the rising edge every ~1.25us.
- Filtering the output: The output is filtered by means of the DEGLITCH\_SEL bitfield (e.g. \_PRG\_PP\_MCU\_CTRL[17:16]). The bitfield allows the user to select a window of 5us, 10us, 15us or 20us; the POK must be in a FAIL state for ALL samples within the filter window in order for the POK output from the PRG to be seen as FAIL.

**Note**

DEGLITCH\_SEL defines number of samples; the precise duration of the filter is not well controlled.

- For example, the 5us deglitch window samples the POK 4 times and ALL 4 samples must FAIL before the PRG propagates FAIL to the system.
- For example, the 20us deglitch window samples the POK 16 times and ALL 16 samples must FAIL before the PRG propagates FAIL to the system.

### Note

PRG in POR does not support ping-pong.

**Table 6-13. PRG\_PP Modes**

Mode:	Example Register / Bitfield
Each POK can be configured to apply the <u>undervoltage</u> threshold continuously. 1. OV_SEL is cleared; the threshold voltage is taken from *UV_CTRL 2. POK_PP_EN is cleared	_POK_VDDR_MCU_UV_CTRL _PRG_PP_MCU_CTRL[9]. POK_VDDR_MCU_OV_SEL = 0 _PRG_PP_MCU_CTRL[19] POK_PP_EN = 0
Each POK can be configured to apply the <u>overvoltage</u> threshold continuously. 1. OV_SEL is set; the threshold voltage is taken from *OV_CTRL 2. POK_PP_EN is cleared	_POK_VDDR_MCU_OV_CTRL _PRG_PP_MCU_CTRL[9]. POK_VDDR_MCU_OV_SEL = 1 _PRG_PP_MCU_CTRL[19] = 0
All POK can be configured to apply the <u>undervoltage</u> threshold then the <u>overvoltage</u> threshold iteratively (ping-pong) 1. All OV_SEL are cleared 2. POK_PP_EN is set; the threshold voltage is taken from *UV_CTRL in the UV phase; the threshold voltage is taken from *OV_CTRL in the OV phase	_POK_VDDR_MCU_UV_CTRL _POK_VDDR_MCU_OV_CTRL _PRG_PP_MCU_CTRL[10:8] = 000b _PRG_PP_MCU_CTRL[19] = 1

#### 6.2.4.1.3 POR Overview

The POR module should be viewed as a transparent wrapper to the PRG / POKs instantiated within *except* for the following points:

- The bandgap which supplies all POKs is within the POR. The bandgap generates an untrimmed voltage / current after MCU\_PORz is released. In order to apply the device-specific trim to the bandgap, the user must set \_POR\_CTRL[7]. TRIM\_SEL. The bandgap requires a 100us settling time (during which POK / PRG configuration may occur).
- The device-specific bandgap trim is stored in \_POR\_BANDGAP\_CTRL and it is recommended to not modify this trim value.
- The threshold controls for the POKs within the POR are also enabled when TRIM\_SEL is set.
- As noted above, the PRG within the POR does not support ping-pong application of thresholds; these POKs monitor a fixed threshold.

#### 6.2.4.1.4 POK / PRG(\_PP) /POR Overview

Summarizing this section: The POK block diagram shows a comparator with:

Element of POK	Point of control
resistor divider	*POK*_CTRL registers
hysteresis enable	
comparator enable	*PRG*_CTRL
mux on the output	*POK*_CTRL registers

The output of the POR / PRG\_PP / POK voltage monitoring goes to the ESM. Each undervoltage / overvoltage condition has its own bit in the ESM, and the ESM can be programmed to respond to these bits as an interrupt and/or to generate an external signal to the system.

#### 6.2.4.1.5 Timing

As noted in above, there are three timings that are critical:

- 100-us bandgap settling

- 15-us POK enable settling can be concurrent to 100-us bandgap settling
- -us POK threshold settling which can be concurrent to both the 100-us bandgap settling and the 15us POK settling

Figure 6-5 shows the sampled POK output to the ESM when the POK threshold is ping-ponged.

- A POK settling time of 1.25-us clocks is fixed in the design; this provides settling for the new threshold voltage when the POK is ping-ponged
- The deglitch (filter) time can be chosen as {4, 8, 12, 16} 1.25-us clock cycles.
- One 1.25-us clock period provides an update window to the ESM.

In this case, the ESM sees an update of the POK threshold every  $(+ \{4, 8, 12, 16\} + 1) \times 1.25[\mu s]$ . Since the ESM sees an update of a threshold every ~us to every ~us, the UV and OV flags are individually being updated every ~us to every ~us.

In the case where the PRG does not ping-pong, a fixed threshold is applied. The deglitch (filter) time can be chosen as {4, 8, 12, 16} 1.25-us clock cycles. The filter is a sliding window that evaluates the filtered output every 1.25-us based upon the last  $n$  samples ( $n = \{4, 8, 12, 16\}$ ). In this case, the ESM sees an update of the POK threshold every 1.25 us.

The POKs are sampled by a divided-down CLK\_12M\_RC (WKUP\_RC\_OSC\_12M from Section 5.4.4.1.2). The sampling clock is nominally 12.5 MHz (though because it is an RC-generated clock, the frequency is not precise). This input clock is divided by 16 so that sampling records the POK output on the rising edge every ~1.25 us.

**Figure 6-5. Timing for POK with Ping-Pong and Deglitch of 5us**

#### 6.2.4.1.6 Restrictions

1. POK monitoring occurs within the initial POK settling (from enable). It is therefore required that the initial state of the POK after enable should be discarded; further, the ESM should be configured for its system response after the initial results during the settling time are discarded.
2. Within a PRG, all POKs must ping-pong or all monitor a static threshold
3. It is not advised to change the threshold from UV to OV while the POK is enabled

#### 6.2.4.2 Power System Modules

##### 6.2.4.2.1 Power OK (POK) Modules

##### 6.2.4.2.1.1 POK Programming Model

#### 6.2.4.2.2 PoR/Reset Generator (PRG\_PP) Modules

##### 6.2.4.2.2.1 PRG\_PP Overview

A PRG\_PP (Ping-Pong) module is responsible for implementing enable/disable controls, POK Ping-Pong operation, and event/interrupt masking logic on all POK outputs. [Table 6-14](#) shows PRG\_PP modules allocation within device domains.

**Table 6-14. PRG\_PP Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
PRG_PP_MCU	✓	-	-
PRG_PP_POR	✓	-	-
PRG_PP_MAIN	✓	-	-

#### 6.2.4.2.2.2 PRG\_PP Programming Model

The PRG\_PP modules registers used to control and monitor the status of POK modules are:

- \_PRG\_POR\_CTRL
- \_PRG\_PP\_MCU\_CTRL
- \_PRG\_PP\_MAIN\_CTRL

For more information about control registers, see *Control Module (CTRL\_MMR)*.

#### 6.2.4.2.3 Power Glitch Detect (PGD) Modules

A Power Glitch Detect (PGD) circuit is used to detect short duration “glitches” on the core and MPU power supplies. The PGD provides a low output when no glitch is detected and a high output when a glitch is detected.

Figure 6-6 shows the PGD block diagram.

**Figure 6-6. PGD Block Diagram**

#### Note

A flag status bit in corresponding STAT register is cleared by clearing the [30] RSTB bit in the corresponding CTRL register, see for STAT and CTRL registers for a certain PGD module.

#### 6.2.4.2.4 Voltage and Thermal Manager (VTM)

##### 6.2.4.2.4.1 VTM Overview

This section describes the Voltage and Thermal Manager (VTM) module in the device.

VTM provides the control, status as well as interrupt and event generation related to integrated temperature sensors and thermal events programed by the user. VTM also contains a set of memory mapped registers that store device-specific operating voltages (AVSVNOM) set during device testing. These values may be used for the system AVS software to adjust operating voltages for the device to achieve optimal operating power.

The device supports one VTM module - WKUP\_VTM0. [Table 6-15](#) shows VTM module allocation within device domains.

**Table 6-15. VTM Module Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_VTM0	✓	-	-

##### 6.2.4.2.4.1.1 VTM Features

VTM module supports the following features:

- AVS-Class0 only
- Supports up to 8 temperature monitors
- Programming of temperature-crossing thresholds
- Signals when programed thresholds are exceeded - up to 3 alerts:
  - Three full reference 10-bit temperature threshold points, THPT1, THPT2 and THPT0.
- Supports up to 8 temperature monitors
- Allows resolution of 0.5°C for temperature reading and threshold point temperature alert/interrupt generation.
- Supports PMIC/LDO set-up with Class-0 VDD-VID settings
- Support of tentative customization of OPP voltage per device (in support of multiple OPPs)
- AVS-voltage or thermal management for up to 8 voltage domains
- Maximum temperature alert
- Supports one shot sampling mode and continuous monitoring mode for the sensors

#### Note

The VTM of this family of devices has only temperature sensors.

##### 6.2.4.2.4.1.2 VTM Not Supported Features

- No support for AVS-Class0 with temperature compensation (AVS0 + TC)
- No integrated I2C inside VTM
- No direct hardware triggering of I2C transactions by VTM
- No support for voltage and thermal management of IO voltage domains
- No oversampling of the temperature reading
- No support for eFuse defaults of all register values

#### 6.2.4.2.4.2 VTM Functional Description

##### 6.2.4.2.4.2.1 VTM Temperature Status and Thermal Management

VTM module provides temperature reading and interrupt/alert information for thermal management.

##### 6.2.4.2.4.2.1.1 10-bit Temperature Values Versus Temperature

Table 6-16 shows a table lookup method for translating code to temperature from temperature monitors which correspond to the temperature measured read from the VTM0\_VTM\_TMPSENS\_STAT\_J [9-0] DATA\_OUT bitfields. Table 6-16 also provides the values for the temperatures coded in VTM0\_VTM\_MISC\_CTRL2 [25-16] MAXT\_OUTRG\_ALERT\_THR0 and VTM0\_VTM\_MISC\_CTRL2 [9-0] MAXT\_OUTRG\_ALERT\_THR thresholds.

**Table 6-16. Temperature Translation Table**

Parameter Type	Value								
Temperature [°C] (rounded)	-40	-25	0	25	50	75	100	125	150
Temperature [°C] (unrounded)	-40.03	-24.95	0.01	25.02	49.94	75.03	100.02	124.97	150.00
DATA_OUT Code	28	77	164	260	366	485	620	773	949

Table 6-17 shows a table that gives coefficients of polynomial to calculate code or temperature. The equation to calculate code or temperature is:

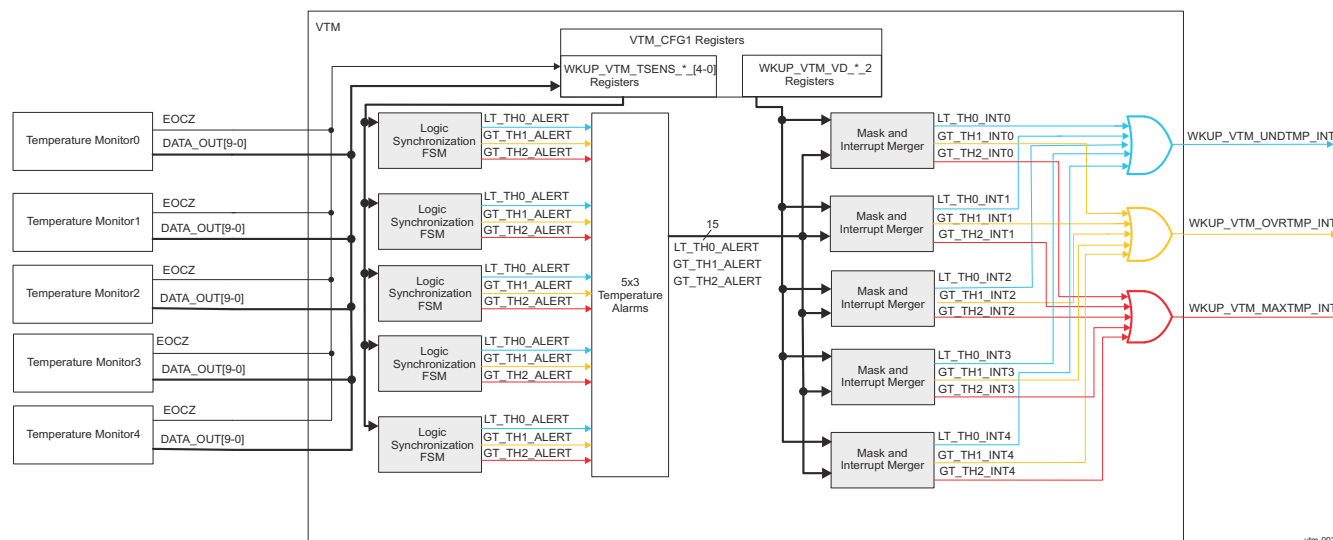

$$y = a4 \times x^4 + a3 \times x^3 + a2 \times x^2 + a1 \times x + a0$$

**Table 6-17. Equation Method to Calculate Code or Temperature**

Function	Unit	Coefficient				
		a4	a3	a2	a1	a0
Code = f(Temperature)	Decimal value of code	4.9847E-08	1.6972E-05	6.8759E-03	3.6509E+00	1.6407E+02
Temperature = f(Code)	°C	-9.2627E-12	6.0373E-08	-1.7058E-04	3.2512E-01	-4.9002E+01

##### 6.2.4.2.4.2.2 VTM Temperature Driven Alerts and Interrupts

All 3 alerts from the temperature monitors are available as inputs of the mask and alert merging logic block of each voltage domain, such that the temperature monitors that are relevant to each voltage domain can be selected as the contributors to the generation of the 3 combined interrupts in each voltage domain (5 shown in sketch; 3 ). This logic is presented in Figure 6-7. The THERM\_MAXTEMP\_OUTRANGE\_ALERT is not shown in this figure. Notice that the same temperature sensor can contribute to more than one voltage domain and each voltage domain can have multiple sensors contributing to the interrupt generation in that VD, see WKUP\_VTM\_VD\_EVT\_SET\_j and WKUP\_VTM\_VD\_EVT\_CLR\_j registers.

**Figure 6-7. VTM Alert and Interrupt Generation**

### Note

The interrupts are only active when the sensor is in continuous mode. A one-shot sampling of the sensor will not trigger any interrupts.

presents the connection of VTM TEMPSSENSOR registers groups to voltage domains.

#### 6.2.4.2.4.2.3 VTM ECC Aggregator

### Note

For more information about ECC Aggregator functionality, see *ECC Aggregator*.

#### 6.2.4.2.4.2.4 VTM Programming Model

##### 6.2.4.2.4.2.4.1 VTM Maximum Temperature Outrange Alert

THERM\_MAXTEMP\_OUTRANGE\_ALERT is used at the device level in order to generate device warm reset. The alert is asserted when the device overheats and exceeds the maximum temperature limit specified for the device, namely 125°C.

The following is the sequence to assert the THERM\_MAXTEMP\_OUTRANGE\_ALERT:

1. For the output to go active ('1'), the VTM has to be configured to operate with at least one of its temperature sensors enabled, and WKUP\_VTM\_TMPSENS\_CTRL\_j[11] MAXT\_OUTRG\_EN = 1 for the corresponding enabled sensor.
2. In addition, WKUP\_VTM\_MISC\_CTRL[0] ANYMAXT\_OUTRG\_ALERT\_EN has to be set to '1'.
3. With the previous configuration set and at least one of the temperature sensors properly configured, and enabled, if the temperature of the die ever exceeds the programmed value in WKUP\_VTM\_MISC\_CTRL2, the VTM output will be driven '1' once the sensor detects the programmed maximum temperature.
4. At the device level the VTM output, THERM\_MAXTEMP\_OUTRANGE\_ALERT, will drive the PLL controllers into warm reset state with the PLL controllers entering condition, at the same time that all the PLLs go into clock bypass mode.
5. By the actions described in No.4, the device will considerably reduce its power consumption, which over the passing of a few seconds will cause the device to reduce its temperature.
6. The VTM sensor continues to read the temperature and once the code corresponding to the programmed value in WKUP\_VTM\_MISC\_CTRL2[25-16] MAXT\_OUTRG\_ALERT\_THR0 is detected the VTM drives THERM\_MAXTEMP\_OUTRANGE\_ALERT = 0.

7. After No.6 is fulfilled, the PLL controllers no longer have the THERM\_MAXTEMP\_OUTRANGE\_ALERT driving the request and thus the PLL controllers bring the SoC out of reset and the boot sequence re-starts. At the same time the PLLs get out of bypass mode and start with their target programmed frequencies for the boot process.

---

#### Note

THERM\_MAXTEMP\_OUTRANGE\_ALERT output of VTM is mapped to WKUP\_VTM\_MISC\_CTRL[0] ANY\_MAXT\_OUTRG\_ALERT\_EN.

---

Notice that exceeding of the programmed value in WKUP\_VTM\_MISC\_CTRL2[9-0] MAXT\_OUTRG\_ALERT\_THR boundary doesn't result in a PORz (cold reset) event, but instead a event. Otherwise if cold reset is applied to the MCU/WKUP domains of the device, the VTM will be fully reset and the output THERM\_MAXTEMP\_OUTRANGE\_ALERT will be cleared to '0' immediately.

#### 6.2.4.2.4.2 Sensors Programming Sequences

##### Sensors Control Modifications Sequence:

1. Write changes to registers.
2. Wait for 900ns to 1us (long enough for sensor period of slowest 1.15 MHz sensor clock plus some extra).
3. New changes can be written to registers.

##### Reset Sensors Sequence:

1. Set the WKUP\_VTM\_TMPSENS\_CTRL\_j[6] CLRZ bit to enable the sensor (so that it has the ENA input high).
2. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
3. Clear WKUP\_VTM\_TMPSENS\_CTRL\_j[6] CLRZ to disable and reset the sensor (as it requires an ENA transition from 1 to 0 to reset initially) .
4. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
5. Now the sensor can be configured and enabled normally.

#### 6.2.4.2.4.2.5 AVS-Class0

Adaptive Voltage Scaling (AVS) Class 0 is a procedure for lowering the voltage on certain device power rails. AVS Class 0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory, based on the strength of the device during manufacturing. This value is written in the device eFuse where it can be read through dedicated registers.

AVS can be enabled by system software after primary boot. Refer to *AVS Support* on how to enable AVS based on these registers.

## 6.3 Reset

This chapter describes the device reset signals and contains details on reset management.

### 6.3.1 Overview

#### Reset Introduction

A reset is designed to bring a device or subsystem into a known state. Resets occur after power up events, as well as through software and hardware reset requests. This section introduces the device reset capabilities and functionality.

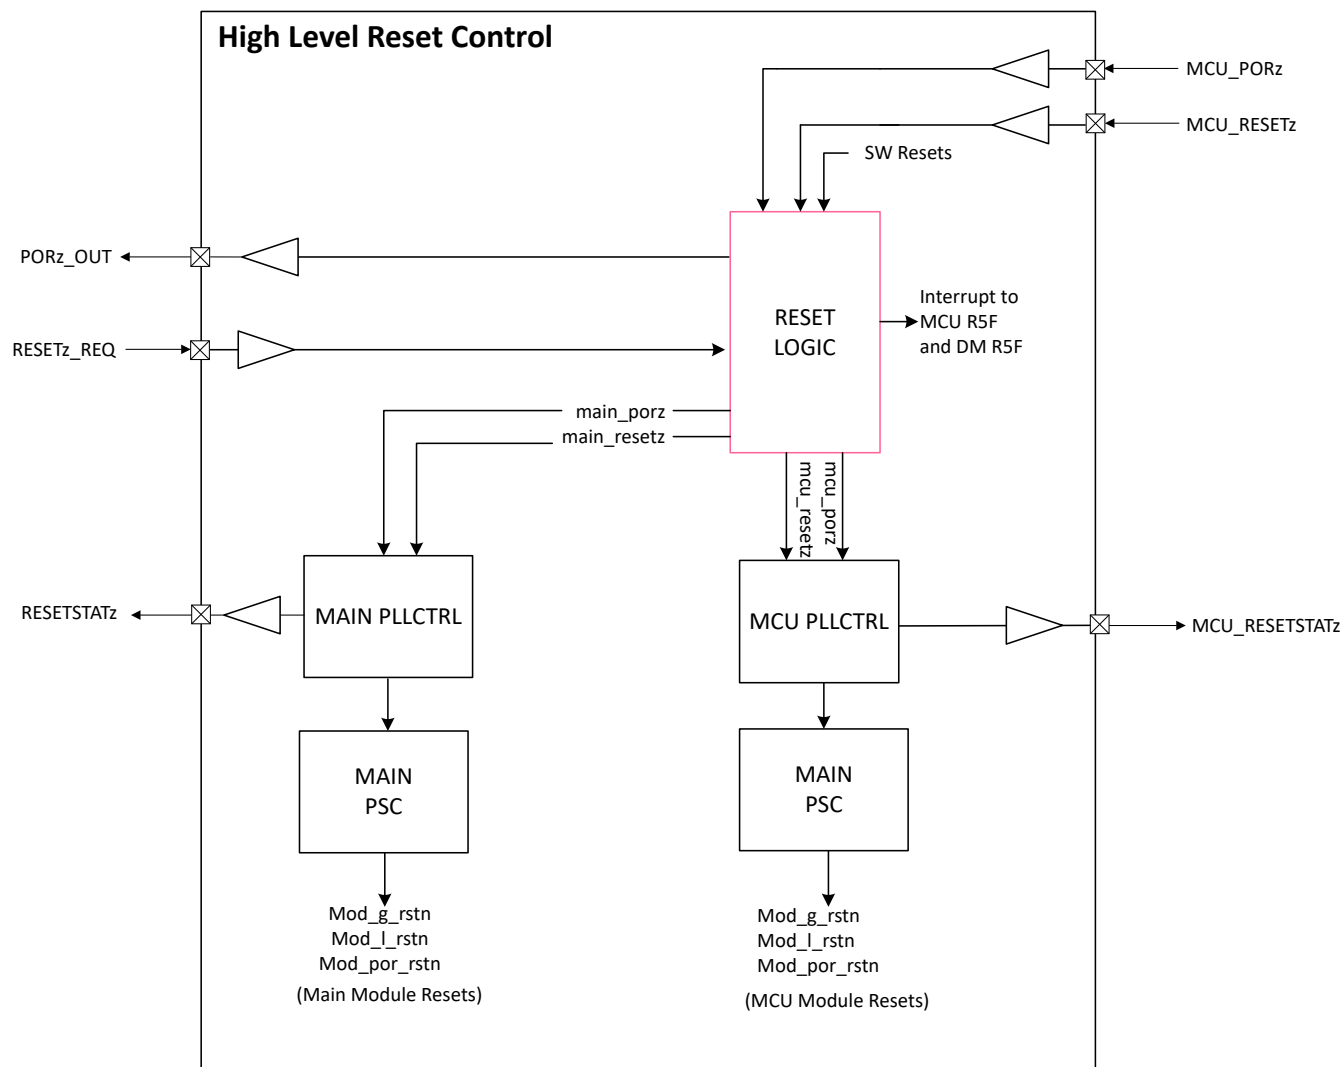

#### Device Resets

The Device Power-on-Reset (POR) is controlled by the external pin MCU\_PORz. This pin is driven by an external (off-chip) "Power-Good" Circuit or Power Management IC (PMIC). The MCU\_PORz pin should be held active LOW (0) during the entire power-up phase. The device should be held in reset until all power supplies are stable with an additional delay for the High Frequency Oscillator (HFOSC0) clock to stabilize.

The SoC is divided into two separate functional Reset Domains: MCU Reset Domain and MAIN Reset Domain (each containing specific processing cores and peripherals).

- MCU Reset Domain: Managed by the MCU Domain, PLLCTRL and PSC, this includes ARM® Cortex®- .
- MAIN Reset Domain: Managed by the MAIN Domain, PLLCTRL and PSC, this includes the high performance application Arm Cortex-A53 cores (A53SS), Device Management and Low Power Management (DM R5F), Security Controller (SMS0) .

Figure 6-8 illustrates the high-level reset domain partition.

**Figure 6-8. High Level Reset Control**

#### 6.3.1.1 MCU Domain Supported Resets

- Power-On-Resets
  - MCU\_PORx device pin: This power-on-reset will reset the entire device including MCU and MAIN domains.
- Warm Resets
  - MCU\_RESETz device pin
  - MCU domain software warm reset
  - MCU domain ESM error reset
  - SMS cold reset

The warm resets listed above will reset the entire device including MCU and MAIN domains.

- Local Module Resets
  - MCU domain LPSC module local reset: This reset is generated by the MCU PSC to locally reset the CPU core

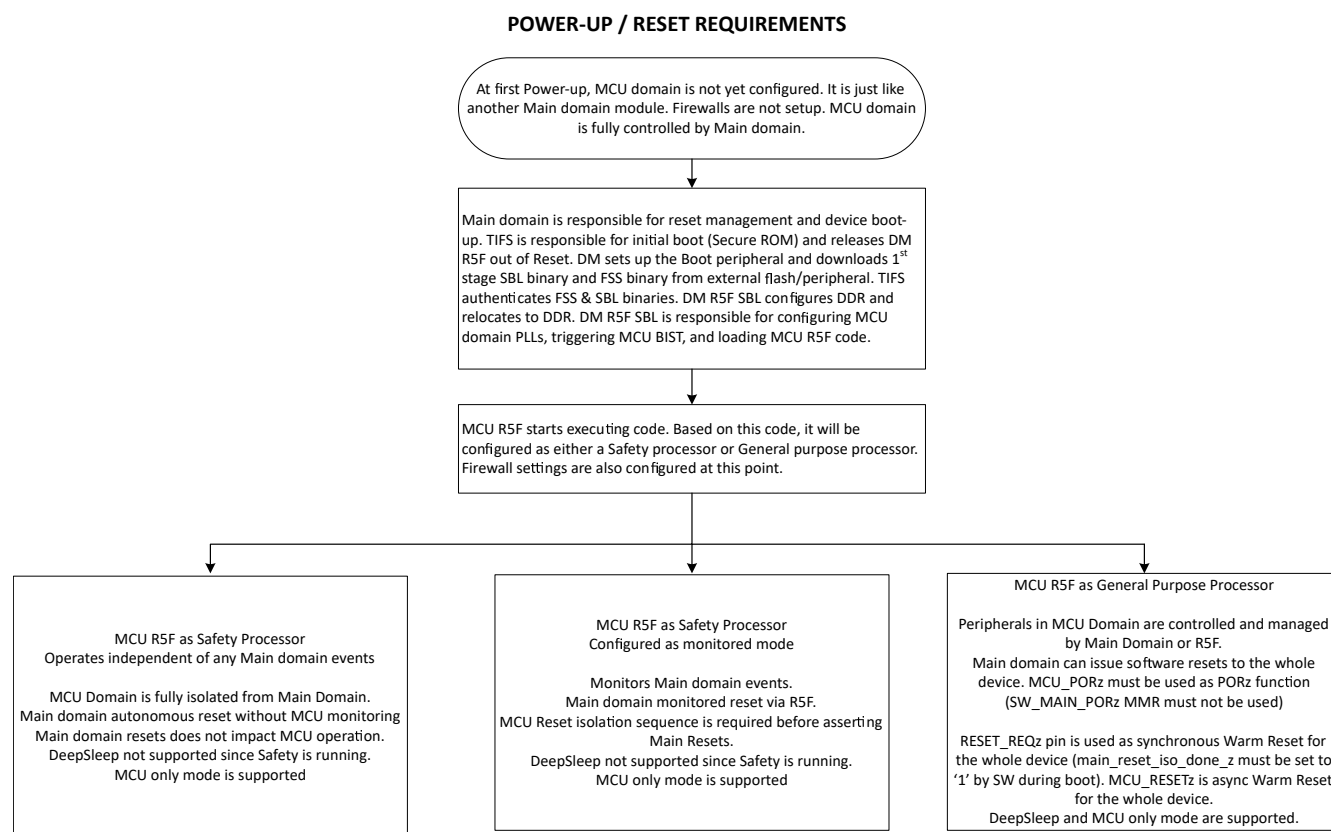

#### 6.3.1.2 MAIN Domain Supported Resets

- Power-On-Resets
  - MAIN domain software POR reset
  - MAIN domain hardware POR reset generated by MCU\_PORz
- Warm Resets
  - RESETz\_REQ device pin
  - MAIN domain ESM error reset
  - MAIN domain software warm reset
  - SMS cold reset
  - MCU domain warm reset will also generate a MAIN domain warm reset
- Local Module Resets
  - MAIN domain LPSC module local reset: This reset is generated by the MAIN PSC to locally reset the Processor cores (A53, SMS, DM R5F, PRUSS)

The device can be configured via software such that a Main domain resets can be isolated from MCU domain. When the MCU domain is configured for reset isolation, MAIN domain resets will only reset the MAIN domain and the MCU domain will remain unaffected by all MAIN domain resets. All MCU domain resets will cause a reset to the entire device (including MAIN and MCU domains).

#### 6.3.1.3 High-Level Reset Flow

**High Level Reset Flow** explains the high-level device power-up and reset use cases.

**Figure 6-9. High Level Reset Flow**

**6.3.1.4 Reset Terminology**

<b>DM</b>	Device Management (including Low Power Management)
<b>POR</b>	Power-On-Reset
<b>ESM</b>	Error Signaling Module

DM_WDT_RST_n	MCU MAIN	DM Watchdog Timeout Reset during Deepsleep	Async	Internal Signal	<a href="#">MCU_RESETz Details</a>

### 6.3.3 Reset Status

[Reset Status](#) shows the Reset Status functionality. An output pin or software bit is used to represent the status of a specific individual reset.

**Table 6-19. Reset Status**

Reset Status Name	Reset Status Source	Reset Status Info	Signal Active Level	Reset Signal Details
Status Register	Register	4 bits in CTRLMMR on MCU warm reset status and assertion.	Status bits read active HIGH (1) when a particular reset is asserted.	
Status Register	Register	4 bits in CTRLMMR on WKUP warm reset status and assertion.	Status bits read active HIGH (1) when a particular reset is asserted.	
PORz_OUTz	Output Pin	On/Off pin status of MAIN PORz reset	Active LOW (0)	<a href="#">MAIN_PORz_OUT Status Pin</a>
RESETSTATz	Output Pin	On/Off pin status of MAIN warm reset	Active LOW (0)	<a href="#">MAIN_RESETSTATz Status Pin</a>
MCU_RESETSTATz	Output Pin	On/Off pin status of MCU PORz reset	Active LOW (0)	<a href="#">MCU_RESETSTATz Status Pin</a>
MCU_ERRORn	Output Pin	On/Off pin status of MCU ESM_ERROR reset	Active LOW (0)	<a href="#">MCU_SAFETY_ERR ORn Status Pin</a>

### 6.3.3.1 Reset Source Status Registers

All warm reset sources which trigger a device/domain warm reset are captured in the MCU domain CTRLMMR reset status register. This register is only reset on MCU\_PORz.

The MCU domain CTRLMMR register is shadowed in MAIN domain CTRLMMR so that MAIN domain processors can read it without directly accessing the MCU domain CTRLMMR.

After recovery from warm reset, software can read the CTRLMMR reset source register to identify the source of previous reset. After reading this reset source register, software must clear the register.

Reset status bits read active HIGH (1) when a particular reset is triggered.

The following reset sources, which cause MCU and MAIN domain resets, are captured in the MCU domain CTRLMMR reset source register:

- MCU\_RESETz (Reset by Hardware Pin)
- SW\_MCU\_WARMRSTz (Reset by MCU domain CTRLMMR <sup>1</sup>)
- SW\_MAIN\_PORz\_MCU\_MMR (Reset by MCU domain CTRLMMR <sup>1</sup>)
- SW\_MAIN\_PORz\_MAIN\_MMR (Reset by MAIN domain CTRLMMR <sup>1</sup>)
- MAIN\_RESET\_REQz (Reset by Hardware Pin)
- SW\_MAIN\_WARMRSTz\_MCU\_MMR (Reset by MCU domain CTRLMMR <sup>1</sup>)
- SW\_MAIN\_WARMRSTz\_MAIN\_MMR (Reset by MAIN domain CTRLMMR <sup>1</sup>)
- SMS\_COLD\_OUT\_RST\_n (Reset by SMS)
- SMS\_WARM\_OUT\_RST\_n (Reset by SMS)
- THERM\_MAXTEMP\_OUTRANGE\_ALERT (Reset by VTM Max Temperature Alert)
- SYSR\_ASSERTRESET\_n (Reset by DEBUGSS)
- ESM\_ERROR\_RST\_n (Reset by ESM Error)
- DM\_WDT\_RST\_n (Reset by WKUP WDT Timeout during Deepsleep mode)
- DM\_MAIN\_PORz (Reset by DS\_MAIN\_POR\_PDOFF a WKUP domain CTRLMMR <sup>1</sup> during deepsleep)
  - MCU ESM Error will reset entire device
  - MAIN ESM Error will only reset MAIN domain when MCU domain is isolated. When MCU domain is not isolated, it will warm reset both MCU and MAIN domains.

#### Note

1. MAIN domain software WARMRSTz and PORz control registers are defined in both WKUP domain CTRLMMR and MCU domain CTRLMMR.

When the MCU domain is isolated from MAIN domain, MCU processor can reset the MAIN domain, by programming the reset control registers defined in the MCU domain CTRLMMR. This way MCU does not need to access MAIN domain CTRLMMR for MAIN domain reset action.

When a MAIN domain processor (A53, SMS, R5F) needs to issue resets to MAIN domain on error detection they will use the WARMRESETz and PORz MMR bits defined in the WKUP domain CTRLMMR.

### 6.3.3.2 MCU\_RESETSTATz Status Pin

The MCU\_RESETSTATz pin indicates the internal reset status of the device (active LOW). When LOW, it indicates that the MCU and MAIN domains are in warm reset state. When HIGH, it indicates that the MCU is out of warm reset state. Refer to [Section 6.3.3.4](#) for MAIN domain reset status.

### 6.3.3.3 MCU\_ERRORn Status Pin

The MCU\_ERRORn pin indicates the MCU domain ESM status. This Output is used to signal an external agent that it needs to (or may need to) intervene because of an error. The Error Pin Output is active Low or PWM, based on the ESM Error Pin Control register pwm\_en field (Refer ESM IP). This pwm\_en field should only be modified when the ESM is disabled, based on the Global Enable register. Refer ESM chapter for details.

While in Power-On-Reset, the Error Pin is active (asserted low). SoC drives a Low via a weak internal pull-down. After Power-On-Reset condition is removed, ESM will drive the Error Pin. During a Warm Reset the state of the Error Pin is unchanged (i.e. the Error Pin logic is only reset by asserting MCU\_PORz low).

When MCU\_ERRORn output pin is configured to operate in level mode, a LOW indicates the MCU ESM module has registered an error. A HIGH indicates that there are no MCU ESM errors.

When MCU\_ERRORn output pin is configured to operate in PWM mode, no error is indicated by continuous toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external device (such as a PMIC) that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external device.

---

#### Note

This signal can be used by external safety devices to determine the device status and assert MCU\_PORz if necessary.

---

#### 6.3.3.4 RESETSTATz Status Pin

This pin indicates warm reset status (active LOW) of the MAIN domain.

When LOW, it indicates that the MAIN domain is in a warm reset state.

When HIGH, it indicates that the MAIN domain is out of reset.

The status of this signal will be captured in registers.

#### 6.3.3.5 PORz\_OUT Status Pin

This pin indicates the POR status of the MAIN domain (active LOW).

When LOW, it indicates the MAIN domain is in the POR state.

When HIGH, it indicates the MAIN domain is out of the POR state.

---

#### Note

PORz\_OUT may be used to enable and/or disable output buffers of attached devices that share pins associated with BOOTMODE inputs, such that appropriate boot configuration values are allowed to propagate into the device without contention.

---

### 6.3.4 Reset Controls

The reset control registers enable, disable, and adjust specific reset operations. This section explains how to control certain device resets.

#### 6.3.4.1 Reset Control Registers

[MCU Domain Reset Control Registers](#) shows the CTRLMMR registers that are able to enable and disable reset abilities and options.

**Table 6-20. MCU Domain Reset Control Registers**

Control Name	Control Action	Control Register
MCU_ESM_ERROR_RST_ENz	Enable MCU ESM_ERRORz reset	
SMS_COLD_RESET_ENz	Enable SMS cold reset of MCU domain	

**Table 6-21. MAIN Domain Reset Control Registers**

Control Name	Control Action	Control Register
MAIN_ESM_ERROR_RST_ENz	Enable MAIN ESM_ERRORz Reset	
SMS_COLD_RESET_ENz	Enable SMS Cold Reset of MAIN Domain	

#### Note

For more information, see *Control Module (CTRLMMR)*.

#### 6.3.4.2 Reset Isolation

##### Reset Isolation Introduction

It is possible to isolate certain SoC modules and subsystems and prevent them from undergoing an arbitrarily generated warm reset. This is known as Reset Isolation. This section describes the device reset isolation capabilities.

[Simple Reset Isolation Sequence Diagram](#) shows a simple description of the device reset isolation sequence.

**Figure 6-15. Simple Reset Isolation Sequence Diagram**

##### MCU Reset Isolation Details

[Detailed Reset Isolation Sequence Diagram](#) shows a detailed description of the MCU reset isolation sequences.

**Figure 6-16. Detailed Reset Isolation Sequence Diagram**

### 6.3.5 Reset Details

#### Reset Details Introduction

The Reset Details section will break down the available device resets and explain operating details such as sequencing and reset logic diagrams. It also includes any additional information related to the device resets.

### 6.3.5.1 POR Resets

#### 6.3.5.1.1 SW\_MAIN\_PORz Reset

##### Reset Overview

This reset is a software controlled MAIN domain POR reset defined in and .

This software reset will generate a MAIN domain PORz.

processor in MCU domain can trigger PORz to the MAIN domain by writing to the register.

MAIN domain processors can reset the MAIN domain by writing to the register.

When the MCU domain is configured as a safety domain it must be isolated from SW\_MAIN\_PORz.

A reset isolation sequence for the MCU domain must be complete prior to reset propagation.

and define a 4-bit field, SW\_MAIN\_POR[7:4], for generating a software-controlled POR for the MAIN domain (SW\_MAIN\_PORz).

When SW\_MAIN\_POR [7:4] field is set to “0110”, the MAIN domain is in POR reset state (SW\_MAIN\_PORz = LOW).

When SW\_MAIN\_POR [7:4] is set to any other value, the MAIN domain is out of POR reset state (SW\_MAIN\_PORz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

##### MCU Domain Effect

When MCU domain is configured as an independent domain, then the entire MCU domain is reset isolated.

When MCU domain is not configured as independent domain then this SW\_MAIN\_PORz must not be used. Instead MCU\_PORz pin functions should be used.

MCU IOs are not affected.

##### MAIN Domain Effect

All modules in MAIN domain are reset (including reset isolated modules).

IOs will enter safe state (as defined in the BALL STATE DURING RESET column of the Datasheet Pin Attributes table while this reset is active.

MAIN domain CTRLMMR boot configuration register is reset.

Device BOOTMODE pins will be re-latched after this reset is de-asserted.

Device will re-boot. During boot-up, R5FSS (secondary boot loader) will poll the CTRLMMR reset status and MCU ACTIVE MAGIC WORD registers and configure MCU domain/ processor accordingly.

##### Additional Details

###### PORz\_OUT:

This pin indicates POR status output of the MAIN domain (active LOW).

When LOW, it indicates the MAIN domain is in POR state.

When HIGH, it indicates that the MAIN domain is out of POR state.

---

**Note**

PORz\_OUT may be used to enable and/or disable output buffers of attached devices that share IOs associated with BOOTMODE inputs, such that appropriate boot configuration values are allowed to propagate into the device without contention

---

---

**Note**

The boot mode pins are latched internally on the rising edge of PORz\_OUT and are reset isolated from all other device resets.

---

**6.3.5.1.2 MCU\_PORz Reset****Reset Overview**

This is the POR reset signal (active LOW) for the entire device, controlled by the MCU\_PORz HW Pin.

When LOW, it performs a POR reset on the entire device (MCU and MAIN domains) and puts IOs in a safe state (as defined in the BALL STATE DURING RESET column of the datasheet Pin Attributes table).

**MCU Domain Effect**

All modules in MCU domain are reset.

MCU IOs are in HHV state (Reset State).

When MCU\_PORz is de-asserted, MCU IOs will enter the default state defined in the device Datasheet. MCU domain will be reconfigured by the device boot processor (secondary boot loader).

**MAIN Domain Effect**

All modules in the MAIN domain are reset.

MAIN domain IOs are in HHV state (as defined in the BALL STATE DURING RESET column of the datasheet Pin Attributes table).

When MCU\_PORz is de-asserted, the MAIN domain IOs will enter default state as defined in the BALL STATE AFTER RESET column of the datasheet Pin Attributes table.

The device boot processor (secondary boot loader) will setup as Safety or General-Purpose Processor.

### 6.3.5.2 Warm Resets

#### 6.3.5.2.1 MAIN Domain Warm Reset Sequence Flow

[MAIN Domain Warm Reset Sequence Flowchart](#) explains the process for a typical MAIN domain warm reset.

**Figure 6-17. MAIN Domain Warm Reset Sequence Flowchart**

#### 6.3.5.2.2 MAIN\_RESETz\_REQ Reset

##### Reset Overview

This reset signal is the MAIN domain warm reset request (active LOW) controlled by the RESET\_REQz HW pin. When LOW is detected, reset hardware generates an interrupt to processors (A53SS/R5FSS) so they can complete the reset isolation sequence before reset is propagated.

##### MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to MAIN domain.

MCU IOs are not affected.

When MCU domain is not configured as independent, then this reset will also warm reset MCU domain.

##### MAIN Domain Effect

This is a MAIN domain warm reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for warm reset isolated modules and MAIN domain CTRLMMR register bits which are reset only on MAIN\_PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

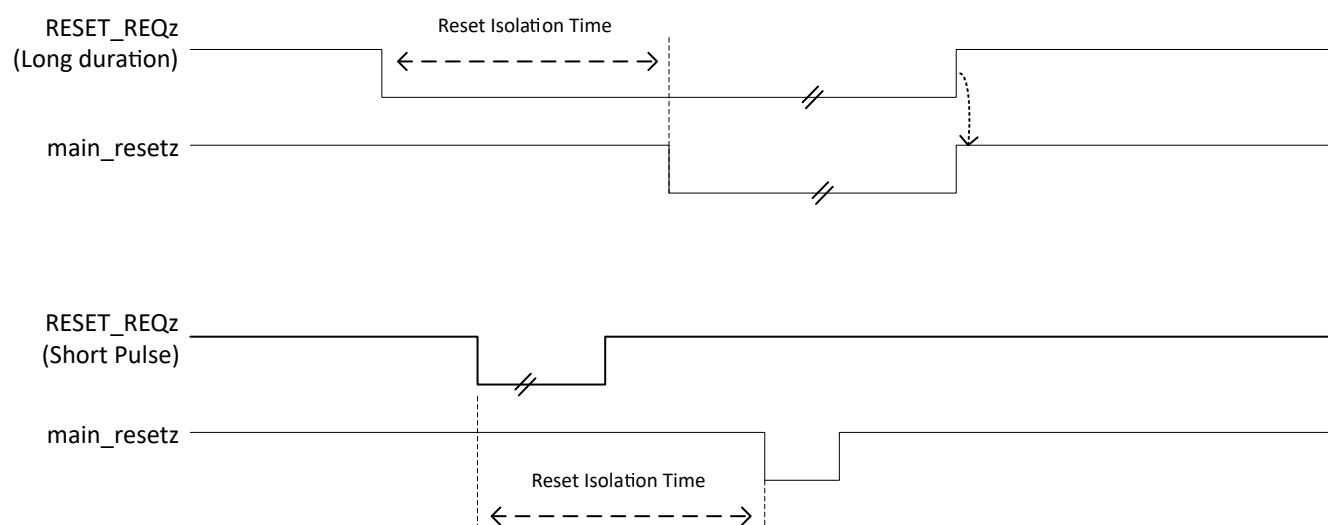

Reason for this reset is captured in the CTRLMMR reset source register. After reset is de-asserted, device will boot-up. During device boot-up, DM R5F secondary boot loader will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU processor accordingly.

##### Reset Sequence

The RESET\_REQz reset sequence is described below.

[RESET\\_REQz Sequence](#) shows the timing between the RESET\_REQz reset signal and the internal RESETz (MAIN domain warm reset) signal. Refer to the datasheet for timing and pulse width requirements.

### MAIN WARM RESET (RESET\_REQz Pin)

**Figure 6-18. RESET\_REQz Sequence**

### Additional Reset Details

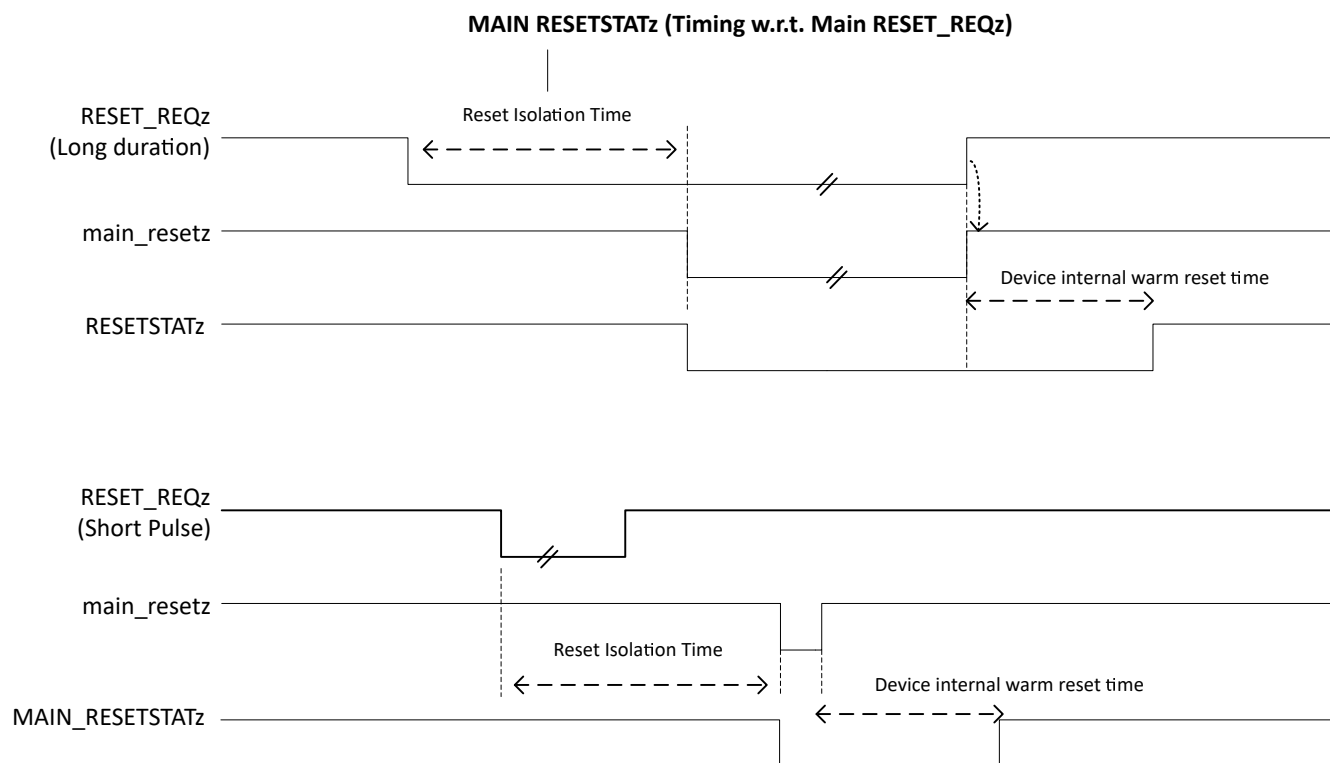

#### RESETSTATz:

The RESETSTATz pin indicates the MAIN domain internal reset status (active LOW). This is a reflection of the reset status after the RESET\_REQz reset signal (RESET\_REQz HW Pin) is asserted.

When LOW, it indicates that the MAIN domain is in internal reset state.

When HIGH, it indicates that the MAIN domain is out of internal reset state.

[RESETSTATz Timing](#) shows the timing between the RESET\_REQz reset signal and the RESETSTATz output. Refer to the datasheet for timing and pulse width requirements.

**Figure 6-19. RESETSTATz Timing**

#### Note

For more details see [MAIN\\_RESETSTATz Status Pin](#).

### 6.3.5.2.3 SW\_MAIN\_WARMRSTz Reset

#### Reset Overview

This reset is software controlled MAIN domain warm reset defined in and .

The can issue a warm reset to the MAIN domain, by writing to the MCU domain CTRLMMR register.

The MAIN domain processors can issue a warm reset the WKUP domain, by writing to the MAIN domain CTRLMMR register.

---

#### Note

When is configured as safety processor it must be reset isolated from this MAIN domain warm reset.

A reset isolation sequence for MCU domain has to be complete prior to this reset propagation.

---

WKUP domain CTRLMMR and MCU domain CTRLMMR registers define a 4-bit field, SW\_MAIN\_WARMRST[3:0] for generating a software controlled warm reset for the MAIN domain (SW\_MAIN\_WARMRSTz).

When SW\_MAIN\_WARMRST[3:0] field is set to “0110”, a MAIN domain warm reset is active (SW\_MAIN\_WARMRSTz = LOW).

When SW\_MAIN\_WARMRST[3:0] is set to any other value, the MAIN domain warm reset is inactive (SW\_MAIN\_WARMRSTz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

---

#### Note

This software reset is equivalent to RESET\_REQz reset signal (RESET\_REQz HW Pin) functionality.

---

#### MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

#### MAIN Domain Effect

This is a MAIN domain reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for reset isolated modules and MAIN domain CTRLMMR register bits which are reset only on MAIN\_PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in MAIN domain CTRLMMR reset status register . After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/ processor accordingly.

#### 6.3.5.2.4 MCU\_RESETz Reset

##### Reset Overview

The MCU\_RESETz signal is the warm reset input (active low) to the entire device, controlled by the MCU\_RESETz HW Pin.

When active, it resets all modules in the MCU and MAIN domains.

MCU\_RESETz will not reset selected and register bits. These bits are only reset by PORz.

##### MCU Domain Effect

All modules in MCU domain are reset except for bits which are reset only on MCU\_PORz.

IOs are not affected.

is reset.

When MCU\_RESETz is de-asserted, the MCU domain needs to be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

##### MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only by PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU\_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register .

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/ processor accordingly.

##### Additional Details

MCU\_RESETSTATz:

This pin indicates internal MCU\_RESETz reset status (active LOW).

When LOW, it indicates that the device, both MCU and MAIN domains, are in internal reset state.

When HIGH, it indicates that the device MAIN domains, are is out of internal reset state.

---

##### Note

In order for the MAIN domain to come out of reset, RESETz\_REQ (RESET\_REQz HW Pin) must also be de-asserted.

---

---

##### Note

For more details see [MCU\\_RESETSTATz Status Pin](#).

---

### 6.3.5.2.5 SW\_MCU\_WARMRSTz Reset

#### Reset Overview

This is a software MCU domain warm reset defined in MCU domain CTRLMMR.

MCU CTRLMMR defines a 4-bit field, SW\_MCU\_WARMRST[11:8] for generating a software warm reset in the MCU domain (SW\_MCU\_WARMRSTz).

When SW\_MCU\_WARMRST[11:8] field is set to “0110”, MCU warm reset is active (SW\_MCU\_WARMRSTz = LOW).

When SW\_MCU\_WARMRST[11:8] is set to any other value, MCU warm reset is inactive (SW\_MCU\_WARMRSTz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

---

#### Note

This software reset is equivalent to MCU\_RESETz warm reset signal (MCU\_RESETz HW Pin) functionality.

---

#### MCU Domain Effect

All modules in the MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU\_PORz.

IOs are not affected.

processor is reset.

When MCU\_RESETz is de-asserted, the MCU domain needs to be reconfigured by the R5FSS (secondary boot loader) in the MAIN domain.

#### MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU\_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in CTRLMMR reset source register.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/ processor accordingly.

### 6.3.5.3 SMS Resets

#### 6.3.5.3.1 SMS\_WARM\_OUT\_RST\_n Reset (MAIN Domain)

##### Reset Overview

The SMS will issue this reset upon a security error.

When this reset is enabled in MAIN domain, it causes a MAIN domain warm reset.

This is a synchronous reset type (needs to complete reset isolation sequence).

---

##### Note

This reset behavior is same as the RESETz\_REQ reset signal (RESET\_REQz HW Pin).

---

##### MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

##### MAIN Domain Effect

This is a MAIN domain warm reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for CTRLMMR register bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in CTRLMMR reset source status register . After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/ processor accordingly.

#### 6.3.5.3.2 SMS\_COLD\_OUT\_RST\_n Reset (MAIN Domain)

##### Reset Overview

This reset is a MAIN domain warm reset that is executed from the SMS. This is an asynchronous reset type (takes effect immediately). This SMS reset of the Main domain is enabled only when the SMS\_COLD\_RESET\_EN\_z bit in WKUP domain CTRLMMR is '0'.

---

##### Note

This reset behavior is same as the RESETz\_REQ reset signal (RESET\_REQz HW Pin) with the exception that it takes effect immediately without need for any reset isolation sequence.

---

##### MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

**MAIN Domain Effect**

This is a MAIN domain asynchronous warm reset. Propagates immediately without any reset isolation sequence.

All modules in MAIN domain are reset except CTRLMMR register bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in CTRLMMR reset status register. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/ processor accordingly.

#### 6.3.5.3.3 SMS\_COLD\_OUT\_RST\_n Reset (MCU Domain)

##### Reset Overview

The device SMS will issue this reset upon a security error.

When this reset is enabled in MCU domain, it causes a whole device warm reset.

This SMS reset of the MCU domain is enabled only when the SMS\_COLD\_RESET\_ENz bit in MCU domain CTRLMMR is '0'.

When the is configured as a safety processor, it can block this reset from resetting the MCU domain.

This is an asynchronous reset type (takes effect immediately)

---

##### Note

This reset behavior is same as MCU\_RESETz reset signal (MCU\_RESETz HW Pin).

---

##### MCU Domain Effect

All modules in MCU domain are reset except for CTRLMMR bits which are reset only on MCU\_PORz.

IOs are not affected.

is reset.

When MCU\_RESETz is de-asserted, the MCU domain will be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

##### MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU\_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register .

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/ processor accordingly.

### 6.3.5.4 VTM Thermal Alert Reset

#### Reset Overview

The VTM has a hardware alert signal that indicates a fault when any of the sensors listed in detect that the device is nearing the maximum temperature allowed.

This alert can be used to reset the device or part of the device to reduce the temperature. This alert is not a standard interrupt and so it does not include the usual set, clear and enable features. It does include an overall enable MMR bit, VTM\_CFG2\_MISC\_CTRL, along with enables per sensor from VTM\_CFG1 Registers.

The VTM module outputs an alert signal (THERM\_MAXTEMP\_OUTRANGE\_ALERT), when the device temperature goes beyond a maximum threshold.

This reset signal creates a MCU domain warm reset.

VTM alert will be active as long as the error condition (Device Temperature > Maximum Temperature Threshold) is still TRUE.

When the error goes away, VTM alert will be de-asserted and device will come out of warm reset.

---

#### Note

This signal, when asserted HIGH, will cause a device warm reset similar to MCU\_RESETz.

---

#### MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU\_PORz.

IOs are not affected.

This reset is active as long as the VTM alert is active.

When THERM\_MAXTEMP\_OUTRANGE\_ALERT is de-asserted, the MCU domain needs to be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

#### MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on MAIN\_PORz.

IOs are not affected.

All processor cores are reset (A53SS and R5FSS).

When THERM\_MAXTEMP\_OUTRANGE\_ALERT is de-asserted, the device goes through full initialization procedure. The reason for this reset is captured in the CTRLMMR reset source register .

#### Additional Reset Details

VTM alert use-case example:

VTM sends out a warning signal before generating the Max Temp Alert.

There are 2 different threshold settings for max temperature limits.

The first one has a lower threshold which will generate an interrupt to the processor for taking action to reduce frequency, turn-off power domains, etc. This should eventually lower the temperature and avoid the Max Temp Alert.

If the interrupt does not fix the rising temperature, then VTM will issue a Max Temp Alert. This will cause a device warm reset. The VTM Max Temp Alert will be active as long as die temperature is above the programmed threshold.

Device warm reset will default certain power domains to off mode (default at power-up). This should eventually lower the die temperature further.

Software can read the reset status register to poll on the cause of the warm reset. If it is from VTM, then it can wait for additional time before turning on the power domains.

### 6.3.5.5 MAIN ESM\_ERRORz Reset

#### Reset Overview

This reset is issued when a MAIN domain processor (A53SS, SMS, or R5FSS) detects a catastrophic software error or a MAIN domain WDT timeout event occurs.

Errors in the MAIN domain cause the MAIN ESM module to trigger ESM\_ERRORz.

This is routed as internal MAIN domain warm reset when enabled by the WKUP domain CTRLMMR reset control bit (MAIN\_ESM\_ERROR\_RST\_ENz).

This is an asynchronous reset type (takes effect immediately).

#### Reset MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

#### Reset MAIN Domain Effect

All modules in MAIN domain are reset except for MAIN domain CTRLMMR bits which are reset only on PORz.

IOs are not affected.

The device will re-boot. During boot-up, the R5FSS (secondary boot loader) will poll the CTRLMMR reset registers and reconfigure the MCU domain/ processor accordingly.

---

#### Note

If the device boot fails, and the MCU\_ERRORn level is still LOW, then an external safety device should issue the MCU\_PORz Reset to allow the device to recover from this error.

---

### 6.3.5.6 MCU ESM\_ERRORz Reset

#### Reset Overview

This reset is issued when the detects a catastrophic safety error or a MCU WDT timeout occurs.

Errors in the MCU domain cause the MCU ESM module to trigger error output.

This is routed as a device warm reset when enabled by the MCU domain bit (MCU\_ESM\_ERROR\_RST\_ENz).

This is an asynchronous reset type (takes effect immediately).

#### MCU Domain Effect

All modules in MCU domain are reset except for MCU domain bits which are reset only on PORz.

IOs are not affected.

Error is reported on MCU\_ERRORn pin.

When SAFETY\_ERROR\_RST\_n is de-asserted, the MCU domain needs to be reconfigured by the R5FSS (secondary boot loader) in the MAIN domain.

External hardware (PMIC or secondary MCU safety channel) must issue MCU\_PORz to recover from this error.

#### MAIN Domain Effect

All modules in MAIN domain are reset except for reset isolated modules and MAIN domain bits which are reset only on PORz.

IOs are not affected.

Device will re-boot. During boot-up, the R5FSS (secondary boot loader) will poll the CTRLMMR reset source register and configure the MCU domain/ processor accordingly.

If the device boot fails, and MCU\_ERRORn level is still LOW, then an external safety device should issue the MCU\_PORz reset to allow the device to recover from the error.

### 6.3.5.7 DM\_WDT\_RST\_n Reset

#### Reset Overview

During Deepsleep resume sequence if the Device Manager is unable to respond due to a software bug, the WKUP domain WDT timer will issue this reset signal.

When this reset is enabled in MCU domain, it causes a whole device warm reset.

This WKUP WDT reset is enabled only when the DM\_WDT\_RST\_EN\_z bit in MCU domain CTRLMMR is '0'.

When the is configured as a safety processor, it can block this reset from resetting the MCU domain. This is an asynchronous reset type (takes effect immediately)

---

#### Note

This reset behavior is same as MCU\_RESETz reset signal (MCU\_RESETz HW Pin).

---

#### MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU\_PORz.

IOs are not affected. is reset.

When this reset is de-asserted, the MCU domain will be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

### **MAIN Domain Effect**

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When this reset is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register.

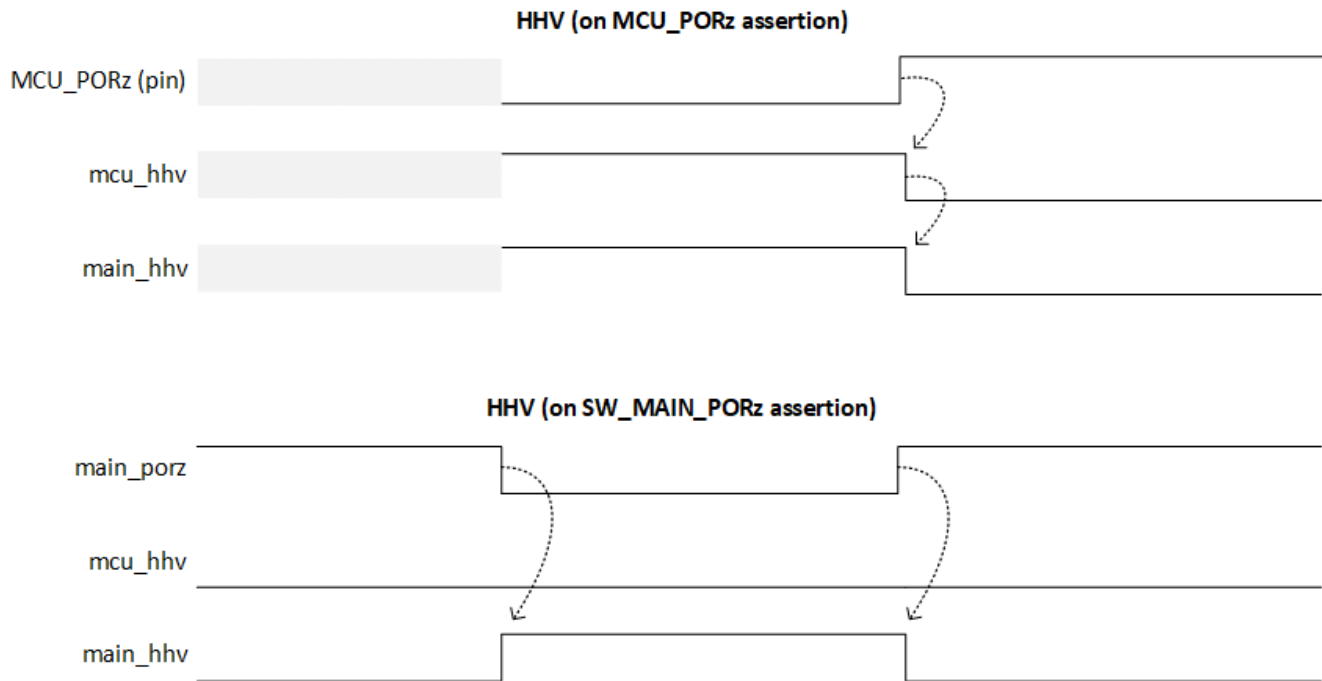

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/ processor accordingly.

### 6.3.5.8 HHV

IOs support HHV mode during power up. HHV is active when PORz signal is driven LOW.

HHV allows IO cells to be tri-stated and is an IO feature. All IO cells have HHV which is asserted (driven) by HHV generated during PORz assertion. There are default pull values during this HHV/PORz assertion specified in the device Datasheet for each pin. All HHV logic controlling the buffer output enable and associated default internal pull for each IO will be applied.

[HHV Timing Diagram](#) demonstrates the timing sequence for the device HHV signals.

**Figure 6-20. HHV Timing Diagram**

### 6.3.5.9 BOOTMODE Pin Latching

This device requires several Boot Mode controls to enable device boot. The BOOTMODE inputs are not implemented on dedicated pins. They are multiplexed with other signal functions, where pins associated with the BOOTMODE inputs are defined in the Pin Attributes table. The logic state of the BOOTMODE inputs are latched on the rising edge of PORz\_OUT. Valid logic states must be maintain as long as PORz\_OUT is held low. The latched values are reflected in WKUP CTRL MMRs for read/write access.

**Figure 6-21. BOOTMODE Pin Latching**

### 6.3.5.10 Power-on-Reset Sequence

Figure 6-22 and Figure 6-23 give a high-level overview of the device power-up sequence.

**Figure 6-22. Power-up/Boot Flow Chart**

**Figure 6-23. Power-up/Boot Timing Chart**

## 6.4.2 Clock Inputs

### 6.4.2.1 Overview

Various external clock inputs are needed to drive the device. Summary of these input clock signals is as follows:

- High frequency oscillators
  - MCU\_OSC0\_XO/MCU\_OSC0\_XI — external main crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to PLLs within MCU and MAIN domain.
- Low frequency oscillators
  - LSOSC0\_IN/LFOSC0\_OUT - external 32.768KHz crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to RTC and Timers within MCU and MAIN domain.
- General purpose clock inputs
  - MCU\_EXT\_REFCLK0 — optional external system clock input (MCU domain).
  - EXT\_REFCLK1— optional external system clock input (MAIN domain).
- External CPTS reference clock inputs
  - CP\_GEMAC\_CPTS0\_RFT\_CLK — CPTS reference clock input for CPSW and Timers in MAIN.
- External audio reference clock inputs/outputs
  - AUDIO\_EXT\_REFCLK[1:0] — optional McASP high-frequency input clocks when configured to operate as an input.

---

#### Note

Other clock inputs that are routed directly to the subsystems are described in the respective subsystem chapters.

---

### 6.4.3 Clock Outputs

The device provides several system clock outputs. Summary of these output clock signals is as follows:

- MCU\_SYCLKOUT0
- MCU\_OBCLK0
- SYCLKOUT0
- OBCLK0
- WKUP\_CLKOUT0
- CLKOUT0
- AUDIO\_EXT\_REFCLK[1:0]
- AUDIO\_EXT\_REFCLK[2:0]

Other clock outputs, that are routed directly from subsystems to device pins, are described in the respective module chapter.

Observation clock pins - MCU\_OBCLK0 OBCLK0 serve the following purposes:

- During testing, PLLs on the device are configured to output all operating frequencies desired by each module to characterize PLL performance.
- System debug: during debug, clocks from various PLLs can be inspected for possible clues. Example clock glitches, lock loss etc.

#### Note

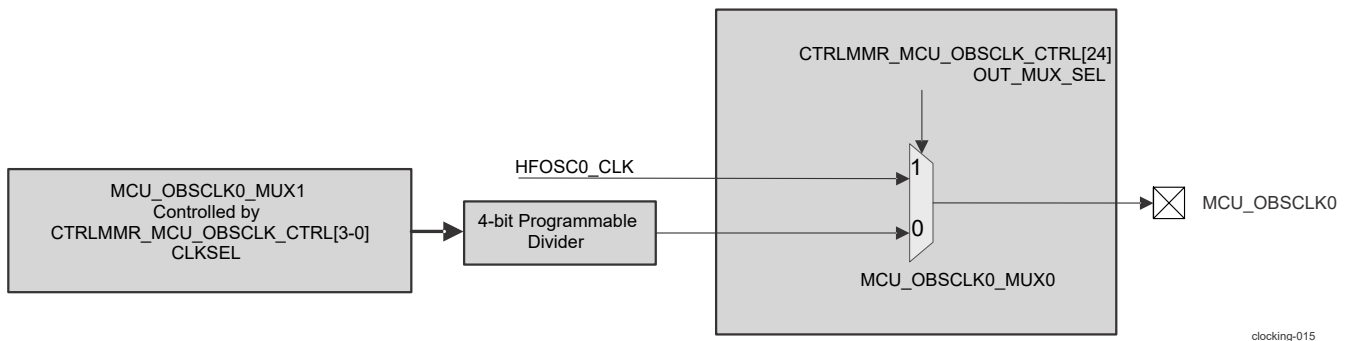

Maximum frequency supported on both MCU\_OBCLK0 OBCLK0 pins is 200 MHz. Hence the divider at the output of each OBCLK mux must be programmed to meet this limitation.

Unlike the OBCLK pins which can select several different clocks for output, system clock pins (MCU\_SYCLKOUT0 and SYCLKOUT0) are hardwired to dedicated clock resources (see [Section 6.4.3.2](#))

#### 6.4.3.1 Observation Clock Pins

##### 6.4.3.1.1 MCU\_OBCLK0 Pin

MCU\_OBCLK0 output is controlled by MCU\_CTRL\_MMR\_CFG0\_MCU\_OBCLK\_CTRL register in the MCU\_CTRL\_MMR0 module; for more information about control registers, refer to *Control Module (CTRL\_MMR)*. Two muxes are connected in series - MCU\_OBCLK0\_MUX0 and MCU\_OBCLK0\_MUX1, see [Figure 6-25](#).

**Figure 6-25. MCU\_OBCLK Muxes Diagram**

How to select the output of MCU\_OBCLK0\_MUX1 is described in [Table 6-22](#).

**Table 6-22. MCU\_OBCLK0\_MUX1 Output Clock Selection**

MCU_CTRL_MMR_CFG0_MCU_OBCLK_CTRL <sup>(2)</sup> [3:0] CLK_SEL	MCU_OBCLK0_MUX1 Output Clock Selection <sup>(1)</sup>
0x0	CLK_12M_RC
0x1	0 (GND) <sup>(3)</sup>
0x2	MCU_PLL0_HSDIV0_CLKOUT

**Table 6-22. MCU\_OBSCLK0\_MUX1 Output Clock Selection (continued)**

MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL <sup>(2)</sup> [3-0] CLK_SEL	MCU_OBSCLK0_MUX1 Output Clock Selection <sup>(1)</sup>

0x7	HFOSC0_CLKOUT_32K
0x8	MCU_SYSCLK0
0x9	DEVICE_CLKOUT_32K
0xA-0xF	RESERVED <sup>(3)</sup>

(1) Software-controlled 4-bit divider is used to obtain the divided versions of the clocks passed to MCU\_OBSCLK1 mux

(2) For more information about control registers, refer to *Control Module (CTRL\_MMR)*.

(3) GND - ground

The value of the software-controlled 4-bit divider is determined by the MCU\_CTRL\_MMR\_CFG0\_MCU\_OBSCLK\_CTRL[11-8] CLK\_DIV field; for more information about control registers, see *Control Module (CTRL\_MMR)*.

#### Note

MCU\_OBSCLK1\_MUX0 is provided as a low jitter output for HFOSC0\_CLK. In this configuration, MCU\_CTRL\_MMR\_CFG0\_MCU\_OBSCLK\_CTRL[3-0] should be configured as 0x1 (1, selecting a logical low signal) and MCU\_CTRL\_MMR\_CFG0\_MCU\_OBSCLK\_CTRL[24] should be configured as 0x1.

#### 6.4.3.1.2 OBSCLK0 Pin

The OBSCLK0 output pin is controlled by MAIN\_CTRL\_MMR\_CFG0\_OBSCLK0\_CTRL register in the CTRL\_MMR0 module; for more information about control registers, refer to *Control Module (CTRL\_MMR)*. [Figure 6-26](#) shows a block diagram of internal OBSCLK0 mux connections.

**Figure 6-26. OBSCLK0 Muxes Diagram****Table 6-23. OBSCLK0 Clock Selection**

MAIN_CTRL_MMR_CFG0_OBSCLK0_CTRL <sup>(2)</sup> [4-0] CLK_SEL	OBSCLK0 Selection <sup>(1)</sup>

(1) Software-controlled 8-bit divider is used to obtain the divided versions of the clocks passed to output pins

(2) For more information about control registers, refer to *Control Module (CTRL\_MMR)*.

(3) GND - ground

The value of the software-controlled 8-bit divider is determined by register MAIN\_CTRL\_MMR\_CFG0\_OBSCCLK0\_CTRL[15-8] CLK\_DIV; for more information about control registers, refer to *Control Module (CTRL\_MMR)*.

#### 6.4.3.2 System Clock Pins

##### 6.4.3.2.1 MCU\_SYSCCLKOUT0

MCU\_SYSCCLKOUT0 is divided by 4 and then send out of the device as a LVCMOS clock signal (MCU\_SYSCCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

#### Note

MCU\_SYSCCLKOUT0 cannot be used as a clock source for external devices on the board.

##### 6.4.3.2.2 SYSCCLKOUT0

SYSCCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (SYSCCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

#### Note

SYSCCLKOUT0 cannot be used as a clock source for external devices on the board.

##### 6.4.3.2.3 WKUP\_CLKOUT0

The WKUP\_CLKOUT0 output pin is controlled by the WKUP\_CTRL\_MMR\_CFG0\_CLKOUT\_CTRL register in the WKUP\_CTRL\_MMR0 module; for more information about control registers, refer Control Module (CTRL\_MMR). [Figure 6-27](#) shows a block diagram of internal WKUP\_CLKOUT0 mux connections.

**Figure 6-27. WKUP\_CLKOUT0 Mux Diagram**
**Table 6-24. WKUP\_CLKOUT0\_MUX Output Clock Selection**

WKUP_CTRL_MMR_CFG0_CLKOUT_CTRL <sup>(1)</sup> [2-0] WKUP_CLKOUT_SEL	WKUP_CLKOUT0_MUX Output Clock Selection

0x4	MAIN_PLL2_HSDIV9_CLKOUT
0x5	DEVICE_CLKOUT_32K
0x6	CLK_12M_RC
0x7	HFOSC0_CLKOUT

(1) For more information about control registers, refer Control Module (CTRL\_MMR).

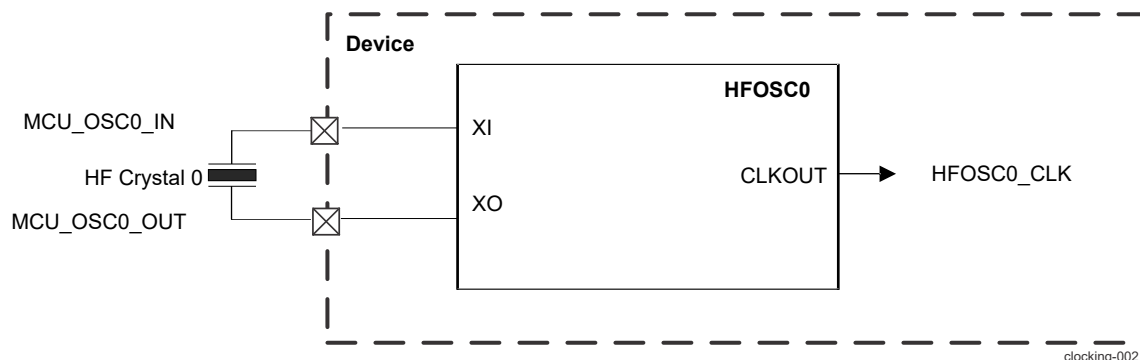

#### 6.4.4 Device Oscillators

The device has the possibility to source clocks of an external high-frequency oscillator - HFOSC0 and external 32.768KHz oscillator - LFOSC0. The device has also one internal RC oscillator - CLK\_12M\_RC.

### 6.4.4.1 Device Oscillators Integration

#### 6.4.4.1.1 High-Frequency Oscillator with External Crystal

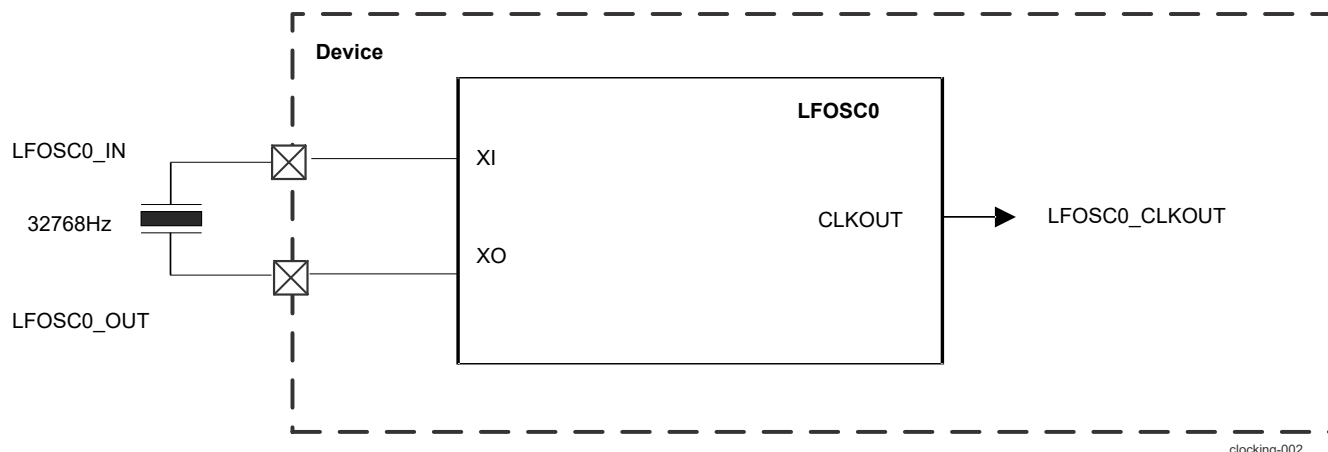

By default, HFOSC0 is enabled after PORz. It supports a bypass mode. In this mode, an external clock can be driven on the XI Pin.

**Figure 6-28. HFOSC0 Integration Diagram**

#### 6.4.4.1.2 Low-Frequency Oscillator with External Crystal

By default, LFOSC0 is disabled after PORz. It supports a bypass mode. In this mode, an external clock can be driven on the XI Pin.

**Figure 6-29. LFOSC0 Integration Diagram**

#### 6.4.4.1.3 Internal RC Oscillator

CLK\_12M\_RC is always oscillate mode.

The 12.5-MHz RC clock output (CLK\_12M\_RC) is used by the on-chip Reset Glue logic, Power Reset Generator (PRG) circuits, HFOSC0 Loss Circuits, Dual Clock Comparator (DCC) and Timer Modules.

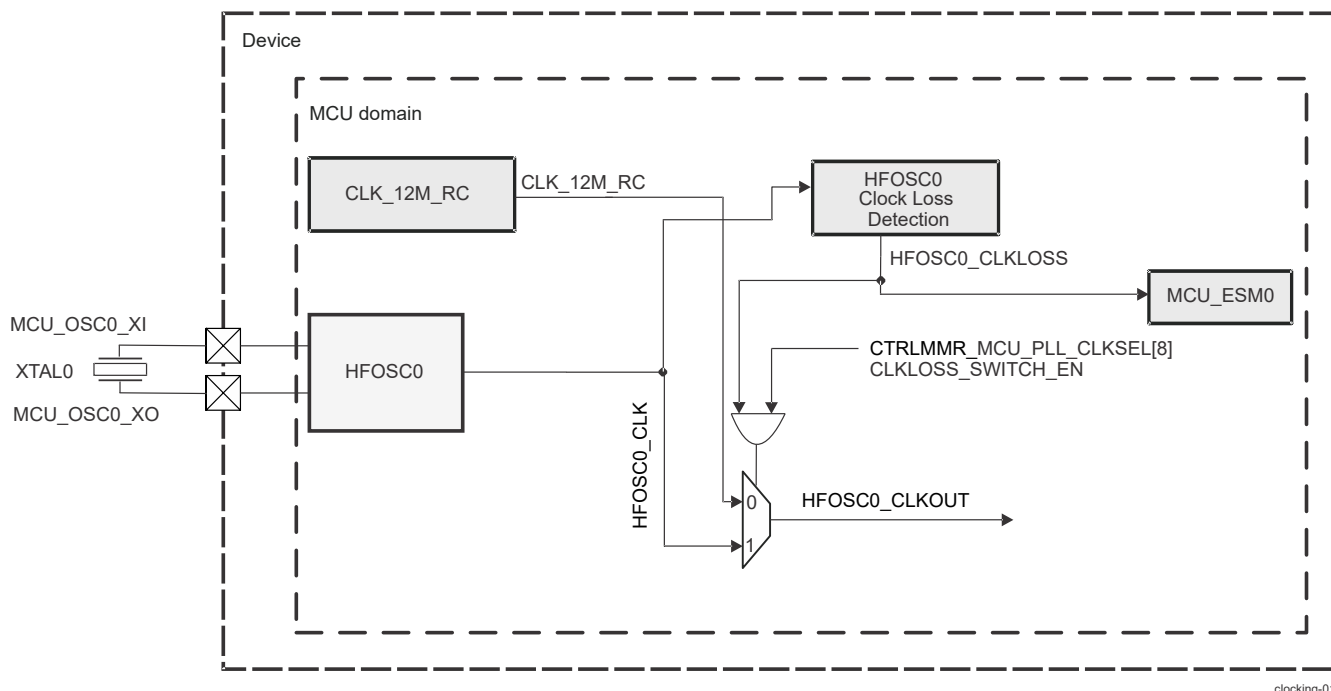

#### Note

An output clock of CLK\_12M\_RC is further divided down to generate a 32-kHz clock (CLK\_32K\_RC). This clock is used by SMS and Timer Modules.

The actual value of the derived CLK\_32K\_RC will vary with PVT variations.

#### 6.4.4.2 Oscillator Clock Loss Detection

The device supports HFOSC0 clock loss circuitry to detect when HFOSC0\_CLK stops toggling. Dedicated hardware logic monitors HFOSC0 clock using CLK\_12M\_RC clock. When HFOSC0\_CLK stops toggling for 9 CLK\_12M\_RC clock periods, a HFOSC0 clock stop loss condition is detected. If CTRLMMR\_MCU\_PLL\_CLKSEL[8] CLKLOSS\_SWITCH\_EN is set, the reference clock is switched from HFOSC0\_CLKOUT to CLK\_12M\_RC to allow the device to operate with a slower clock. The HFOSC0\_CLK clock loss condition is reported as an error to MCU\_ESM0 regardless of the value of CTRLMMR\_MCU\_PLL\_CLKSEL[8] CLKLOSS\_SWITCH\_EN. Integration diagram of HFOSC0 clock loss detection is presented in Figure 6-30.

**Figure 6-30. HFOSC0 Clock Loss Detection Integration Diagram**

MCU\_ESM0 can optionally generate an interrupt to MCU\_ and DM\_R5FSS0 so they can save some critical contents such as error logging to scratch pad memory or external flash. ESM must also be configured to report this error on the MCU\_ERRORn pin.

HFOSC0 clock loss is a catastrophic failure since this clock is the most critical system clock. During the clock loss condition an external system intervention is required.

The clock loss mux is not a glitch free mux. The mux control is synchronized to the CLK\_12M\_RC clock. Since HFOSC0\_CLK has stopped switching the mux should transition to RC Clock without producing glitches.

During clock-loss condition, the device reports the error to the external device through MCU\_ERRORn pin - the pin is driven Low. The recovery mechanism is up to the external system (such as a PMIC to take action). For example, it can try a full system power cycle to see if the system recovers. If the system does not recover then, it has to take some other action such as to check system clocks, external crystal or supply rails.

Device PLLs will lose lock when clock loss is detected. During this time 12.5-MHz RC clock is output through the bypass muxes. The PLL will relock to a new frequency based on 12.5 MHz RC clock.

In an event of clock glitch which may potentially hang the device, then the SMS watchdog timer will expire and will generate an internal reset for the whole device.

### 6.4.5 PLLs

Phase-Locked Loop circuits (PLLs) in the device are clock generator PLLs, which multiply the lower-frequency reference clock up to the operating frequency of the respective subsystem(s).

#### 6.4.5.1 MCU Domain PLL Overview

MCU\_PLL0 (MCU PLL) with MCU\_PLLCTRL0 are present in the device in MCU domain. An overview is shown on [Figure 6-31](#). For more specific information about PLLs see [Section 6.4.5.5, PLLs Device-Specific Information](#).

**Figure 6-31. MCU Domain PLLs Integration**

#### 6.4.5.2 MAIN Domain PLLs Overview

The following are the PLLs in the device in MAIN domain:

- PLL0 (MAIN PLL) with PLLCTRL0
- PLL1 (PER0 PLL)
- PLL2 (PER1 PLL)
- PLL5 (VIDEO PLL)
- PLL7 (C7x PLL)
- PLL8 (ARM0 PLL)
- PLL12 (DDR PLL)
- PLL15 (SMS PLL)
- PLL17

Overview of the device PLLs with their reference clock options in MAIN domain is shown on [Figure 6-32](#). For more specific information about PLLs see [Section 6.4.5.5, PLLs Device-Specific Information](#).

#### Note

The external muxes of choosing the reference clocks are glitch-free muxes.

**Figure 6-32. MAIN Domain PLLs Integration**

#### 6.4.5.3 PLL Reference Clocks

##### 6.4.5.3.1 PLLs in MCU Domain

The reference clock MCU\_PLL0\_REF\_CLK for the PLL in MCU domain is chosen between the internal high-frequency (HF) oscillator with external crystal (HFOSC0) and 12.5-MHz free-running RC oscillator. The selection is made through CTRLMMR\_MCU\_PLL\_CLKSEL[8] CLKLOSS\_SWCH\_EN, see [Table 6-25](#).

**Table 6-25. PLL MCU Domain Reference Clock Selection - HFOSC0\_CLKOUT Selection**

CTRLMMR_MCU_PLL_CLKSEL <sup>(1)</sup> [8] CLKLOSS_SWCH_EN	MCU_PLL0_REF_CLK
0 (default)	HFOSC0_CLK
1	CLK_12M_RC if clock loss is detected or HFOSC0_CLK if clock loss is not detected

(1) For more information about control registers, see *Control Module (CTRL\_MMR)*.

##### 6.4.5.3.2 PLLs in MAIN Domain

Each PLL in MAIN domain has a dedicated register (CTRLMMR\_MAIN\_PLLn\_CLKSEL, n = 0 to 2, 8, 12, 15, 16, 17) in CTRL\_MMR0 that contains associated control bits.

#### 6.4.5.4 Generic PLL Overview

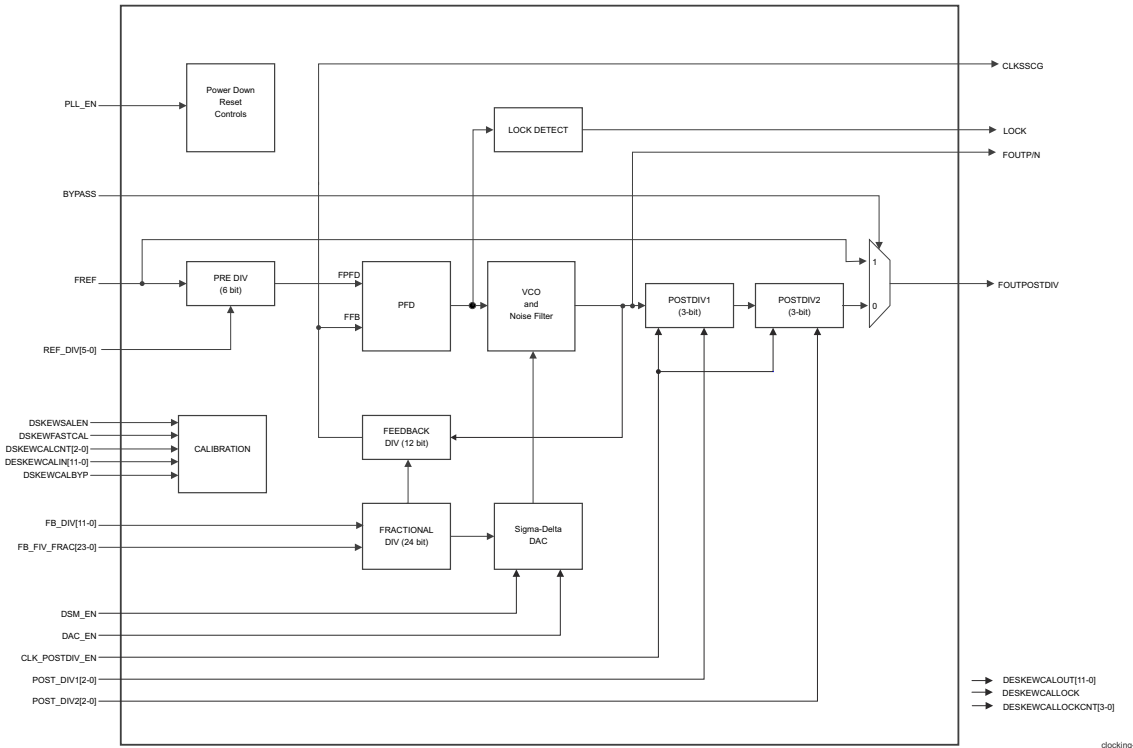

To generate high-frequency clocks, the device supports multiple on-chip PLLs controlled directly by the Top-level Clocking. Their type is Fractional PLL with Calibration (PLLTS16FFCLAFRACF2).

### Note

This chapter discusses only the PLLs that are directly controlled by the Top-level Clocking. The other PLLs embedded in and managed by other subsystems are described in their respective subsystems.

#### 6.4.5.4.1 PLLs Output Clocks Parameters

Figure 6-33 shows the functional architecture of a generic PLL for PLLTS16FFCLAFRACF2 type.

**Figure 6-33. Generic PLL Functional Diagram for PLLTS16FFCLAFRACF2 Type**

#### 6.4.5.4.1.1 PLLs Input Clocks

As shown in Figure 6-33 the reference clock (FREF) input is used to generate the synthesized clock, but can also be used as the bypass clock for some outputs of the PLL whenever the PLL enters bypass mode. It is mandatory for the PLL clock synthesis.

#### 6.4.5.4.1.2 PLL Output Clocks

##### 6.4.5.4.1.2.1 PLLTS16FFCLAFRACF2 Type Output Clocks

Table 6-26 describes the output clocks of PLLTS16FFCLAFRACF2.

**Table 6-26. PLLTS16FFCLAFRACF2 Output Clocks**

Output	Description	Frequency
FOUTP	Positive phase VCO output (no post divider)	$(FREF / REF\_DIV) * (FB\_DIV + FB\_DIV\_FRAC)$
FOUTN	Negative phase VCO output (no post divider)	$(FREF / REF\_DIV) * (FB\_DIV + FB\_DIV\_FRAC)$
FOUTPOSTDIV	VCO-divided clock output.	$FOUTP / (POST\_DIV1 * POST\_DIV2)$

Where:

- REF\_DIV is the software-configured division ratio binary value.

- FB\_DIV is the software-configured division ratio binary value.
- FB\_DIV\_FRAC is the software-configured fractional division.
- POST\_DIV1 is the software-configured division ratio binary value.
- POST\_DIV2 is the software-configured division ratio binary value.

#### Note

POST\_DIV1 and POST\_DIV2 valid values are from 1 to 7. To ensure correct operation, POST\_DIV1 must always be programmed to a value equal to or greater than POST\_DIV2.

#### Note

For device-specific information about clock output parameters and synthesized clocks, see [Table 6-31](#) and [Table 6-32](#).

#### 6.4.5.4.1.2.2 PLL Lock

PLL module outputs a lock status signal to indicate that the PLL has achieved frequency lock. When the PLL detects no cycle slips between the feedback clock (FFB) and reference clock FPDF (FREF/ REF\_DIV[5-0]) for 128 consecutive cycles, it asserts the lock signal high. When the PLL detects any cycle slip, lock signal will go low and stays low until it detects no cycle slip for 128 consecutive cycles. This lock signal is captured in <PLL\_name>\_STAT[0] LOCK bit. Software can read this bit to determine if the PLL has achieved frequency lock before selecting the PLL clock through external bypass mux.

When PLL losses lock, there is a hardware mechanism to automatically bypass the PLL clock to the reference clock (FREF) using the external glitch free mux. BYP\_ON\_LOCKLOSS bit in <PLL\_name>\_CTRL register enables this automatic bypass mode on PLL lock loss. When the PLL re-locks, the glitch free mux switches to PLL clock out.

The PLL Lock signal is also routed to ESM module for error reporting. ESM can be configured to generate interrupts to MCU\_R5FSS and R5FSS0/1 and assert Low on MCU\_ERRORn pin on PLL Lock loss for further action.

#### 6.4.5.4.1.2.3 HSDIVIDER

A PLL may contain up to 10 HSDIVIDER modules to produce more clocks with divided ratio based on the PLL synthesized clock frequency. HSDIVIDER provides only one output. The HSDIVIDER output clock frequency is given by the equations in [Table 6-27](#).

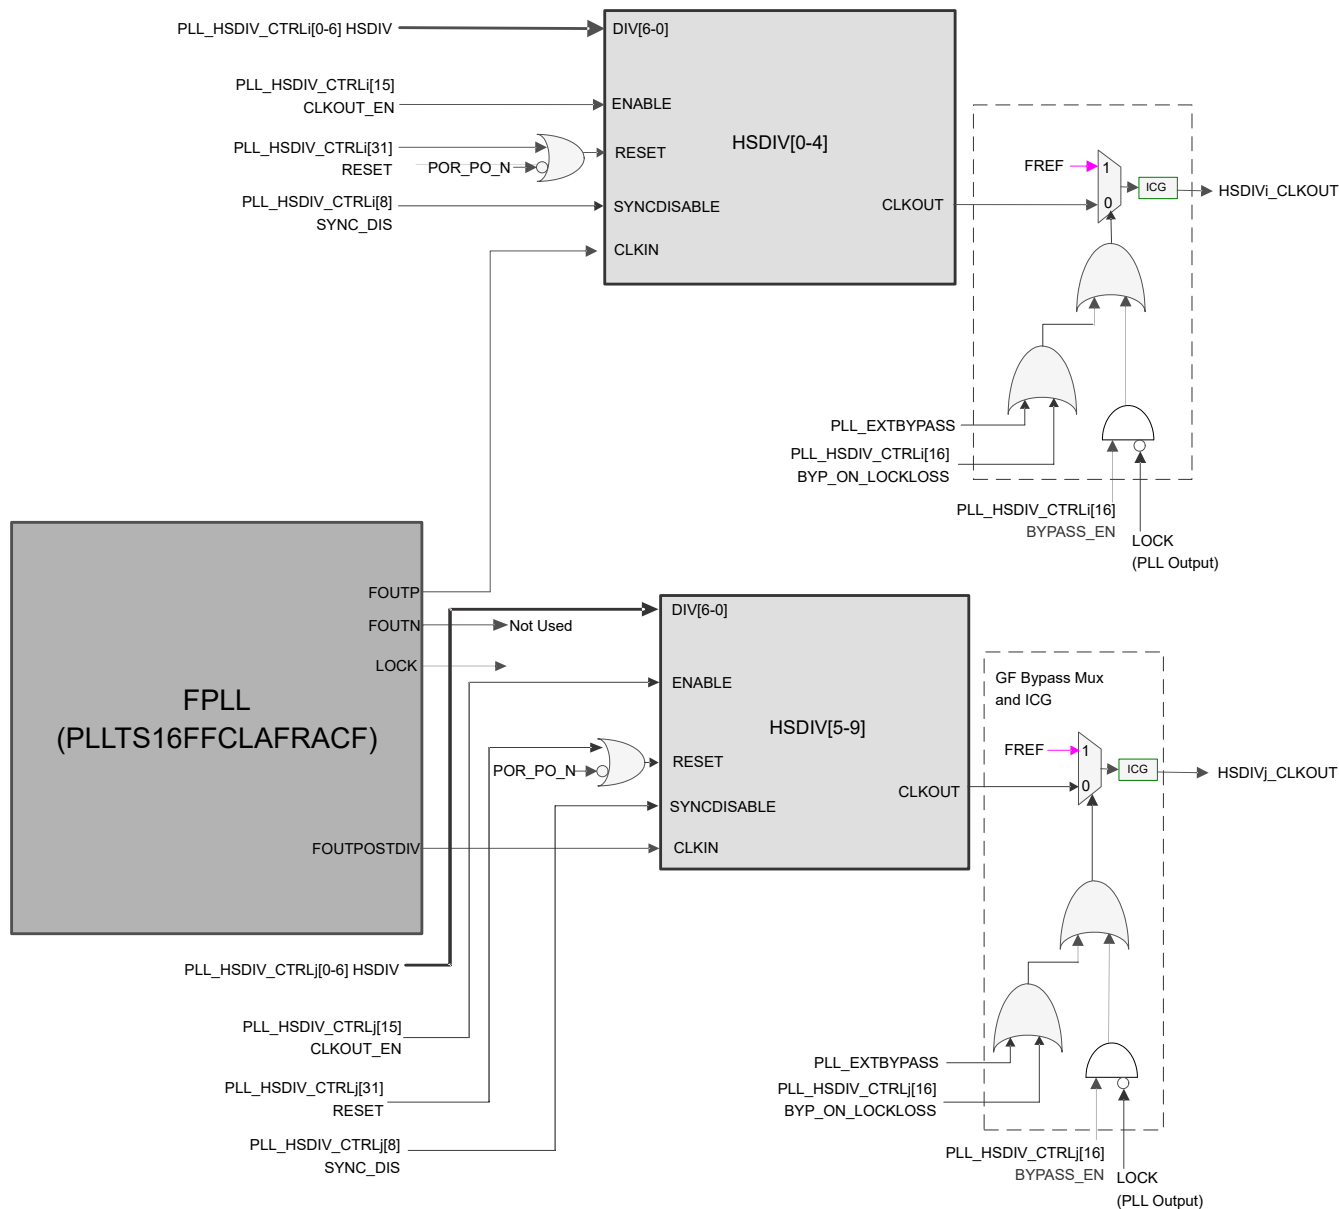

**Table 6-27. HSDIV\_CLKOUT Frequency With PLL State**

Equation	PLL Mode
$\text{HSDIV\_CLKOUT} = \text{FOUTP} / (\text{HSDIV} + 1)$	Locked
$\text{HSDIV\_CLKOUT} = \text{FREF}$	Before lock or during relock

Where:

- FOUTP is the PLL lock frequency.
- HSDIV is the software-configured division ratio binary value.

[Figure 6-34](#) describes the connection between a HSDIV and a specific type of PLL. Signals related only to this connections are shown in both figures.

clocking-016

(1)<sub>i</sub> = 0 to 4; <sub>j</sub> = 5 to 9

**Figure 6-34. PLLTS16FFCLAFRAC2 and HSDIV Connection**

#### 6.4.5.4.1.2.4 ICG Module

ICG module ensures that when a particular HSDIV is not enabled the HSDIV clock output is gated off. This is a hardware module with no software control.

#### 6.4.5.4.1.2.5 PLL Power Down

PLLTS16FFCLAFRAC2 is disabled with MCU\_PLL0\_CTRL[15] PLL\_EN or PLLn\_CTRL[15] PLL\_EN.

#### 6.4.5.4.1.2.6 PLL Calibration

PLLTS16FFCLAFRAC2 has calibration feature. The calibration settings are done via <PLL\_Name>\_CAL\_CTRL register. The calibration status can be monitored by reading

<PLL\_Name>\_CAL\_STAT register. For more information about device-specific information about calibration feature, see [Table 6-33](#).

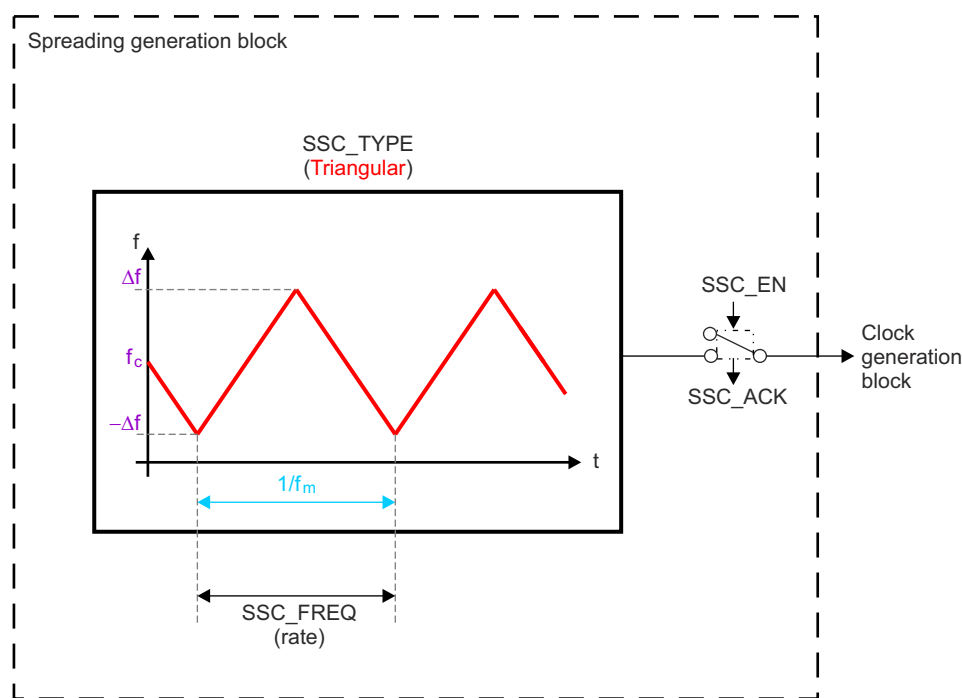

#### 6.4.5.4.2 PLL Spread Spectrum Modulation Module

Spread Spectrum Modulation (SSMOD) modules on the device reduces Electro Magnetic Interference (EMI). It is a fully-digital circuit, used to modulate the frequency of the selected fractional PLLs. Programming options include selection of center spread or down spread, modulation depth, and modulation shape. The default modulation profile is triangular.

All PLLs in this family of device have SSMOD module.

SSMOD in the PLL is performed by changing the feedback divider (FRAC and FB\_DIV) in a triangular pattern. This varies the frequency of the output clock in a triangular pattern. The frequency of this pattern is the modulation frequency ( $f_m$ ). It is programmed as a ratio of the CLKIN/4.

[Figure 6-35](#) shows a diagram of the spreading generation block.

prcm-086

**Figure 6-35. Spreading Generation Block Diagram**

#### Note

$\Delta f$  is the deviation from the center frequency. The total spreading deviation is equal to twice  $\Delta f$ . The peak ( $\Delta M$ ) or the amplitude of the triangular/square pattern as a percent of  $M$  would be equal to the percent of the frequency spread ( $\Delta f$ ),  $\Delta M/M = \Delta f/f_c$ .

$f_c$  is the original output clock frequency.

$f_m$  is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal to add some controlled deviation to the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces EMI. SSMOD\_DOWNSPREAD can control the position of the generated signal. It is controlled by the <PLL\_name>\_CTRL[4] DOWNSPREAD\_EN

bit of the corresponding registers. If the DOWNSPREAD\_EN bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0.

The value of SSMOD\_FREQ controls the rate of the generated signal. It can be programmed as a ratio of the reference clock:  $f_{ref} / 4$ . The value that must be programmed is calculated as follows:

$ModFreqDivider = f_{ref} / (4 \times f_m)$ , where  $f_m < f_{ref} / 70$ ,  $f_{ref} = f_{inp} / (1+N)$ , and  $f_{inp}$  is the input clock for the PLL.

#### 6.4.5.4.2.1 Definition of SSMOD

The aim of the SSMOD is to add a variation to the frequency of an original clock, which spreads the generated interference over a larger band of frequencies.

In theory, SSMOD means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 MHz at one time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be spread out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating an SSMOD by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.

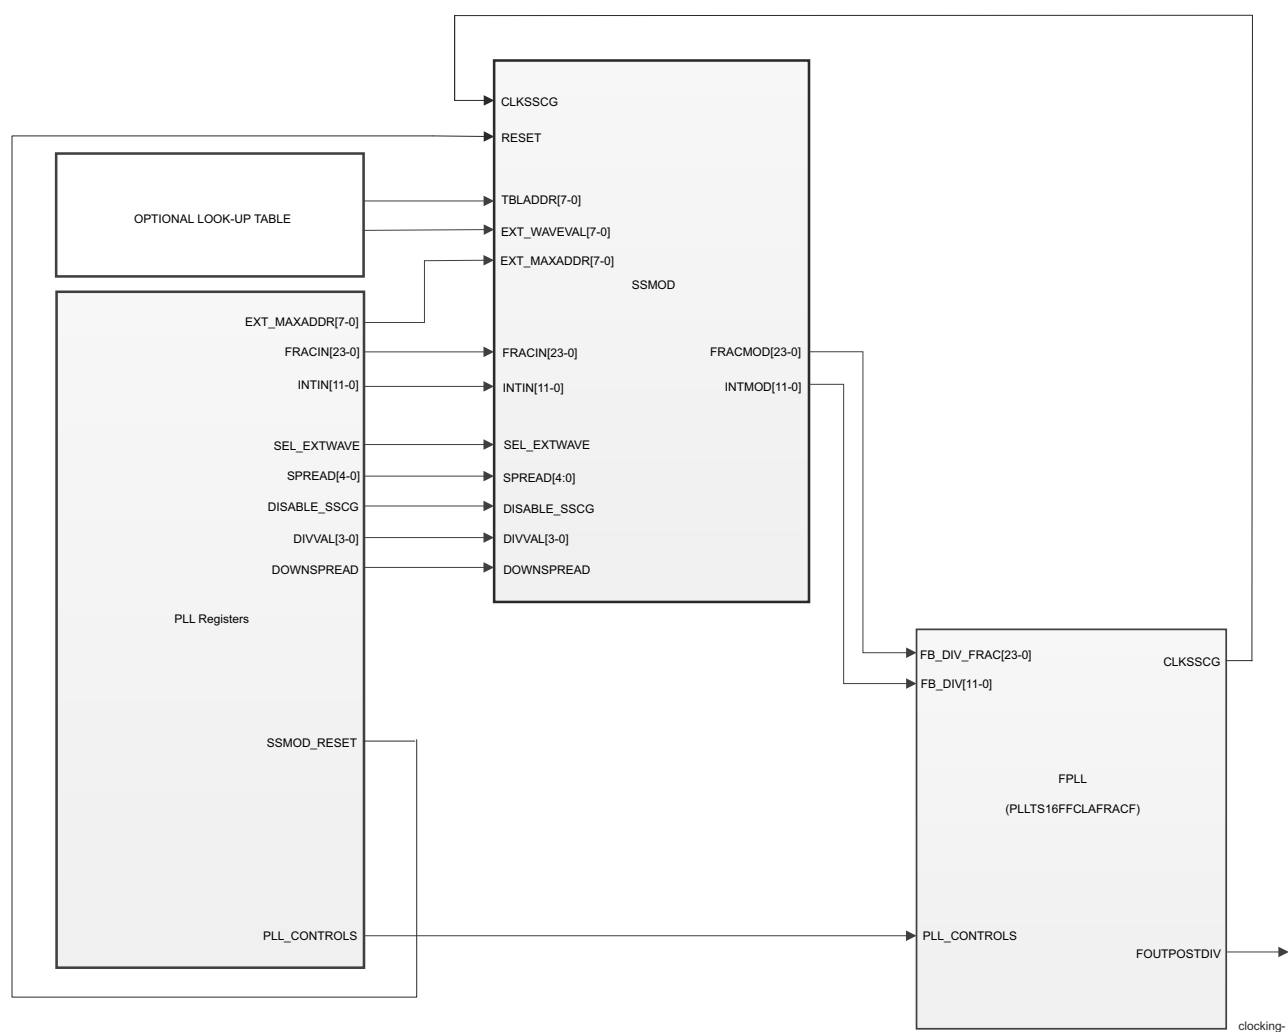

#### 6.4.5.4.2.2 SSMOD Configuration

Table 6-28 describes the PLL SSMOD control bitfields. Figure 6-36 describes the connection between a SSMOD and a PLL.

**Table 6-28. SSMOD related bitfields**

Parameter	Register	Description
SSMOD enable control	<PLL_name>n_SS_CTRL[31] <sup>(1)</sup> BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[31] BYPASS_EN)	Enable/disable the PLL SSMOD feature.
Wave table maximum address	<PLL_name>n_SS_CTRL[25-18] <sup>(1)</sup> WV_TBL_MAXADDR (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[25-18] WV_TBL_MAXADDR)	Wave table maximum address. Indicates the maximum number of address bits used to access the external wave table. These bits are not used if <PLL_name>n_SS_CTRL[0] WAVE_SEL = 0
Type of spread	<PLL_name>n_SS_CTRL[4] <sup>(1)</sup> DOWNSPREAD_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[4] DOWNSPREAD_EN)	Selects center spread or down spread clock variance
Wave table selection	<PLL_name>n_SS_CTRL[0] <sup>(1)</sup> WAVE_SEL (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[0] WAVE_SEL)	Wave pattern select External wave table should only be selected
Modulation divider	<PLL_name>n_SS_SPREAD[19-16] <sup>(1)</sup> MOD_DIV (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[19-16] MOD_DIV)	Input clock divider. This divider sets the modulation frequency.
Spread Depth	<PLL_name>n_SS_SPREAD[4-0] <sup>(1)</sup> SPREAD (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[4-0] SPREAD)	Sets the spread modulation depth.

### 6.4.5.5 PLLs Device-Specific Information

Table 6-29 lists the basic information of the MCU PLL.

**Table 6-29. Basic Information of MCU\_PLL0**

PLL name	Type	HSDIV Available	Input clock	Comments
MCU_PLL0	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV4	HFOSC0_CLKOUT	See (1), (2), and (3)

(1) See Figure 6-33, *Generic PLL Functional Diagram for PLLTS16FFCLAFRACF2 type* for overview of the PLL.

(2) See Section 6.4.5.5.2 for synthesized clock parameters.

(3) See Section 6.4.5.5.3 for clock output parameters.

Table 6-30 lists the basic information of each of the MAIN PLLs.

**Table 6-30. Basic Information of MAIN Domain PLLs**

PLL name	Type	HSDIV Available	Input clock	Comments
PLL0	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV4, HSDIV5, HSDIV6, HSDIV7, HSDIV8, HSDIV9	MAIN_PLL0_REFCLK	See (1), (2), and (3)
PLL1	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV4, HSDIV5, HSDIV6	MAIN_PLL1_REFCLK	See (1), (2), and (3)
PLL2	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV4, HSDIV5, HSDIV6, HSDIV7, HSDIV8, HSDIV9	MAIN_PLL2_REFCLK	See (1), (2), and (3)
PLL5	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1, HSDIV2	MAIN_PLL5_REFCLK	(1), (2), and (3)
PLL6	PLLTS16FFCLAFRACF2	HSDIV0	MAIN_PLL6_REFCLK	(1), (2), and (3)
PLL7	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1	MAIN_PLL7_REFCLK	(1), (2), and (3)
PLL8	PLLTS16FFCLAFRACF2	HSDIV0	MAIN_PLL8_REFCLK	See (1), (2), and (3)
PLL12	PLLTS16FFCLAFRACF2	HSDIV0	MAIN_PLL12_REFCLK	See (1), (2), and (3)
PLL15	PLLTS16FFCLAFRACF2	HSDIV0, HSDIV1	MAIN_PLL15_REFCLK	See (1), (2), and (3)
PLL17	PLLTS16FFCLAFRACF2	HSDIV0	MAIN_PLL17_REFCLK	See (1), (2), and (3)

(1) See Figure 6-33, *Generic PLL Functional Diagram for PLLTS16FFCLAFRACF2 type* for overview of the PLL.

(2) See Section 6.4.5.5.2 for synthesized clock parameters.

(3) See Section 6.4.5.5.3 for clock output parameters.

#### 6.4.5.5.1 SSMOD Related Bitfields Table

[Table 6-28](#) lists SSMOD related bitfields for all types of PLLs.

#### 6.4.5.5.2 Clock Synthesis Inputs to the PLLs

Table 6-31 lists the clock synthesis parameters for PLLTS16FFCLAFRACF2 type.

**Table 6-31. Clock synthesis Parameters for PLLTS16FFCLAFRACF2 Type**

Parameter Name	Register
FB_DIV	<PLL_name>_FREQ_CTRL0[11-0] FB_DIV_INT (For example, MCU_PLL0 - MCU_PLL0_FREQ_CTRL0[11-0] FB_DIV_INT)
FB_DIV_FRAC	<PLL_name>_FREQ_CTRL1[23-0] FB_DIV_FRAC (For example, MCU_PLL0 - MCU_PLL0_FREQ_CTRL1[23-0] FB_DIV_FRAC)
POST_DIV2	<PLL_name>_DIV_CTRL[26-24] POST_DIV2 (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[26-24] POST_DIV2)
POST_DIV1	<PLL_name>_DIV_CTRL[18-16] POST_DIV1 (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[18-16] POST_DIV1)
REF_DIV	<PLL_name>_DIV_CTRL[5-0] REF_DIV (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[5-0] REF_DIV)

#### Note

For PLLTS16FFCLAFRACF2 type - POST\_DIV1 and POST\_DIV2 values are from 1 to 7. To ensure correct operation, POST\_DIV1 must always be programmed to a value equal to or greater than POST\_DIV2.

#### 6.4.5.5.3 Clock Output Parameter

Table 6-32 lists the control/status bit fields for output clocks.

**Table 6-32. Clock Output Parameter for PLLTS16FFCLAFRACF2 Type**

Clock Output/Divider	Parameter Name	Control/Status Bit Field
<PLL_name>_CLKOUT, <PLL_name>_HSDIVj_CLKOUT <sup>(1)</sup>	Control	<PLL_name>_CTRL[31] BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[31] BYPASS_EN)
<PLL_name>_HSDIVj_CLKOUT <sup>(1)</sup>	Control	<PLL_name>_HSDIV_CTRLj[15] CLKOUT_EN (For example, MCU_PLL0 - MCU_PLL0_HSDIV_CTRL0[15] CLKOUT_EN and MCU_PLL0_HSDIV_CTRL1[15] CLKOUT_EN)
<PLL_name>_HSDIVj_CLKOUT <sup>(1)</sup>	Divider control	<PLL_name>_HSDIV_CTRLj[6-0] HSDIV (For example, MCU_PLL0 - MCU_PLL0_HSDIV_CTRL0[6-0] HSDIV and MCU_PLL0_HSDIV_CTRL1[6-0] HSDIV)
PLL bypass mux	Control	<PLL_name>_CTRL[16] BYP_ON_LOCKLOSS (For example, MCU_PLL0 - MCU_PLL0_CTRL[16] BYP_ON_LOCKLOSS)
Enable 4-phase clock generator	Control	<PLL_name>_CTRL[5] CLK_4PH_EN (ignored if <PLL_name>_CTRL[4] CLK_POSTDIV_EN = 0) (For example, MCU_PLL0 - MCU_PLL0_CTRL[5] CLK_4PH_EN)
Post divide CLK enable	Control	<PLL_name>_CTRL[4] CLK_POSTDIV_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[4] CLK_POSTDIV_EN)
Delta-Sigma modulator enable	Control	<PLL_name>_CTRL[1] DSM_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[1] DSM_EN)

**Table 6-32. Clock Output Parameter for PLLTS16FFCLAFRACF2 Type (continued)**

Clock Output/Divider	Parameter Name	Control/Status Bit Field
Enable fractional noise canceling DAC	Control	<PLL_name>_CTRL[0] DAC_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[0] DAC_EN)

(1) j is the number of HSDIV for the current PLL.

#### 6.4.5.5.4 Calibration Related Bitfields

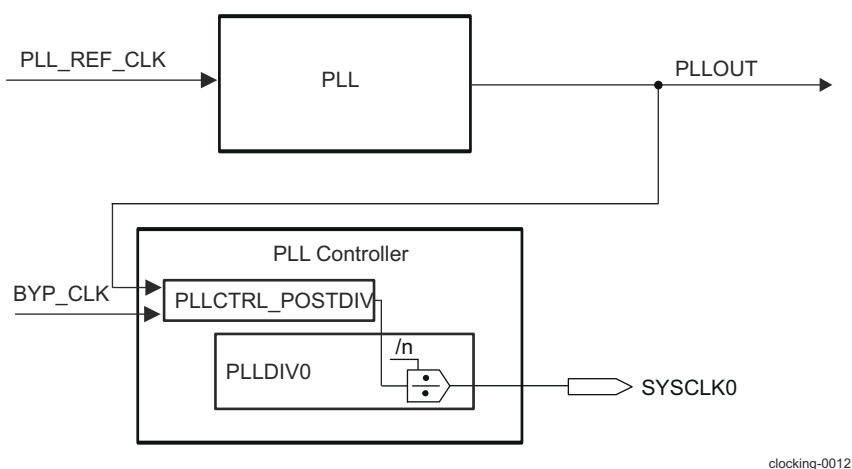

Table 6-33 lists the calibration related bitfields/bits.

**Table 6-33. Recalibration Feature Parameters**

Recalibration feture	Parameter Name	Control/Status Bit Field
Calibration enable to actively adjust for input skew	Control	<PLL_name>_CAL_CTRL[31] CAL_EN (For example, PLL12 - PLL12_CAL_CTRL[31] CAL_EN)
Fast calibration enabled	Control	<PLL_name>_CAL_CTRL[20] FAST_CAL (For example, PLL12 - PLL12_CAL_CTRL[20] FAST_CAL)
Calibration loop programmable counter	Control	<PLL_name>_CAL_CTRL[18-16] CAL_CNT (For example, PLL12 - PLL12_CAL_CTRL[18-16] CAL_CNT)
Calibration bypass	Control	<PLL_name>_CAL_CTRL[15] CAL_BYP (For example, PLL12 - PLL12_CAL_CTRL[15] CAL_BYP)
Calibration input	Control	<PLL_name>_CAL_CTRL[11-0] CAL_IN (For example, PLL12 - PLL12_CAL_CTRL[11-0] CAL_IN)
Output of the calibration block	Status	<PLL_name>_CAL_STAT[11-0] CAL_OUT (For example, PLL12 - PLL12_CAL_STAT[11-0] CAL_OUT)

#### 6.4.5.6 PLL Controller (PLLCTRL)

The PLLCTRL manages clock alignment of CBASS clocks to the peripherals in Main and MCU domains. In addition PLLCTRL is also responsible for controlling reset propagation through the chip and providing DFT hooks for testability. Two PLL Controllers are implemented in the device - PLLCTRL0 and MCU\_PLLCTRL0. They are respectively related to PLL0 and MCU\_PLL0.

**Figure 6-37. PLL Controller**

---

**Note**

PLLCTRL\_POSTDIV is not supported in this family of devices.

---

---

**Note**

The PLL Controllers registers can be accessed by any controller in the device.

A SYSCLK0 clock out of a PLLCTRL is the only synchronous clock in that domain. That means  
- MCU\_SYSCLK0 out of MCU\_PLLCTRL is the synchronous CBASS clock in MCU domain and  
SYSCLK0 out of Main PLLCTRL is the synchronous CBASS clock in Main domain.

---

#### 6.4.5.7 PLL, PLLCTRL, and HSDIV Controllers Programming Guide

##### 6.4.5.7.1 PLL Initialization

###### 6.4.5.7.1.1 Kick Protection Mechanism

---

**Note**

PLL configuration registers are write-protected at power-up. Software must first un-lock the PLLn\_LOCKKEY0 and PLLn\_LOCKKEY1 registers prior to writing to any chip-level registers.

---

The un-lock process shall follow the steps:

1. Write value 0x68EF3490 to PLLn\_LOCKKEY0 register.
2. Write value 0xD172BC5A to PLLn\_LOCKKEY1 register.

After these two steps a write access to the PLL registers is allowed. Writing any other data value to either of these two registers locks the kicker mechanism and blocks any writes to the PLL registers.

---

---

**Note**

In order to ensure that all PLL registers are write protected, software must always re-lock the kicker mechanism after completing the register writes.

---

###### 6.4.5.7.1.2 PLLCTRL Initialization

---

**Note**

For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Datasheet.

---

Initially, the device powers up in PLL bypass mode. The bypass mux is a glitch free mux and is located outside the PLL module. BYPASS\_EN bit controls the bypass mux section. During Power-up, the bypass mux defaults to select FREF clock (PLL clock bypass mode).

The following shows the PLL initialization sequence.

1. Wait until supplies are stable and PORz is de-asserted. By this time the reference clock source must be up and running.
2. Default controls settings:
  - By default PLL\_EN signal is Low provided by <PLL\_name>\_CTRL register default state. This signal behaves like a reset control to the PLL.
  - By default INTL\_BYP\_EN signal is low provided by <PLL\_name>\_CTRL register default state.
  - By default BYPASS\_EN signal is high provided by PLL MMR CTRL default state. PLL clock will be bypassed externally by a glitch free mux. The output of the mux will be the reference clock FREF.
  - LOCK output of PLL will be Low.

3. Program the PLL to a valid setting that runs the VCO within the specified range. The following bits/bitfields must be programmed appropriately by software: DSM\_EN, DAC\_EN, CLK\_POSTDIV\_EN, CLK\_4PH\_EN, REF\_DIV[5:0], FB\_DIV[11:0], FB\_DIV\_FRAC[23:0], POST\_DIV1[2:0], POST\_DIV2[2:0].
4. Wait for 1  $\mu$ s to allow the PLL internal reset to complete (PLL powerdown switch pulls the loop filter voltage from rail-to-rail, which ensures the PLL will be completely powered down from any state).
5. Assert PLL\_EN to a High (by writing a '1' into PLL\_EN bit in <PLL\_name>\_CTRL register).
6. Wait for PLL Lock output to go high. Software can read the LOCK bit in <PLL\_name>\_STATS register to check if PLL has locked.
7. De-assert BYPASS\_EN signal to a Low by writing 0 into BYPASS\_EN bit in <PLL\_name>\_CTRL register.
8. Glitch free mux safely switches to the PLL clock output.

#### Note

In the case of brown out (supply dips below datasheet minimum) or loss of the reference clock, the state of the PLL will be undetermined. A full reset sequence should be initiated.

**Changing PLL setting:** During normal operation, before changing PLL settings, the PLL clock must be bypassed by setting BYPASS\_EN control to a high. Then follow steps 2 to 8 from the above sequence.

#### 6.4.5.7.1.3 PLL Programming Requirements

- A PLL VCO frequency must be set to > 1500 MHz
  - For best PLL performance, maximize VCO frequency where possible.
- A PLL must always operate in Fractional Mode (DAC\_EN and DSM\_EN set to '1'). This is true even when the FB\_DIV is a integer.
- A PLL Reference clock frequency must be > 10 MHz.
- REF\_DIV[5:0] must be set to "000001".
- Calibration procedures for FRACF PLLs in integer mode or fractional mode:
  - **Programming FRACF in Integer Mode with calibration (Static or Auto Calibration)**
    - Set all the common PLL settings (PREDIV, FBDIV, ...)
    - DACEN: 0
    - DSMEN = 0 (INT MODE)
    - FASTCAL=1
    - CALBYPASS=0
    - CALCNT[2:0]=2
    - CALIN[11:0]=0
    - CAL\_EN=1
    - SET PLL\_EN = 1
    - WAIT FOR PLL\_LOCK AND CAL\_LOCK GO HI
    - CAPTURE AND STORE CALCODE WHEN CAL\_LOCK GOES HI IF IT WILL BE USED LATER
    - IF CAL\_LOCK times out ( > 2 ms ) then continue
    - CAL\_EN=0 (OPTIONAL, THIS WILL FREEZE CALIBRATION & INTERNAL CALCODE)
  - **Programming FRACF in Fractional Mode (with Static Calcode)**
    - Set all common PLL settings to nearest integer (PREDIV, FBDIV,...)
    - Run calibration as outlined in integer mode
    - CAPTURE AND STORE CALCODE WHEN CAL\_LOCK GOES HI IF IT WILL BE USED LATER
    - IF CAL\_LOCK times out ( > 2 ms ) then continue
    - CAL\_EN=0 (THIS WILL FREEZE CALIBRATION & INTERNAL CALCODE)
    - IF CAL\_LOCK timed out, keep CALBYPASS=0
    - IF CAL\_LOCK IS ASSERTED AND CALCODE IS CAPTURED APPLY CALCODE TO CALIN
    - CALBYPASS=1 CALCODE IS SET BY CALIN
    - ENABLE FRACTIONAL MODE
  - **Programming FRACF in Fractional Mode (Auto-Calibration Not Allowed)**
    - Set all the common PLL settings (PREDIV, FBDIV, ...)
    - DACEN=1

- DSMEN=1 (FRAC MODE)
- FASTCAL =X
- CALBYPASS=1 CALCODE IS SET BY CALIN
- CALCNT[2:0]=XX
- CALIN[11:0] = 0 (OR DESIRED CALCODE)
- CAL\_EN = 0
- SET PLL\_EN = 1
- WAIT FOR PLL\_LOCK

PLL Integer mode with Calibration enabled is recommended for applications sensitive to phase noise or jitter: Examples include Refclk for SerDes, PHY, DDR etc. See individual product datasheets for specific SoC requirements. Calibration can be bypassed for digital clocks like ARM. If Calibration is bypassed, CALIN needs to be set to 0.

When Calibration is enabled, PLL Lock time will be longer since SOC needs to wait for CAL\_LOCK. Applications sensitive to phase noise must wait for CAL\_LOCK to go high.

#### 6.4.5.7.2 HSDIV PLL Programming

<PLL\_Name>\_HSDIV\_CTRLk[15] CLKOUT\_EN = 0 cleanly disables the HSDIV output clock

<PLL\_Name>\_HSDIV\_CTRLk[6:0] HSDIV = <value> for divider

<PLL\_Name>\_HSDIV\_CTRLk[8] SYNC\_DIS = 0 insures that the divider changes occur synchronously to the internal divider of the HSDIV block.

when the clock is required,

<PLL\_Name>\_HSDIV\_CTRLk[15] CLKOUT\_EN = 1 cleanly enables the HSDIV output clock

#### 6.4.5.7.3 PLL Controllers Programming - Dividers PLLDIVn and GO Operation

The GO operation is required to change the divider ratios of the PLLDIVn registers. [Section 6.4.5.7.3.1, GO Operation](#), discusses the GO operation. [Section 6.4.5.7.3.2, Software Steps to Modify PLLDIVn Ratios](#), provides the software steps required to change the divider ratios.

##### 6.4.5.7.3.1 GO Operation

The GO operation writes to the RATIO field in the PLLDIVn. Registers do not change the dividers' divide ratios immediately. The PLLDIV dividers change to the new RATIO rates only during a GO operation. This section discusses the GO operation and alignment of the SYSCLKs.

The PLL Controller clock align control register (ALNCTL) determines which SYSCLKs must be aligned. Before a GO operation, program ALNCTL so that the appropriate clocks are aligned during the GO operation.

A GO operation is initiated by setting the GOSSET bit in PLLCMD to 1. During a GO operation:

- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL and SYS *n* bit in DCHANGE set to 1 is paused at the low edge. Then the PLL Controller restarts all these SYSCLKs simultaneously, aligned at the rising edge. When the SYSCLKs are restarted, SYSCLK *n* toggles at the rate programmed in the RATIO field in PLLDIVn.
- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL cleared and the SYS *n* bit in DCHANGE set immediately changes to the new rate programmed in the RATIO field.
- The GOSTAT bit in PLLSTAT is set throughout the duration of a GO operation.

#### CAUTION

To help prevent errors, all device operation must be stopped before the GO operation.

##### 6.4.5.7.3.2 Software Steps to Modify PLLDIV Ratios

Perform the following steps to modify PLLDIV.

1. Check that the GOSTAT bit in PLLSTAT is cleared to show that no GO operation is currently in progress.

2. Program the RATIO field in PLLDIV $n$  to the desired new divide-down rate. If the RATIO field changed, the PLL Controller will flag the change in the corresponding bit of DCHANGE.
3. Set the respective ALN  $n$  bits in ALNCTL to align any SYSCLKs after the GO operation.
4. Set the GOSET bit in PLLCMD to initiate the GO operation to change the divide values and align the SYSCLKs as programmed.
5. Read the GOSTAT bit in PLLSTAT to make sure the bit returns to 0 to indicate that the GO operation has completed.

#### 6.4.5.7.4 Entire Sequence for Programming PLLCTRL, HSDIV, and PLL

Table 6-34 shows the entire sequence of programming PLLCTRL, HSDIV, and PLL from an unknown state to a defined non-spread-spectrum state.

**Table 6-34. Programming Sequence of PLLCTRL, HSDIV, and PLL**

Step	Description
Unlock PLL registers	<PLL_Name>_LOCKKEY0 (= 0x68EF3490) <PLL_Name>_LOCKKEY1 (= 0xD172BC5A)
If PLL0	Configure PLLCTRL block into bypass mode PLLCTL[0] PLEN = 0 PLLCTL[5] PLENSRC = 0
Configure external bypass so that no transient clock propagates	<PLL_Name>_CTRL[31] BYPASS_EN = 1
Delay	
Disable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 0
Delay	
Disable PLL	<PLL_Name>_CTRL[15] PLL_EN = 0
Delay	
Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 1
If PLL0	Check PLLSTAT[0] GOSTAT to make sure that divider change is not currently in-progress GOSTAT should equal 0. Clear GOSET bit PLLCMD[0] GOSET = 0 Configure divider in PLLCTRL to /1 PLLDIV1 = 0x8000 (enable divider and divide by 1) PLLDIV2 = 0x00 (disable divider and divide by 1) Set alignment control bits ALNCTL = 3 Set GOSET bit to initiate the divider change PLLCMD[0] GOSET = 1 Check PLLSTAT[0] GOSTAT to make sure that divider change has completed GOSTAT should equal 0.
Configure HSDIV(s) divider value	<PLL_Name>_HSDIV_CTRLk[6-0] HSDIV (=val)
Clear HSDIV(s) SYNC_DIS	<PLL_Name>_HSDIV_CTRLk[8] SYNC_DIS = 0
Delay	
Clear Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 0
Configure PLL multiplier	Integer portion of divider <PLL_Name>_FREQ_CTRL0[11-0] (=val) Fractional portion of divider <PLL_Name>_FREQ_CTRL1[23-0] (=val)
Configure PLL dividers	Reference clock divider <PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1 Post divider 1 <PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1

**Table 6-34. Programming Sequence of PLLCTRL, HSDIV, and PLL (continued)**

Step	Description
	Post divider 2 <PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1
Configure "random" PLL controls	<PLL_Name>_CTRL[8] INTL_BYP_EN = 0 <PLL_Name>_CTRL[5] CLK_4PH_EN = 0 <PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1 <PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1 <PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1 <PLL_Name>_CTRL[1] DSM_EN = 1 <PLL_Name>_CTRL[0] DAC_EN = 1 <PLL_Name>_SS_CTRL[31] BYPASS_EN (SSMOD) = 1 <PLL_Name>_CTRL[4] CLK_POSTDIV_EN – if PLL has more than 5 HSDIV blocks, 1; else 0. <PLL_Name>_CTRL[16] BYP_ON_LOCKLOSS (= {0, 1})
Delay	
Enable PLL	<PLL_Name>_CTRL[15] PLL_EN = 1
Wait for Lock	Wait for MCU_PLL0_STAT[0] LOCK = 1
Enable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 1
Delay	
Configure external bypass to pass PLL	<PLL_Name>_CTRL[31] BYPASS_EN = 0
Delay	
If PLL0	Configure PLLCTRL block into PLL mode PLLCTL[0] PLEN = 0
Lock PLL registers	<PLL_Name>_LOCKKEY0 (= any value) <PLL_Name>_LOCKKEY1 (= any value)

#### 6.4.5.7.5 Dual Clock Comparator (DCC)

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference. Internal 12.5 MHz RC oscillator clock is used to validate HFOSC0\_CLKOUT. Then HFOSC0\_CLKOUT (most accurate clock) is used to validate/track all other clocks in the device. An additional use of this module is to measure the frequency of a selectable clock source, using an external input clock source of known frequency (MCU\_EXT\_REFCLK0, EXT\_REFCLK1 pins). There is one instance of DCC module in MCU domain and seven instances of DCC modules in Main domain to monitor critical clocks. Refer to DCC chapter for details.

## 7.1 Arm Cortex-A53 Subsystem (A53SS)

This section describes the Arm® Cortex®-A53 Subsystem (A53SS) in the device.

## 7.1.1 A53SS Overview

### 7.1.1.1 A53SS Introduction

The SoC implements one cluster of quad-core Arm® Cortex® A53 MPCore™, with 32KB L1 instruction, 32KB L1 data, per core and 512KB L2 shared cache.

The Cortex®-A53 cores are general-purpose processors that can be used for running customer applications.

#### Note

Notes on references used in this document:

- A53SS is also referred to as Arm® CorePac.
- Cortex®-A53 is often shortened to A53.

The A53SS is built around the Cortex®-A53 MPCore™ (Arm® A53 Cluster), which is provided by Arm and configured by TI. It is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management, debug and emulation capabilities.

The A53 processor is a multi-issue out-of-order superscalar execution engine with integrated L1 Instruction and Data Caches, compatible with Arm®v8-A architecture. It delivers significantly more performance than its predecessors at a higher level of power efficiency.

The Arm®v8-A architecture brings a number of new features. These include 64-bit data processing, extended virtual addressing and 64-bit general purpose registers. The A53 processor is Arm's first Arm®v8-A processor aimed at providing power-efficient 64-bit processing. It features an in-order, 8-stage, dual-issue pipeline, and improved integer, Arm® Neon™, Floating-Point Unit (FPU) and memory performance.

The A53 CPU supports two execution states: AArch32 and AArch64. The AArch64 state gives the A53 CPU its ability to execute 64-bit applications, while the AArch32 state allows the processor to execute existing Arm®v7-A applications.

### 7.1.1.2 A53SS Features

The A53SS module supports the following features:

- Quad Core A53 Cluster
  - Full Arm®v8-A Architecture Compliant
    - AArch32 and AArch64 Execution States
    - All exception levels EL0-3
    - A32 Instruction Set (Previously Arm instruction set)
    - T32 instruction set (Previously Thumb instruction set)
    - A64 Instruction Set
  - Data Coherency within Cluster (L1/L2 caches)
  - Advanced SIMD and Floating Point Extensions (Arm® Neon™)
  - Armv8 Cryptography Extensions
  - Arm GICv3 architecture
  - In-order pipeline with symmetric dual-issue of most instructions
  - Harvard L1 with system MMU
    - 32 KB Instruction Cache
    - 32 KB Data Cache
  - 512KB Shared L2 Cache
  - Generic Timer(s)
  - Debug
- 128-Bit VBUSM Initiator Interfaces (for axi\_r and axi\_r channels)
- 128-Bit VBUSM Target Interface (for Accelerator Coherency Port)
- 64-bit Grey-coded system input time
- 48-bit Grey-coded debug input time

- 48-bit Grey-coded debug input time
- Integrated PBIST controller with BISTOR

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

## 7.1.2 A53SS Functional Description

### 7.1.2.1 A53SS Block Diagram

#### 7.1.2.2 Arm Cortex-A53 Cluster

The Arm Cortex-A53 Cluster is provided by Arm and configured by TI. [Table 7-1](#) summarizes the configuration of the Arm Cortex-A53 Cluster on this SoC.

**Table 7-1. Arm A53 Cluster Configuration**

Parameter	Value
Core Type	A53
Core Revision	r0p4
Number of Cores	4
Bus Width	256
L1 Instruction Cache Size	32K
L1 Data Cache Size	32K
L2 Cache Size	512K
SCU-L2 Cache Protection	Included
Advanced SIMD and Floating Point Extension	Included
Cryptography Extension	Included
CPU Cache Protection	Included
AMBA5 CHI or AMBA4 ACE Interface	AMBA4 ACE (configured for AXI using tie-offs)
Accelerator Coherency Port (ACP)	Included
V7 or v8 Debug Memory Map	v8

#### Note

For a brief list of features supported by the Arm Cortex-A53 Cluster, see [A53SS Features](#).

For detailed description of the Arm A53 Cluster, see the *ARM®Cortex®-A53 MPCore Processor Technical Reference Manual*.

#### 7.1.2.3 A53SS Interfaces and Async Bridges

The A53SS has the following main interfaces:

- 64-bit graycoded system input time
  - Graycode value provided by Global Timebase Counter (GTC)
  - Dedicated decoder (64-bit input) for graycode-to-binary conversion
- 48-bit graycoded debug input time
  - Graycode value provided by GTC
  - Dedicated decoder (48-bit input) for graycode-to-binary conversion
- 32-bit VBUSP target interface for debug
  - Supported by VBUSP2APB Bridge, which performs VBUSP-to-APB conversion (for controlling the Arm A53 Cluster internal debug logic)
- 32-bit ATB output port for debug/trace
  - Supported by ATB Bridge, which performs clock and voltage level conversion on the combined ATB interface
  - Connected to the Debug Subsystem
- Cross Trigger Interface (CTI) for debug
  - Connected to the Debug Subsystem
- Interface(s) with Arm GIC-500 Interrupt Controller

- Supported by GIC AXI Streaming Bridge, which performs clock and voltage level conversion on the AXI streaming protocol
- Interrupts (PPIs) from Arm A53 Cluster to GIC-500
- Interrupts (IRQ, FIQ, VIRQ, VFIQ) from GIC-500 to Arm A53 Cluster
- Power/clock interface(s)
  - Dedicated PLL for each Arm A53 Cluster
  - Dedicated LPSC for each Arm A53 Cluster, and also for each A53 core

#### 7.1.2.4 A53SS Interrupts

##### 7.1.2.4.1 A53SS Interrupt Inputs

The A53 CPU receives interrupts at its inputs (IRQ, FIQ, VIRQ, VFIQ) via the dedicated Arm GIC-500 Interrupt Controller, which resides at the SoC level (MAIN Domain) and is integrated inside the GIC0 Subsystem. The GIC-500 supports all four A53 cores in the system.

The GIC-500 is compliant to the Arm GICv3 standard and supports four types of interrupts:

- *Software Generated Interrupts (SGI)*
  - There are 16 SGIs (ID0-ID15)
  - These are inter-processor interrupts
- *Private Peripheral Interrupts (PPI)*
  - There are 16 PPIs (ID16-ID31)
  - These are wired interrupts dedicated to a specific CPU
  - Many are reserved to specific functions via convention
- *Shared Peripheral Interrupts (SPIs)*
  - There are 256 SPIs (ID32-ID288)
  - These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC500
- *Locality-Specific Peripheral Interrupts (LPI)*
  - There are 57,344 LPIs
  - These interrupts are used for message-based interrupts from a peripheral

The mapping of PPIs and SPIs to the GIC-500 interrupt inputs can be found in *Interrupts*.

#### Note

For a brief list of features supported by the GIC-500 module, see the *Interrupts* chapter.

For detailed description of the GIC-500 module, see the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

##### 7.1.2.4.2 A53SS Interrupt Outputs

[A53SS Interrupt Outputs](#) lists the interrupts generated by the A53SS.

**Table 7-2. A53SS Interrupt Outputs**

Interrupt Name (TI) <sup>(1)</sup>	Interrupt Name (Arm)	Interrupt Description
<b>A53 Core Interrupts (PPIs)<sup>(2)</sup></b>		
A53_COREy_VCPUMNTIRQ	VCPUMNTIRQn	This interrupt indicates that a Virtual CPU Interface on the corresponding core needs serviced. This interrupt is serviced by software switching to the virtual CPU and finding what specific service needs done.
A53_COREy_CNTHPIRQ	CNTHPIRQn	This interrupt indicates a physical timer event at the EL2 (Hypervisor) exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL2 and service accordingly.

**Table 7-2. A53SS Interrupt Outputs (continued)**

Interrupt Name (TI) <sup>(1)</sup>	Interrupt Name (Arm)	Interrupt Description
A53_COREy_CNTPNIRQ	CNTPNIRQn	This interrupt indicates a physical timer event at the EL1 Non-Secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 Non-Secure and service accordingly.
A53_COREy_CNTPSIRQ	CNTPSIRQn	This interrupt indicates a physical timer event at the EL1 Secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 Secure and service accordingly.
A53_COREy_CNTVIRQ	CNTVIRQn	This interrupt indicates a Virtual timer event. Service of this interrupt is dependent on what the timer was set for. Software should take exception and service accordingly.
A53_COREy_PMUIRQ	PMUIRQn	This interrupt is generated by the Performance Monitor Unit (PMU). The PMU can generate an interrupt based on several conditions, depending on programming. Software should take exception and query the PMU as to the cause of the interrupt, and act accordingly.
A53_COREy_DCCIRQ	COMMIRQn	Communications Channel receive or transmit interrupt
A53_COREy_CTIIRQ	CTIIRQn	Cross Trigger Interface interrupt

(1) In this column, y is the A53 Core index (0 or 1)

(2) These are 'per core' interrupts

### Note

The mapping of these interrupts in the system is summarized in *A53SS Integration*, and can also be found in *Interrupts*.

For more detailed description of these interrupts and their handling, see the *Arm® Cortex®-A53 MPCore Processor Technical Reference Manual*.

## 7.1.2.5 A53SS Power Management and Clocking

### 7.1.2.5.1 A53SS Power Management

Each Arm A53 Cluster and each A53 CPU reside in a separate power domain, as follows:

There is a dedicated Local Power Sleep Controller (LPSC) for each Arm A53 Cluster, and for each A53 core, as well. The LPSC assignment is as follows:

For more details on these LPSCs, including power-up/down sequences, see *Power*.

### 7.1.2.5.2 A53SS Clocking

There is a dedicated PLL for each Arm A53 Cluster. The PLL assignment is as follows:

- PLL8 (ARM0 PLL): Dedicated for Arm A53 Cluster 0

For more details on these PLLs, see *Clocking*.

### 7.1.2.6 A53SS Debug

The A53SS supports the standard Arm debug architecture. Details on Arm debug can be found in the *On-chip Debug* chapter and the relevant Arm specifications.

### 7.1.2.7 A53SS Global and Debug Timestamps

The A53SS has two timebase input interfaces:

- 64-bit global timestamp: Used for synchronizing the Arm internal timers (via the ARM CNTVALUEB [63:0] bus)
- 48-bit debug timestamp: Can be embedded in Arm trace streams at periodic and strategic locations, allowing the temporal relationship of different trace sources to be determined

Both of them are fed by the Global Timebase Counter (GTC), which provides a 64-bit graycode value. The A53SS includes two graycode decoders (for global time and debug time, respectively), which take the asynchronous graycoded times, synchronize them to the appropriate clock, and convert them to binary time, as required by Arm.

#### Note

Both graycode decoders are 64-bit but the one dedicated to debug time has a 48-bit input (the upper 16 bits are tied to 0).

For more details on the GTC, see *Global Timebase Counter (GTC)*.

#### 7.1.2.8 A53SS Watchdog

The A53SS does not have an integrated watchdog timer. Instead, this feature is provided externally by the Real Time Interrupt Module (RTI) module, which implements a windowed watchdog timer capable of issuing warm reset to the SoC, when necessary.

For more details on the RTI windowed watchdog feature, see *Real Time Interrupt Module (RTI/WWDT)*.

#### 7.1.2.9 A53SS Functional Safety - ECC Error Injection Support

In the quad A53 CBA subsystem, there are five ECC aggregators – one for each core and one for the corepac level. Debug domain is not safety critical.

No CBASS/Bridge interconnect safety is supported. Only RAM safety is supported.

The following A53SS ECC Aggregator instances are instantiated:

- A53SS0\_ECC\_AGGR0: ECC Aggregator for Arm A53 Cluster 0, Core 0
- A53SS0\_ECC\_AGGR1: ECC Aggregator for Arm A53 Cluster 0, Core 1
- A53SS0\_ECC\_AGGR2: ECC Aggregator for Arm A53 Cluster 0, Core 2
- A53SS0\_ECC\_AGGR3: ECC Aggregator for Arm A53 Cluster 0, Core 3
- A53SS0\_ECC\_AGGR\_COREPAC: ECC Aggregator for Arm A53 Cluster 0

##### 7.1.2.9.1 A53 ECC Aggregators During Low Power States

- When a cpu core is in WFI/WFE, the corresponding core ECC Aggregator MMR regions is not accessible and will return error status.
- Similarly when L2 is in WFI, the corepac ECC Aggregator MMR region is not accessible and will return error status.

##### 7.1.2.9.2 Auto-initialization of Memories

All A53 L1 and L2 memory initialization is handled by the Arm core. The TI ECC aggregator is used in inject-only mode and this cannot be used for initialization. The Arm CPU will initialize the cache memories after reset.

There are no other memories in the A53 subsystem beside the cache memories

##### 7.1.2.9.3 A53 SRAM Safety

The Arm A53 Cluster natively supports ECC/parity protection on A53 SRAMs and error injection on few memories. The A53SS adds error injection capability on all internal SRAM. This is a valuable TI addition to the Arm native implementation.

**Table 7-3. A53 SRAM Safety Support**

RAM	A53 Error Injection Support	TI Error Injection Support
L1 I-Cache Data	No	Single error injection
L1 I-Cache Tag	No	Single error injection
L1 D-Cache Data	Double error injection	Single and double error injection
L1 D-Cache Tag	No	Single error injection
L1 Data Dirty	No	Single error injection

**Table 7-3. A53 SRAM Safety Support (continued)**

RAM	A53 Error Injection Support	TI Error Injection Support
TLB RAM	No	Single error injection
SCU Duplicate Tag	No	Single and double error injection
L2 Tag RAM	Double error injection	Single and double error injection
L2 Data RAM	Double error injection	Single and double error injection

The ECC Aggregator for the cores stimulates errors in the following RAMs:

- L1 I-Cache Data RAM
- L1 I-Cache Tag RAM
- L1 D-Cache Data RAM
- L1 D-Cache Tag RAM
- L1 D-Cache Dirty RAM
- TLB RAM
- L1 SCU L1-D Duplicate Tag RAM

The ECC Aggregator for the L2 cache stimulates errors in the following RAMs:

- L2 Data RAM
- L2 Tag RAM

#### 7.1.2.9.4 A53 SRAM ECC Aggregator Configurations

There are several schemas of memory protection employed inside of the processors. The tables below describe the schema and arrangement. This describes what bits are protected, how they are protected, the behavior when an error is detected and what bits can be disturbed for ECC testing purposes. This also lists the RAMID associated with each memory to the corresponding ECC Aggregator.

The key for the protection schemes is as follows:

- Parity – Parity Bit(s) to protect data
- ECC – Error Correction Code to protect Data
- SED – Single Error Detection
- SECEDED – Single Error Correction, Double Error Detection
- SEDSEC – Single Error Detection, Single Error Correction

**Table 7-4. CPU Memories Safety Details**

Memory	Protection	RAM Arrangement	CPU (Core ECC Aggr) Rams Ram ID	Notes
L1 I-Cache Data	Parity SED	41 – Parity for 40:21 40:21 – Instruction 20 – Parity for 19:0 19:0 – Instruction	0-3	Error detection results in both lines being invalidated then refetched from L2 or memory
L1 I-Cache Tag	Parity SED	31 – Parity for 30:0 30:0 – Data	4-5	Error detection results in both lines being invalidated, then line refetched from L2 or memory
L1 D-cache Data	ECC SECEDED	38:32 – ECC 31:0 – Data	6-13	Error results in line being cleaned and invalidated from L1 with single bit errors corrected as part of eviction. Line refetched from L2 or memory
L1 D-Cache Tag	Parity SED	30 – Parity for 29:0 29:0 – Tag	14-17	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Error results in line cleaned and invalidated from L1. SCU duplicate tags are used to get the correct address. Line refetched from L2 or memory

**Table 7-4. CPU Memories Safety Details (continued)**

Memory	Protection	RAM Arrangement	CPU (Core ECC Aggr) Rams Ram ID	Notes
L1 D-cache Dirty	Parity SEDSEC	11:10 – Way 1/3 Dirty copy 2 and 1. Parity for 4 9:8 – Way 0/2 Dirty copy 2 and 1. Parity for 0 7 – Way 1/3 Outer Allocation Hint 6 – Way 1/3 Age 5:4 – Way 1/3 Partial MOESI 3 – Way 0/2 Outer Allocation Hint 2 – Way 0/2 Age 1:0 – Way 0/2 Partial MOESI	18	Error results in line cleaned and invalidated from L1 with single bit errors corrected as part of the eviction. Only dirty bit is protected. Other bits are just performance hints
TLB	Parity SED	116 – parity for 113:62 115 – Parity for 61:31 114 – Parity for 30:0 113:62 – Page Attributes 61:31 – Entry Identifiers 30:0 – Address	19-22	Error detection results in entry invalidated, new pagewalk to refetch.
SCU L1 Duplicate Tag	ECC SECDED	37:31 - ECC for 30:0 30:0 - Duplicate Tag	23-26 (accessed by each Core's ecc_aggr)	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Corretable Error – Tag rewritten with correct value, access retried Uncorrectable Error – Tag is invalidated

**Table 7-5. L2 Memories Safety Details**

Memory	Protection	RAM Arrangement	RAM_ID (L2 Cache RAMs)	Notes
L2 Tag	ECC SECDED	37:31 – ECC for 30:0 30:0 - Tag	0-15	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Corretable Error – Tag rewritten with correct value, access retried. Uncorrectable Error – Tag is invalidated
L2 Victim	None	–	–	Performance Hint Only – Error has no functional impact
L2 Data	ECC SECDED	71:64 – ECC for 63:0 63:0 – Data	16-23	Error results in Data corrected inline, access may stall for 1-2 cycles. After correction, line might be evicted
Branch Predictor	None	–	–	Performance Hint Only – Error has no functional impact

#### 7.1.2.10 A53SS Boot

For A53SS boot sequence and any other A53SS boot details, see *Control Module (CTRL\_MMR)*.

#### 7.1.2.11 A53SS Interprocessor Communication

The Arm A53 core(s) can communicate with other device cores (R5FSS, DMSC M3) by supporting interrupt generation to and from these cores. The interprocessor communication (IPC) interrupts are assigned in the corresponding BOOTCFG0 memory-mapped registers (MMRs) called IPC\_SETx / IPC\_CLRx. For more information, see *Control Module (CTRL\_MMR)*.

## 7.2 Arm Cortex R5F Subsystem (R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (R5FSS) in the device.

<b>7.2.1 R5FSS Overview</b> .....	<b>845</b>
<b>7.2.2 R5FSS Functional Description</b> .....	<b>847</b>

### 7.2.1 R5FSS Overview

The R5FSS is a dual-core implementation of the Arm® Cortex®-R5F processor configured for split or single-core operation. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

#### Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

#### 7.2.1.1 R5FSS Features

Each R5FSS supports the following features:

- Dual-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - Boot-time configurable to be in single- or dual-core (split) mode
    - Dual-core mode: Two independently operating cores (asymmetric multi processing, no coherence)
    - Single-core mode: Only one operating core (CPU0)
      - CPU0 uses TCM resources of both cores
      - CPU1 caches and interrupts are unused in this mode
  - L1 memory system
    - 32KB instruction cache
      - 4x8KB ways
      - SECDED ECC protected per 64 bits
    - 32KB data cache
      - 4x8KB ways
      - SECDED ECC protected per 32 bits
    - 64KB tightly-coupled memory (TCM) per CPU
      - SECDED ECC protected per 32 bits
      - TCM hard error cache Implemented in CPU
      - Readable/writable from system
      - TCMs initialized (to 0's) at reset
      - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
        - 32KB TCMA (ATCM)
        - 16KB TCMB0 (B0TCM)
        - 16KB TCMB1 (B1TCM)
      - In dual-core mode, TCM is 64KB in total (per core):
        - 32KB TCMA
        - 16KB TCMB0 + 16KB TCMB1
      - In single-core mode, TCM is 128KB in total (per core):
        - 64KB TCMA
        - 32KB TCMB0 + 32KB TCMB1
  - Low interrupt latency with restartable instructions
  - Non-maskable interrupt (NMI)
  - Full-precision floating point (VFPv3)
  - 16 region memory protection unit (MPU)
  - 8 breakpoints
  - 8 watchpoints
  - Dynamic branch prediction with global history buffer and 4-entry return stack

- CoreSight debug access port (DAP)
- CoreSight embedded trace macrocell (ETM-R5) interface
- Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses (per core)
  - 64-bit VBUSM target for TCM access (per core)
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access (per core)
  - 32-bit VBUSP target configuration port (per core)
  - 32-bit VBUSP target debug port
    - Allows access to all R5FSS internal debug logic
- Synchronous clock domain crossing on all interfaces
  - Both CPU and interface clocks run at the same frequency (1:1 ratio)
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
  - 4 regions
    - Base address + size
    - Must be size aligned
- Integrated vectored interrupt manager (VIM)
  - 256 interrupts per core
    - Only interrupts connected to R5F core 0 are available in single-core mode
    - Each interrupt programmable as either IRQ or FIQ
    - Each interrupt has a programmable enable mask
    - Each interrupt has a programmable 4-bit priority
  - Priority interrupt supported
  - Vectored interrupt interface
    - Compatible with R5F VIC port
    - Programmable 32-bit vector address per interrupt
      - Address is SECDED error protected
      - Default vector addresses provided on DED
    - Split or single-core capable
    - Software interrupt generation
- Integrated ECC aggregators
  - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
  - One ECC aggregator per core to cover all RAMs and caches associated with that core
- Standard Arm CoreSight debug and trace architecture at the R5FSS level
  - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
  - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
  - From ROM or external memory
  - From TCM

See [Section 7.2.2](#) for a functional block diagram and more details on the R5FSS.

#### 7.2.1.2 R5FSS Not Supported Features

The R5FSS does *not* support the following native R5F features in this device:

- ACP port (no coherence)
- Bus parity / ECC
- Multiple power domains

## 7.2.2 R5FSS Functional Description

### 7.2.2.1 R5FSS Block Diagram

Figure 7-2 shows the R5FSS block diagram.

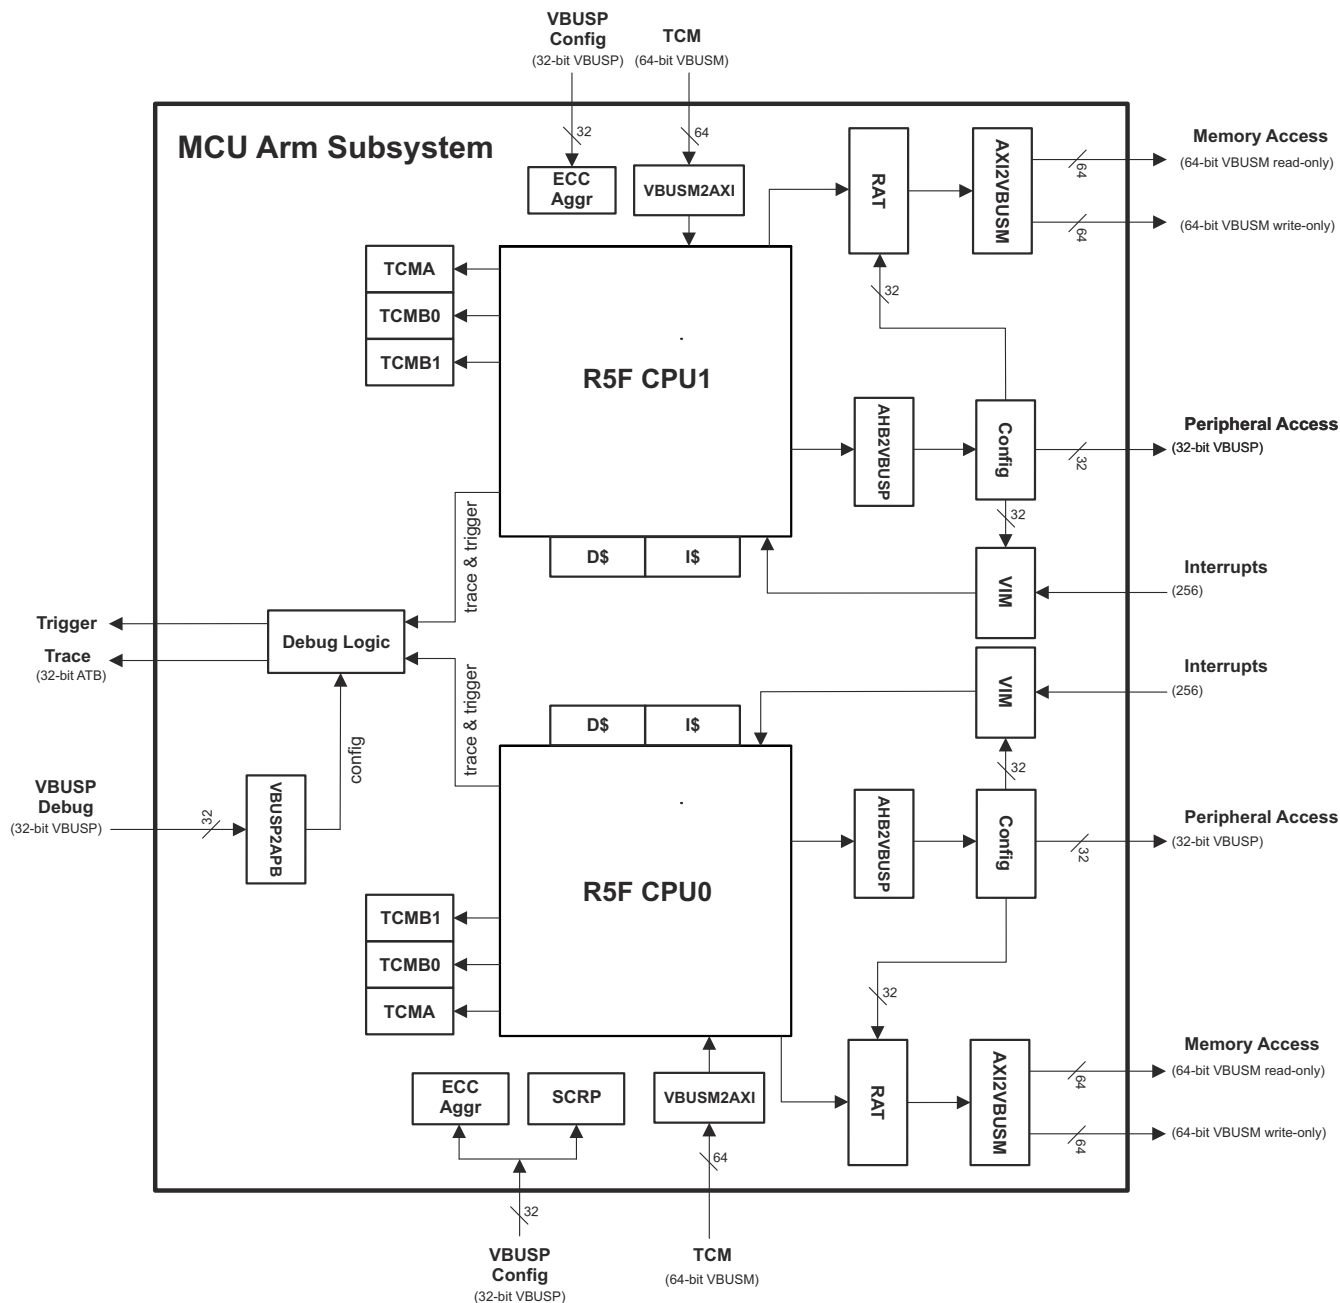

Figure 7-2. R5FSS Block Diagram

#### 7.2.2.2 R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile. Each R5FSS implements two R5F cores, CPU0 and CPU1, each with their own RAMs and interfaces. While in reset, they can be bootstrapped to work in one of two modes: split or single-core.

In split mode, each R5F core works completely independent from the other (asymmetric multi-processing, or AMP). Each core uses its own RAMs and interfaces, with no coherence between the two cores. The only

restriction is that CPU0 must be in a higher power/reset state than CPU1. For instance, CPU1 cannot be out of reset if CPU0 is not.

In single-core mode:

- CPU0 is the only operating core
- CPU1 TCMs are stacked on CPU0 TCMs and are accessible only by CPU0 and CPU0 TCM interface
- The TCM size for CPU0 is essentially doubled in this mode (128KB)
- CPU1 caches and interrupts are not used

For a brief list of features supported by the R5F processor in this device, see [Section 7.2.1.1](#). For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

#### 7.2.2.2.1 L1 Caches

The R5F has a Harvard cache architecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

#### 7.2.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPU<sub>n</sub>\_INITRAMA and CPU<sub>n</sub>\_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPU<sub>n</sub>\_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000\_0000 and the initial address of BTCM is 20'h41010. If the CPU<sub>n</sub>\_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000\_0000 and the initial base address of ATCM is 20'h41010.

### Note

This base address of 0x41010 for ATCM/BTCM based on the CPU<sub>n</sub>\_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in [Section 7.2.2.3.2](#). The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See [Section 7.2.2.11](#) for details on TCM booting.

#### 7.2.2.2.3 R5FSS Special Signals

[Table 7-6](#) through [Table 7-7](#) list some R5FSS features associated with special signals.

**Table 7-6. R5FSS0 Special Features**

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
Dual- or single-core mode 0 = Dual mode 1 = Single mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU <sub>n</sub> execution halt when coming out of reset (CPU <sub>n</sub> _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPU <sub>n</sub> exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU <sub>n</sub> VIM base address	0x2FFF_0000
CPU <sub>n</sub> RAT base address	0x2FFE_0000
CPU <sub>n</sub> RAT accesses ID	0x4 (CPU0); 0x5 (CPU1)
CPU <sub>n</sub> ATCM enable at reset (CPU <sub>n</sub> _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPU <sub>n</sub> VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	Not used
CPU <sub>n</sub> VBUSM normal peripheral port size	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port base address	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port size	Not used
CPU <sub>n</sub> clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

**Table 7-7. R5FSS1 Special Features**

Feature	Comment
Cluster affinity group ID	R5F Cluster 1 (ID = 0x1)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
Dual- or single-core mode 0 = Dual mode 1 = Single mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU <sub>n</sub> execution halt when coming out of reset (CPU <sub>n</sub> _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPU <sub>n</sub> exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU <sub>n</sub> VIM base address	0x2FFF_0000
CPU <sub>n</sub> RAT base address	0x2FFE_0000
CPU <sub>n</sub> RAT accesses ID	0x6 (CPU0); 0x7 (CPU1)
CPU <sub>n</sub> ATCM enable at reset (CPU <sub>n</sub> _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPU <sub>n</sub> VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	Not used
CPU <sub>n</sub> VBUSM normal peripheral port size	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port base address	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port size	Not used
CPU <sub>n</sub> clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

### 7.2.2.3 R5FSS Interfaces

#### 7.2.2.3.1 Initiator Interfaces

The R5FSS has several initiator interfaces per core:

- 64-bit VBUSM initiator pair (1 read – “RMST”, 1 write – “WMST”) for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator “PMST” for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

#### 7.2.2.3.2 Target Interfaces

The R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target (per core)
  - Region [0]: ECC aggregator block
- 64-bit TCM target (per core)
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

#### 7.2.2.4 R5FSS Power, Clocking and Reset

##### 7.2.2.4.1 R5FSS Power

The following R5FSS power considerations should be noted:

- R5FSS has a single power domain for all its internal logic
- When operating in split mode, CPU0 must be in a higher power/reset state than CPU1.

For more details on R5FSS power management, including power-up and power-down sequences, see *Power*.

##### 7.2.2.4.2 R5FSS Clocking

The R5FSS has four clock inputs:

- CPU0\_CLK: This is the clock for CPU0 logic
- CPU1\_CLK: This is the clock for CPU1 logic
- CPU0\_ICLK: This is the clock for CPU0 interfaces
- CPU1\_ICLK: This is the clock for CPU1 interfaces

CPU0\_CLK and CPU1\_CLK are the clocks for all of the internal CPU logic, while CPU0\_ICLK and CPU1\_ICLK are the clocks for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic). CPU1 clocks are automatically gated in single-core mode.

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

##### 7.2.2.4.3 R5FSS Reset

The R5FSS has four reset inputs:

- CPU0\_RST: This is the reset for the non-debug logic of CPU0
- CPU0\_DBG\_RST: This resets the CPU0 debug logic, excluding the APB interface
- CPU1\_RST: This is the reset for the non-debug logic of CPU1
- CPU1\_DBG\_RST: This resets the CPU1 debug logic, excluding the APB interface

In addition to the reset signals, there are two halt signals:

- CPU0\_HALT
- CPU1\_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

### 7.2.2.5 R5FSS Vectored Interrupt Manager (VIM)

#### 7.2.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU(s). It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs per R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS\_VIM\_PRI\_INT\_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS\_VIM\_INTR\_EN\_SET\_j register
  - Interrupt disable is done via the R5FSS\_VIM\_INTR\_EN\_CLR\_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS\_VIM\_INTMAP\_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS\_VIM\_VEC\_INT\_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected
- Split or single-core capable
  - In single-core mode, only interrupts connected to VIM interrupt core 0 are available
- Software interrupt generation

#### 7.2.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the two R5F cores can be found in *Interrupt Sources*.

#### 7.2.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN\_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS\_VIM\_INTMAP\_j register) and is enabled (via the R5FSS\_VIM\_INTR\_EN\_SET\_j register), then it will cause an IRQ to assert
- *CoreN\_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

#### 7.2.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS\_VIM\_VEC\_INT\_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

### Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-3 shows the VIM RAM interrupt vector map.

VIM RAM Address Space	VIM RAM Entries
Base Address + 0h	Interrupt 0 Vector
Base Address + 4h	Interrupt 1 Vector
Base Address + 8h	Interrupt 2 Vector
⋮	⋮
Base Address + 3F8h	Interrupt 254 Vector
Base Address + 3FCh	Interrupt 255 Vector

**Figure 7-3. VIM RAM Interrupt Vector Map**

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See Table 7-8 for the VIM RAM ID in the ECC aggregator map.

#### 7.2.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS\_VIM\_FIQVEC register; IRQ: reading the R5FSS\_VIM\_IRQVEC register, or the *coreN\_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS\_VIM\_FIQVEC register, or R5FSS\_VIM\_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ register, so that software may continue where it left off.

#### 7.2.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS\_VIM\_DEDVEC register is used to provide the default vector for the *coreN\_IRQADDRV* signal, the R5FSS\_VIM\_IRQVEC register, and the R5FSS\_VIM\_FIQVEC register. The R5FSS\_VIM\_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
  - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch

3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

---

#### Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt. This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

---

#### 7.2.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

#### 7.2.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in [Section 7.2.2.5.8.1](#), but the procedures in [Section 7.2.2.5.8.2](#) or [Section 7.2.2.5.8.3](#) (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in [Section 7.2.2.5.8.4](#), but the procedure in [Section 7.2.2.5.8.5](#) may be used as an alternative.

---

#### Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

---

#### 7.2.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
  - a. CPU asserts *coreN\_IRQACK* high
  - b. VIM asserts *coreN\_IRQADDRV* to indicate that the *coreN\_IRQADDR* bus is stable with the correct vector address
  - c. CPU reads *coreN\_IRQADDR*, jumps to that address, and de-asserts *coreN\_IRQACK* low
  - d. VIM de-asserts *coreN\_IRQn* and *coreN\_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
  - e. VIM loads the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, which causes the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt

- b. Level
  - i. Clear the interrupt at the source
  - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 7.2.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS\_VIM\_IRQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN\_IRQn* will re-assert, allowing priority interruption of an interrupt
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 7.2.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS\_VIM\_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_IRQSTS\_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source

- ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register

#### 7.2.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS\_VIM\_FIQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN\_FIQn* will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS\_VIM\_FIQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTFIQ[31] VALID bit

#### 7.2.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS\_VIM\_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_FIQSTS\_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register.

### 7.2.2.6 R5FSS Region Address Translation (RAT)

The R5F is a 32-bit processor, which means it can only access 4GB of directly addressable memory. The R5FSS includes a region-based address translation (RAT) unit per core, which allows the R5F to access higher address ranges. The R5FSS RAT module translates a 32-bit input address into a 36-bit output address. It supports 4 regions. For more details on RAT functionality, refer to *Region-based Address Translation (RAT) Module*.

### 7.2.2.7 R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of R5FSS CPU0 and CPU1 ECC aggregators, see *R5FSS\_CPU0\_ECC\_AGGR\_CFG\_REGS Registers* and *R5FSS\_CPU1\_ECC\_AGGR\_CFG\_REGS Registers*, respectively.

[Table 7-8](#) provides the RAM ID for each core. This is needed for bit field [10-0] ECC\_VECTOR in the corresponding R5FSS\_CPU0\_VECTOR / R5FSS\_CPU1\_VECTOR register (part of the ECC aggregator register space).

**Table 7-8. RAM ID Map for ECC Aggregator (Per Core)**

RAM ID	Memory Name
0	CPU0/1 ITAG RAM0
1	CPU0/1 ITAG RAM1
2	CPU0/1 ITAG RAM2
3	CPU0/1 ITAG RAM3
4	CPU0/1 IDATA BANK0
5	CPU0/1 IDATA BANK1
6	CPU0/1 IDATA BANK2
7	CPU0/1 IDATA BANK3
8	CPU0/1 DTAG RAM0
9	CPU0/1 DTAG RAM1
10	CPU0/1 DTAG RAM2
11	CPU0/1 DTAG RAM3
12	CPU0/1 DDIRTY RAM
13	CPU0/1 DDATA RAM0
14	CPU0/1 DDATA RAM1
15	CPU0/1 DDATA RAM2
16	CPU0/1 DDATA RAM3
17	CPU0/1 DDATA RAM4
18	CPU0/1 DDATA RAM5
19	CPU0/1 DDATA RAM6
20	CPU0/1 DDATA RAM7
21	CPU0/1 ATCM BANK0
22	CPU0/1 ATCM BANK1
23	CPU0/1 B0TCM BANK0
24	CPU0/1 B0TCM BANK1

RAM ID	Memory Name
25	CPU0/1 B1TCM BANK0
26	CPU0/1 B1TCM BANK1
27	CPU0/1 VIM RAM

### 7.2.2.8 R5FSS Memory View

The memory view of each R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see [Section 7.2.2.2.2](#).
- Peripheral interface locations: The R5F natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map*, for the complete R5F memory view for this device.

### 7.2.2.9 R5FSS Interrupts

All interrupts that are generated by the R5FSS are summarized in *R5FSS0/1 Hardware Requests*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.
- RAT exception interrupt.

Interrupt outputs: FPIXcm, FPUFCm, FPOFCm, FPDZCm, FPIDCm, and FPIOCm from R5F are not connected. Consequently, the only way to check the status of the cumulative exception status flags is by reading the FPSCR register.

### 7.2.2.10 R5FSS Debug and Trace

The R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

### 7.2.2.11 R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
  - a. To boot from ATCM, set CPU<sub>n</sub>\_INITRAMA (or CPU<sub>n</sub>\_INITRAMB to boot from BTCM)
  - b. Assert CPU<sub>n</sub>\_LOCZRAMA properly for the desired TCM
2. Assert CPU<sub>n</sub>\_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
  - a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPU<sub>n</sub>\_HALT

#### 7.2.2.12 R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are four ECC interrupts to the ESM that aggregate different categories of ECC events – CPU0 single error, CPU0 multi error, CPU1 single error, and CPU1 multi error events. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS\_EVNT\_BUS\_ESM\_SET register, it can be cleared by setting all the bits of the R5FSS\_EVNT\_BUS\_ESM\_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS\_EVNT\_BUS\_ESM\_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS\_EVNT\_BUS\_ESM\_CLR register to clear the interrupt.

The R5 core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5 core. For more details, refer to Arm R5 TRM.

**Table 7-9. R5 Event Bus Single-Bit Error Events**

Event Bus Bit #	Description	Associated Status Register
22	Instruction cache tag RAM parity or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0
23	Instruction cache data RAM parity or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS1 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS1
24	Data cache tag or dirty RAM parity error or correctable ECC error, from data-side or ACP.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS2 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS2
25	Data cache data RAM parity error or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS3 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS3
40	ATCM single-bit ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS4 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS4
41	B0TCM single-bit ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS5 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS5

**Table 7-9. R5 Event Bus Single-Bit Error Events (continued)**

Event Bus Bit #	Description	Associated Status Register
42	B1TCM single-bit ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS6 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS6
43	TCM correctable ECC error reported by load/store unit.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS7 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS7
44	TCM correctable ECC error reported by prefetch unit.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS8 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS8

**Table 7-10. R5 Event Bus Multi-Bit Error Events**

Event Bus Bit #	Description	Associated Status Register
26	TCM fatal ECC error reported from the prefetch unit.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS0
27	TCM fatal ECC error reported from the load/store unit.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS1 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS1
33	Data cache data RAM fatal ECC error.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS2 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS2
34	Data caches tag/dirty RAM fatal ECC error, from data-side or ACP.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS3 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS3
37	ATCM multi-bit ECC error.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS4 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS4
38	B0TCM multi-bit ECC error.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS5 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS5
39	B1TCM multi-bit ECC error.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS6 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS6

## 7.3 Cortex R5F Subsystem (R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (R5FSS) in the device.

### 7.3.1 R5FSS Overview

The R5FSS is a single-core implementation of the Arm® Cortex®-R5F processor that acts as the Device Manager responsible for boot, resource management, and power management functions. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

#### Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

#### 7.3.1.1 R5FSS Features

The R5FSS supports the following features:

- Single-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - L1 memory system
    - 32KB instruction cache
    - 4x8KB ways

- SECDED ECC protected per 64 bits
- 32KB data cache
  - 4x8KB ways
  - SECDED ECC protected per 32 bits
- 64KB tightly-coupled memory (TCM)
  - SECDED ECC protected per 32 bits
  - TCM hard error cache Implemented in CPU
  - Readable/writable from system
  - TCMs initialized (to 0's) at reset
  - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Low interrupt latency with restartable instructions
- Non-maskable interrupt (NMI)
- Full-precision floating point (VFPv3)
- 16 region memory protection unit (MPU)
- 8 breakpoints
- 8 watchpoints
- Dynamic branch prediction with global history buffer and 4-entry return stack
- CoreSight debug access port (DAP)
- CoreSight embedded trace macrocell (ETM-R5) interface
- Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses
  - 64-bit VBUSM target for TCM access
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access
  - 32-bit VBUSP target configuration port
  - 32-bit VBUSP target debug port
    - Allows access to all R5FSS internal debug logic
- Synchronous clock domain crossing on all interfaces
  - Interfaces can run at an integer multiple of the core frequency
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
  - 4 regions
    - Base address + size
    - Must be size aligned
- Integrated vectored interrupt manager (VIM)
  - 256 interrupts
    - Each interrupt programmable as either IRQ or FIQ
    - Each interrupt has a programmable enable mask
    - Each interrupt has a programmable 4-bit priority
  - Priority interrupt supported
  - Vectored interrupt interface
    - Compatible with R5F VIC port
    - Programmable 32-bit vector address per interrupt
      - Address is SECDED error protected
      - Default vector addresses provided on DED
    - Software interrupt generation
- Integrated ECC aggregators
  - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
  - One ECC aggregator to cover all RAMs and caches

- Standard Arm CoreSight debug and trace architecture at the R5FSS level
  - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
  - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
  - From ROM only

See [Section 7.3.2](#) for a functional block diagram and more details on the R5FSS.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

## 7.3.2 R5FSS Functional Description

### 7.3.2.1 R5FSS Block Diagram

Figure 7-4 shows the R5FSS block diagram.

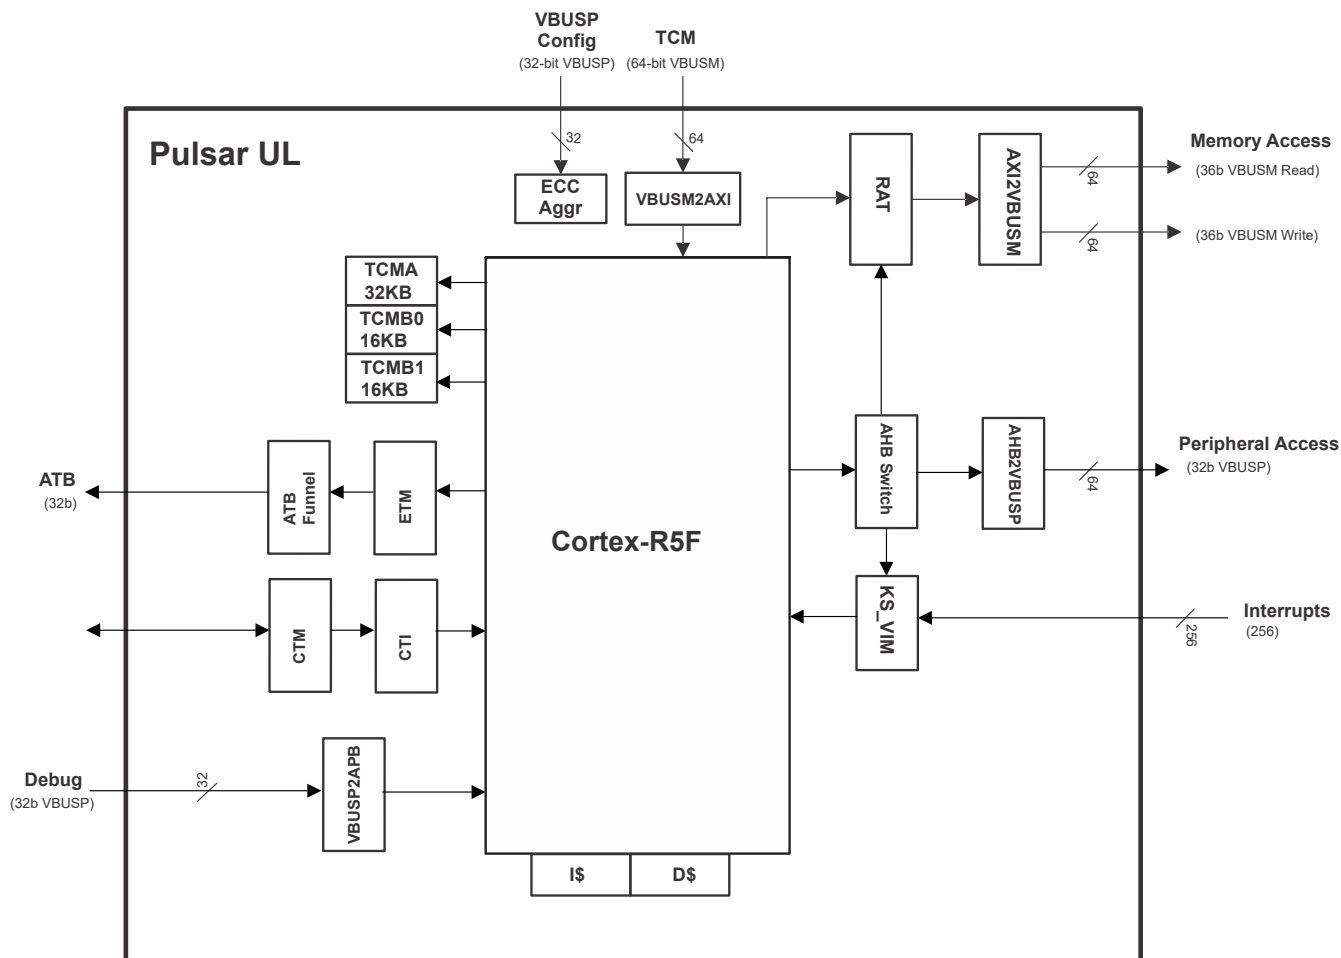

Figure 7-4. R5FSS Block Diagram

#### 7.3.2.2 R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile.

For a brief list of features supported by the R5F processor in this device, see [Section 7.3.1.1](#). For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

##### 7.3.2.2.1 L1 Caches

The R5F has a Harvard cache architecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

##### 7.3.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions

that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPU<sub>Un</sub>\_INITRAMA and CPU<sub>Un</sub>\_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPU<sub>Un</sub>\_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000\_0000 and the initial address of BTCM is 20'h41010. If the CPU<sub>Un</sub>\_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000\_0000 and the initial base address of ATCM is 20'h41010.

#### Note

This base address of 0x41010 for ATCM/BTCM based on the CPU<sub>Un</sub>\_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in [Section 7.3.2.3.2](#). The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See [Section 7.3.2.11](#) for details on TCM booting.

#### 7.3.2.2.3 R5FSS Special Signals

[Table 7-11](#) lists some R5FSS features associated with special signals.

**Table 7-11. R5FSS Special Features**

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
CPU <sub>Un</sub> execution halt when coming out of reset (CPU <sub>Un</sub> _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPU <sub>Un</sub> exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU <sub>Un</sub> VIM base address	0x2FFF_0000
CPU <sub>Un</sub> RAT base address	0x2FFE_0000
CPU <sub>Un</sub> RAT accesses ID	0x4 (CPU0)
CPU <sub>Un</sub> ATCM enable at reset (CPU <sub>Un</sub> _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state

**Table 7-11. R5FSS Special Features (continued)**

Feature	Comment
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPU <sub>n</sub> VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	Not used
CPU <sub>n</sub> VBUSM normal peripheral port size	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port base address	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port size	Not used
CPU <sub>n</sub> clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

### 7.3.2.3 R5FSS Interfaces

#### 7.3.2.3.1 Initiator Interfaces

The R5FSS has several initiator interfaces:

- 64-bit VBUSM initiator pair (1 read - "RMST", 1 write - "WMST") for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator "PMST" for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

#### 7.3.2.3.2 Target Interfaces

The R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target
  - Region [0]: ECC aggregator block
- 64-bit TCM target
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

### 7.3.2.4 R5FSS Power, Clocking and Reset

#### 7.3.2.4.1 R5FSS Power

The following R5FSS power considerations should be noted:

- R5FSS has a single power domain for all its internal logic

For more details on R5FSS power management, including power-up and power-down sequences, see *Power*.

#### 7.3.2.4.2 R5FSS Clocking

The R5FSS has four clock inputs:

- CPU0\_CLK: This is the clock for CPU0 logic
- CPU0\_ICLK: This is the clock for CPU0 interfaces

CPU0\_CLK is the clock for all of the internal CPU logic, while CPU0\_ICLK is the clock for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic).

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

#### 7.3.2.4.3 R5FSS Reset

The R5FSS has two reset inputs:

- CPU0\_RST: This is the reset for the non-debug logic of CPU0
- CPU0\_DBG\_RST: This resets the CPU0 debug logic, excluding the APB interface

In addition to the reset signals, there is one halt signal:

- CPU0\_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

### 7.3.2.5 R5FSS Vectored Interrupt Manager (VIM)

#### 7.3.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU. It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs for the R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS\_VIM\_PRI\_INT\_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS\_VIM\_INTR\_EN\_SET\_j register
  - Interrupt disable is done via the R5FSS\_VIM\_INTR\_EN\_CLR\_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS\_VIM\_INTMAP\_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS\_VIM\_VEC\_INT\_j register
  - Protected with SECCED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected

- Software interrupt generation

#### 7.3.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the R5F core can be found in *Interrupt Sources*.

#### 7.3.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- **CoreN\_IRQn**: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS\_VIM\_INTMAP\_j register) and is enabled (via the R5FSS\_VIM\_INTR\_EN\_SET\_j register), then it will cause an IRQ to assert
- **CoreN\_FIQn**: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

#### 7.3.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS\_VIM\_VEC\_INT\_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

#### Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-5 shows the VIM RAM interrupt vector map.

VIM RAM Address Space	VIM RAM Entries
Base Address + 0h	Interrupt 0 Vector
Base Address + 4h	Interrupt 1 Vector
Base Address + 8h	Interrupt 2 Vector
Base Address + 3F8h	Interrupt 254 Vector
Base Address + 3FCh	Interrupt 255 Vector

**Figure 7-5. VIM RAM Interrupt Vector Map**

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See [Table 7-14](#) for the VIM RAM ID in the ECC aggregator map.

### 7.3.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS\_VIM\_FIQVEC register; IRQ: reading the R5FSS\_VIM\_IRQVEC register, or the *coreN\_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS\_VIM\_FIQVEC register, or R5FSS\_VIM\_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ register, so that software may continue where it left off.

### 7.3.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS\_VIM\_DEDVEC register is used to provide the default vector for the *coreN\_IRQADDRV* signal, the R5FSS\_VIM\_IRQVEC register, and the R5FSS\_VIM\_FIQVEC register. The R5FSS\_VIM\_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
  - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

---

#### Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt. This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

---

### 7.3.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

### 7.3.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in [Section 7.3.2.5.8.1](#), but the procedures in [Section 7.3.2.5.8.2](#) or [Section 7.3.2.5.8.3](#) (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in [Section 7.3.2.5.8.4](#), but the procedure in [Section 7.3.2.5.8.5](#) may be used as an alternative.

### Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

#### 7.3.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
  - a. CPU asserts *coreN\_IRQACK* high
  - b. VIM asserts *coreN\_IRQADDRV* to indicate that the *coreN\_IRQADDR* bus is stable with the correct vector address
  - c. CPU reads *coreN\_IRQADDR*, jumps to that address, and de-asserts *coreN\_IRQACK* low
  - d. VIM de-asserts *coreN\_IRQn* and *coreN\_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
  - e. VIM loads the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, which causes the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 7.3.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS\_VIM\_IRQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN\_IRQn* will re-assert, allowing priority interruption of an interrupt
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source

- b. Level
  - i. Clear the interrupt at the source
  - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
- 4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 7.3.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS\_VIM\_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_IRQSTS\_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register

#### 7.3.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS\_VIM\_FIQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN\_FIQn* will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_PRIFIQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register. This way, the level should be gone at the input to the VIM, it will

avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt

4. Write any value to the R5FSS\_VIM\_FIQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTFIQ[31] VALID bit

#### 7.3.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS\_VIM\_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_FIQSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_FIQSTS\_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register.

#### 7.3.2.6 R5FSS Region Address Translation (RAT)

The R5F is a 32-bit processor, which means it can only access 4GB of directly addressable memory. The R5FSS includes a region-based address translation (RAT) unit per core, which allows the R5F to access higher address ranges. The R5FSS RAT module translates a 32-bit input address into a 36-bit output address. It supports 4 regions. For more details on RAT functionality, refer to *Region-based Address Translation (RAT) Module*.

##### 7.3.2.6.1 WKUP R5FSS Usage

R5 is a micro controller with 32b address, which is only able to access up to 4GB address space. However, Sitara™ SoC supports 36b address and majority of the memory region beyond lower 4GB are implemented. Region based address translation block, called RAT, is introduced to allow R5 core to access full 36b SoC memory map.

Each R5 core has its own RAT block, and only R5 core itself is able to program the RAT.

[Figure 7-6](#) shows the main R5's default 32b memory map view when main R5 is out of reset.

The full RAT functionality is described in [Section 7.3.2.6.2, RAT Function](#).

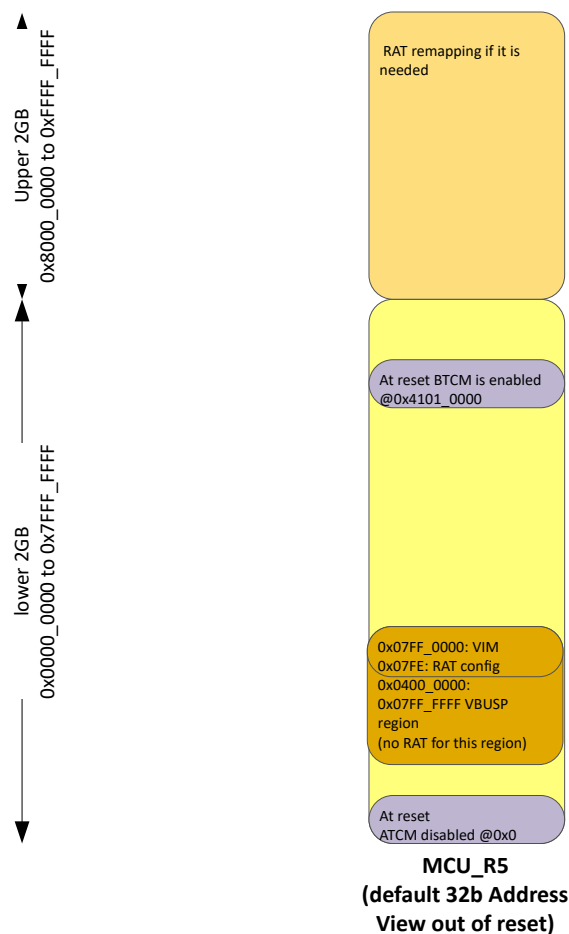

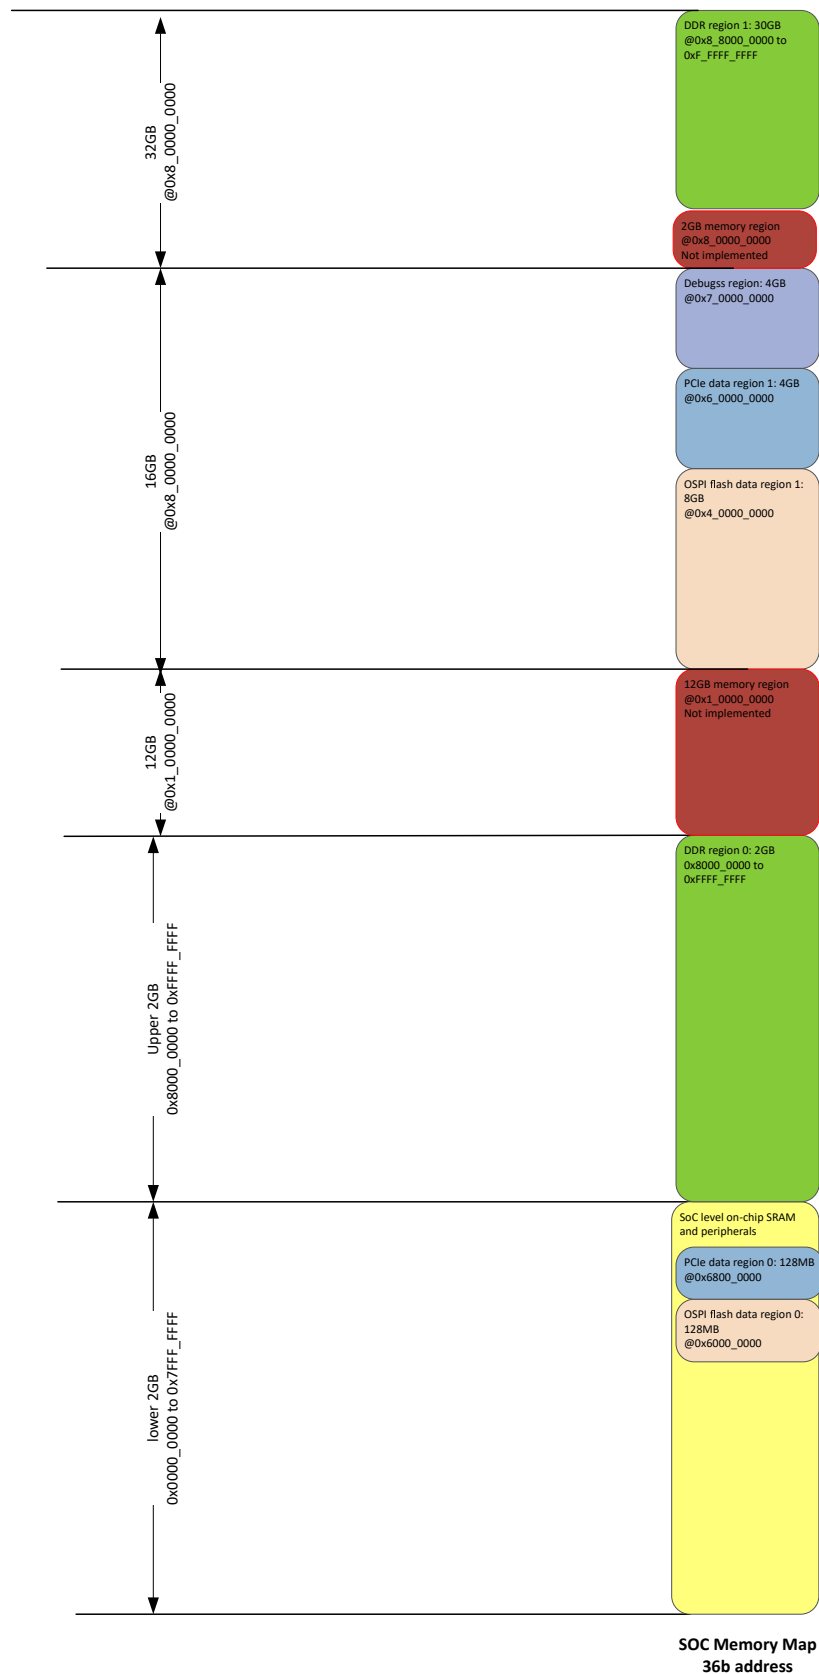

Figure 7-6. R5 Core Default Memory Map View

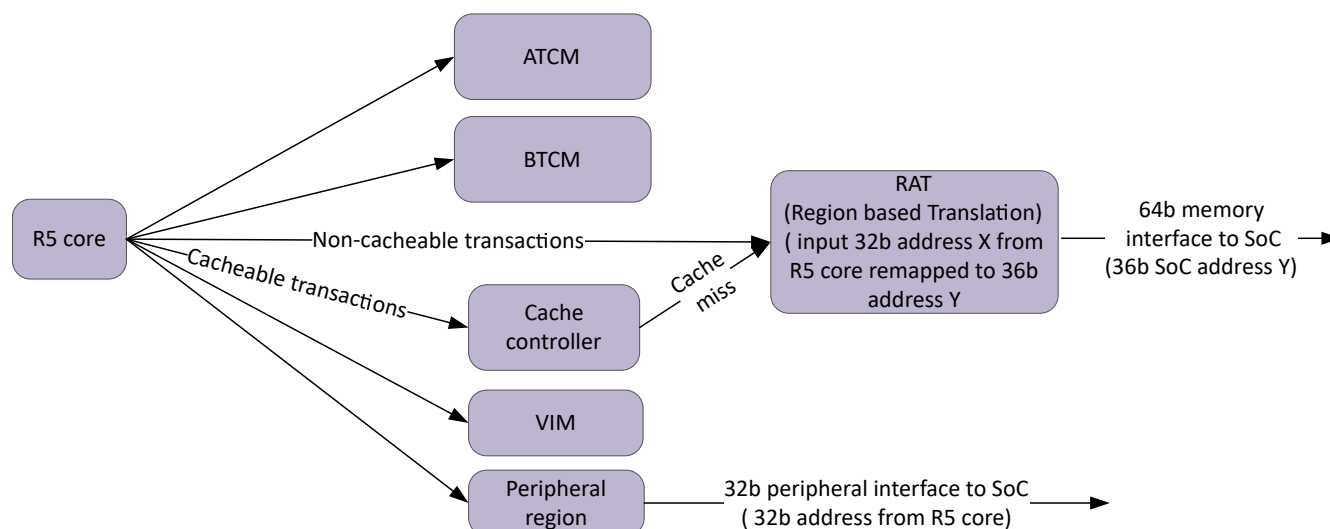

**Figure 7-7. Typical Sitara SoC Memory Map View**

RAT block enables R5 core to have full access on the SoC memory map including the memory region at and above 0x1\_0000\_0000.

Figure 7-8 shows how R5 access various end points, including its own ATCM, BTCM, VIM and SoC memory and peripherals. R5's ATCM is by default at address 0x0, and its BTCM is at address 0x4101\_0000. R5 uses address 0x07FF\_0000 to access its VIM and 0x07FE\_0000 to access the RAT configuration region and all the other transactions between address range 0x0400\_0000 to 0x07FF\_FFFF are sent to the 32b peripheral interface to access the peripherals in SoC. The transactions with the rest of address are sent to RAT block, which could go through address remapping function from original R5's 32b address to 36b SoC address.

**Figure 7-8. R5 Internal Address Decoding**

### 7.3.2.6.2 RAT Function

RAT block is responsible to do a region based address translation. For each region, user can define the starting address and size of the region and remapping the transactions to use a new address range.

The starting address and region size need to be aligned. For example, if the region size is 16KB, the starting address for that region needs to be 16KB aligned. And region size should be minimum 4KB or larger to avoid transactions cross the region boundaries.

Each RAT block supports multiple programmable regions. And it is important that those regions are not overlapping with each other.

RAT block is by default disabled, which means RAT block does not do address remapping. The 32b address coming from R5 core is directly sent out to the SoC level. The user can program each RAT remapping region individually. For the transactions does not hit any remapping region, RAT block just simply forwards the transactions to the SoC level with its original address.

### 7.3.2.6.3 How to use RAT Block in R5

Table 7-12 shows the default R5 memory map view. Without enabling RAT function, all the regions beyond 4GB address space will not be accessible by R5.

Sitara™ SoC memory map is constructed the way to allow R5 and high level application processor such as A53 have similar memory map as possible. This methodology enables that R5 and ARM A53 core have a common memory map for all the SoC level memories and SoC level peripherals except a few exceptions:

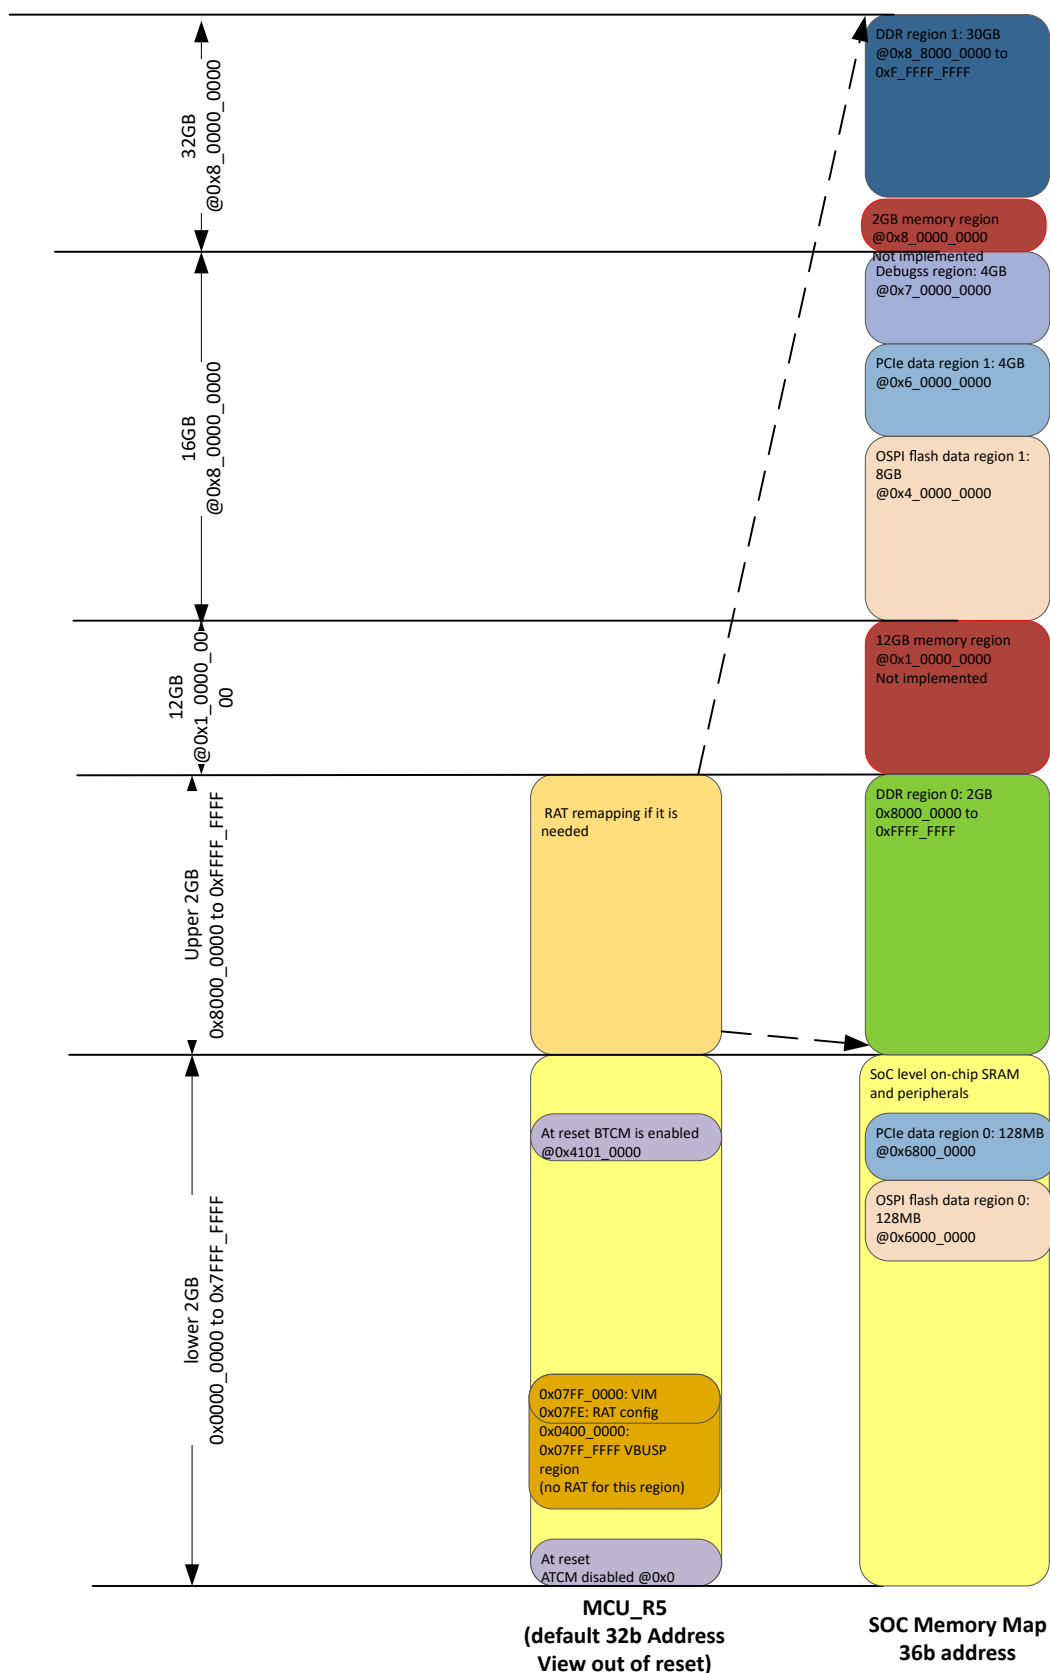

- DDR's data space beyond 32b address, basically upper DDR data space beyond 2GB
- PCIe data space beyond 32b address
- OSPI data space beyond 32b address
- Debug configuration region

**Table 7-12. R5 Memory map by Default**

	<b>R5 Memory Map(32b)</b>	<b>SoC Memory Map (36b)</b>
SoC Level peripheral and on-chip SRAM	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF
2GB DDR region	Same as SoC memory map: 0x8000_0000 to 0xFFFF_FFFF	0x8000_0000 to 0xFFFF_FFFF
Additional DDR region	Not accessible	0x8_8000_0000 (30GB)
Additional 8GB OSP Space	Not accessible	0x4_0000_0000 (4GB) 0x5_0000_0000 (4GB)
Additional PCIe data space	Not accessible	0x6_000_0000
Debug configuration region	Not accessible	0x7_0000_0000

Even though all the transactions other than going to ATCM/BTCM and transactions between address range 0x0400\_0000 to 0x07FF\_FFFF could use RAT block to remap to different address, it is recommended that only use RAT block to remap the R5 transactions with address between 0x8000\_0000 to 0xFFFF\_FFFF.

- Any transactions from R5 with address between 0x0 to 0x7FFF\_FFFF are sent out to SoC directly (unless it is targeted to its internal end points such as A/B TCM, its VIM and RAT configuration)
- Only enable RAT to remap the transactions with address between 0x8000\_0000 to 0xFFFF\_FFFF if R5 needs to access the following address space:
  - PCIe data space at address 0x6\_0000\_0000
  - OSPI data space address 0x4\_0000\_0000 and 0x5\_0000\_0000
  - Debug configuration region at address 0x7\_0000\_0000
  - DDR data space at address 0x8\_8000\_0000

**Figure 7-9. Example of Using RAT to Access Full 36b SoC Memory Map**

#### 7.3.2.6.4 Example of Using RAT to Access Full 36b SoC Memory Map

This section shows an example on how to utilize RAT block to allow R5 to access 36 SoC Memory Map. The RAT block inside R5 has up to 8 address remapping regions.

Assuming R5 needs to access the following region:

- All the SoC level on-chip SRAM
- All the SoC level peripherals
- Access 512MB OSPI region at address 0x4\_0000\_0000
- Access 1GB DDR region at address 0x9\_0000\_0000
- Access 512MB DDR region at address 0x8000\_0000

First of all, we need to construct 32b R5 memory map as following and how those memory spaces are mapped to SoC level, shown in [Table 7-13](#). Users can define where the OSPI and DDR data space placed inside R5's memory map and how they should be mapped to SoC level address map. [Table 7-13](#) just shows one of the many possible ways to construct the memory map.

**Table 7-13. Example of R5 Address Mapping**

	R5 Memory Map(32b)	SoC Memory Map (36b)	RAT Remapping
SoC Level peripheral and on-chip SRAM (This is guaranteed by SoC Hardware design. No user configuration is needed)	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF	Not RAT Remapping
512MB OSPI data region (user defined)	0x8000_0000 to 0x9FFF_FFFF	0x4_0000_0000 to 0x4_1FFF_FFFF	Using RAT remapping region 0
512MB DDR space (user defined)	0xA000_0000 to 0xBFFF_FFFF	0x8000_0000 to 0x9FFF_FFFF	Using RAT remapping region 1
Additional 1GB DDR Space (user defined)	0xC000_0000 to 0xFFFF_FFFF	0x9_0000_0000 to 0x9_3FFF_FFFF	Using RAT remapping region 2

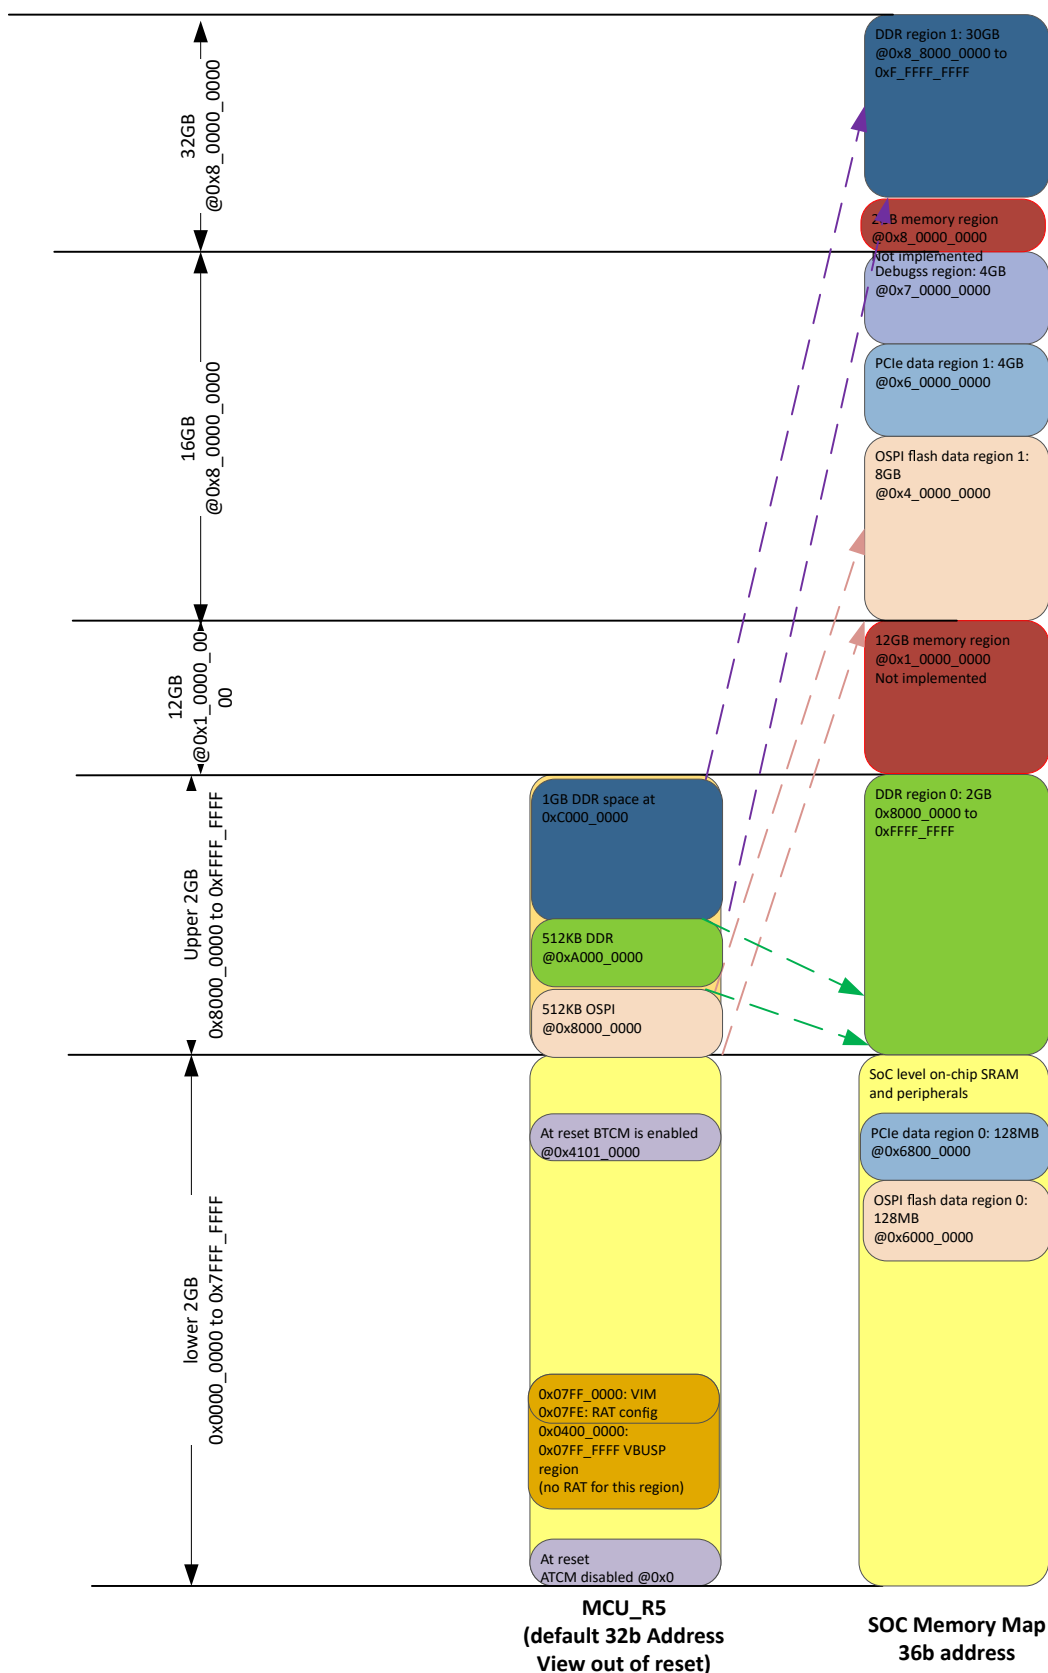

In this example, only three RAT regions are needed:

- Region 0 is used to remap R5's address between 0x8000\_0000 to 0x9FFF\_FFFF to SoC level address 0x4\_0000\_0000 to 0x4\_1FFF\_FFFF
- Region 1 is used to remap R5's address between 0xA000\_0000 to 0xBFFF\_FFFF to 0x8000\_0000 to 0x9FFF\_FFFF
- Region 2 is used to remap R5's address 0xc000\_0000 to 0xFFFF\_FFFF to 0x9\_0000\_0000 to 0x9\_3FFF\_FFFF.

In order achieving those mappings, those are the setting of the RAT configuration registers:

	Region 0	Region 1	Region 2	Other regions
Region control register	Enabled, size set to 512MB	Enabled, size set to 512MB	Enabled, size set to 1GB	disabled
Region base(32b)	0x8000_0000	0xA000_0000	0xc000_0000	Don't care
Region translated lower address(32b)	0x0000_0000	0x8000_0000	0x0000_0000	Don't care
Region translated upper address	0x4	0x0	0x9	Don't care

[Figure 7-10](#) shows how RAT is remapping the address between R5's 32b address to 36b SoC address.

**Figure 7-10. RAT Configuration Example**

### 7.3.2.7 R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of the R5FSS aggregators, see R5FSS\_CPU0\_ECC\_AGGR\_CFG\_REGS Registers and R5FSS\_CPU1\_ECC\_AGGR\_CFG\_REGS Registers, respectively.

[Table 7-14](#) provides the RAM ID. This is needed for bit field [10-0] ECC\_VECTOR in the corresponding R5FSS\_CPU0\_VECTOR register (part of the ECC aggregator register space).

**Table 7-14. RAM ID Map for ECC Aggregator (Per Core)**

RAM ID	Memory Name
0	CPU0 ITAG RAM0
1	CPU0 ITAG RAM1
2	CPU0 ITAG RAM2
3	CPU0 ITAG RAM3
4	CPU0 IDATA BANK0
5	CPU0 IDATA BANK1
6	CPU0 IDATA BANK2
7	CPU0 IDATA BANK3
8	CPU0 DTAG RAM0
9	CPU0 DTAG RAM1
10	CPU0 DTAG RAM2

### 7.3.2.8 R5FSS Memory View

The memory view of the R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see [Section 7.3.2.2.2](#).
- Peripheral interface locations: The R5F natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map*, for the complete R5F memory view for this device.

### 7.3.2.9 R5FSS Interrupts

All interrupts that are generated by the R5FSS are summarized in *Module Integration*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.
- RAT exception interrupt: This is described in [Section 7.3.2.6](#).

### 7.3.2.10 R5FSS Debug and Trace

The R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

### 7.3.2.11 R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
  - a. To boot from ATCM, set CPUUn\_INITRAMA (or CPUUn\_INITRAMB to boot from BTCM)
  - b. Assert CPUUn\_LOCZRAMA properly for the desired TCM
2. Assert CPUUn\_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
  - a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUUn\_HALT

### 7.3.2.12 R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are two ECC interrupts to the ESM that aggregate different categories of ECC events – CPU single error, CPU multi error. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS\_EVNT\_BUS\_ESM\_SET register, it can be cleared by setting all the bits of the R5FSS\_EVNT\_BUS\_ESM\_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS\_EVNT\_BUS\_ESM\_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS\_EVNT\_BUS\_ESM\_CLR register to clear the interrupt.

The R5F core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5F core. For more details, refer to Arm R5 TRM.

**Table 7-15. R5F Event Bus Single-Bit Error Events**

Event Bus Bit #	Description	Associated Status Register
22	Instruction cache tag RAM parity or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0

### 7.3.3 Vectored Interrupt Manager (VIM)

This section describes the VIM module in the device.

#### 7.3.3.1 VIM Overview

The Vectored Interrupt Manager (VIM) aggregates interrupts to a CPU. It is intended for use with a Cortex R5 from ARM. The VIM has up to 1024 interrupt inputs, which may be either level or pulse. Each interrupt has a programmable priority (0-highest through 15-lowest). Each interrupt may also be mapped as an IRQ or FIQ (FIQ is also often denoted as Non-Maskable Interrupt, or NMI).

##### 7.3.3.1.1 VIM Features

- 32-1024 Interrupt inputs
  - Configurable by groups of 32
- Each interrupt has its own 4-bit programmable priority
  - Supports Priority interruption of interrupts
- Each interrupt has its own enable mask
- Each interrupt can be programmed as either an IRQ or FIQ
- Each interrupt has its own programmable 32-bit Vector address associated with it
  - Protected with SECDDED
- One IRQn and FIQn output
- Vectored Interrupt Interface
  - Compatible with ARM Cortex R5 VIC Port
- Default Vector provided when a Double-Bit error is detected
- Provides clock phase inputs so VIM can run at CPU clock while interface runs at a different, synchronous clock

##### 7.3.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

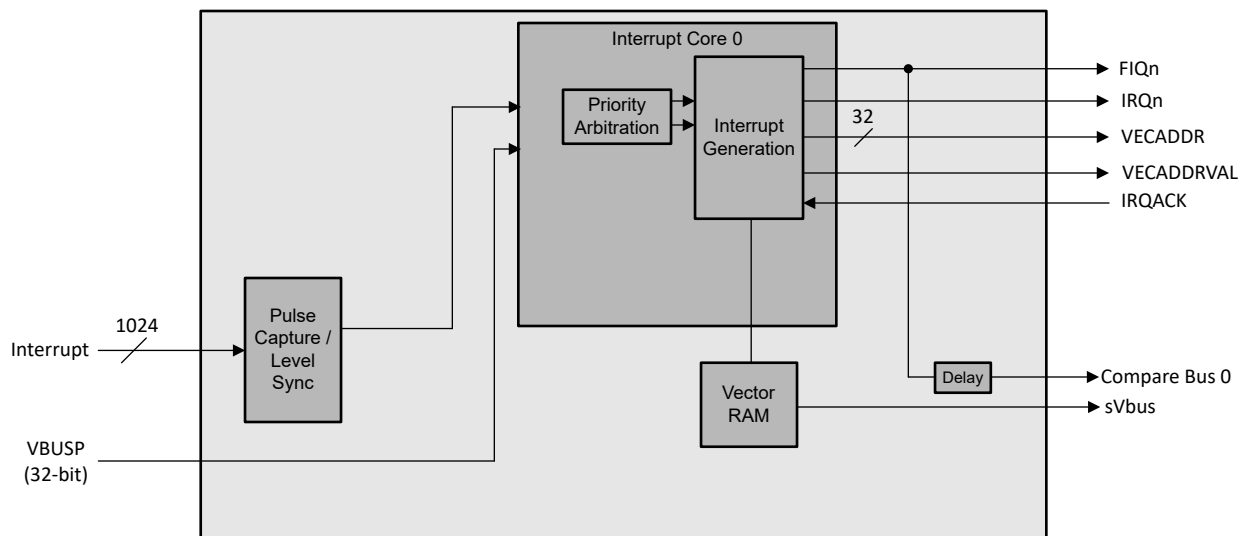

#### Note

Some features may not be available. See *Module Integration* for more information.

### 7.3.3.2 VIM Functional Description

#### 7.3.3.2.1 Block Diagram

Figure 7-11 shows the Vectored Interrupt Manager block diagram.

**Figure 7-11. VIM Block Diagram**

#### 7.3.3.2.2 Interrupt Inputs

The VIM can have up to 1024 interrupt inputs, build-time configurable by multiples of 32 (*num\_interrupts* parameter). Each interrupt can be either a level or a pulse (both active high).

Level interrupts are synchronized to the VIM clock. This synchronized value is captured in to a flop.

Pulse interrupts use rising edge detection. Each input has its own edge detection circuit. It is recommended that if pulses are pipelined between the source and the VIM, that the pipe stage replicates the pipe flop and ORs the output in order to protect against transient errors in the pipeline flop. Once an edge has been detected, the raw status is set.

There is no minimum pulse width, as true edge detection is used. The input signal should, however, be glitch free.

#### 7.3.3.2.3 Interrupt Outputs

The VIM has two interrupt outputs, *coreN\_IRQn* and *coreN\_FIQn* (active low levels). Each interrupt input for core *N* can be programmed to influence either the *coreN\_IRQn* or *coreN\_FIQn* output via the Group *M* Interrupt Map Register (Base Address + 0x200 + *N*\*0x20 + 0x18).

#### 7.3.3.2.4 Priority Interrupt / Nested Interrupts

Each interrupt has a priority number assigned to it (set using the 4.1.20 Interrupt Q Priority Register (Base Address + 0x1000 + *Q*\*0x4) register). Legal values are 0 to 15 where 0 is the highest priority and 15 is the lowest priority. The highest priority interrupt is the pending interrupt with the smallest priority number. If two pending interrupts have the same priority, the interrupt lowest numerically (0 through maximum number of interrupts) is prioritized. IRQs and FIQs are prioritized separately.

The VIM supports the interrupt of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate, but both use the same mechanism. When an interrupt goes from pending to active (FIQ: reading the FIQ Vector Address (Base Address + 0x1C), IRQ: reading the IRQ Vector Address (Base Address + 0x18) or the *coreN\_IRQACK* going high), then the interrupt is loaded into the corresponding Active Register, and all interrupts of an equal or lesser priority are masked off (see note below). If, before this interrupt is cleared (writing the FIQ Vector Address (Base Address + 0x1C) or IRQ Vector Address (Base Address + 0x18)) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. The CPU may or may not service the higher priority interrupt. If the CPU switches this interrupt to active, by reading the corresponding Vector Address Register (or *coreN\_IRQACK* going high for an IRQ), then the currently active interrupt will be pushed on to a stack. When an interrupt is cleared by writing the Vector Address Register, if there are any interrupts on the stack, the first entry is popped off and put back into the Active

Register, so that software may continue where it left off. Note that the IRQVEC/FIQVEC address registers are *not* repopulated with the old vector as it's assumed that the ISR is picking back up where it left off. Only the interrupt number and priority are restored to the ACTIRQ/ACTFIQ registers. If software needs the vector again, it will have to read it by using the interrupt number.

#### Note

“Masked off” means that they are masked off from priority arbitration to interrupt the currently active interrupt, it does NOT mean that the status bits in the registers are masked off. That is, this priority masking has NO EFFECT on whether the status bits are visible in the masked registers such as the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04).

#### 7.3.3.2.5 VIC Port

The VIM is designed to work with the VIC interface of an ARM Cortex R5.

#### 7.3.3.2.6 Latency

There are several factors that go in to the speed of processing an interrupt: the interrupt controller, the processor, and the system latency.

The VIM behaves deterministically (except for synchronizer delay). [Table 7-17](#) shows the latency of the VIM.

**Table 7-17. VIM Latency**

Step	Cycles	Note
Edge Detection	2-3	Synchronizing to VIM Clock
Interrupt Capture	1	
Prioritization and Vector Read	1	IRQ Could be stalled here if an FIQ is reading the Vector RAM
		IRQ/FIQ output asserted

The next factor is the processor itself

**Table 7-18. Processor Interrupt Latency**

Step	Cycles <sup>(1)</sup>	Note
Take Exception		
Store State		Stack system registers etc
Read Vector	1	Through MMR or VIC interface (for IRQ. VIC interface will be faster)
Jump to Vector		

(1) These steps are dependent on the processor. See R5 spec for details.

The final factor is system latency to access the actually instructions for the ISR. This will be dependent on where the instructions are (cache, TCM, system memory etc) and dependent on the system latency to reach those memories (1 cycle for cache/TCM, System dependent for external memory)

#### 7.3.3.2.7 Safety

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DED Vector Address (Base Address + 0x30) is used instead for the coreN\_IRQADDRV, IRQ Vector Address (Base Address + 0x18), and FIQ Vector Address (Base Address + 0x1C). The DED Vector Address should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling. Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
  - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device

4. Sit in a loop (or WFI) while something external (say the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

An interrupt that has an uncorrectable vector error and thus uses the DED Vector, will still have the priority of the original interrupt (that is for masking purposes). This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by an external ECC aggregator through sVbus ports.

### 7.3.3.2.8 IDLE

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface because it does not have a clock IPG. To clock stop the sub-system that includes the VIM, disable (mask) all interrupts and wait for the IDLE signal to assert.

### 7.3.3.3 Interrupt Conditions

#### 7.3.3.3.1 CPU Interrupts

See [Table 7-19](#) for the interrupts generated by the module.

**Table 7-19. Interrupts**

Interrupt	Description
core0_IRQn	IRQ Interrupt (Active Low)
core0_FIQn	FIQ Interrupt (Active Low)

#### 7.3.3.3.2 Interrupt Description

##### 7.3.3.3.2.1 coreN\_IRQn

This is a normal interrupt, active low level, for Core N. It can be serviced via the VIC interface or through the MMR interface.

##### 7.3.3.3.2.2 coreN\_FIQn

This is a fast (or non-maskable) interrupt, active low level, for Core N. FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface.

#### 7.3.3.3.3 Interrupt Condition Control

##### 7.3.3.3.3.1 coreN\_IRQn

Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (Group N Interrupt Map Register (Base Address + 0x200 + N\*0x20 + 0x18)) and is enabled (Group N Interrupt Enabled Set Register (Base Address + 0x200 + N\*0x20 + 0x08)), and its priority is not masked (4.1.11 IRQ Priority Mask Register (Base Address + 0x28)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an IRQ to assert.

##### 7.3.3.3.3.2 coreN\_FIQn

Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ (Group N Interrupt Map Register (Base Address + 0x200 + N\*0x20 + 0x18)) and is enabled (Group N Interrupt Enabled Set Register (Base Address + 0x200 + N\*0x20 + 0x08)), and its priority is not masked (4.1.12 FIQ Priority Mask Register (Base Address + 0x2C)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an FIQ to assert.

#### 7.3.3.3.4 Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM software wants to take advantage of. For IRQs, it is recommended to use 3.4.1 IRQ through the Vector

Interface, but 3.4.2 or 3.4.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives. For FIQs, it is recommended to use 3.4.4 FIQ, but 3.4.5 may be used as an alternative.

#### Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

#### 7.3.3.3.4.1 IRQ through the Vector Interface

If the attached CPU has the Vector Interface enabled, then the following method is used for servicing IRQs

1. Hardware handshake
  - a. CPU asserts coreN\_IRQACK signal high
  - b. VIM asserts coreN\_IRQADDRV to indicate that the coreN\_IRQADDR bus is stable with the correct Vector Address
  - c. CPU reads the coreN\_IRQADDR, jumps to that address, and de-asserts coreN\_IRQACK signal low
  - d. VIM de-asserts coreN\_IRQn\_intr and coreN\_IRQADDRV, VIM masks all IRQs with the same or lower priority
  - e. VIM loads the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service an interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the IRQ Vector Address (Base Address + 0x18)
  - a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
  - b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

#### 7.3.3.3.4.2 IRQ through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the Vector Interface.

1. Read the IRQ Vector Address (Base Address + 0x18) and jump to that address to service the ISR
  - a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the IRQn output. If another interrupt of a higher priority becomes available, the IRQn will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service the interrupt

3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the IRQ Vector Address (Base Address + 0x18)
  - a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
  - b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

#### 7.3.3.3.4.3 IRQ through MMR Interface (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, priority masking will not work if route 1b is used (below) as the hardware prioritization may not match the software prioritization scheme. In this case, software would be responsible for doing all priority operations

1. Determine which interrupt to service
  - a. Read the Prioritized IRQ (Base Address + 0x08) to determine which interrupt is the highest priority IRQ currently asserted OR
  - b. Optionally read the IRQ Group Status (Base Address + 0x10) to determine which groups have IRQs pending, then read the Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10) and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Read the IRQ Vector Address (Base Address + 0x18)
  - a. Note, this step can be done any time before step 4
  - b. Value is ignored
4. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source

- ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x10)
  1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
  2. If the source maintains the level, then it means there is another interrupt
5. Write any value to the IRQ Vector Address (Base Address + 0x18)

#### 7.3.3.3.4.4 FIQ

When an FIQ interrupt is received, the CPU should follow these steps.

1. Read the FIQ Vector Address (Base Address + 0x1C) and jump to that address to service the ISR
  - a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the FIQn output. If another interrupt of a higher priority becomes available, the FIQn will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the Prioritized FIQ (Base Address + 0x0C) (which corresponds to the vector address) to be loaded into the Active FIQ (Base Address + 0x24) and the valid bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active FIQ (Base Address + 0x24) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M*\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the FIQ Vector Address (Base Address + 0x1C)
  - a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
  - b. This will clear the valid bit of the Active FIQ (Base Address + 0x24)

#### 7.3.3.3.4.5 FIQ (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQ Vector Address (Base Address + 0x1C) is never read). Software would be responsible for doing all priority operations

1. Determine which interrupt to service
  - a. Read the Prioritized FIQ (Base Address + 0x0C) to determine which interrupt is the highest priority FIQ currently asserted OR
  - b. Optionally read the FIQ Group Status (Base Address + 0x14) to determine which groups have IRQs pending, then read the Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14) and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt

3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M*\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt

### 7.3.3.4 Memory Map

Each Interrupt Core (*N* = 0) has its own MMR interface with its own independent memory map

**Table 7-20. Core *N* Memory Map**

Address Offset	Register
0x00	Revision Register
0x04	Info Register
0x08	Prioritized IRQ
0x0C	Prioritized FIQ
0x10	IRQ Group Status
0x14	FIQ Group Status
0x18	IRQ Vector Address
0x1C	FIQ Vector Address
0x20	Active IRQ
0x24	Active FIQ
0x28-0x2F	<i>Reserved</i>
0x30	DED Vector Address
0x34-0x1FF	<i>Reserved</i>
0x400 + <i>M</i> *0x20 + 0x00	Group <i>M</i> Interrupt Raw Status/Set Register
0x400 + <i>M</i> *0x20 + 0x04	Group <i>M</i> Interrupt Enabled Status/Clear Register
0x400 + <i>M</i> *0x20 + 0x08	Group <i>M</i> Interrupt Enabled Set Register
0x400 + <i>M</i> *0x20 + 0x0C	Group <i>M</i> Interrupt Enabled Clear Register
0x400 + <i>M</i> *0x20 + 0x10	Group <i>M</i> Interrupt IRQ Enabled Status/Clear Register
0x400 + <i>M</i> *0x20 + 0x14	Group <i>M</i> Interrupt FIQ Enabled Status/Clear Register
0x400 + <i>M</i> *0x20 + 0x18	Group <i>M</i> Interrupt Map Register
0x400 + <i>M</i> *0x20 + 0x1C	Group <i>M</i> Type Map Register
0x1000 + <i>Q</i> *0x4 – 0x1FFF	Interrupt <i>Q</i> Priority Register
0x2000 + <i>Q</i> *0x4 – 0x2FFF	Interrupt <i>Q</i> Vector Register

There are *M* interrupt groups (0 through *num\_groups*-1) with 32 interrupts per group.

There are *Q* interrupt inputs where *Q* = *M* \* 32.

Accesses to the Interrupt Q Vector Register (Base Address + 0x2000 + Q\*0x4) must be word-aligned, 32-bit accesses. Any write received with no bytes enabled will be ignored. Any writes receive with all bytes enabled will be executed. Any other write will not execute and will return an error status of Addressing Error.

### 7.3.3.5 Module I/O

#### 7.3.3.5.1 Clocks, Reset, Emulation

**Table 7-21. Clocks, Reset, Emulation**

Pin Name	Type	Function
core0_clk	In	Clock for Core 0
core0_phase	In	Phase Indicator for Core 0
core0_srst_n	In	Sync Module Reset for Core 0
core0_arst_n	In	Async Module Reset for Core 0
core0_clkstop_idle	Out	Clock Stop Idle

#### 7.3.3.5.2 VBUSP Target Interface

(N=0). Core0 interface is used for interrupt core 0.

**Table 7-22. VBUSP Target Interface**

Pin Name	Type	Function
coreN_cfg_req	In	Request
coreN_cfg_address[13:0]	In	Address (byte address)
coreN_cfg_dir	In	Direction (read or write)
coreN_cfg_xcnt[2:0]	In	Transaction Count
coreN_cfg_byten[3:0]	In	Byte enables
coreN_cfg_wdata[31:0]	In	Write data
coreN_cfg_rdatap[31:0]	Out	Read data
coreN_cfg_rready	Out	Read ready
coreN_cfg_wready	Out	Write ready
coreN_cfg_rstatus[2:0]	Out	Read Status
coreN_cfg_emudbg	In	Emulation Debug

#### 7.3.3.5.3 Interrupt Inputs

Core0 interface is used for interrupt core 0.

**Table 7-23. Interrupt Inputs**

Pin Name	Type	Function
core0_in_intr[Q-1:0]	In	Core 0 Interrupt Inputs

#### 7.3.3.5.4 Interrupt Outputs

**Table 7-24. Interrupt Outputs**

Pin Name	Type	Function
core0_IRQn_intr	Out	IRQ Interrupt for core 0– Active Low Level
core0_FIQn_intr	Out	FIQ Interrupt for core 0 – Active Low Level

#### 7.3.3.5.5 VIC Interfaces

(N=0). Core0 interface is used for interrupt core 0.

**Table 7-25. VIC Interfaces**

Pin Name	Type	Function
coreN_vic_IRQADDRV	Out	IRQ Address Valid
coreN_vic_IRQADDR[31:2]	Out	IRQ Address
coreN_vic_IRQACK	In	Interrupt Acknowledge

#### 7.3.3.5.6 Compare Outputs

These pins will never be on an isolation boundary and therefore their isolation values are don't-care. Y is dependent on the configuration

**Table 7-26. Compare Outputs**

Pin Name	Type	Function
core0_compare_bus[Y:0]	Out	Comparison Bus for Core0 to CCMR5

#### 7.3.3.5.7 ECC Control and Status Bus

(N=0). Core0 interface is used for interrupts for core 0.

**Table 7-27. ECC Control and Status Bus**

Signal Name	Dir	Default Val	Description
coreN_ramecc_strb	In	1'b0	Strobe to sample the incoming serial data
coreN_ramecc_txd	In	1'b0	Output serial data
coreN_ramecc_rxd	Out	1'b0	Input serial data
coreN_ramecc_pend[1:0]	Out	2'd0	Level Interrupt source

#### 7.3.3.5.8 DFT

**Table 7-28. DFT**

Signal Name	Dir	Default Val	Description
dft_clk_force_en	In	1'b0	DFT Clock Force Enable
dft_partition_enn	In	1'b0	DFT Clock Partition Enable
dft_scan_en	In	1'b0	DFT Scan Enable
dft_async_rst_sel	In	1'b0	DFT Async Reset Select
dft_test_async_rst_n	In	1'b0	DFT Async Test Reset
dft_tft_mcp_dis	In	1'b0	DFT MCP Disable
dft_local_clk_en	In	1'b0	DFT Local Clock Enable

#### 7.3.3.5.9 RAM GPIO

**Table 7-29. RAM GPIO**

Signal Name	Dir	Default Val	Description
coreN_ramdft_gpi[255:0]	In	256'd0	RAM GPI
coreN_ramdft_gpo[255:0]	Out	256'd0	RAM GPO

#### 7.3.3.6 Programmer's Guide

##### 7.3.3.6.1 Initialization Sequence

At initialization, the following tasks should be performed:

1. Program the DED Vector Address (Base Address + 0x30)
2. Program Group M Interrupt Map Register (Base Address + 0x200 + M\*0x20 + 0x18)
3. Program Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C)
4. Program Interrupt Q Priority Register (Base Address + 0x1000 + Q\*0x4)

5. Program Interrupt Q Vector Register (Base Address + 0x2000 + Q\*0x4)
6. Enable interrupts via the Group M Interrupt Enabled Set Register (Base Address + 0x400 + M\*0x20 + 0x08)

Note that the Interrupt Q Vector Register (Base Address + 0x2000 + Q\*0x4) for each interrupt that will be enabled must be written before the interrupt is enabled, even if software is not going to use the vector. Whenever an interrupt is prioritized, the RAM location for the interrupt is read, and if that location is un-initialized, an ECC error will be reported. If the vectors aren't being used, then the RAM can be initialized by writing 0x0 to every location.

#### 7.3.3.6.2 DED Behavior

Whenever there is 2-bit error detect on a Vector Address, the DED Vector Address (Base Address + 0x30) overrides all other vectors. Software should provide an ISR to handle this scenario at this address.

#### 7.3.3.6.3 Power Up/Down Sequence

Before a clean power down, software should check that there are no pending interrupts, disable all interrupts, and wait for the clkstop\_idle output.

## 7.4 Device Manager Cortex R5F Subsystem (WKUP\_R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (WKUP\_R5FSS) in the device.

### 7.4.1 WKUP\_R5FSS Overview

The WKUP\_R5FSS is a single-core implementation of the Arm® Cortex®-R5F processor that acts as the Device Manager responsible for boot, resource management, and power management functions. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

#### Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

There is one WKUP\_R5FSS subsystem in the device. [Table 7-30](#) shows WKUP\_R5FSS allocation across device domains.

**Table 7-30. R5FSS Allocation Across Device Domains**

Module Instance	Domain		
	MCU	MAIN	WKUP
WKUP_R5FSS	–	–	✓

#### 7.4.1.1 WKUP\_R5FSS Features

The WKUP\_R5FSS supports the following features:

- Single-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - L1 memory system
    - 32KB instruction cache
      - 4x8KB ways
      - SECDED ECC protected per 64 bits
    - 32KB data cache

- 4x8KB ways
- SECDED ECC protected per 32 bits
- 64KB tightly-coupled memory (TCM)
  - SECDED ECC protected per 32 bits
  - TCM hard error cache Implemented in CPU
  - Readable/writable from system
  - TCMs initialized (to 0's) at reset
  - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Low interrupt latency with restartable instructions
- Non-maskable interrupt (NMI)
- Full-precision floating point (VFPv3)
- 16 region memory protection unit (MPU)
- 8 breakpoints
- 8 watchpoints
- Dynamic branch prediction with global history buffer and 4-entry return stack
- CoreSight debug access port (DAP)
- CoreSight embedded trace macrocell (ETM-R5) interface
- Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses
  - 64-bit VBUSM target for TCM access
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access
  - 32-bit VBUSP target configuration port
  - 32-bit VBUSP target debug port
    - Allows access to all WKUP\_R5FSS internal debug logic
  - ECC/Parity support on all internal SoC bus interfaces
  - ECC/Parity support on internal SoC bus bridges
- Synchronous clock domain crossing on all interfaces
  - Interfaces can run at an integer multiple of the core frequency
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
  - 4 regions
    - Base address + size
    - Must be size aligned
- Integrated vectored interrupt manager (VIM)
  - 256 interrupts
    - Each interrupt programmable as either IRQ or FIQ
    - Each interrupt has a programmable enable mask
    - Each interrupt has a programmable 4-bit priority
  - Priority interrupt supported
  - Vectored interrupt interface
    - Compatible with R5F VIC port
    - Programmable 32-bit vector address per interrupt
      - Address is SECDED error protected
      - Default vector addresses provided on DED
    - Software interrupt generation
- Integrated ECC aggregators
  - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
  - One ECC aggregator to cover all RAMs and caches

- Standard Arm CoreSight debug and trace architecture at the R5FSS level
  - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
  - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
  - From ROM only

See [Section 7.4.2](#) for a functional block diagram and more details on the WKUP\_R5FSS.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

## 7.4.2 WKUP\_R5FSS Functional Description

### 7.4.2.1 WKUP\_R5FSS Block Diagram

Figure 7-12 shows the WKUP\_R5FSS block diagram.

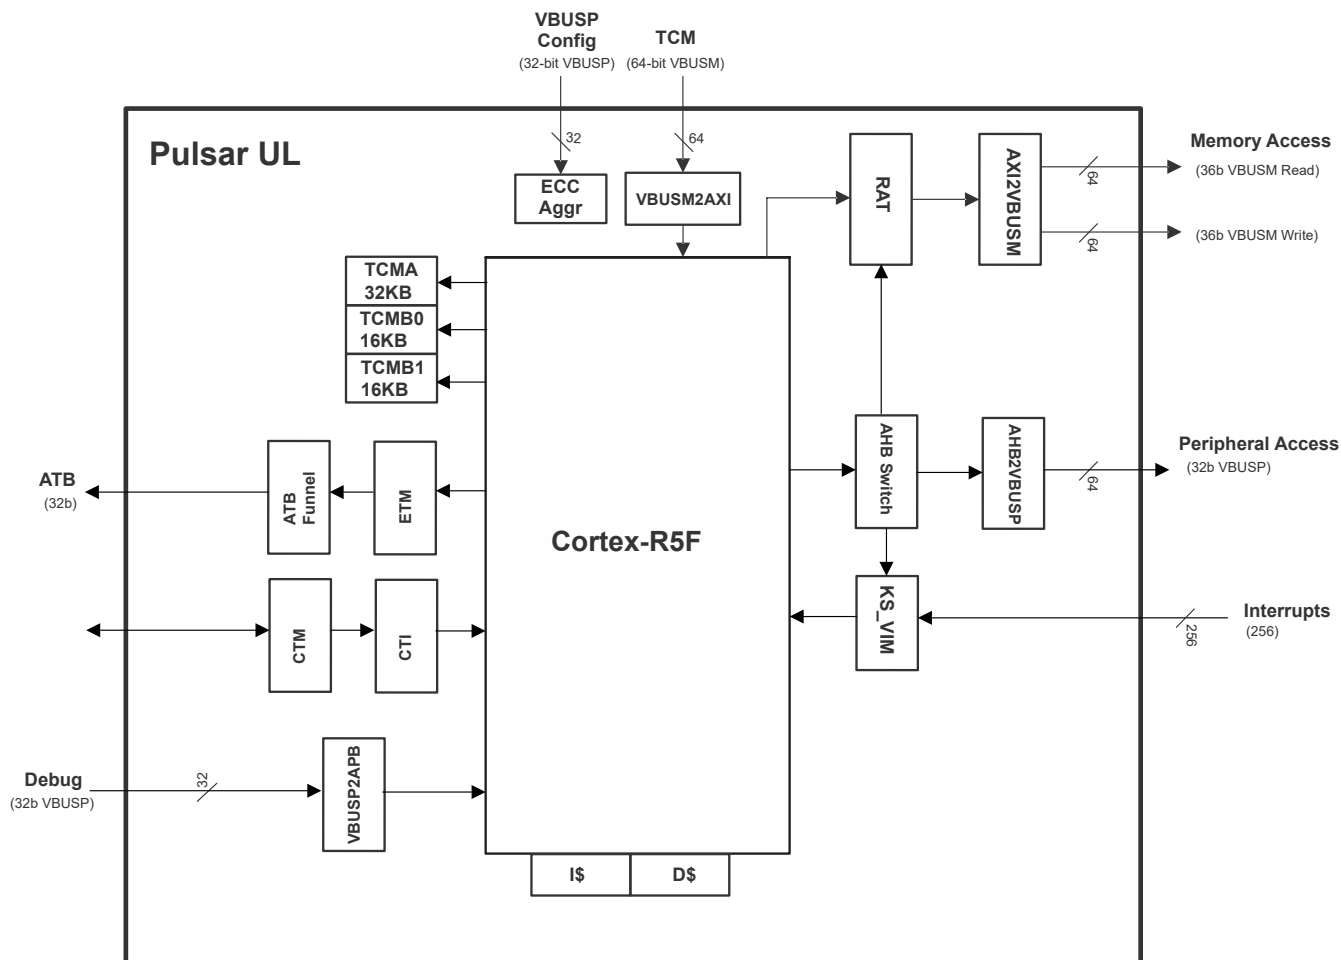

Figure 7-12. WKUP\_R5FSS Block Diagram

### 7.4.2.2 WKUP\_R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile.

For a brief list of features supported by the R5F processor in this device, see [Section 7.4.1.1](#). For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

#### 7.4.2.2.1 L1 Caches

The R5F has a Harvard cache architecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

#### 7.4.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions

that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPU<sub>Un</sub>\_INITRAMA and CPU<sub>Un</sub>\_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPU<sub>Un</sub>\_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000\_0000 and the initial address of BTCM is 20'h41010. If the CPU<sub>Un</sub>\_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000\_0000 and the initial base address of ATCM is 20'h41010.

#### Note

This base address of 0x41010 for ATCM/BTCM based on the CPU<sub>Un</sub>\_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in [Section 7.4.2.3.2](#). The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See [Section 7.4.2.11](#) for details on TCM booting.

#### 7.4.2.2.3 WKUP\_R5FSS Special Signals

[Table 7-31](#) lists some WKUP\_R5FSS features associated with special signals.

**Table 7-31. WKUP\_R5FSS Special Features**

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
CPU <sub>Un</sub> execution halt when coming out of reset (CPU <sub>Un</sub> _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPU <sub>Un</sub> exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU <sub>Un</sub> VIM base address	0x2FFF_0000
CPU <sub>Un</sub> RAT base address	0x2FFE_0000
CPU <sub>Un</sub> RAT accesses ID	0x4 (CPU0)
CPU <sub>Un</sub> ATCM enable at reset (CPU <sub>Un</sub> _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state

**Table 7-31. WKUP\_R5FSS Special Features (continued)**

Feature	Comment
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPU <sub>n</sub> VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	Not used
CPU <sub>n</sub> VBUSM normal peripheral port size	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port base address	Not used
CPU <sub>n</sub> VBUSM virtual peripheral port size	Not used
CPU <sub>n</sub> clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

#### 7.4.2.3 WKUP\_R5FSS Interfaces

##### 7.4.2.3.1 Initiator Interfaces

The WKUP\_R5FSS has several initiator interfaces:

- 64-bit VBUSM initiator pair (1 read - "RMST", 1 write - "WMST") for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator "PMST" for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

##### 7.4.2.3.2 Target Interfaces

The WKUP\_R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target
  - Region [0]: ECC aggregator block
- 64-bit TCM target
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

#### 7.4.2.4 WKUP\_R5FSS Power, Clocking and Reset

##### 7.4.2.4.1 WKUP\_R5FSS Power

The following WKUP\_R5FSS power considerations should be noted:

- WKUP\_R5FSS has a single power domain for all its internal logic

For more details on WKUP\_R5FSS power management, including power-up and power-down sequences, see *Power*.

##### 7.4.2.4.2 WKUP\_R5FSS Clocking

The WKUP\_R5FSS has four clock inputs:

- CPU0\_CLK: This is the clock for CPU0 logic
- CPU0\_ICLK: This is the clock for CPU0 interfaces

CPU0\_CLK is the clock for all of the internal CPU logic, while CPU0\_ICLK is the clock for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic).

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

##### 7.4.2.4.3 WKUP\_R5FSS Reset

The R5FSS has two reset inputs:

- CPU0\_RST: This is the reset for the non-debug logic of CPU0
- CPU0\_DBG\_RST: This resets the CPU0 debug logic, excluding the APB interface

In addition to the reset signals, there is one halt signal:

- CPU0\_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

#### 7.4.2.5 WKUP\_R5FSS Vectored Interrupt Manager (VIM)

##### 7.4.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU. It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs for the R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS\_VIM\_PRI\_INT\_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS\_VIM\_INTR\_EN\_SET\_j register
  - Interrupt disable is done via the R5FSS\_VIM\_INTR\_EN\_CLR\_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS\_VIM\_INTMAP\_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS\_VIM\_VEC\_INT\_j register
  - Protected with SECDDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port

- Default vector provided when a double-bit error is detected
- Software interrupt generation

#### 7.4.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the R5F core can be found in *Interrupt Sources*.

#### 7.4.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- **CoreN\_IRQn**: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS\_VIM\_INTMAP\_j register) and is enabled (via the R5FSS\_VIM\_INTR\_EN\_SET\_j register), then it will cause an IRQ to assert
- **CoreN\_FIQn**: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

#### 7.4.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS\_VIM\_VEC\_INT\_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

#### Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-13 shows the VIM RAM interrupt vector map.

VIM RAM Address Space	VIM RAM Entries
Base Address + 0h	Interrupt 0 Vector
Base Address + 4h	Interrupt 1 Vector
Base Address + 8h	Interrupt 2 Vector
Base Address + 3F8h	Interrupt 254 Vector
Base Address + 3FCh	Interrupt 255 Vector

**Figure 7-13. VIM RAM Interrupt Vector Map**

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See [Table 7-34](#) for the VIM RAM ID in the ECC aggregator map.

#### 7.4.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS\_VIM\_FIQVEC register; IRQ: reading the R5FSS\_VIM\_IRQVEC register, or the *coreN\_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS\_VIM\_FIQVEC register, or R5FSS\_VIM\_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ register, so that software may continue where it left off.

#### 7.4.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS\_VIM\_DEDVEC register is used to provide the default vector for the *coreN\_IRQADDRV* signal, the R5FSS\_VIM\_IRQVEC register, and the R5FSS\_VIM\_FIQVEC register. The R5FSS\_VIM\_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
  - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

---

#### Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt. This makes it possible for a higher priority interrupt to supersede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

---

#### 7.4.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

#### 7.4.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in [Section 7.4.2.5.8.1](#), but the procedures in [Section 7.4.2.5.8.2](#) or [Section 7.4.2.5.8.3](#) (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in [Section 7.4.2.5.8.4](#), but the procedure in [Section 7.4.2.5.8.5](#) may be used as an alternative.

### Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

#### 7.4.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
  - a. CPU asserts *coreN\_IRQACK* high
  - b. VIM asserts *coreN\_IRQADDRV* to indicate that the *coreN\_IRQADDR* bus is stable with the correct vector address
  - c. CPU reads *coreN\_IRQADDR*, jumps to that address, and de-asserts *coreN\_IRQACK* low
  - d. VIM de-asserts *coreN\_IRQn* and *coreN\_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
  - e. VIM loads the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, which causes the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 7.4.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS\_VIM\_IRQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN\_IRQn* will re-assert, allowing priority interruption of an interrupt
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse

- i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 7.4.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS\_VIM\_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_IRQSTS\_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register

#### 7.4.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS\_VIM\_FIQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN\_FIQn* will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source

- ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS\_VIM\_FIQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTFIQ[31] VALID bit

#### 7.4.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS\_VIM\_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_FIQSTS\_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register.

#### 7.4.2.6 WKUP\_R5FSS Region Address Translation (RAT)

##### 7.4.2.6.1 WKUP R5FSS Usage

R5 is a micro controller with 32b address, which is only able to access up to 4GB address space. However, Sitara™ SoC supports 36b address and majority of the memory region beyond lower 4GB are implemented. Region based address translation block, called RAT, is introduced to allow R5 core to access full 36b SoC memory map.

Each R5 core has its own RAT block, and only R5 core itself is able to program the RAT.

[Figure 7-14](#) shows the main R5's default 32b memory map view when main R5 is out of reset.

The full RAT functionality is described in [Section 7.3.2.6.2, RAT Function](#).

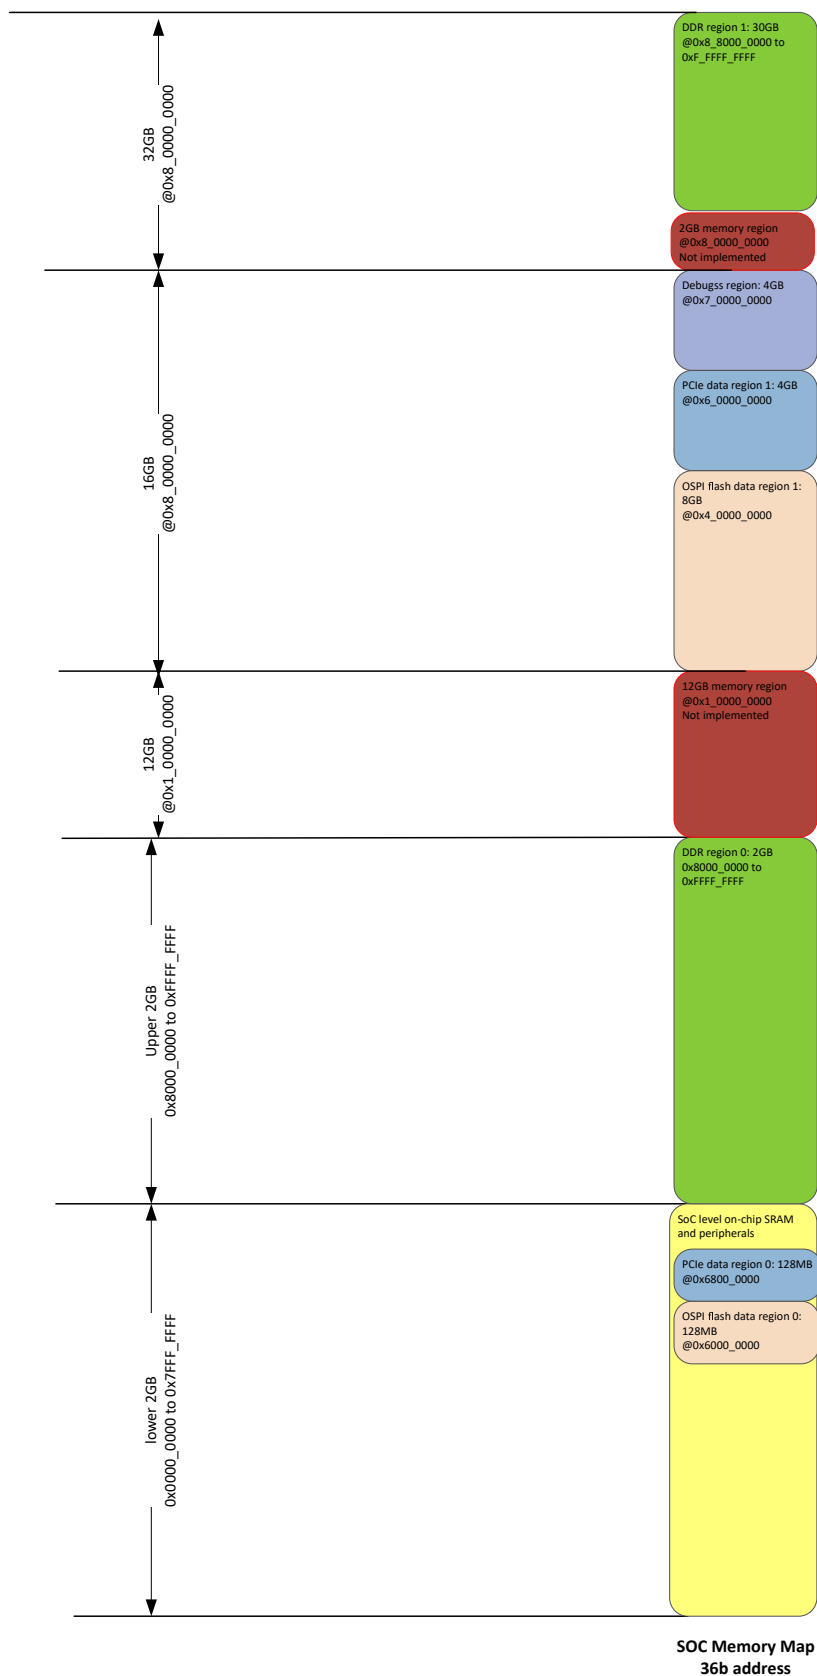

Figure 7-14. R5 Core Default Memory Map View

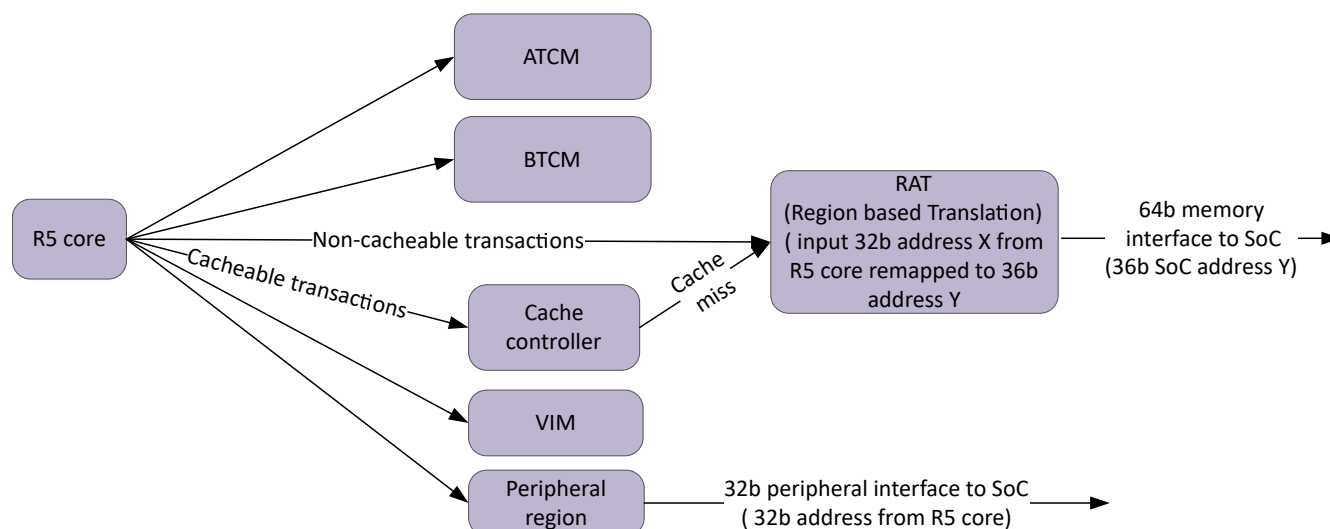

**Figure 7-15. Typical Sitara SoC Memory Map View**

RAT block enables R5 core to have full access on the SoC memory map including the memory region at and above 0x1\_0000\_0000.

Figure 7-16 shows how R5 access various end points, including its own ATCM, BTCM, VIM and SoC memory and peripherals. R5's ATCM is by default at address 0x0, and its BTCM is at address 0x4101\_0000. R5 uses address 0x2FFF\_0000 to access its VIM and 0x2FFE\_0000 to access the RAT configuration region and all the other transactions between address range 0x2000\_0000 to 0x2FFF\_FFFF are sent to the 32b peripheral interface to access the peripherals in SoC. The transactions with the rest of address are sent to RAT block, which could go through address remapping function from original R5's 32b address to 36b SoC address.

**Figure 7-16. R5 Internal Address Decoding**

#### 7.4.2.6.2 RAT Function

RAT block is responsible to do a region based address translation. For each region, user can define the starting address and size of the region and remapping the transactions to use a new address range.

The starting address and region size need to be aligned. For example, if the region size is 16KB, the starting address for that region needs to be 16KB aligned. And region size should be minimum 4KB or larger to avoid transactions cross the region boundaries.

Each RAT block supports multiple programmable regions. And it is important that those regions are not overlapping with each other.

RAT block is by default disabled, which means RAT block does not do address remapping. The 32b address coming from R5 core is directly sent out to the SoC level. The user can program each RAT remapping region individually. For the transactions does not hit any remapping region, RAT block just simply forwards the transactions to the SoC level with its original address.

#### 7.4.2.6.3 How to use RAT Block in R5

Table 7-32 shows the default R5 memory map view. Without enabling RAT function, all the regions beyond 4GB address space will not be accessible by R5.

Sitara™ SoC memory map is constructed the way to allow R5 and high level application processor such as A53 have similar memory map as possible. This methodology enables that R5 and ARM A53 core have a common memory map for all the SoC level memories and SoC level peripherals except a few exceptions:

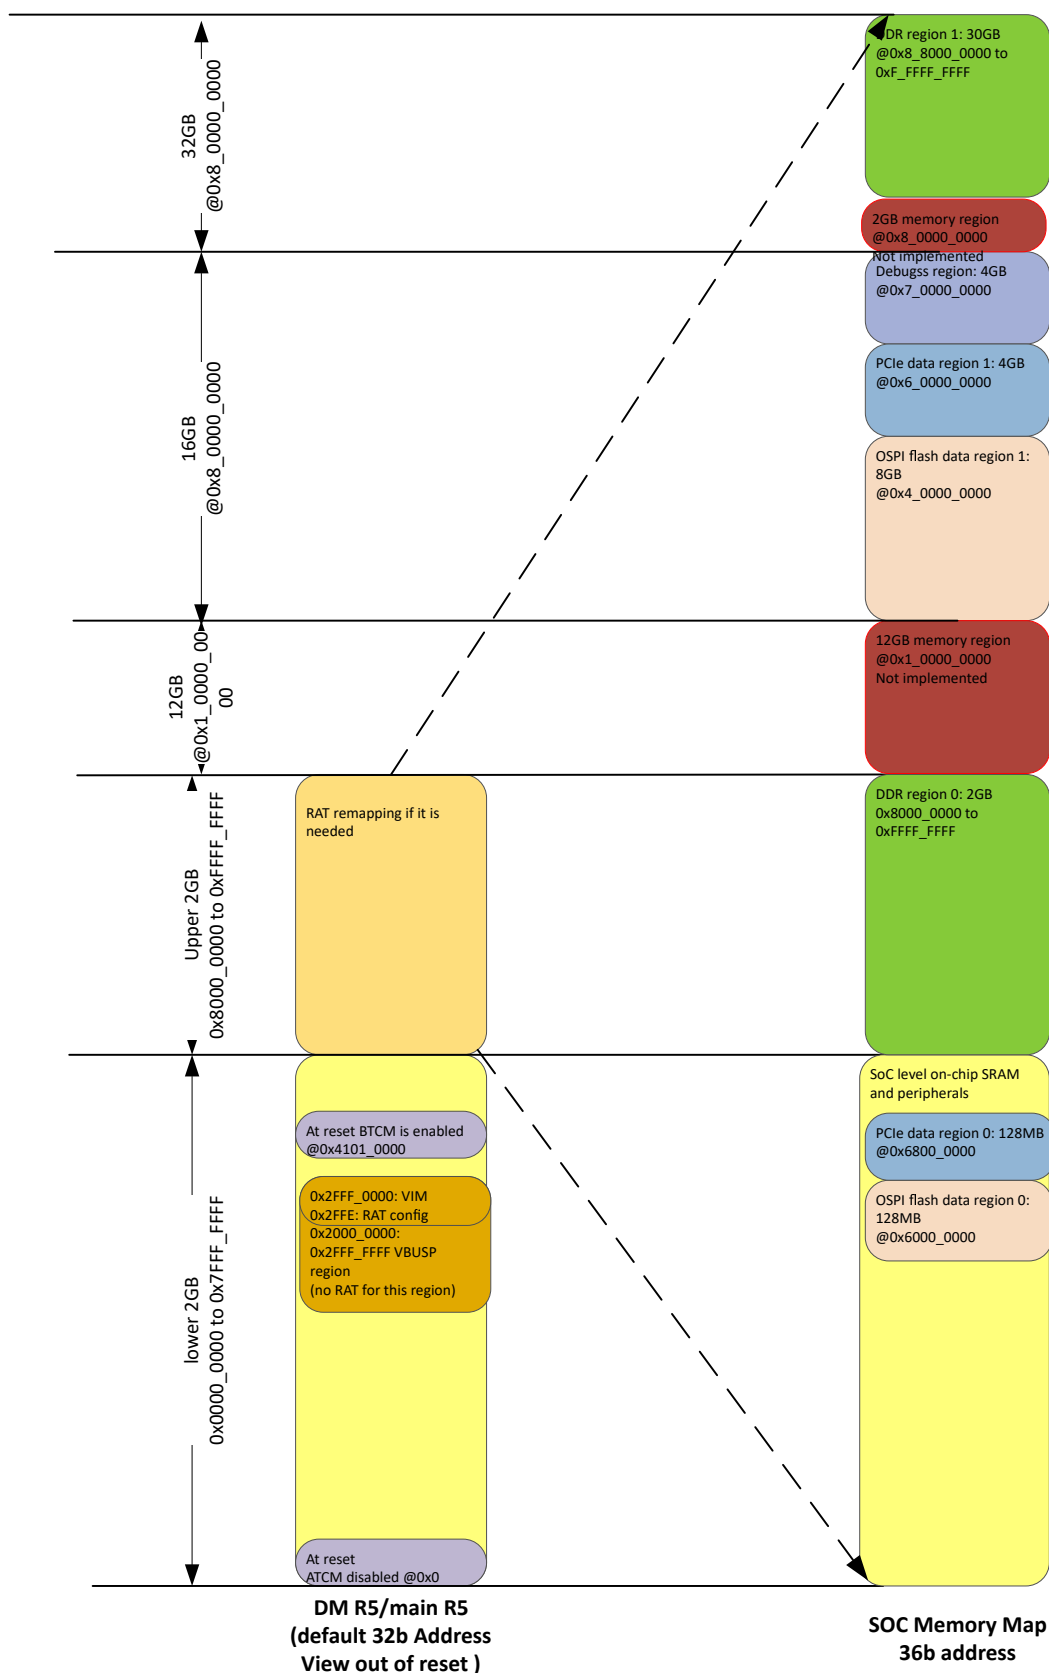

- DDR's data space beyond 32b address, basically upper DDR data space beyond 2GB
- PCIe data space beyond 32b address
- OSPI data space beyond 32b address
- Debug configuration region

**Table 7-32. R5 Memory map by Default**

	<b>R5 Memory Map(32b)</b>	<b>SoC Memory Map (36b)</b>
SoC Level peripheral and on-chip SRAM	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF
2GB DDR region	Same as SoC memory map: 0x8000_0000 to 0xFFFF_FFFF	0x8000_0000 to 0xFFFF_FFFF
Additional DDR region	Not accessible	0x8_8000_0000 (30GB)
Additional 8GB OSP Space	Not accessible	0x4_0000_0000 (4GB) 0x5_0000_0000 (4GB)
Additional PCIe data space	Not accessible	0x6_000_0000
Debug configuration region	Not accessible	0x7_0000_0000

Even though all the transactions other than going to ATCM/BTCM and transactions between address range 0x2000\_0000 to 0x2FFF\_FFFF could use RAT block to remap to different address, it is recommended that only use RAT block to remap the R5 transactions with address between 0x8000\_0000 to 0xFFFF\_FFFF.

- Any transactions from R5 with address between 0x0 to 0x7FFF\_FFFF are sent out to SoC directly (unless it is targeted to its internal end points such as A/B TCM, its VIM and RAT configuration)
- Only enable RAT to remap the transactions with address between 0x8000\_0000 to 0xFFFF\_FFFF if R5 needs to access the following address space:
  - PCIe data space at address 0x6\_0000\_0000
  - OSPI data space address 0x4\_0000\_0000 and 0x5\_0000\_0000
  - Debug configuration region at address 0x7\_0000\_0000
  - DDR data space at address 0x8\_8000\_0000

**Figure 7-17. Example of Using RAT to Access Full 36b SoC Memory Map**

#### 7.4.2.6.4 Example of Using RAT to Access Full 36b SoC Memory Map

This section shows an example on how to utilize RAT block to allow R5 to access 36 SoC Memory Map. The RAT block inside R5 has up to 8 address remapping regions.

Assuming R5 needs to access the following region:

- All the SoC level on-chip SRAM
- All the SoC level peripherals
- Access 512MB OSPI region at address 0x4\_0000\_0000
- Access 1GB DDR region at address 0x9\_0000\_0000
- Access 512MB DDR region at address 0x8000\_0000

First of all, we need to construct 32b R5 memory map as following and how those memory spaces are mapped to SoC level, shown in [Table 7-33](#). Users can define where the OSPI and DDR data space placed inside R5's memory map and how they should be mapped to SoC level address map. [Table 7-33](#) just shows one of the many possible ways to construct the memory map.

**Table 7-33. Example of R5 Address Mapping**

	R5 Memory Map(32b)	SoC Memory Map (36b)	RAT Remapping
SoC Level peripheral and on-chip SRAM (This is guaranteed by SoC Hardware design. No user configuration is needed)	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF	Not RAT Remapping
512MB OSPI data region (user defined)	0x8000_0000 to 0x9FFF_FFFF	0x4_0000_0000 to 0x4_1FFF_FFFF	Using RAT remapping region 0
512MB DDR space (user defined)	0xA000_0000 to 0xBFFF_FFFF	0x8000_0000 to 0x9FFF_FFFF	Using RAT remapping region 1
Additional 1GB DDR Space (user defined)	0xC000_0000 to 0xFFFF_FFFF	0x9_0000_0000 to 0x9_3FFF_FFFF	Using RAT remapping region 2

In this example, only three RAT regions are needed:

- Region 0 is used to remap R5's address between 0x8000\_0000 to 0x9FFF\_FFFF to SoC level address 0x4\_0000\_0000 to 0x4\_1FFF\_FFFF
- Region 1 is used to remap R5's address between 0xA000\_0000 to 0xBFFF\_FFFF to 0x8000\_0000 to 0x9FFF\_FFFF
- Region 2 is used to remap R5's address 0xc000\_0000 to 0xFFFF\_FFFF to 0x9\_0000\_0000 to 0x9\_3FFF\_FFFF.

In order achieving those mappings, those are the setting of the RAT configuration registers:

	Region 0	Region 1	Region 2	Other regions
Region control register	Enabled, size set to 512MB	Enabled, size set to 512MB	Enabled, size set to 1GB	disabled
Region base(32b)	0x8000_0000	0xA000_0000	0xc000_0000	Don't care
Region translated lower address(32b)	0x0000_0000	0x8000_0000	0x0000_0000	Don't care
Region translated upper address	0x4	0x0	0x9	Don't care

[Figure 7-18](#) shows how RAT is remapping the address between R5's 32b address to 36b SoC address.

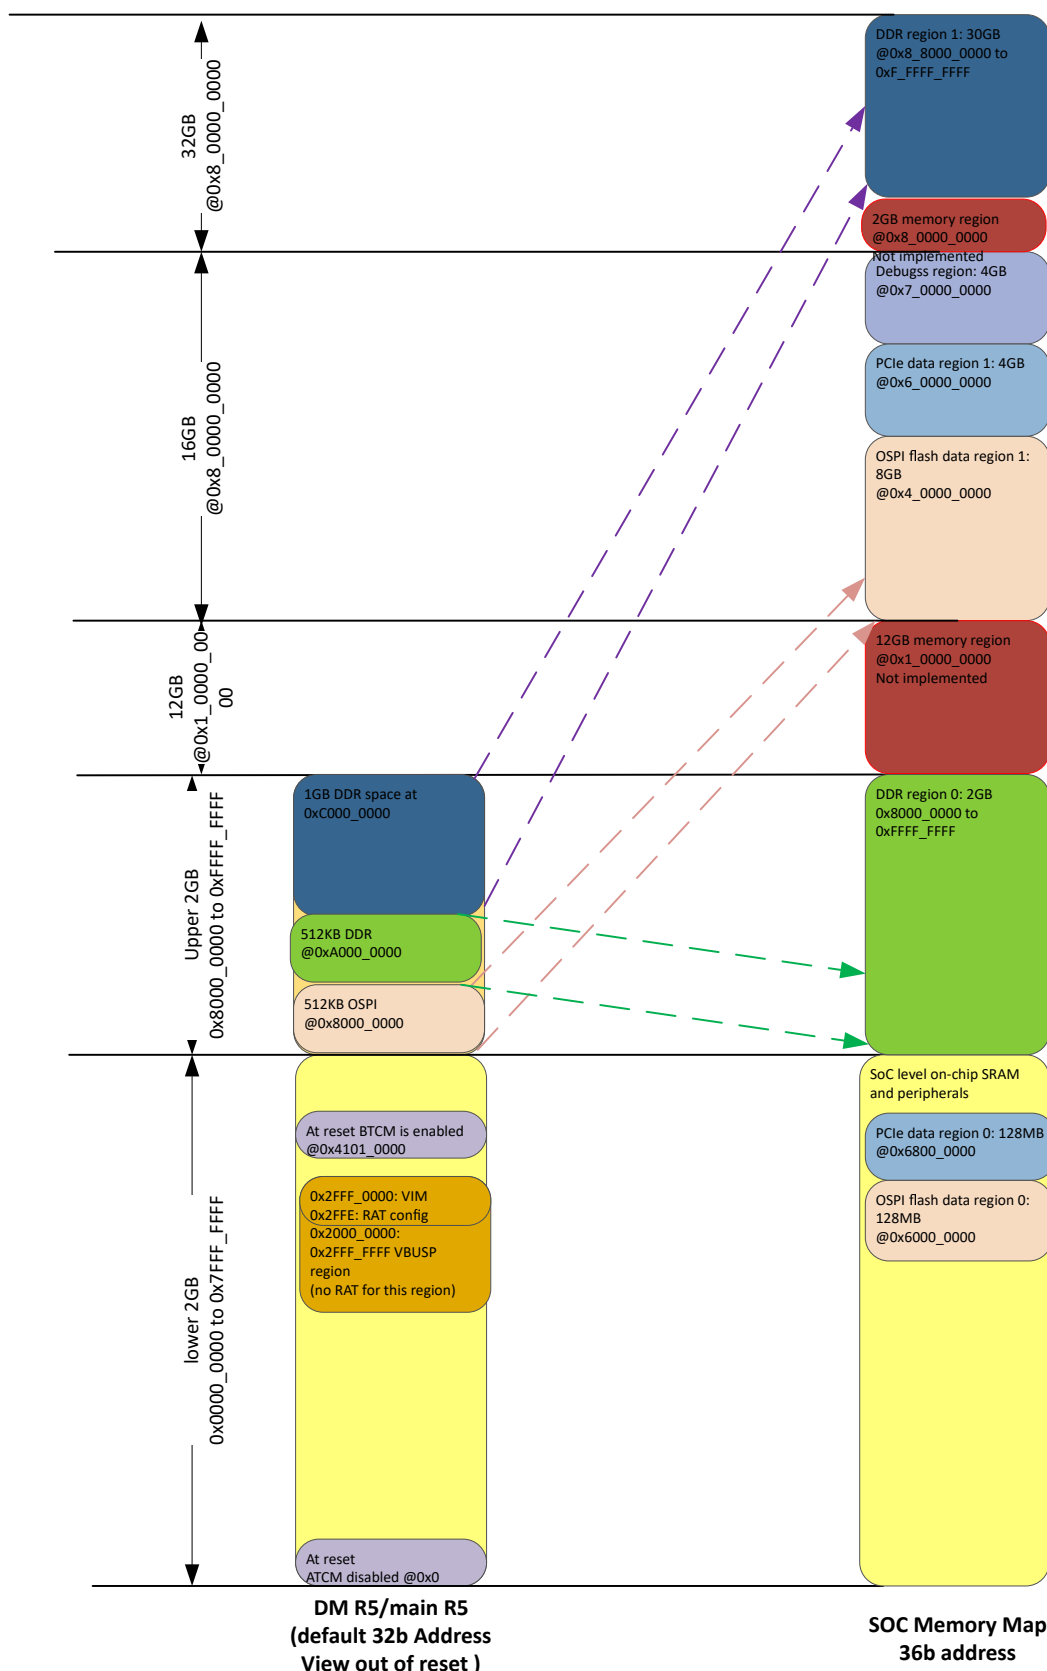

Figure 7-18. RAT Configuration Example

#### 7.4.2.7 WKUP\_R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The R5F can also monitor any ECC errors on its SoC buses and bridges through the ECC aggregator. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of the WKUP\_R5FSS aggregators, see R5FSS\_CPU0\_ECC\_AGGR\_CFG\_REGS Registers and R5FSS\_CPU1\_ECC\_AGGR\_CFG\_REGS Registers, respectively.

[Table 7-34](#) provides the RAM ID. This is needed for bit field [10-0] ECC\_VECTOR in the corresponding R5FSS\_CPU0\_VECTORR5FSS\_CPU0\_VECTOR register (part of the ECC aggregator register space).

**Table 7-34. RAM ID Map for ECC Aggregator (Per Core)**

RAM ID	Memory Name
0	CPU0 ITAG RAM0
1	CPU0 ITAG RAM1
2	CPU0 ITAG RAM2
3	CPU0 ITAG RAM3
4	CPU0 IDATA BANK0
5	CPU0 IDATA BANK1

27	CPU0 VIM RAM

#### 7.4.2.8 WKUP\_R5FSS Memory View

The memory view of the R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see [Section 7.4.2.2.2](#).
- Peripheral interface locations: The R5F natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map* for the complete R5F memory view for this device.

#### 7.4.2.9 WKUP\_R5FSS Interrupts

All interrupts that are generated by the WKUP\_R5FSS are summarized in *Module Integration*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.
- RAT exception interrupt: This is described in [Section 7.4.2.6](#).

#### 7.4.2.10 WKUP\_R5FSS Debug and Trace

The WKUP\_R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

#### 7.4.2.11 WKUP\_R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
  - a. To boot from ATCM, set CPUUn\_INITRAMA (or CPUUn\_INITRAMB to boot from BTCM)
  - b. Assert CPUUn\_LOCZRAMA properly for the desired TCM
2. Assert CPUUn\_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
  - a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUUn\_HALT

#### 7.4.2.12 WKUP\_R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are two ECC interrupts to the ESM that aggregate different categories of ECC events – CPU single error, CPU multi error. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the WKUP\_R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS\_EVNT\_BUS\_ESM\_SET register, it can be cleared by setting all the bits of the R5FSS\_EVNT\_BUS\_ESM\_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS\_EVNT\_BUS\_ESM\_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS\_EVNT\_BUS\_ESM\_CLR register to clear the interrupt.

The R5F core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5F core. For more details, refer to Arm R5 TRM.

**Table 7-35. R5F Event Bus Single-Bit Error Events**

Event Bus Bit #	Description	Associated Status Register
22	Instruction cache tag RAM parity or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0

## 7.5 Vectored Interrupt Manager (VIM)

This section describes the VIM module in the device.

### 7.5.1 VIM Overview

The Vectored Interrupt Manager (VIM) aggregates interrupts to a CPU. It is intended for use with a Cortex R5 from ARM. The VIM has up to 1024 interrupt inputs, which may be either level or pulse. Each interrupt has a programmable priority (0-highest through 15-lowest). Each interrupt may also be mapped as an IRQ or FIQ (FIQ is also often denoted as Non-Maskable Interrupt, or NMI).

#### 7.5.1.1 VIM Features

- 32-1024 Interrupt inputs
  - Configurable by groups of 32
- Each interrupt has its own 4-bit programmable priority
  - Supports Priority interruption of interrupts
- Each interrupt has its own enable mask
- Each interrupt can be programmed as either an IRQ or FIQ
- Each interrupt has its own programmable 32-bit Vector address associated with it
  - Protected with SECDDED
- One IRQn and FIQn output
- Vectored Interrupt Interface
  - Compatible with ARM Cortex R5 VIC Port
- Default Vector provided when a Double-Bit error is detected
- Provides clock phase inputs so VIM can run at CPU clock while interface runs at a different, synchronous clock

#### 7.5.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

Some features may not be available. See *Module Integration* for more information.

### 7.5.2 VIM Functional Description

#### 7.5.2.1 Block Diagram

[Figure 7-19](#) shows the Vectored Interrupt Manager block diagram.

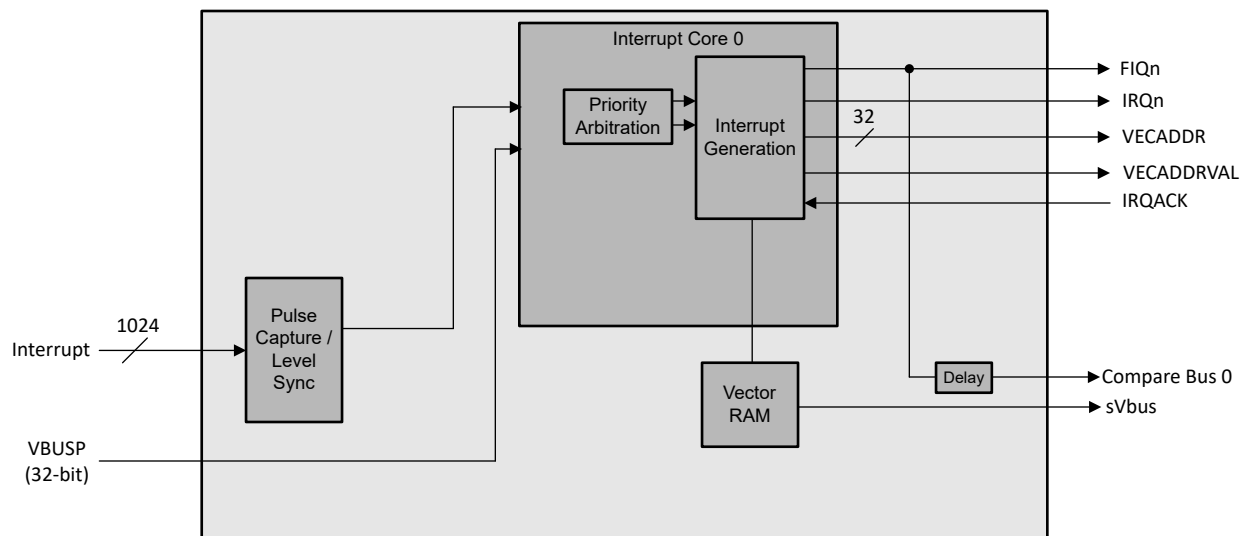

Figure 7-19. VIM Block Diagram

### 7.5.2.2 Interrupt Inputs

The VIM can have up to 1024 interrupt inputs, build-time configurable by multiples of 32 (*num\_interrupts* parameter). Each interrupt can be either a level or a pulse (both active high).

Level interrupts are synchronized to the VIM clock. This synchronized value is captured in to a flop.

Pulse interrupts use rising edge detection. Each input has its own edge detection circuit. It is recommended that if pulses are pipelined between the source and the VIM, that the pipe stage replicates the pipe flop and ORs the output in order to protect against transient errors in the pipeline flop. Once an edge has been detected, the raw status is set.

There is no minimum pulse width, as true edge detection is used. The input signal should, however, be glitch free.

### 7.5.2.3 Interrupt Outputs

The VIM has two interrupt outputs, *coreN\_IRQn* and *coreN\_FIQn* (active low levels). Each interrupt input for core *N* can be programmed to influence either the *coreN\_IRQn* or *coreN\_FIQn* output via the Group *M* Interrupt Map Register (Base Address + 0x200 + *N*\*0x20 + 0x18).

### 7.5.2.4 Priority Interrupt / Nested Interrupts

Each interrupt has a priority number assigned to it (set using the 4.1.20 Interrupt Q Priority Register (Base Address + 0x1000 + *Q*\*0x4) register). Legal values are 0 to 15 where 0 is the highest priority and 15 is the lowest priority. The highest priority interrupt is the pending interrupt with the smallest priority number. If two pending interrupts have the same priority, the interrupt lowest numerically (0 through maximum number of interrupts) is prioritized. IRQs and FIQs are prioritized separately.

The VIM supports the interrupt of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate, but both use the same mechanism. When an interrupt goes from pending to active (FIQ: reading the FIQ Vector Address (Base Address + 0x1C), IRQ: reading the IRQ Vector Address (Base Address + 0x18) or the *coreN\_IRQACK* going high), then the interrupt is loaded into the corresponding Active Register, and all interrupts of an equal or lesser priority are masked off (see note below). If, before this interrupt is cleared (writing the FIQ Vector Address (Base Address + 0x1C) or IRQ Vector Address (Base Address + 0x18)) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. The CPU may or may not service the higher priority interrupt. If the CPU switches this interrupt to active, by reading the corresponding Vector Address Register (or *coreN\_IRQACK* going high for an IRQ), then the currently active interrupt will be pushed on to a stack. When an interrupt is cleared by writing the Vector Address Register, if there are any interrupts on the stack, the first entry is popped off and put back into the Active

Register, so that software may continue where it left off. Note that the IRQVEC/FIQVEC address registers are *not* repopulated with the old vector as it's assumed that the ISR is picking back up where it left off. Only the interrupt number and priority are restored to the ACTIRQ/ACTFIQ registers. If software needs the vector again, it will have to read it by using the interrupt number.

#### Note

“Masked off” means that they are masked off from priority arbitration to interrupt the currently active interrupt, it does NOT mean that the status bits in the registers are masked off. That is, this priority masking has NO EFFECT on whether the status bits are visible in the masked registers such as the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04).

#### 7.5.2.5 VIC Port

The VIM is designed to work with the VIC interface of an ARM Cortex R5.

#### 7.5.2.6 Latency

There are several factors that go in to the speed of processing an interrupt: the interrupt controller, the processor, and the system latency.

The VIM behaves deterministically (except for synchronizer delay). [Table 7-37](#) shows the latency of the VIM.

**Table 7-37. VIM Latency**

Step	Cycles	Note
Edge Detection	2-3	Synchronizing to VIM Clock
Interrupt Capture	1	
Prioritization and Vector Read	1	IRQ Could be stalled here if an FIQ is reading the Vector RAM
		IRQ/FIQ output asserted

The next factor is the processor itself

**Table 7-38. Processor Interrupt Latency**

Step	Cycles <sup>(1)</sup>	Note
Take Exception		
Store State		Stack system registers etc
Read Vector	1	Through MMR or VIC interface (for IRQ. VIC interface will be faster)
Jump to Vector		

(1) These steps are dependent on the processor. See R5 spec for details.

The final factor is system latency to access the actually instructions for the ISR. This will be dependent on where the instructions are (cache, TCM, system memory etc) and dependent on the system latency to reach those memories (1 cycle for cache/TCM, System dependent for external memory)

#### 7.5.2.7 Safety

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DED Vector Address (Base Address + 0x30) is used instead for the coreN\_IRQADDRV, IRQ Vector Address (Base Address + 0x18), and FIQ Vector Address (Base Address + 0x1C). The DED Vector Address should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling. Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
  - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device

4. Sit in a loop (or WFI) while something external (say the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

An interrupt that has an uncorrectable vector error and thus uses the DED Vector, will still have the priority of the original interrupt (that is for masking purposes). This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by an external ECC aggregator through sVbus ports.

#### 7.5.2.8 IDLE

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface because it does not have a clock IPG. To clock stop the sub-system that includes the VIM, disable (mask) all interrupts and wait for the IDLE signal to assert.

### 7.5.3 Interrupt Conditions

#### 7.5.3.1 CPU Interrupts

See [Table 7-39](#) for the interrupts generated by the module.

**Table 7-39. Interrupts**

Interrupt	Description
core0_IRQn	IRQ Interrupt (Active Low)
core0_FIQn	FIQ Interrupt (Active Low)

#### 7.5.3.2 Interrupt Description

##### 7.5.3.2.1 coreN\_IRQn

This is a normal interrupt, active low level, for Core N. It can be serviced via the VIC interface or through the MMR interface.

##### 7.5.3.2.2 coreN\_FIQn

This is a fast (or non-maskable) interrupt, active low level, for Core N. FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface.

#### 7.5.3.3 Interrupt Condition Control

##### 7.5.3.3.1 coreN\_IRQn

Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (Group N Interrupt Map Register (Base Address + 0x200 + N\*0x20 + 0x18)) and is enabled (Group N Interrupt Enabled Set Register (Base Address + 0x200 + N\*0x20 + 0x08)), and its priority is not masked (4.1.11 IRQ Priority Mask Register (Base Address + 0x28)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an IRQ to assert.

##### 7.5.3.3.2 coreN\_FIQn

Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ (Group N Interrupt Map Register (Base Address + 0x200 + N\*0x20 + 0x18)) and is enabled (Group N Interrupt Enabled Set Register (Base Address + 0x200 + N\*0x20 + 0x08)), and its priority is not masked (4.1.12 FIQ Priority Mask Register (Base Address + 0x2C)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an FIQ to assert.

#### 7.5.3.4 Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM software wants to take advantage of. For IRQs, it is recommended to use 3.4.1 IRQ through the Vector

Interface, but 3.4.2 or 3.4.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives. For FIQs, it is recommended to use 3.4.4 FIQ, but 3.4.5 may be used as an alternative.

#### Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

#### 7.5.3.4.1 IRQ through the Vector Interface

If the attached CPU has the Vector Interface enabled, then the following method is used for servicing IRQs

1. Hardware handshake
  - a. CPU asserts coreN\_IRQACK signal high
  - b. VIM asserts coreN\_IRQADDRV to indicate that the coreN\_IRQADDR bus is stable with the correct Vector Address
  - c. CPU reads the coreN\_IRQADDR, jumps to that address, and de-asserts coreN\_IRQACK signal low
  - d. VIM de-asserts coreN\_IRQn\_intr and coreN\_IRQADDRV, VIM masks all IRQs with the same or lower priority
  - e. VIM loads the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service an interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the IRQ Vector Address (Base Address + 0x18)
  - a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
  - b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

#### 7.5.3.4.2 IRQ through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the Vector Interface.

1. Read the IRQ Vector Address (Base Address + 0x18) and jump to that address to service the ISR
  - a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the IRQn output. If another interrupt of a higher priority becomes available, the IRQn will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service the interrupt

3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the IRQ Vector Address (Base Address + 0x18)
  - a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
  - b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

#### 7.5.3.4.3 IRQ through MMR Interface (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, priority masking will not work if route 1b is used (below) as the hardware prioritization may not match the software prioritization scheme. In this case, software would be responsible for doing all priority operations

1. Determine which interrupt to service
  - a. Read the Prioritized IRQ (Base Address + 0x08) to determine which interrupt is the highest priority IRQ currently asserted OR
  - b. Optionally read the IRQ Group Status (Base Address + 0x10) to determine which groups have IRQs pending, then read the Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10) and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Read the IRQ Vector Address (Base Address + 0x18)
  - a. Note, this step can be done any time before step 4
  - b. Value is ignored
4. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + M\*0x20 + 0x10)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source

- ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x10)
  1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
  2. If the source maintains the level, then it means there is another interrupt
5. Write any value to the IRQ Vector Address (Base Address + 0x18)

#### 7.5.3.4.4 FIQ

When an FIQ interrupt is received, the CPU should follow these steps.

1. Read the FIQ Vector Address (Base Address + 0x1C) and jump to that address to service the ISR
  - a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the FIQn output. If another interrupt of a higher priority becomes available, the FIQn will re-assert, allowing priority interruption of an interrupt.
  - b. Reading this register will cause the value from the Prioritized FIQ (Base Address + 0x0C) (which corresponds to the vector address) to be loaded into the Active FIQ (Base Address + 0x24) and the valid bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active FIQ (Base Address + 0x24) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M*\*0x20 + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the FIQ Vector Address (Base Address + 0x1C)
  - a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
  - b. This will clear the valid bit of the Active FIQ (Base Address + 0x24)

#### 7.5.3.4.5 FIQ (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQ Vector Address (Base Address + 0x1C) is never read). Software would be responsible for doing all priority operations

1. Determine which interrupt to service
  - a. Read the Prioritized FIQ (Base Address + 0x0C) to determine which interrupt is the highest priority FIQ currently asserted OR
  - b. Optionally read the FIQ Group Status (Base Address + 0x14) to determine which groups have IRQs pending, then read the Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x14) and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt

3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 +  $M \times 0x20$  + 0x1C) to determine type)
  - a. Pulse
    - i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x14)
    - ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x14)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt

#### 7.5.4 Memory Map

Each Interrupt Core ( $N = 0$ ) has its own MMR interface with its own independent memory map

**Table 7-40. Core *N* Memory Map**

Address Offset	Register
0x00	Revision Register
0x04	Info Register
0x08	Prioritized IRQ
0x0C	Prioritized FIQ
0x10	IRQ Group Status
0x14	FIQ Group Status
0x18	IRQ Vector Address
0x1C	FIQ Vector Address
0x20	Active IRQ
0x24	Active FIQ
0x28-0x2F	Reserved
0x30	DED Vector Address
0x34-0x1FF	Reserved
$0x400 + M \times 0x20 + 0x00$	Group <i>M</i> Interrupt Raw Status/Set Register
$0x400 + M \times 0x20 + 0x04$	Group <i>M</i> Interrupt Enabled Status/Clear Register
$0x400 + M \times 0x20 + 0x08$	Group <i>M</i> Interrupt Enabled Set Register
$0x400 + M \times 0x20 + 0x0C$	Group <i>M</i> Interrupt Enabled Clear Register
$0x400 + M \times 0x20 + 0x10$	Group <i>M</i> Interrupt IRQ Enabled Status/Clear Register
$0x400 + M \times 0x20 + 0x14$	Group <i>M</i> Interrupt FIQ Enabled Status/Clear Register
$0x400 + M \times 0x20 + 0x18$	Group <i>M</i> Interrupt Map Register
$0x400 + M \times 0x20 + 0x1C$	Group <i>M</i> Type Map Register
$0x1000 + Q \times 0x4 - 0x1FFF$	Interrupt <i>Q</i> Priority Register
$0x2000 + Q \times 0x4 - 0x2FFF$	Interrupt <i>Q</i> Vector Register

There are *M* interrupt groups (0 through *num\_groups*-1) with 32 interrupts per group.

There are *Q* interrupt inputs where  $Q = M \times 32$ .

Accesses to the Interrupt Q Vector Register (Base Address + 0x2000 + Q\*0x4) must be word-aligned, 32-bit accesses. Any write received with no bytes enabled will be ignored. Any writes receive with all bytes enabled will be executed. Any other write will not execute and will return an error status of Addressing Error.

### 7.5.5 VIM Registers

#### 7.5.5.1 Revision Register (Base Address + 0x00)

**Table 7-41. Revision Register (Base Address + 0x00)**

Bits	Field	Type	Reset	Description
31:30	scheme	r	01	Always read as 01. Writes have no effect.
29:28	bu	r	10	Always read as 10.
27:16	func	r	0x090	Always read as the assigned func id.
15:11	rtl	r	0x0	RTL version of the module. The "R" value in the X.Y.R.Z as defined by K3.
10:8	major	r	0x0	Major revision of module. The "X" value in the X.Y.R.Z defined in K3.
7:6	custom	r	0x0	Special version.
5:0	minor	r	0x1	Minor revision of module. The "Y" value in the X.Y.R.Z defined in K3

#### 7.5.5.2 Info Register (Base Address + 0x04)

**Table 7-42. Info Register (Base Address + 0x04)**

Bits	Field	Type	Reset	Description
31:11	<i>reserved</i>	r/o	0	Always read as 0. Writes have no effect.
10:0	Interrupts	r/o	<i>num_groups</i> * 32	Indicates the number of interrupts supported by this VIM

#### 7.5.5.3 Prioritized IRQ (Base Address + 0x08)

**Table 7-43. Prioritized IRQ (Base Address + 0x08)**

Bits	Field	Type	Reset	Description
31	valid	r/o	0	Indicates that the num field of this register is valid 1 – num field is valid (pending IRQ interrupt) 0 – num field is invalid (no pending IRQ interrupts)
30:20	<i>reserved</i>	r/o	0	Always read as 0. Writes have no effect.
19:16	pri	r/o	0	This field indicates the priority of the pending IRQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	<i>reserved</i>	r/o	0	Always read as 0. Writes have no effect.
9:0	num	r/o	0	This field indicates the interrupt number of the pending IRQ interrupt with the highest priority. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the <i>num_groups</i> parameter

#### 7.5.5.4 Prioritized FIQ (Base Address + 0x0C)

**Table 7-44. Prioritized FIQ (Base Address + 0x0C)**

Bits	Field	Type	Reset	Description
31	valid	r/o	0	Indicates that the num field of this register is valid 1 – num field is valid (pending FIQ interrupt) 0 – num field is invalid (no pending FIQ interrupts)
30:20	reserved	r/o	0	Always read as 0. Writes have no effect.
19:16	pri	r/o	0	This field indicates the priority of the pending FIQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	reserved	r/o	0	Always read as 0. Writes have no effect.
9:0	num	r/o	0	This field indicates the interrupt number of the pending FIQ interrupt with the highest priority. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the <i>num_groups</i> parameter

#### 7.5.5.5 IRQ Group Status (Base Address + 0x10)

**Table 7-45. IRQ Group Status (Base Address + 0x10)**

Bits	Field	Type	Reset	Description
31:0	sts	r/o	0	This field indicates that one or more interrupts in Group <i>M</i> are mapped to IRQ, unmasked, and pending. Bit 0 corresponds to Group 0; Bit 1 corresponds to Group 1 etc. The interrupts associated with each group are $[(M*32)+31:M*32]$

#### 7.5.5.6 FIQ Group Status (Base Address + 0x14)

**Table 7-46. FIQ Group Status (Base Address + 0x14)**

Bits	Field	Type	Reset	Description
31:0	sts	r/o	0	This field indicates that one or more interrupts in Group <i>M</i> are mapped to FIQ, unmasked, and pending. Bit 0 corresponds to Group 0; Bit 1 corresponds to Group 1 etc. The interrupts associated with each group are $[(M*32)+31:M*32]$

### 7.5.5.7 IRQ Vector Address (Base Address + 0x18)

**Table 7-47. IRQ Vector Address (Base Address + 0x18)**

Bits	Field	Type	Reset	Description
31:2	addr	r/w	0x0	<p>This field contains the upper 30 bits of the 32-bit interrupt vector address (addresses must be 32-bit aligned) of the currently pending highest priority IRQ (as indicated by the num field of the <a href="#">Prioritized IRQ (Base Address + 0x08)</a>). This field is only valid if the valid flag in the <a href="#">Prioritized IRQ (Base Address + 0x08)</a> register is set.</p> <ul style="list-style-type: none"> <li>Reading this register returns the Interrupt Vector Address of the pending IRQ with the highest priority. It also has the following effects <ul style="list-style-type: none"> <li>Mask all IRQ interrupts of an equivalent or lower priority</li> <li>De-asserts the IRQn signal</li> <li>De-asserts the coreN_IRQADDRV signal (if set)</li> <li>Loads <a href="#">Active IRQ (Base Address + 0x20)</a></li> </ul> </li> <li>Writing any value to this register will not alter its contents, but will have the following effect <ul style="list-style-type: none"> <li>Remove the mask on all priorities</li> </ul> </li> </ul>
1:0	reserved	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

### 7.5.5.8 FIQ Vector Address (Base Address + 0x1C)

**Table 7-48. FIQ Vector Address (Base Address + 0x1C)**

Bits	Field	Type	Reset	Description
31:0	addr	r/w	0x0	<p>This field contains the upper 30 bits of the 32-bit interrupt vector address (addresses must be 32-bit aligned) of the currently pending highest priority FIQ (as indicated by the num field of the <a href="#">Prioritized FIQ (Base Address + 0x0C)</a>). This field is only valid if the valid flag in the <a href="#">Prioritized FIQ (Base Address + 0x0C)</a> register is set.</p> <ul style="list-style-type: none"> <li>Reading this register returns the Interrupt Vector Address of the pending FIQ with the highest priority. It also has the following effects <ul style="list-style-type: none"> <li>Mask all FIQ interrupts of an equivalent or lower priority</li> <li>De-asserts the FIQ n signal</li> <li>Loads <a href="#">Active FIQ (Base Address + 0x24)</a></li> </ul> </li> <li>Writing any value to this register will not alter its contents, but will have the following effect <ul style="list-style-type: none"> <li>Remove the mask on all FIQ priorities</li> </ul> </li> </ul>
1:0	reserved	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

### 7.5.5.9 Active IRQ (Base Address + 0x20)

**Table 7-49. Active IRQ (Base Address + 0x20)**

Bits	Field	Type	Reset	Description
31	valid	r/o	0	<p>Indicates that the num field of this register is valid. This field is set whenever the <a href="#">IRQ Vector Address (Base Address + 0x18)</a> is read. It is cleared whenever the <a href="#">IRQ Vector Address (Base Address + 0x18)</a> is written.</p> <p>1 – num field is valid (active IRQ interrupt)  0 – num field is invalid (no active IRQ interrupts)</p>

**Table 7-49. Active IRQ (Base Address + 0x20) (continued)**

Bits	Field	Type	Reset	Description
30:20	<i>reserved</i>	<i>r/o</i>	0	Always read as 0. Writes have no effect.
19:16	<i>pri</i>	<i>r/o</i>	0	This field indicates the priority of the active IRQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	<i>reserved</i>	<i>r/o</i>	0	Always read as 0. Writes have no effect.
9:0	<i>num</i>	<i>r/o</i>	0	This field indicates the interrupt number of the active IRQ interrupt. This field is loaded with the value from the <a href="#">Prioritized IRQ (Base Address + 0x08)</a> whenever the <a href="#">IRQ Vector Address (Base Address + 0x18)</a> is read. This field is only valid if the valid flag (bit 8) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the <i>num_groups</i> parameter

#### 7.5.5.10 Active FIQ (Base Address + 0x24)

**Table 7-50. Active FIQ (Base Address + 0x24)**

Bits	Field	Type	Reset	Description
31	<i>valid</i>	<i>r/o</i>	0	Indicates that the num field of this register is valid. This field is set whenever the <a href="#">FIQ Vector Address (Base Address + 0x1C)</a> is read. It is cleared whenever the <a href="#">FIQ Vector Address (Base Address + 0x1C)</a> is written. 1 – num field is valid (active FIQ interrupt) 0 – num field is invalid (no active FIQ interrupts)
30:20	<i>reserved</i>	<i>r/o</i>	0	Always read as 0. Writes have no effect.
19:16	<i>pri</i>	<i>r/o</i>	0	This field indicates the priority of the ACTIVE FIQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	<i>reserved</i>	<i>r/o</i>	0	Always read as 0. Writes have no effect.
9:0	<i>num</i>	<i>r/o</i>	0	This field indicates the interrupt number of the active FIQ interrupt. This field is loaded with the value from the <a href="#">Prioritized FIQ (Base Address + 0x0C)</a> whenever the <a href="#">FIQ Vector Address (Base Address + 0x1C)</a> is read. This field is only valid if the valid flag (bit 8) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the <i>num_groups</i> parameter

#### 7.5.5.11 IRQ Priority Mask Register (Base Address + 0x28)

**Table 7-51. IRQ Priority Mask Register (Base Address + 0x28)**

Bits	Field	Type	Reset	Description
31:16	<i>reserved</i>	<i>r/o</i>	0	Always read as 0. Writes have no effect.
15:0	<i>msk</i>	<i>r/w</i>	0xFFFF	This field is a bit vector to enable all IRQ interrupts of a given priority. Bit 0 corresponds to priority = 0 (highest) Bit 1 corresponds to priority = 1 etc.... 0 – IRQ of this priority are disabled 1 – IRQ of this priority are enabled

### 7.5.5.12 FIQ Priority Mask Register (Base Address + 0x2C)

**Table 7-52. FIQ Priority Mask Register (Base Address + 0x2C)**

Bits	Field	Type	Reset	Description
31:16	<i>reserved</i>	r/o	0	Always read as 0. Writes have no effect.
15:0	<i>msk</i>	r/w	0xFFFF	This field is a bit vector to enable all FIQ interrupts of a given priority. Bit 0 corresponds to priority = 0 (highest) Bit 1 corresponds to priority = 1 etc.... 0 – FIQ of this priority are disabled 1 – FIQ of this priority are enabled

### 7.5.5.13 DED Vector Address (Base Address + 0x30)

**Table 7-53. DED Vector Address (Base Address + 0x30)**

Bits	Field	Type	Reset	Description
31:2	<i>addr</i>	r/w	0x0	This field contains the upper 30 bits of the 32-bit interrupt vector address (the address must be 32-bit aligned) of an interrupt to be used if an uncorrectable double-bit error (DED) is detected in any of the interrupt vector addresses. If there is a DED, both the <a href="#">IRQ Vector Address (Base Address + 0x18)</a> and <a href="#">FIQ Vector Address (Base Address + 0x1C)</a> registers (along with the VECADDR output) will be populated with the value in this field instead of their normal vector. See section <a href="#">Section 7.3.3.2.4 , Priority Interrupt / Nested Interrupts</a> . Safety on how to handle interrupts when there has been a DED <ul style="list-style-type: none"> <li>ECC Aggregator will indicate where there was a DED. Software may go correct that one location</li> <li>Software may keep an ISR at the DED Vector which corrects the vectors or otherwise deals with the scenario</li> <li>This mechanism is provided because there is no way to indicate on the coreN_IRQADDR to the CPU that the vector is invalid, and it is undesirable to have the CPU jump to a random address</li> </ul>
1:0	<i>reserved</i>	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

### 7.5.5.14 Group M Interrupt Raw Status/Set Register (Base Address + 0x400 + M\*0x20 + 0x00)

**Table 7-54. Group M Interrupt Raw Status/Set Register (Base Address + 0x400 + M\*0x20 + 0x00)**

Bits	Field	Type	Reset	Description
31:0	<i>sts</i>	r/w1ts	0x0	This is the raw status of the events in Group M. Each bit corresponds to event Q where $Q = M*32 + \text{Bit}$ (Example: bit 0 is event $M*32+0$ , bit 1 is $M*32 + 1$ etc...) <p>Read:</p> 0 – Inactive 1 – Active/Pending <p>Write:</p> 0 – No effect 1 – Set to Interrupt Raw Status

#### 7.5.5.15 Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04)

**Table 7-55. Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x04)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	<p>This is the masked status of the events in Group <i>M</i>. Each bit corresponds to event <i>Q</i> where <math>Q = M*32 + \text{Bit}</math> (Example: bit 0 is event <math>M*32+0</math>, bit 1 is <math>M*32 + 1</math> etc...)</p> <p>Read:</p> <p>0 – Inactive or Disabled 1 – Active/Pending and Enabled</p> <p>Write:</p> <p>0 – No effect 1 – Clear Interrupt Raw Status</p>

#### 7.5.5.16 Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M*\*0x20 + 0x08)

**Table 7-56. Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M*\*0x20 + 0x08)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1ts	0x0	<p>This field is used to enable the mask of events in Group <i>M</i>. Each bit corresponds to event <i>Q</i> where <math>Q = M*32 + \text{Bit}</math> (Example: bit 0 is event <math>M*32+0</math>, bit 1 is <math>M*32 + 1</math> etc...)</p> <p>Read:</p> <p>0 – Disabled 1 – Enabled</p> <p>Write:</p> <p>0 – No effect 1 – Set Enable</p>

#### 7.5.5.17 Group *M* Interrupt Enabled Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x0C)

**Table 7-57. Group *M* Interrupt Enabled Clear Register (Base Address + 0x400 + *M*\*0x20 + 0x0C)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	<p>This field is used to disable the mask of events in Group <i>M</i>. Each bit corresponds to event <i>Q</i> where <math>Q = M*32 + \text{Bit}</math> (Example: bit 0 is event <math>M*32+0</math>, bit 1 is <math>M*32 + 1</math> etc...)</p> <p>Read:</p> <p>0 – Disabled 1 – Enabled</p> <p>Write:</p> <p>0 – No effect 1 – Clear Enable</p>

**7.5.5.18 Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x10)**
**Table 7-58. Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x10)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	<p>This is the masked status of the events in group <i>M</i> that are mapped to IRQ. Each bit corresponds to event <i>Q</i> where <math>Q = M \times 32 + \text{Bit}</math> (Example: bit 0 is event <math>M \times 32 + 0</math>, bit 1 is <math>M \times 32 + 1</math> etc...)</p> <p>Read:</p> <p>0 – Inactive, Disabled, or not an IRQ 1 – Active/Pending, Enabled, and IRQ</p> <p>Write:</p> <p>0 – No effect 1 – Clear Interrupt Raw Status (if IRQ)</p>

**7.5.5.19 Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x14)**
**Table 7-59. Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 +  $M \times 0x20$  + 0x14)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	<p>This is the masked status of the events in group <i>M</i> that are mapped to FIQ. Each bit corresponds to event <i>Q</i> where <math>Q = M \times 32 + \text{Bit}</math> (Example: bit 0 is event <math>M \times 32 + 0</math>, bit 1 is <math>M \times 32 + 1</math> etc...)</p> <p>Read:</p> <p>0 – Inactive, Disabled, or not an FIQ 1 – Active/Pending, Enabled, and FIQ</p> <p>Write:</p> <p>0 – No effect 1 – Clear Interrupt Raw Status (if FIQ)</p>

**7.5.5.20 Group *M* Interrupt Map Register (Base Address + 0x400 +  $M \times 0x20$  + 0x18)**
**Table 7-60. Group *M* Interrupt Map Register (Base Address + 0x400 +  $M \times 0x20$  + 0x18)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w	0x0	<p>This field is used to indicate which interrupt the corresponding event influences (if enabled) for event group <i>M</i>. Each bit corresponds to event <i>Q</i> where <math>Q = M \times 32 + \text{Bit}</math> (Example: bit 0 is event <math>M \times 32 + 0</math>, bit 1 is <math>M \times 32 + 1</math> etc...)</p> <p>0 – IRQ Interrupt (default) 1 – FIQ Interrupt</p>

### 7.5.5.21 Group *M* Type Map Register (Base Address + 0x400 + *M*\*0x20 + 0x1C)

**Table 7-61. Group *M* Type Map Register (Base Address + 0x400 + *M*\*0x20 + 0x1C)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w	0x0	This field is used to indicate whether the source of an interrupt is a level (default) or a pulse for event group <i>M</i> . This is informational so that an ISR may query this register and know whether it has to clear a pulse event or a level event (see <a href="#">Section 7.3.3.3.4 Interrupt Handling</a> ). The value has no effect on how the VIM hardware functions. The input interrupts are agnostic as to whether they are pulse or level. Each bit corresponds to event <i>Q</i> where $Q = M*32 + \text{Bit}$ (Example: bit 0 is event $M*32+0$ , bit 1 is $M*32 + 1$ etc...) <p>0 – Level (default)</p> <p>1 – Pulse</p>

### 7.5.5.22 Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q*\*0x4)

**Table 7-62. Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q*\*0x4)**

Bits	Field	Type	Reset	Description
31:4	<i>reserved</i>	r/o	0	Always read as 0. Writes have no effect.
3:0	pri	r/w	0xF	This is the priority for interrupt <i>Q</i> . If two interrupts have the same priority, then whichever interrupt has the lower number <i>Q</i> wins arbitration <p>0 – Highest Priority</p> <p>1</p> <p>....</p> <p>14</p> <p>15 – Lowest Priority (Default)</p>

### 7.5.5.23 Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q*\*0x4)

**Table 7-63. Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q*\*0x4)**

Bits	Field	Type	Reset	Description
31:2	addr	r/w		This is the 32-bit Vector Address associated with interrupt <i>Q</i> . It is the address that will be reflected in the <a href="#">IRQ Vector Address (Base Address + 0x18)</a> or <a href="#">FIQ Vector Address (Base Address + 0x1C)</a> and the VECADDR pin when interrupt <i>Q</i> is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1:0	<i>reserved</i>	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

## 7.5.6 Module I/O

### 7.5.6.1 Clocks, Reset, Emulation

**Table 7-64. Clocks, Reset, Emulation**

Pin Name	Type	Function
core0_clk	In	Clock for Core 0
core0_phase	In	Phase Indicator for Core 0
core0_srst_n	In	Sync Module Reset for Core 0
core0_arst_n	In	Async Module Reset for Core 0
core0_clkstop_idle	Out	Clock Stop Idle

### 7.5.6.2 VBUSP Target Interface

(N=0). Core0 interface is used for interrupt core 0.

**Table 7-65. VBUSP Target Interface**

Pin Name	Type	Function
coreN_cfg_req	In	Request
coreN_cfg_address[13:0]	In	Address (byte address)
coreN_cfg_dir	In	Direction (read or write)
coreN_cfg_xcnt[2:0]	In	Transaction Count
coreN_cfg_byten[3:0]	In	Byte enables
coreN_cfg_wdata[31:0]	In	Write data
coreN_cfg_rdatap[31:0]	Out	Read data
coreN_cfg_ready	Out	Read ready
coreN_cfg_wready	Out	Write ready
coreN_cfg_rstatus[2:0]	Out	Read Status
coreN_cfg_emudbg	In	Emulation Debug

### 7.5.6.3 Interrupt Inputs

Core0 interface is used for interrupt core 0.

**Table 7-66. Interrupt Inputs**

Pin Name	Type	Function
core0_in_intr[Q-1:0]	In	Core 0 Interrupt Inputs

### 7.5.6.4 Interrupt Outputs

**Table 7-67. Interrupt Outputs**

Pin Name	Type	Function
core0_IRQn_intr	Out	IRQ Interrupt for core 0— Active Low Level
core0_FIQn_intr	Out	FIQ Interrupt for core 0 – Active Low Level

### 7.5.6.5 VIC Interfaces

(N=0). Core0 interface is used for interrupt core 0.

**Table 7-68. VIC Interfaces**

Pin Name	Type	Function
coreN_vic_IRQADDRV	Out	IRQ Address Valid
coreN_vic_IRQADDR[31:2]	Out	IRQ Address
coreN_vic_IRQACK	In	Interrupt Acknowledge

### 7.5.6.6 Compare Outputs

These pins will never be on an isolation boundary and therefore their isolation values are don't-care. Y is dependent on the configuration

**Table 7-69. Compare Outputs**

Pin Name	Type	Function
core0_compare_bus[Y:0]	Out	Comparison Bus for Core0 to CCMR5

### 7.5.6.7 ECC Control and Status Bus

(N=0). Core0 interface is used for interrupts for core 0.

**Table 7-70. ECC Control and Status Bus**

Signal Name	Dir	Default Val	Description
coreN_amecc_strb	In	1'b0	Strobe to sample the incoming serial data
coreN_amecc_txd	In	1'b0	Output serial data
coreN_amecc_rxd	Out	1'b0	Input serial data
coreN_amecc_pend[1:0]	Out	2'd0	Level Interrupt source

### 7.5.6.8 DFT

**Table 7-71. DFT**

Signal Name	Dir	Default Val	Description
dft_clk_force_en	In	1'b0	DFT Clock Force Enable
dft_partition_enn	In	1'b0	DFT Clock Partition Enable
dft_scan_en	In	1'b0	DFT Scan Enable
dft_async_rst_sel	In	1'b0	DFT Async Reset Select
dft_test_async_rst_n	In	1'b0	DFT Async Test Reset
dft_tft_mcp_dis	In	1'b0	DFT MCP Disable
dft_local_clk_en	In	1'b0	DFT Local Clock Enable

### 7.5.6.9 RAM GPIO

**Table 7-72. RAM GPIO**

Signal Name	Dir	Default Val	Description
coreN_ramdft_gpi[255:0]	In	256'd0	RAM GPI
coreN_ramdft_gpo[255:0]	Out	256'd0	RAM GPO

## 7.5.7 Programmer's Guide

### 7.5.7.1 Initialization Sequence

At initialization, the following tasks should be performed:

1. Program the DED Vector Address (Base Address + 0x30)
2. Program Group M Interrupt Map Register (Base Address + 0x200 + M\*0x20 + 0x18)
3. Program Group M Type Map Register (Base Address + 0x200 + M\*0x20 + 0x1C)
4. Program Interrupt Q Priority Register (Base Address + 0x1000 + Q\*0x4)
5. Program Interrupt Q Vector Register (Base Address + 0x2000 + Q\*0x4)
6. Enable interrupts via the Group M Interrupt Enabled Set Register (Base Address + 0x400 + M\*0x20 + 0x08)

Note that the Interrupt Q Vector Register (Base Address + 0x2000 + Q\*0x4) for each interrupt that will be enabled must be written before the interrupt is enabled, even if software is not going to use the vector. Whenever an interrupt is prioritized, the RAM location for the interrupt is read, and if that location is un-initialized, an ECC

error will be reported. If the vectors aren't being used, then the RAM can be initialized by writing 0x0 to every location.

### 7.5.7.2 DED Behavior

Whenever there is 2-bit error detect on a Vector Address, the DED Vector Address (Base Address + 0x30) overrides all other vectors. Software should provide an ISR to handle this scenario at this address.

### 7.5.7.3 Power Up/Down Sequence

Before a clean power down, software should check that there are no pending interrupts, disable all interrupts, and wait for the clkstop\_idle output.

## 7.6 Video Encoder/Decoder (VENC/VDEC)

The following sections describe the video accelerator details for the device.

### 7.6.1 Introduction

The Video Accelerator is a 4K codec that supports both HEVC and H.264/AVC video formats. It provides high performance encode and decode capability up to 8bit 4K@60fps with a single-core architecture.

The Video Accelerator can encode and/or decode any resolution up to 8192 x 4320. It guarantees real-time performance for encoding/decoding 4K 60fps based on its sophisticated, latency tolerant hardware architecture. The Video Accelerator is highly optimized for memory bandwidth loading and excellent power management.

The Video Accelerator contains a 32-bit processor called V-CPU, which is responsible for parsing bitstream syntax in decoder or encoding bitstream syntax in encoder from sequence to slice header unit, pre-scanning slice data, controlling the underlying video hardware blocks called V-CORE. The V-CPU also communicates with host CPU through host register interface. The V-CORE performs actual processing of coded slice data: entropy decoding, inverse scan, inverse transform/quantization, motion compensation, and loop filtering in decoder and motion estimation, intra prediction, RDO, and entropy coding in encoder. This software and hardware combined architecture can provide flexibility and high throughput at the same time.

### 7.6.2 Features

#### 7.6.2.1 Performance

#### H.265/HEVC Encoder

- Capable of encoding HEVC Main and Main Still Picture Profile @ L5.1 High tier
  - Maximum resolution: 8192x8192
    - The maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 256x128
  - Constraints
    - A picture width shall be multiple of 8.
    - A picture height shall be multiple of 8.

**Table 7-73. HEVC Encoder Performance**

PicWidth	PicHeight	MHz/60fps 160Mbps
3840	2160	500

#### H.264/AVC Encoder

- Capable of encoding Baseline/Constrained Baseline/Main/High Profiles Level @ L5.2
  - Maximum resolution: 8192x8192
    - The maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 256x128
  - Constraints

- A picture width shall be multiple of 8.
- A picture height shall be multiple of 8.

**Table 7-74. H.264/AVC Encoder Performance**

PicWidth	PicHeight	MHz/60fps 72Mbps
3840	2160	500

### H.265/HEVC Decoder

- Capable of decoding HEVC Main and Main Still Picture Profile @ L5.1 High tier
  - Maximum resolution: 8192x4320
    - The Maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 8x8

**Table 7-75. H.265/HEVC Decoder Performance**

PicWidth	PicHeight	MHz/60fps 160Mbps
3840	2160	450.00

### H.264/AVC Decoder

- Capable of decoding Baseline/Constrained Baseline/Main/High Profiles @ L5.2
  - Maximum resolution: 8192x4320
    - The Maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 32x32

**Table 7-76. H.264/AVC Decoder Performance**

PicWidth	PicHeight	MHz/60fps 72Mbps
3840	2160	450.00

## 7.6.2.2 Codec Related Features

### H.265/HEVC Encoder

- Fully compatible with ISO/IEC 23008-2 high efficiency video coding main profile
- I/P slices
- CTU64
  - Supportable prediction unit (PU) size: 32 x 32, 16 x 16, 8 x 8
  - Supportable transform unit (TU) size: 32 x 32 to 4 x 4
- Parallel tools
  - Wavefront parallel processing (WPP) encoding with a single slice
  - Multi slice: Independent slice segment and dependent slice segment
- High performance offline CABAC encoding
- Motion estimation
  - 1/4-pel precision motion vectors
  - Search range [+/-128H, +/-64V] with an adaptive search center
  - Two reference frames for P-slice
  - Long-term reference for P picture
- Custom tuning tools
  - Custom Lambda map and lambda table
  - Custom mode decision
  - Fully programmable user scaling list
- In-loop filter
  - Deblocking filter

- Sample adaptive offset (SAO)
- Loop filtering across slices
- Strong intra smoothing on/off
- Transform skip
- Lossless coding
- Picture/CTU/subCTU level of rate control
- Region of interest (ROI) encoding with custom QP map
- 3DNR
- Adaptive intra refresh (AIR) for error resilience

### H.264/AVC Encoder

- Compatible with the ITU-T recommendation H.264 specification. All coding tools in the baseline, con- strained baseline, main, and high profiles are supported.
  - With a few exceptions:
    - Interlaced coding tools are not supported.
    - FMO/ASO tool of H.264 is not supported.
- 16 x 16, 8 x 8 and 4 x 4 block sizes are supported and configurable.
- Motion estimation
  - 1/4-pel accuracy motion estimation with programmable search range up to  $[\pm 64, \pm 48]$
  - One reference frame for P-slice
- Intra prediction
  - Luma 14 x 4 Mode: 9 modes
  - Luma 18 x 8 Mode: 9 modes
  - Luma 116 x 16 Mode: 4 modes (vertical, horizon, DC, plane)
  - Chroma mode: 3 modes (vertical, horizon, DC)
- Custom tuning tools
  - User-defined mode (skip, intra) map
  - User-defined QP map
  - Lambda tuning for custom mode decision
  - Fully programmable user scaling list
- In-loop deblocking filter
- CABAC/CAVLC support
- Error resilience tools:
  - Cyclic intra refresh (CIR)
  - Multi-slice structure
- A frame level and MB level of rate control
- Region of interest (ROI) encoding with custom QP map

### H.265/HEVC decoder

- Fully compatible with ISO/IEC 23008-2 high efficiency video coding main/MSP (main still picture) profile. All coding tools in the profile are supported.
- I/P/B slices
  - All intra-prediction modes
  - All inter-prediction modes
- Variable CTU size: 64 x 64 to 16 x 16
  - Variable prediction unit (PU) size: 64 x 64 to 4 x 4
  - Variable transform unit (TU) size: 32 x 32 to 4 x 4
- Advanced motion vector prediction (AMVP) and merge mode
- A quarter motion compensation with 8 tap filters
- Uniform reconstruction quantization (URQ)
- Parallel coding tools
  - Multi tile
  - Wavefront parallel processing (WPP)-encoded bitstream support
  - Multi slice: Independent slice segment and dependent slice segment

- High performance CABAC decoding
- In-loop deblocking filtering
- Sample adaptive offset (SAO)
- Loop filtering across slice/tile boundaries
- Data reporting to the external host
- Robust error concealment
- Sequence change detection

### H.264/AVC Decoder

- Fully compatible with the ITU-T recommendation H.264 specification. All coding tools in the baseline/constrained baseline/main/high profile are supported.
  - With a few exceptions:
    - Interlaced coding tools are not supported.
    - FMO/ASO tool of H.264 is not supported.
- Variable block size (16 x 16, 16 x 8, 8 x 16, 8 x 8, 8 x 4, 4 x 8 and 4 x 4)
- CABAC/CAVLC support
- In-loop deblocking filter
- Error detection, concealment and error resilience tools

### 7.6.2.3 Non-Codec Related Features

#### Rotation and mirroring

The Video Accelerator supports 8 modes of rotation and mirroring. The PRP block can do rotations of the source picture in 90, 180, or 270 degrees and vertical or horizontal flip before starting to encode the operation.

#### Bit-depth and chroma format conversion

The PRP block is responsible for source format conversion in the encoder IP. 422 (planar/semi-planar) to 420 conversion can be made before encoding operation.

#### Frame buffer compression

To overcome bandwidth suffering and at the same time to ensure real-time encode/decode performance, TI has carefully designed lossless, great access patterned frame buffer compression technology and employed it into the WAVE IP series. WAVE521CL achieves significant reduction in bandwidth while sustaining fast processing capability.

#### Long Burst Write

The Video Accelerator includes burst write back (BWB) module that enables 128-byte burst write access to external memory for better bus utilization. It collects a group of short write requests from loop filter block in 128-byte unit and sends it out to the external memory more efficiently. BWB works for an external Display module or other post processing module that needs to read decoded frames in raster scan order.

The FBC/FBD block also writes or reads 128-byte burst length of compressed frame data from/to the external memory.

#### 3DNR

The Video Accelerator employs temporal noise reduction technology, also called 3DNR (3D noise reduction), for better quality of image under low light. Video noise appears easily in a low light level. It is an important issue in surveillance camera because images are captured often under dark conditions or indoors, which can make identification difficult.

The Video Accelerator can detect and filter noise for each color component Y, Cb, and Cr of a frame. This achieves both good video quality and enhancement of coding efficiency. Noise reduction is done while encoding. Therefore, additional read/write bandwidth is not required.

### Note

3DNR is supported in the H.265/HEVC encoder only.

### Latency tolerance

The Video Accelerator can afford to reach real time performance under memory access latency if the number of cycles per CTU retains less than 500 cycles. The Video Accelerator is designed to be less sensitive to pipeline delay, especially at a peak bitrate, which might eventually incur performance drop. With use of decoupling techniques and inter-pipe queues, it can hide this sort of delay and deliver high performance at any situation.

### Subframe synchronization

The Video Accelerator supports subframe synchronization for low latency coding. By receiving dedicated subframe-ready signals from the image process unit (IPU) or by setting host interface registers from host CPU, the Video Accelerator can start encoding process as early as the minimum set of raw video data is ready.

### Programmability

The Video Accelerator embeds the 32-bit CPU and 16-bit DSP dedicated to bitstream processing and their video hardware control. Host interface registers and interrupts are provided for communication between a host processor and the Video Accelerator.

### Low Power Consumption

The Video Accelerator can ensure ultra-low power operation by gating the clock sources for some internal hardware blocks in an idle state.

### Trick mode

The Video Accelerator supports trick mode such as fast/slow forward playback and fast/slow reverse playback for video applications. By seeking an intra random access point (IRAP) picture as entry points of bitstream, the Video Accelerator can skip non-IRAP pictures and start decoding from an IRAP picture or decode a thumbnail of a picture.

### Frame-based processing

V-CPU processor operates video operation on a frame by frame basis. While frame operation is running, there is no need for communication between the host processor and the Video Accelerator. This is the key feature for promising the lowest burden to host processor for video operations.

By issuing a picture processing, the host application can perform its own operations until it receives an interrupt from the Video Accelerator informing of the completion of picture processing.

### Handling multi-instances

The Video Accelerator supports multiple instances, which can be helpful for multi-channel encoder and/or decoder applications. To support this multi-instance operation, the Video Accelerator uses an internal context parameter set for each instance. While creating a new instance and starting picture processing, a set of these context parameters is created and updated automatically in the Video Accelerator. Because of this internal context management scheme, different encoder and/or decoder tasks running on the host processor can control Video Accelerator operations independently with their own instances.

When creating a new instance, an application task will get a new handle specifying an instance if a new handle is available on the Video Accelerator. All of the following operations for the given application task could be separately handled on the Video Accelerator by using this task-specific handle. Because the Video Accelerator can only perform one picture processing task at a time, each application task should check whether the Video Accelerator is ready or not before starting a new picture operation. By calling a function for closing a certain instance, the application can easily terminate a single task of video operation on the Video Accelerator.

### 7.6.3 Block Diagram

Figure 7-20 shows the hierarchical architecture of the Video Accelerator and external bus interfaces.

**Figure 7-20. Video Accelerator Block Diagram**

The Video Accelerator is built on a layer structure for efficient video processing. It is composed of two main parts, V-CPU and V-CORE. V-CPU is a 32-bit processor where the Video Accelerator L1 driver software is running. It mainly encodes and decodes a high-level syntax of bitstream - SPS/PPS/SH, and communicates with the host processor, such as receiving a picture level command from the host processor or sending the result of video task through the 32-bit AMBA3 APB bus. V-CPU can also parse necessary parameters and give necessary slice/tile-level information to the underlying V-CORE hardware.

Particularly in case of an HEVC decoder, V-CPU uses a virtual wavefront parallel processing (VWPP) scheme to balance processing load among V-CORES and to simplify its operation. During the VWPP, V-CPU parses bitstream and extracts some data from bitstream such as CABAC context, QP, and start address for each row and tile. After that, V-CPU reorders the data to meet the WPP processing sequence and dispatches them to the appropriate V-CORES.

V-CORE can encode and decode a slice unit of data. It consists of a 16-bit DSP called a bit processor unit (BPU) and a group of video codec hardware blocks called a video codec engine (VCE).

- BPU is responsible for packing and parsing of coded slice data, CTU/CU/PU/TU-level parameter derivation, and finally passing slice data over to the VCE. To speed up entropy encoding/decoding, some hardware accelerators are included in the BPU.
- On the other hand, VCE is an actual hardware core executing a series of decoding process - encoding and decoding process - motion estimation, intra-prediction, RDO, and entropy coding with their hardwired logics, motion compensation, inverse-transformation/quantization, and loop filter with their hardwired logics. HEVC and H.264/AVC decoders share most of the internal VCE memories and full logics in certain VCE blocks like intra-prediction for small gate count.

They are doing these tasks with CTU-based pipelines and FIFO queues to ensure real-time speed and performance. When it comes to system connection as shown in the [Figure 7-20](#), there is one 32-bit AMBA3 APB interface connecting to the host processor, and there are two 128-bit AMBA3 AXI bus interfaces connecting to the external memory controller for reading and writing picture data and temporal data.

- Primary AXI: AXI interface to read or write work data and coded picture (bitstream), decoded picture data and so forth.
- Secondary AXI (optional): On-chip-SRAM connected AXI interface to read or write temporal buffer required for V-CORE operation. This is an optional interface that can be used to alleviate bandwidth usage.

## 7.7 Vision Pre-processing Accelerator (VPAC)

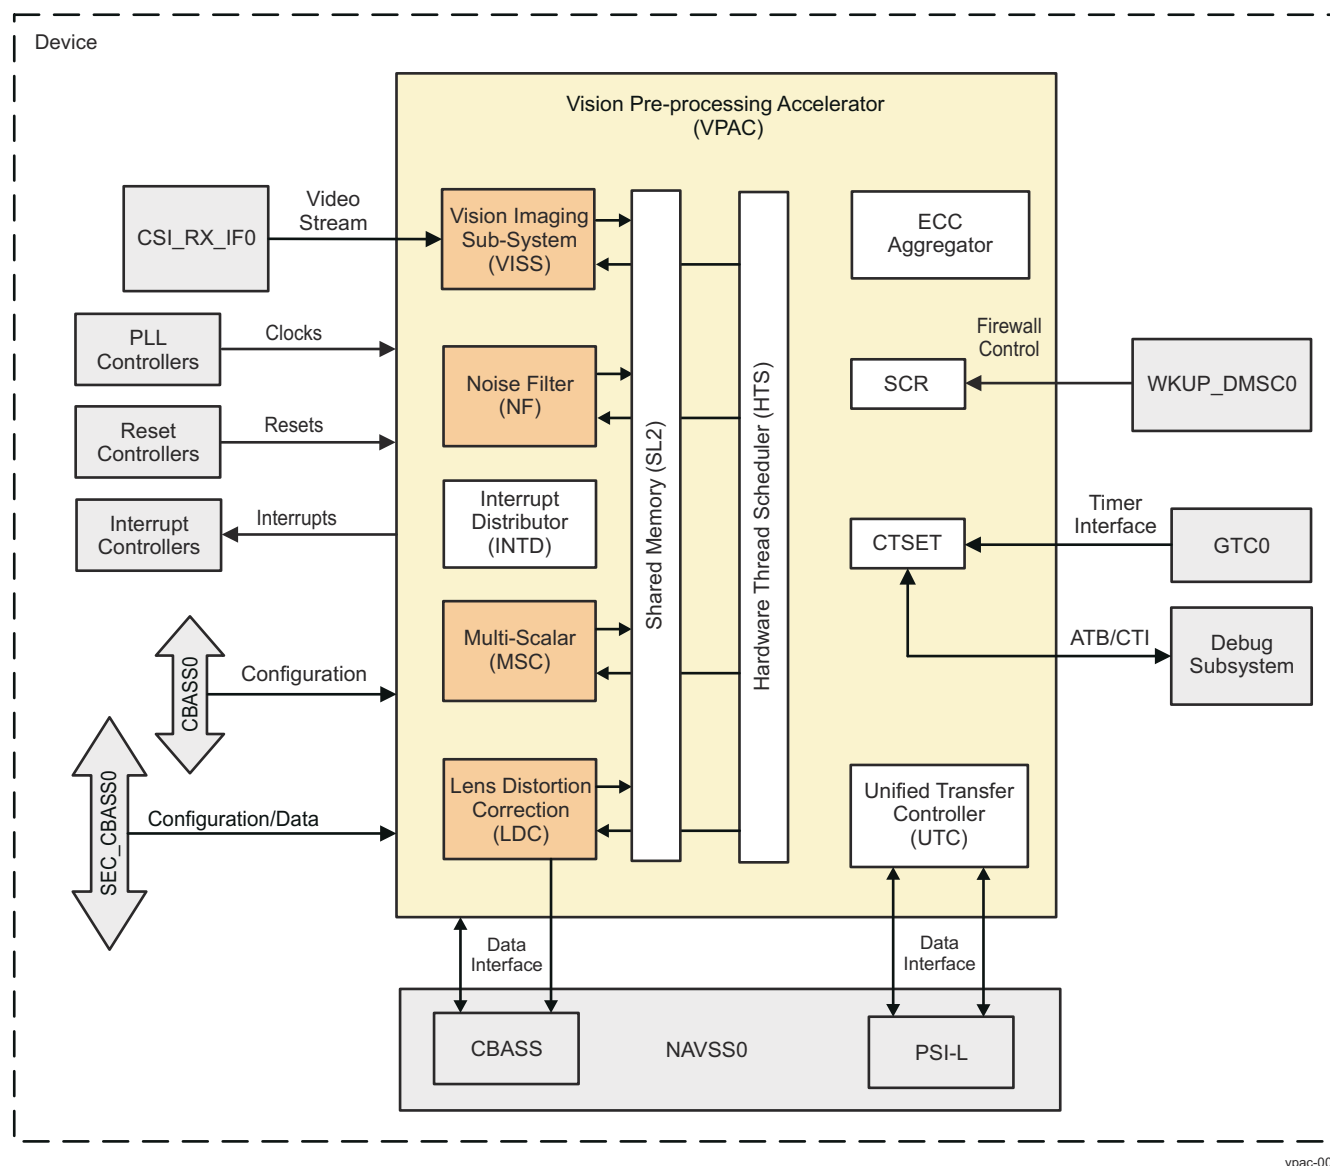

This chapter describes the Vision Pre-processing Accelerator (VPAC) in the device.

### 7.7.1 VPAC Overview

The Vision Pre-processing Accelerator (VPAC) subsystem is a set of common vision primitive functions, performing pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation. The VPAC offloads these common tasks from the main SoC processors (ARM, DSP, etc.), so these CPUs can be utilized for differentiated high-level algorithms. The VPAC is designed to support multiple cameras by working in time-multiplexing mode. The VPAC also includes an imaging pipe, which can be integrated on-the-fly with external camera sensor, as well as does memory-to-memory (M2M) processing on pixel data.

The VPAC subsystem provides 4 processing blocks: Vision Imaging Sub-System (VISS), Lens Distortion Correction (LDC), Multi-Scalar (MSC) and Noise Filter (NF), along with Hardware Thread Scheduler (HTS), Load Store Engine (LSE), and 512 KB of internal L2 memory

[Figure 7-21](#) provides an overview of the VPAC subsystem.

**Figure 7-21. VPAC Overview**

### 7.7.1.1 VPAC Features

The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS). The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/Local Brightness and Contrast Enhancement (GLBCE), Spatial Noise Filtering, demosaicing, color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:
  - Performance is up to 1 pixel/cycle
  - Up to 16-bit input RAW formats (8b, 12b, 14b, 16b) (see [Section 7.7.2.6](#))
    - Support for generic 2x2 RAW format (Bayer, RCCB, RCCC, etc.)
    - Support for 4x4 RGB-IR RAW format
  - Processing up to 4096 pixels/line (8MP frame)
  - Support for concurrent 12-bit and 8-bit YUV output
  - Support for other color spaces:

- RGB output
- Support for color saturation and gray scale for HSV/HSL, etc.
- Support for multiple WDR/HDR formats (for 2x2 RAW formats):
  - Combined Companded format (up to 16-bit companded)
  - Separated Exposures – up to 3 frame Motion Adaptive HDR Merge
  - Staggered HDR
  - Digital Lateral Overlap (DLO)
- Support of statistics for Auto-Exposure/Auto-White-Balance or Auto-Focus (configurable option to select either AE/AWB or AF)
- Support for Flexible CFA for generating multi-plane output for any 2x2 RAW format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
  - Can generate up to 4 independent color planes
  - Support for up to 3 directions per color plane
  - Adaptive threshold based on intensity measure
- Supports pattern conversion (remosaicing RGB-IR(4x4) CFA format raw data into 2x2 Bayer pattern) and IR demosaicing
- Support for multiple color format output generation
  - Supports traditional 12-bit YUV output
  - Support for 8-bit YUV output (see [Section 7.7.2.6](#))
  - Supports RGB output (8-bit only)
  - Supports saturation outputs (8 bits only)
  - Supports Grayscale/Luma/IR/Clear output
- Global/Local Brightness and Contrast Enhancement module (16-bit)
- Spatial Noise Filter (NSF4V)
  - Supports raw input image in generic 2x2 color pattern format including Bayer pattern
  - Supports 16-bit raw input image
  - Spatially adaptive noise level threshold
  - Configurable soft or hard thresholding
  - Supports elliptical lens shading gain adjustment of adaptive noise threshold with 2 sets of independent settings
  - White Balance gain
  - Signal level detection with flexible cross-color-channel or independent averaging
- Option to bypass visual enhancement functions (NSF4V and GLBCE)
- Edge Enhancement (EE)
  - Enhance the visual quality of the image (Luma only)
  - Edge enhancer filter and the edge sharpener filter can be combined by configuration
  - Option to bypass visual enhancement functions (CAC, NSF4V, and GLBCE)
- Lens Distortion Correction (LDC) block. The LDC engine is YUV domain processor designed to perform perspective and geometric transforms. This can be used for creating several effects, including but not limited to:
  - Lens Distortion Correction, including Fish Eye Lenses
  - Epipolar rectification for Stereo
  - Generic perspective transforms for rotation scaling or Augmented Reality like effects

The output of the LDC block can be sent to external memory (DDR) or sent to other VPAC sub-module (Scalar, Noise filter) for further pre-processing via local shared memory (SL2). The LDC block provides the following main features:

- Performance up to 1 cycle/pixel (bilinear) and 2 cycles/pixel (bicubic)
- Autonomous memory-to-memory operation
- Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Supported formats (see [Section 7.7.2.6](#)):

- YUV420 12-bit packet input and YUV420 12-bit packed output
- YUV420 12-bit unpacked input and YUV420 12-bit unpacked output
- YUV420 8-bit packet input and YUV420 8-bit packed output
- YUV422 8-bit packed input and YUV420 8-bit packed output
- YUV422 8-bit packed input and YUV422 8-bit packed output
- Supports up to 8192 x 8192 image dimension
- Pixel Interpolation
  - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode to offer double throughput
- Support of Luma Only or Chroma Only Mode
- Supports variable block size frame processing (9 regions)
- Multi-Scalar (MSC) block. The MSC block reads data from memory (DDR or on-chip) to shared memory (SL2) and generates up to 10 scaled outputs from a given input with various scaling ratios (between 1x and x0.25). The output of the MSC block can be sent to external memory (DDR) from the local shared memory (SL2), or can be further noise filtered using the VPAC Noise Filter (NF) block. The MSC supports two independent threads (scalars), which combined can generate up to max 10 scales. The MSC block provides the following main features:
  - Multi-scaling capable: 10 simultaneous scaled outputs from 1 or 2 input planes; up to 2 simultaneous processing thread with total of 10 scaled output with 1 to N and 1 to M configurations (where N+M <=10)
  - Each scaling engine can be configured to perform Pyramid or inter-octave scale generation
  - Scaling ratio supported: 1x ~ x/4 (with 1x scaling, MSC can perform a 3~5-tap generic separable convolution filtering)
  - 5-tap separable filter kernel implementation
  - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
  - Poly phase implementation with support of 64 or 32 phases poly phase support
  - 4 sets of 5-tap x 32 phase coefficients (two can be combined to support 5-tap x 64 phase coefficients and one of set can hold additional 5-tap customer filter coefficients for non-resizing filter)
  - 2 additional sets of 5-tap Gaussian filter coefficients (single-phase) dedicated for Pyramid (Octave) generation
  - Coefficients in 10-bit (S10Q8 format - signed value of 10 bits with 8-bit fraction)
  - Separate initial horizontal and vertical phase programming option
  - Support for two planes of data processing
    - Data in a plane can be uniform (for example, Y plane) or interleaved (Cb/Cr interleaved)
  - 8-bit or 12-bit component data
  - Performance up to 1 input pixel/cycle
  - Output data rate is dependent on downscaling ratio
  - Programmable input and output ROI (or clipping) for each scaler
  - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (frame resolution support is not constrained by MSC line buffer)
- Noise Filter (NF). The NF block reads data from memory (DDR or on-chip) to shared memory (SL2) and does Bilateral filtering to remove noise. The output of the NF block can be sent to external memory (DDR) from shared memory (SL2) or can be further re-sized using the MSC block. The NF block provides the following main features:
  - Support for bilateral and general filtering
  - Supports filter size up to 5x5
  - Supports true 2D bilateral filtering
  - Supports filter size up to 5x5 of programmable static weights
  - LUT based bilateral weights generation (8-bit for weight)
  - Supported formats: one plane (interleaved plane and non-interleaved) YUV 420, 12-bit or 8-bit
  - Performance up to 1 pixel/cycle
- Hardware Thread Scheduler (HTS). The HTS block used for inter-processor communication among various VPAC sub-modules (VISS, LDC, Scalar, and NF) and with the local DMA Engine (UTC). The HTS block provides the following main features:
  - Scheduling the HWA threads and associated tasks

- Enables rate-controlled task execution
- Support running several independent threads asynchronously in the sub-system
- Debug functions:
  - Halting HWA threads at logical task boundary
  - Handling pipeline suspend and subsequent abort by software intervention
- Shared Level 2 (SL2) memory. The SL2 is used as intermediate storage for Hardware Accelerator (HWA) to exchange data across VPAC sub-modules (that is, VISS, LDC, MSC, and NF) and from DDR/System Memory. VPAC supports Realtime and Non-Realtime processing threads simultaneously.

### 7.7.2 VPAC Subsystem Level

This section covers VPAC subsystem-level details.

#### 7.7.2.1 VPAC Subsystem Clocks

Each block within the VPAC subsystem receives its own clocking signal:

- MAIN\_CLK is the operation clock for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, INTD, etc.
- VISS0\_CLK is the operation clock for the VISS and its sub-modules
- LDC0\_CLK is the operation clock for the LDC module
- MSC\_CLK is the operation clock for the MSC module
- NF\_CLK is the operation clock for the NF module

For more details on the source of each clock at SoC level, see *VPAC Integration*.

#### 7.7.2.2 VPAC Subsystem Resets

Each block within the VPAC subsystem can be reset through its own HW reset signal:

- MAIN\_RST is the reset for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, etc.
- VISS0\_RST is the reset for the VISS and its sub-modules
- LDC0\_RST is the reset for the LDC module
- MSC\_RST is the reset for the MSC module
- NF\_RST is the reset for the NF module

For more details on the source of each reset signal at SoC level, see *VPAC Integration*.

#### 7.7.2.3 VPAC Subsystem Interrupts

The VPAC subsystem outputs six physical system interrupt lines: VPAC\_LEVEL\_0\_INTR through VPAC\_LEVEL\_5\_INTR. For more information on how the interrupt lines are connected at SoC level, see *VPAC Integration*. The interrupt aggregation within the VPAC subsystem is done using the internal INTD module. Each interrupt line can be mapped to the same list of source interrupt events generated by the modules within the VPAC subsystem.

[Table 7-77](#) shows the INTD interrupt control registers for each VPAC interrupt line. Each interrupt line has a separate set of registers for level and pulse input event types. Each bit in a register corresponds to a particular interrupt event. For more details on the mapping of interrupt events to INTD register bits, see [Table-XXX](#) further below.

- The ENABLE registers enable the mapping of the internal VPAC interrupt events, generated by a module within the VPAC subsystem, to the VPAC output system interrupt lines. Writing a '1' in a register bit position allows the corresponding module interrupt event to trigger the respective system interrupt. Writing a '0' in the same bit position blocks the module interrupt event from triggering the system interrupt.
- The ENABLE\_CLR registers disables the mapping of the internal VPAC interrupt events to the VPAC output system interrupt lines.
- The STATUS registers are used to capture which VPAC sub-module interrupt events, that have been mapped to a system interrupt, are active and pending. This status is used when multiple module interrupts are grouped into a single system interrupt, so the software can read the status register to determine exactly which module interrupt has caused the system interrupt.
  - For level interrupts, the status is based on the active level of the module interrupt input, and when the input is inactive then the status is inactive as well.
  - For pulsed interrupts, the status is set upon the pulse and reflects a pending status and software must clear the pending status since the module does not indicate the inactive status (unlike a level interrupt, which does).
- The STATUS\_CLR registers allows software to clear the pending status of interrupt events. This register is only valid and functional for pulsed interrupts and has no effect for level interrupts.

**Table 7-77. VPAC Subsystem Interrupt Control Registers**

Output System Interrupt Line	Input Interrupt Event Type	Interrupt Enable Registers	Interrupt Clear Registers	Interrupt Status Registers	Interrupt Status Clear Registers
VPAC_LEV_EL_0_INTR	Level	VPAC_INTD_CFG_ENAB LE_REG_LEVEL_VPAC_ OUT_0_0 through VPAC_INTD_CFG_ENAB LE_REG_LEVEL_VPAC_ OUT_0_7	VPAC_INTD_CFG_ENAB LE_CLR_REG_LEVEL_V PAC_OUT_0_0 through VPAC_INTD_CFG_ENAB LE_CLR_REG_LEVEL_V PAC_OUT_0_7	VPAC_INTD_CFG_STATU S_REG_LEVEL_VPAC_O UT_0_0 through VPAC_INTD_CFG_STATU S_REG_LEVEL_VPAC_O UT_0_7	VPAC_INTD_CFG_STATU S_CLR_REG_LEVEL_VP AC_OUT_0_0 through VPAC_INTD_CFG_STATU S_CLR_REG_LEVEL_VP AC_OUT_0_7

The VISS interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_0 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_0 registers. [Table 7-78](#) provides more details on the VISS interrupt events. All VISS interrupts are single pulse event signals.

**Table 7-78. VPAC Subsystem VISS Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	RAWFE_CFG_ERR_INTR	Config read or write memory access occurred during functional operation and likely corrupted functional operation. VISS merges all config error sources from RawFE and refer to RawFE spec for the entire error source list.
1	RAWFE_AEW_PULSE_INTR	H3A AEW interrupt.
2	RAWFE_AF_PULSE_INTR	H3A AF interrupt.
3	RAWFE_H3A_PULSE_INTR	H3A interrupt.
4	RAWFE_H3A_BUF_OVRFLOW_PULSE_INTR	H3A output buffer overflow.
5	NSF4V_LINEMEM_CFG_ERR_INTR	VBUSP diagnostic read access of RAM, while NSF data using RAM for functional purpose.
6	NSF4V_HBLANK_ERR_INTR	Horizontal Blanking too short between lines.
7	NSF4V_VBLANK_ERR_INTR	Vertical Blanking too short between frames.
8	GLBCE_CFG_ERR_INTR	Either non-shadowed registers written or static memories are accessed during active window.
9	GLBCE_FILT_START_INTR	GLBCE started filtering. This interrupt is issued at the rising edge of filtering signal.
10	GLBCE_FILT_DONE_INTR	GLBCE ended filtering. This interrupt is issued at the falling edge of filtering signal.
11	GLBCE_HSYNC_ERR_INTR	Generated when delayed HS/HE signals doesn't match with derived signals from GLBCE core.
12	GLBCE_VSYNC_ERR_INTR	Generated when delayed VS/VE signals doesn't match with derived signals from GLBCE core.
13	GLBCE_VP_ERR_INTR	This interrupt is issued, if there is a data input while filtering is high.

**Table 7-78. VPAC Subsystem VISS Interrupt Events (continued)**

Register Bit	Interrupt Event Name	Description
14	FCFA_CFG_ERR_INTR	Either non-shadowed registers written or line memories are accessed during active window.
15	FCC_CFG_ERR_INTR	Configuration access to registers/memories has corrupted functional operation. Configuration read or write memory access occurred during functional operation. Merged independent error sources at VISS. Refer to Section <i>VISS Flexible Color Processing (FCP)</i> for all sources.
16	FCC_OUTIF_OVF_ERR_INTR	FIFO overflow on FIFO for Y12 LSE I/F. Merged all FCC output overflow error sources at VISS. Refer to Section <i>VISS Flexible Color Processing (FCP)</i> for all sources.
17	FCC_HIST_READ_ERR_INTR	Host was not able to read the entire histogram mem between VS-VE window (triggered when the first access to histogram has been performed but the last has not been performed).
18	EE_CFG_ERR	Configuration happened to EE regions causing corruption during frame processing.
19	EE_SYNCOVF_ERR	EE horizontal synchronization FIFO overflow interrupt.
20	LSE_FR_DONE_EVT_INTR	LSE frame done interrupt.
21	LSE_SL2_RD_ERR_INTR	Set whenever there is an error response on VBUSM read command for any input channel.
22	LSE_SL2_WR_ERR_INTR	Set whenever there is an error response on VBUSM write command for any output channel.
23	LSE_CAL_VP_ERR_INTR	Set whenever one of the following input frame errors is detected at VPORT_INPUT.
24	LSE_OUT_FR_START_EVT_INTR	Output Frame Start (from VISS top level).

The LDC interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_1 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_1 registers. [Table 7-79](#) provides more details on the LDC interrupt events. All LDC interrupts are single pulse event signals.

**Table 7-79. VPAC Subsystem LDC Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	LDC_PIX_IBLK_OUTOFBOUND_INTR	Back mapped pixel co-ordinate goes out of the pre-computed input pixel bounding box.
1	LDC_MESH_IBLK_OUTOFBOUND_INTR	Block mesh co-ordinate goes out of the pre-computed mesh bounding box.
2	LDC_PIX_IBLK_MEMOVF_INTR	Input Pixel block memory overflow.
3	LDC_MESH_IBLK_MEMOVF_INTR	Mesh block memory overflow.
4	LDC_IFR_OUTOFBOUND_INTR	Back mapped input co-ordinate goes out of input frame range.
5	LDC_INT_SZOVF_INTR	Affine and perspective transform precision overflow error.
6	LDC_FR_DONE_EVT_INTR	Frame done LDC.
7	LDC_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.
8	LDC_VBUSM_RD_ERR_INTR	Error on Input VBUSM Read interface.

The MSC interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_2 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_2 registers. [Table 7-80](#) provides more details on the MSC interrupt events. All MSC interrupts are single pulse event signals.

**Table 7-80. VPAC Subsystem MSC Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	MSC_LSE_FR_DONE_EVT_0_INTR	Frame done MSC processing thread 0.
1	MSC_LSE_FR_DONE_EVT_1_INTR	Frame done MSC processing thread 1.
2	MSC_LSE_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.
3	MSC_LSE_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.

The NF interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_2 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_2 registers. [Table 7-81](#) provides more details on the NF interrupt events. All NF interrupts are single pulse event signals.

**Table 7-81. VPAC Subsystem NF Interrupt Events**

Register Bit	Interrupt Event Name	Description
8	NF_FR_DONE_INTR	Frame done NF.
9	NF_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.
10	NF_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.

The HTS interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_3 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_3 registers. [Table 7-82](#) provides more details on the HTS interrupt events. All HTS interrupts are single pulse event signals, save for the SPARE\_PEND\_xxx interrupts, which can be both single pulse events and level events.

**Table 7-82. VPAC Subsystem HTS Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	PIPE_DONE_0	Pipeline 0 done.
1	PIPE_DONE_1	Pipeline 1 done.
2	PIPE_DONE_2	Pipeline 2 done.
3	PIPE_DONE_3	Pipeline 3 done.
4	PIPE_DONE_4	Pipeline 4 done.
5	PIPE_DONE_5	Pipeline 5 done.
6	PIPE_DONE_6	Pipeline 6 done.
7	TDONE	HWA0 thread done.
8	RESERVED	Reserved.
9	TDONE	HWA2 thread done.
10	RESERVED	Reserved.
11	TDONE	HWA4 thread done.
12	TDONE	HWA5 thread done.
13	TDONE	HWA6 thread done.
14	SPARE_DEC_0	Spare 0 scheduler decrement pulse (ehost mode).
15	SPARE_DEC_1	Spare 1 scheduler decrement pulse (ehost mode).
16	SPARE_PEND_0_PULSE	Spare 0 scheduler pend assertion (ehost mode).
17	SPARE_PEND_0_LEVEL	Spare 0 scheduler pend assertion (ehost mode).
18	SPARE_PEND_1_PULSE	Spare 1 scheduler pend assertion (ehost mode).
19	SPARE_PEND_1_LEVEL	Spare 1 scheduler pend assertion (ehost mode).
20	WATCHDOGTIMER_ERR_0	Watchdog Timeout Error for HWA0.
21	RESERVED	Reserved.
22	WATCHDOGTIMER_ERR_2	Watchdog Timeout Error for HWA2.
23	RESERVED	Reserved.
24	WATCHDOGTIMER_ERR_4	Watchdog Timeout Error for HWA4.
25	WATCHDOGTIMER_ERR_5	Watchdog Timeout Error for HWA5.
26	WATCHDOGTIMER_ERR_6	Watchdog Timeout Error for HWA6.

The UTC interrupt events indicating TR complete are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_4 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_4 registers for UTC0, and VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_5 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_5 plus VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_6 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_6 registers for UTC1. [Table 7-83](#)

provides more details on the UTC TR complete interrupt events. All UTC TR complete interrupts are single pulse event signals.

**Table 7-83. VPAC Subsystem UTC TR Complete Interrupt Events**

Register Bit	Interrupt Event Name	Description
31-0	UTC0_COMPLETE_INTR[31:0]	TR complete interrupt.
31-0 plus 31-0	UTC1_COMPLETE_INTR[63:0]	TR complete interrupt.

The UTC interrupt events indicating error are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_7 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_7 registers for both UTC0 and UTC1. [Table 7-84](#) provides more details on the UTC error interrupt events. All UTC error interrupts are single pulse event signals.

**Table 7-84. VPAC Subsystem UTC Error Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	UTC0_ERR	UTC0 error.
1	UTC1_ERR	UTC1 error.
2	UTC0_PROT_ERR_INTR	UTC0 protocol violation.
3	UTC1_PROT_ERR_INTR	UTC1 protocol violation.

The CTSET interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_7 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_7 registers. [Table 7-85](#) provides more details on the CTSET events. All CTSET error interrupts are single pulse event signals.

**Table 7-85. VPAC Subsystem CTSET Interrupt Events**

Register Bit	Interrupt Event Name	Description
4	CTM_PULSE_INTR	Counter Timer Module (CTM) pulse interrupt.

#### 7.7.2.4 VPAC Subsystem SL2 Memory Infrastructure

The SL2 memory subsystem implements an interconnect between DMA and HWAs initiators. It contains 512KB Shared L2 memory to acts temporary local memory to transfer data between external memory and HWAs.

The SL2 memory does not implement ECC, as it contains mostly pixel data.

#### 7.7.2.5 VPAC Subsystem DMA Infrastructure

Two UTC instances are used inside the VPAC subsystem. UTC0 deals with real time (RT) transfer , and UTC1 is used for non-realtime (NRT) transfer. Both UTC0 and UTC1 data transfer channels are used for DMA transfers in and out of the VPAC SL2 memory. All 32 channels of the UTC0 are mapped on *channel\_number* = [95:64] and are recommended to be used for real time data transfer only. All 64 channels of UTC1 are mapped on *channel\_number* = [63:0] and are recommended to be used for all other DMA transfer needs of the VPAC subsystem.

All data movement transactions at VPAC subsystem boundary are multiples of aligned 128-byte transfers.

#### 7.7.2.6 VPAC Subsystem Data Formats Support

[Table 7-86](#) summarizes the data formats supported in VPAC Subsystem.

**Table 7-86. VPAC Subsystem Data Formats Support**

No	Module	Input			Output		
		Bit-depth	Chroma (NV12)	Packing	Bit-depth	Chroma (NV12)	Packing

**Table 7-86. VPAC Subsystem Data Formats Support (continued)**

No	Module	Input			Output		
1	VISS	12	RAW	no	12 & 8	420	yes
2		14	RAW	no	12 & 8	420	yes
3		16	RAW	no	12 & 8	420	yes
4		8	RAW	yes	8	420	yes
5		12	RAW	yes	12 & 8	420	yes
5		All of the above			8	422	yes
6	LDC	8	422	yes	8	420	yes
7		8	422	yes	8	422	yes
8		8	420	yes	8	420	yes
9		12	420	yes/no	12	420	yes
10		12	420	yes/no	12 & 8	420	no
11	MSC	12	Planar	yes	12	planar	yes
12		8	Planar	yes	8	planar	yes
13	NF	12	Y/UV (NV12)	yes	12	UV (NV12)	yes

### 7.7.2.7 VPAC Subsystem Debug Features

The VPAC subsystem is a combination of multiple asynchronous pipelines running concurrently. The Counter, Timer and System Event Trace (CTSET) module within the VPAC subsystem provides the following main features:

- Monitoring up to 255 VPAC events.
- ATB interface compliant trace packets (synchronous to VPAC clock domain).
- Counter (count=8) and Timer (count=4).
- All debug events can be configured to be either selected for trace packet, timer or counter features.
- In one of the combination, debug events can be selected to for timer event out to be used to generate external CTI compliant trigger.

For more information on the CTSET module operation, see Chapter *On-Chip Debug*.

[Table 7-87](#) lists the VPAC subsystem events that are mapped on the CTSET module.

**Table 7-87. VPAC Subsystem CTSET Event List**

Index	Event Name	HWA	Event Type	Event Description
0	viss_err	VISS0	pulse	VISS Related Error message (config, ovf, sync, blank, access, vp) <sup>(1)</sup>
1	rawfe_h3a_pulse_intr	VISS0	pulse	H3A interrupt
2	rawfe_dbg_ctl_vs_event	VISS0	pulse	Verticle start in the beginning of the RAWFE pipeline
3	rawfe_dbg_ctl_ve_event	VISS0	pulse	Verticle end in the beginning of the RAWFE pipeline
4	rawfe_dbg_ctl_hs_event	VISS0	pulse	Horizontal start in the beginning of the RAWFE pipeline
5	rawfe_dbg_ctl_he_event	VISS0	pulse	Horizaontal end in the beginning of the RAWFE pipeline
6	rawfe_dbg_ctl_lse_slv_stall_event	VISS0	pulse	RAWFE is stalling lse target interface due to FCP or MTC stall
7	rawfe_dbg_ctl_lse_mst_stall_event	VISS0	pulse	H3A controller interface to LSE is stalled
8	rawfe_dbg_ctl_lse_intf_stall_event	VISS0	pulse	Within a frame (VS to VE at RFE i/p) LSE is not sending data to RFE
9	rawfe_dbg_ctl_x_y_match_event	VISS0	pulse	X,Y pixel position has reached the start of RAWFE pipeline
10	rawfe_dbg_ctl_dpc_otf_corr_event	VISS0	pulse	DPC OTF corrected a pixel position

**Table 7-87. VPAC Subsystem CTSET Event List (continued)**

Index	Event Name	HWA	Event Type	Event Description
11	rawfe_dbg_ctl_pipe_adv_event	VISS0	pulse	Active pipeline advancement
12	nsf4v_in_hs_event	VISS0	pulse	Start of Active Line at NSF4V input
13	nsf4v_in_vs_event	VISS0	pulse	Start of Active Frame at NSF4V input
14	nsf4v_in_he_event	VISS0	pulse	End of Active Line at NSF4V output
15	nsf4v_in_ve_event	VISS0	pulse	End of Active Frame at NSF4V output
16	glbce_filt_start_intr	VISS0	pulse	GLBCE filtering start ( generated at the rising edge of filtering signal)
17	glbce_filt_done_intr	VISS0	pulse	GLBCE filtering done (generated at falling edge of filtering signal)
18	glbce_sol_event	VISS0	pulse	Start of Active Line at GLBCE input
19	glbce_sof_event	VISS0	pulse	Start of Active Frame at GLBCE input
20	glbce_eol_event	VISS0	pulse	End of Active Line at GLBCE output
21	glbce_eof_event	VISS0	pulse	End of Active Frame at GLBCE output
22	fcfa_sol_event	VISS0	pulse	Start of line processing for CFA input
23	fcfa_sof_event	VISS0	pulse	Start of frame processing for CFA input
24	fcc_stall_event	VISS0	pulse	Stall has occurred on any one of the output LSE interfaces
25	fcc_eol_if_y12_event	VISS0	pulse	End of line on Y12 LSE I/f (only generated for valid lines)
26	fcc_eof_if_y12_event	VISS0	pulse	End of frame on Y12 LSE I/f
27	fcc_eol_if_uv12_event	VISS0	pulse	End of line on UV12 LSE I/f (only generated for valid lines)
28	fcc_eof_if_uv12_event	VISS0	pulse	End of frame on UV12 LSE I/f
29	fcc_eol_if_y8r8_event	VISS0	pulse	End of line on Y8R8 LSE I/f (only generated for valid lines)
30	fcc_eof_if_y8r8_event	VISS0	pulse	End of frame on Y8R8 LSE I/f
31	fcc_eol_if_c8g8_event	VISS0	pulse	End of line on C8G8 LSE I/f (only generated for valid lines)
32	fcc_eof_if_c8g8_event	VISS0	pulse	End of frame on C8G8 LSE I/f
33	fcc_eol_if_s8b8_event	VISS0	pulse	End of line on S8B8 LSE I/f (only generated for valid lines)
34	fcc_eof_if_s8b8_event	VISS0	pulse	End of frame on S8B8 LSE I/f
35	fcc_flexcc_eop_event	VISS0	pulse	End of processing (EOP) for FlexCC
36	lse_fr_done_evt_intr	VISS0	pulse	Frame processing done event
37	lse_out_fr_start_evt_intr	VISS0	pulse	Travelled Frame Start from LSE Core
39	ldc_err	LCD0	pulse	LDC processing error <sup>(2)</sup>
40	mesh_iblk_fetch_start_event	LCD0	pulse	Input mesh block fetch start event
41	mesh_iblk_fetch_done_event	LCD0	pulse	Input mesh block fetch completion event
42	pix_iblk_fetch_start_event	LCD0	pulse	Input pixel block fetch start event (Active for both Y and C)
43	pix_iblk_fetch_done_event	LCD0	pulse	Input pixel block fetch done event (Active for both Y and C)
44	frame_start_event	LCD0	pulse	Frame processing start event
45	lse_stall_event	LCD0	pulse	LSE write stall event

- (1) The signals combined to generate the viss\_err event are: rawfe\_cfg\_err\_intr || glbce\_cfg\_err\_intr || fcfa\_cfg\_err\_intr || fcc\_cfg\_err\_intr || ee\_cfg\_err || nsfv4\_line\_cfg\_err || rawfe\_h3a\_buf\_overflow\_pulse\_intr || nsf4v\_hblank\_err\_intr || nsf4v\_vblank\_err\_intr || glbce\_vp\_err\_intr || glbce\_hsync\_err\_intr || glbce\_vsync\_err\_intr || fcc\_outif\_ovf\_err\_intr || fcc\_hist\_read\_err\_intr || ee\_syncovf\_err || lse\_sl2\_rd\_err\_intr || lse\_sl2\_wr\_err\_intr || lse\_cal\_vp\_err\_intr.
- (2) The signals combined to generate the ldc\_err event: pix\_iblk\_outofbound\_intr || mesh\_iblk\_outofbound\_intr || pix\_iblk\_memovf\_intr || mesh\_iblk\_memovf\_intr || ifr\_outofbound\_intr || int\_szovf\_intr || vpac\_ldc\_sl2\_wr\_err\_intr || vpac\_ldc\_vbusm\_rd\_err\_intr.

The VPAC subsystem also supports halting an execution pipeline using external or user halt request. Halting a pipeline is achieved by not granting thread start to HWA. Once halted, VPAC waits for an external sync trigger or config resume to restart execution. VISS, MSC and NF modules halt at line boundary, and LDC halts at block boundary.

The VPAC subsystem supports generic debug capability/features and ARM cross trigger interface for debug triggers:

- Halting the HWA threads on debug request input at logical trigger boundary.
- Continue/restart VPAC from halted state (step/continue) based on external sync trigger and HTS\_DBG\_CNTL register.
- Debug compliant dbg\_attn output after processing external halt request and when VPAC halts debug enabled pipelines.
- CTI (Cross Trigger Interface) compliant out halted trigger after processing external halt request and reaching halted state of VPAC.

- Stalling all pipelines of VPAC (with configurable option to disable impact of debug features on a pipeline).
- Indicate to Host through readable debug\_rdy bit in HTS to indicate readiness of HWA resource in case of halted (dbgattn asserted)

The VPAC subsystem debug capability supported is as captured in the HTS\_DBG\_CAP register. Ext\_halt, ext\_sync, hwa\_halted are CTI (Cross Trigger Interface) mapped async trigger interface (refer to the async protocol of trigger interface in the ARM® CoreSight™ Architecture Specification).

The VISS module, when used in OTF mode, must not be included as debuggable module within VPAC. VISS must be disabled (HTS: debug pipeline disable) to respond to halt request, otherwise behavior is undefined. The VISS module, when used in memory to memory mode, can be halted. But VISS LUTs must not be read during halted state, as it can corrupt the design pipeline.

### 7.7.2.8 VPAC Subsystem Security Features

The VPAC subsystem implements region based firewall on target endpoints within config CBASS and SL2 CBASS. Both CBASS is driven by independent DMSC FW interface from SoC level. All internal controllers on SL2 SCR are configured with ISC. [Figure 7-22](#) provides FW/ISC summary.

Module	Interconnect	Security component	Parameter	Endpoints	FW_ID( dec)	FW/ISC/QoS config address offset(hex)	privID reset value( dec)

**Figure 7-22. VPAC Subsystem FW/ISC Configuration**

### 7.7.3 VPAC Vision Imaging Subsystem (VISS)

This chapter describes the Vision Imaging Subsystem (VISS).

#### 7.7.3.1 VISS Top Level

This section describes the Vision ISS (VISS) top level details.

##### 7.7.3.1.1 VISS Features

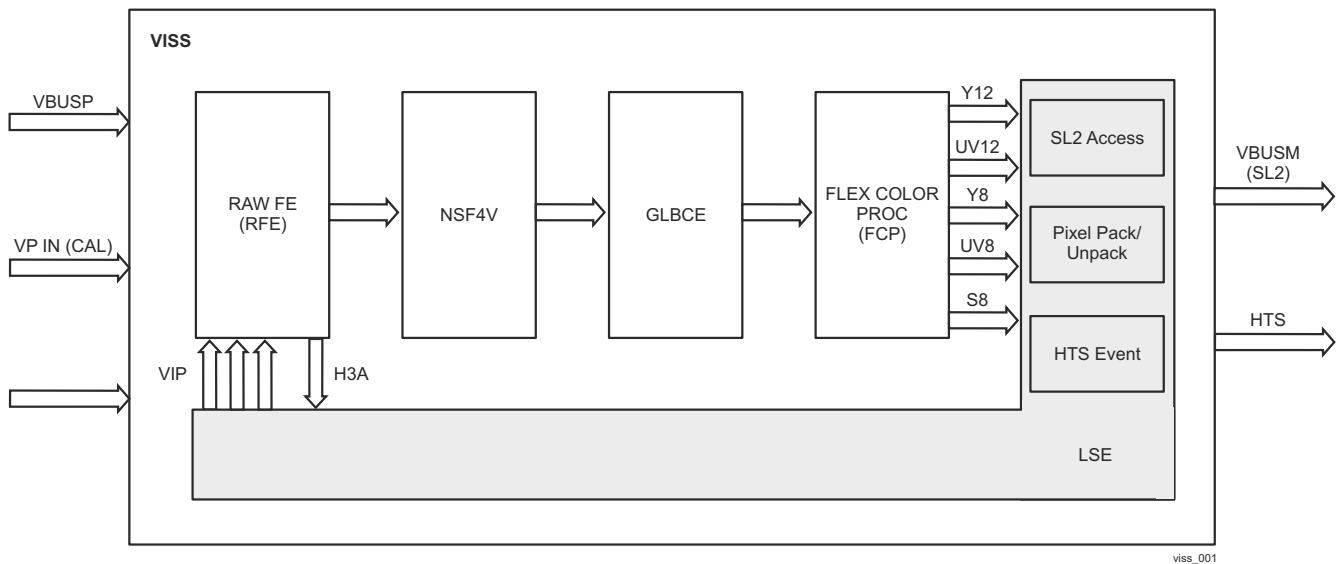

The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS). The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/Local Brightness and Contrast Enhancement (GLBCE), demosaicing, color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:
  - Performance is 1 pixel per cycle
  - Up to 16-bit input RAW formats (8b, 12b, 14b, 16b)
  - Support for concurrent 12-bit and 8-bit YUV output
  - Support for generic 2x2 RAW format (Bayer, RCCB, RCCC etc.)
  - Support for other color spaces:
    - RGB output
    - Support for color saturation and gray scale for HSV/HSL, etc. (Hue is not supported)

##### 7.7.3.1.2 VISS Block Diagram

The VISS module does on-the-fly processing on raw pixels captured from camera sensor (via CSI RX module). It also does memory to memory processing (via DDR memory) for data captured from other sources at SoC level.

Figure 7-23 is simplified block diagram of VISS top level.

**Figure 7-23. VISS Block Diagram**

The VISS consists of the following Hardware Accelerators (HWAs):

- RFE (RAW-FE): The RAW Frond End HW block does RAW pixel (that is, Bayer, RCCC, RGBW, etc.) processing on captured image data from sensor and pass-on to NSF4V, GLBCE block, and then to Flexible Color Processing (FCP) HW block for demosaicing and color conversion.
- NSF4V: Spatial Noise Filter supporting generic 2x2 pixel format with 16-bit pixel size. The NSF4V module can be bypassed in the applications where visual enhancement is not desired.

- **GLBCE:** The GLBCE module is used for dynamic range control within image for visual quality. If contrast enhancement on input image is required for visual quality, the RFE output is processed by the NSF4v and GLBCE blocks. Otherwise, the RFE output is bypassed to FCP.
- **FCP:** The Flexible Color Processing HW receives data from the GLBCE and does demosaicing and color conversion. The output of FCP is sent to VPAC shared memory to be written into DDR for the rest of the vision processing by programmable processors (for example, DSP or Arm), or other Vision HW blocks (for example, DMPAC).
- **LSE:** The Load and Store Engine is an infrastructure block, which performs the following functions:
  - **CAL video port:** The CSI RX module at SoC level receives CSI-2 sensor data, extracts pixels and drives the result data on its video port interface. The video port is mapped onto one of LSE input interfaces for on-the-fly image processing to reduce DDR bandwidth and latency. The LSE also provides horizontal and vertical blanking cycles to allow core data path to settle at proper boundary of line and frame.
  - **SL2 memory access:** This module supports load/store data from/to SL2 using VBUSM interface. Loaded data from SL2 are passed on to unpacker function of LSE for RFE. Packed data after FCP/H3A processing is written into SL2.
  - **Pixel pack/unpack:** Source data (512-bit) for RFE processing is loaded from SL2 and passed onto unpacker function for pixel extraction. Extracted pixels are driven on to the video port of RFE. Similarly, the FCP produced pixels are passed through packer function for eventual write into SL2. The H3A generated data is pseudo mapped as pixels of 32-bit for packing purpose and directly driven by the RFE.
  - **Event control:** The HTS events are generated at line level. These events are routed to LSE to start the processing. For each consumed line, the HTS needs a *task done* indication. For some initial lines of image, there would not be any valid data output. Similarly, the H3A generated data will be at paxel/window height number of lines. For initial lines not producing any valid data, the HTS needs to be indicated with separate mask bits for each output streams. For these initial lines, when there is no valid output due to lines delay inside VISS, the LSE still generates mask output to HTS indicating lack of proper output data.

#### 7.7.3.1.3 VISS Data Flow within VPAC

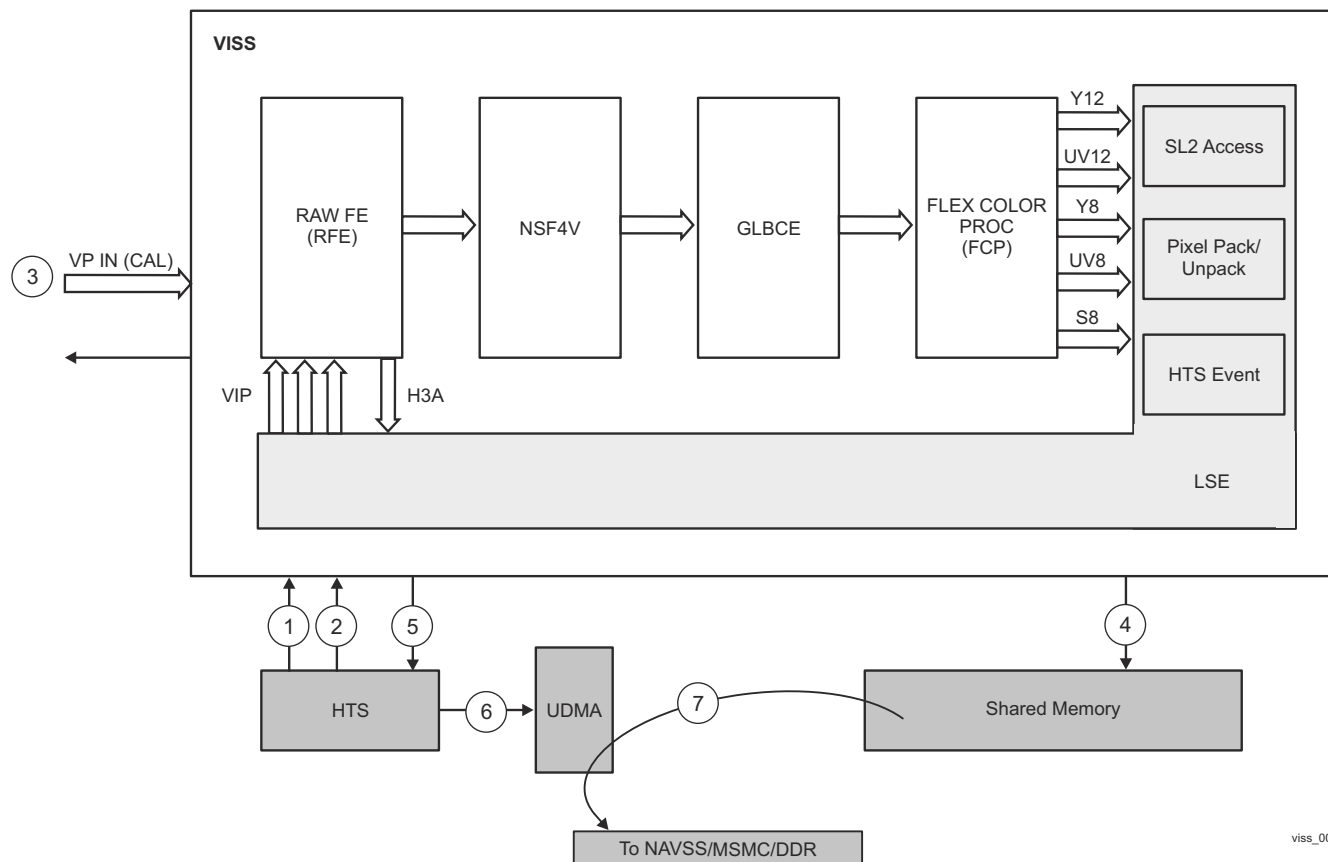

VISS receives data from sensor through:

- CSI RX video port for OTF processing (Sensor -> CSI RX -> LSE -> RFE -> FCP)
- DMA of VPAC (Sensor -> CAL -> DDR -> VPAC\_SL2 -> LSE -> RFE -> FCP)

##### 7.7.3.1.3.1 VISS On-the-fly Processing

The VISS operation is controlled through a single HTS thread. For details of the HTS operation refer to Section *VPAC Hardware Thread Scheduler (HTS)*. The VISS configuration is valid for a single or multiple frame. External-host manages VISS configuration at end of each frame, if required. The HTS controls image processing between lines and handles managing shared memory for VISS inputs/outputs. Sub-frame processing is not natively supported. SW must configure VISS and HTS to start initialization process before enabling sensor capture. After the initialization sequence, the HTS will generate a start trigger to VISS. The generation of the start trigger depends on the availability of H3A data out buffer and FCP data out buffer inside the SL2 memory.

At this stage, the LSE waits for CSI RX video port (VP) to start sending valid pixels. As and when VP data starts streaming in, it is routed to the RFE video port. As RFE and FCP are running in streaming mode, the FCP indicates to LSE about completion of one line of operation. After receiving valid data out, the HTS will trigger UDMA for data store into DDR. Each 'thread done' accompanies output mask for all output buffers. Mask bits indicate to HTS about validity of output buffer as for each thread done all output buffers do not need to be produced. The HTS will issue next start after checking all output buffers availability. The streaming data from CSI RX is storable upto 2KB storage inside VP memory of CSI RX. Any temporary stall can be absorbed, but prolonged stall is buffer overflow inside CSI RX. In VPAC, VISS produced data is transferred using Real Time fabric of NAVSS/MSMC and low predictable latency needs to be guaranteed.

**Figure 7-24. VISS On-the-fly Operation**

The following OTF operation steps are illustrated in [Figure 7-24](#):

1. *Init* from HTS to initialize VISS.
2. Thread start. Step 1+2 prior to enabling CSI RX + PHY + sensor.
3. Video port data streaming. Unit of operation inside VISS at line level.
4. Output data produced by FCP and H3A at line level. H3A will produce data only at those lines which aligns with paxel\_height/window\_height.
5. Production of 1 line depends on consumption of 1 line on VP interface. 'Thread done' triggered after completion of 1 processed line write into SL2. In case there is no valid data to be written into SL2, 'thread done' is generated after consumption of 1 line of data from VP. Note: *Horizontal blanking will be configured inside LSE to facilitate writing complete line out of FCP.*
6. HTS triggers DMA to store output buffer from SL2 to DDR.
7. DMA loads data from SL2 and writes into DDR.

The following assumptions are made for the OTF operation described above:

- UDMA write is mapped onto Real Time Thread for guaranteed QoS. Channel done by UDMA must be generated after completion of write into DDR. Next thread start depend on availability of minimum one buffer for each output line in SL2. More buffers in SL2 can take care of instantaneous drop in UDMA transfer capacity.
- Cycle gap between HTS done and next start must be minimal. CSI RX VP interface will be stalled whenever LSE input buffer on VP interface reaches near full condition.
- Configurable vertical latency times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, even though last line of current frame is already fed into RFE.
- Buffer dependencies:
  - H3A output buffer (AE or AF)

- FCP output buffer (Y12, YV12, Y8, UV8, S8)

#### 7.7.3.1.3.1.1 Non-WDR or Companded WDR Sensors

VISS is enabled for single input data when either sensor does not support WDR or sensor does on-chip WDR merge and pass on merged data after companding to 12 bit / 14 bits as shown in Figure 7-25.

Figure 7-25. VISS Non-WDR/Companded: High Level

#### 7.7.3.1.3.2 VISS Memory to Memory Image Processing

CSI RX writes CSI-2 received pixel data into DDR. Once a frame is written, host is triggered to initiate VISS processing. HTS will go through 'init' sequence to initialize VISS and its SL2 pointers. As UDMA is head of pipeline for memory to memory mode of image processing, its scheduler inside HTS needs to be configured for generating "frame height" number of triggers to fetch image lines one by one. This is essential to bring determinism in pipeline as there is no producer for UDMA load thread.

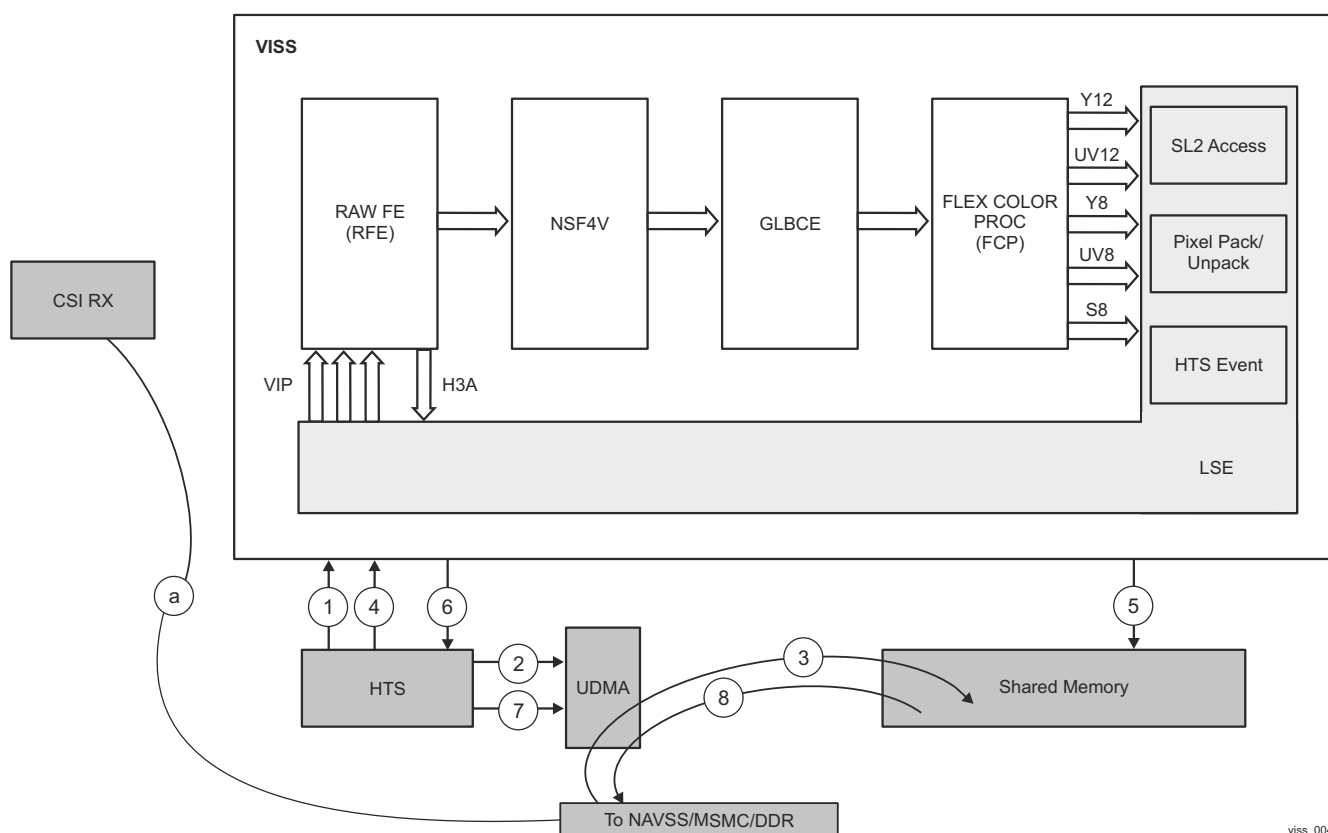

Figure 7-26. VISS Memory to Memory Operation

The following memory to memory operation steps are illustrated in Figure 7-26:

1. CSI-2 stream captured via CSI RX into DDR. This traffic must be routed through Real Time fabric of NAVSS/MSMC. CSI RX capture happens independent of VISS processing.

1. *Init* from HTS to initialize VISS.
2. HTS triggers UDMA to fetch data for processing. There could be max 3 independent input data.
3. UDMA loads the data and stores into SL2.
4. Upon completion of all input buffer loading (at line level) UDMA channel 'done' event triggers VISS thread start (still needs to ensure there are buffer available for writing VISS output data).
5. VISS produces line #N corresponding to loading of line #N + vertical\_latency.
6. 'Tdone' triggered to HTS.
7. HTS triggers UDMA for output buffer transfer into DDR.
8. UDMA loads data from SL2 and write into DDR.

The following assumptions are made for the memory to memory operation described above:

- CSI RX write is mapped onto hard real time fabric of NavSS/MSMC.
- Configurable vertical blanking times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, eventhough last line of current frame is already fed into RFE.
- Buffer dependencies:
  - RFE input buffer (exp0, exp1, exp2)
  - H3A output Buffer (AE or AF)
  - FCP output Buffer (Y12, UV12, Y8, UV8, S8)

#### 7.7.3.1.4 VISS Data Formats Support

Table 7-88 lists the data formats supported by VISS. VISS does not support YUV Input. In case of external YUV Sensor, CSI RX directly writes into DDR and the data is subsequently processed by the rest of VPAC.

**Table 7-88. VISS Data Formats**

Direction	Pixel Width	Pixel Container Width (M2M)	Packing	Video port (OTF)	Comments
VISS Input	RAW12/14/16	16b	No	16b / pixel	1. Companded data/External ISP 2. MSB bits are padded with zeros within fixed width pipeline
	RAW8	8b	Yes	16b / pixel	
	RAW12	12b	Yes	16b / pixel	
VISS Output	YUV420 (12b) NV12	12b	Yes	N/A	
	YUV420 (12b) NV12	16b	No	N/A	
	YUV420 (8b) NV12	8b	Yes	N/A	
	YUV422 (8b) UYVY/YUY2/NV16	8b	Yes	N/A	
	RGB (planar)	8b	Yes	N/A	With RGB output, limited YUV data outputs are available (only 12-bit YUV data is available)
	S8	8bit	Yes	N/A	

#### 7.7.3.1.5 VISS VPORT Interface

The video port (VPORT) interface is used to stream the pixel data from up stream to down stream module. In VISS, the VPORT interface is used to receive data from CSI RX (in streaming mode) and in between VISS sub-modules (RFE -> NSF4V -> GLBCE -> FCP).

The VPORT supports stall signal (VP\_STALL) and also either one pixel or 2 pixel data per cycle.

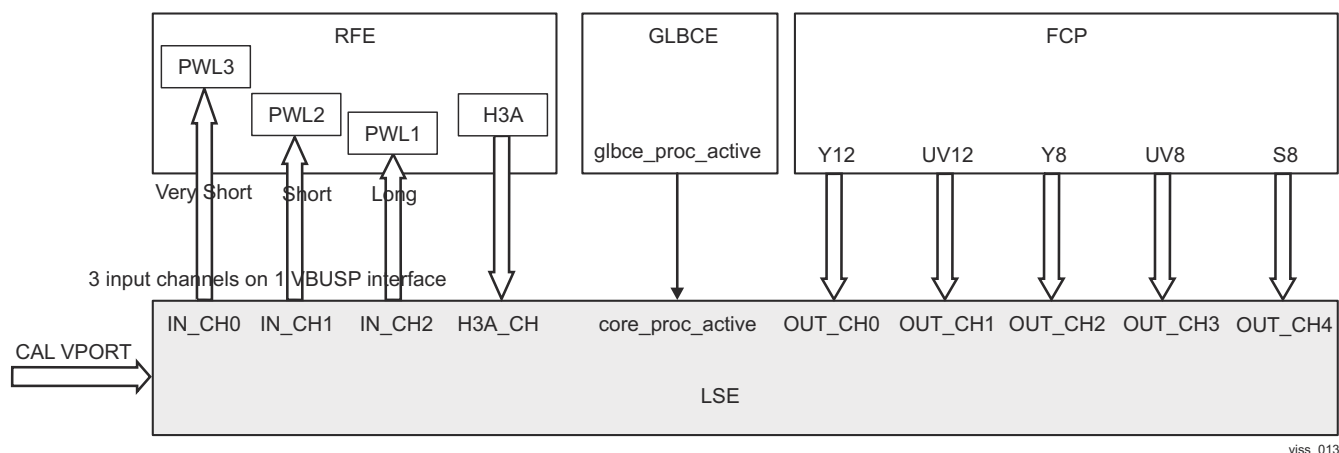

The pixel data (VP\_DATA) received on the VPORT is organized in 32 bits as follows:

- VP\_DATA[15:0] = pixel (n)
- VP\_DATA[31:16] = pixel (n+1). This is ignored, when VPORT\_TWO\_PIXEL = 0
- MSBs are padded with 0's when less than 16 bits are used.

### 7.7.3.1.6 VISS Submodule Integration Specifics

#### 7.7.3.1.6.1 LSE Integration

Figure 7-27 captures the channel integration between LSE and rest of VISS submodules. Though digram shows three input channels between LSE to RFE, 3 channels data is transferred using single VBUSP interface.

**Figure 7-27. VISS LSE Channel Integration**

LSE supports YUV422 interleaving only on 8-bit data.

The LSE configuration for VISS can be read in VISS\_LSE\_STATUS\_PARAM register fields.

For more information on LSE module operation, see Chapter *Load and Store Engine (LSE)*.

#### 7.7.3.1.6.2 PCID

Figure 7-23 captures intergration of PCID into VISS. PCID produces both Bayer and IR data concurrently from input RGBIR image. Bayer channel data is fed to rest of the VISS pipe line and IR channel output is directly written to memory using one of LSE channels. VPORT Delay SYNC\_FIFO supports programbale horizontal delay to match the delay with FCP output.

#### 7.7.3.1.6.3 GLBCE Integration

GLBCE is Global/Local Brightness and Contrast Enhancement module.

The GLBCE module supports the following main features:

- One pixel/cycle operation
- Up to 4096 pixels/line (line size)
- Bayer image
- When GLBCE is off, the RFE/NSF4V output is bypassed to FCP

For more information on GLBCE operation, see [Section 7.7.3.5, VISS Global/Local Brightness and Contrast Enhancement \(GLBCE\) Module](#).

#### 7.7.3.1.6.3.1 GLBCE Startup

GLBCE requires approximately 5400 clock pulses after startup before it could receive data on its video port. Therefore, before RFE -> GLBCE -> FCP path could be used after a GLBCE reset, the SW shall use the following sequence to provide those required clock pulses:

- Prior to enabling rest of VISS pipe, configure VISS clock control to allow free running clock to GLBCE.

- Wait for the 'glbce\_filtering\_done' event. It indicates that GLBCE has received enough PCLK pulses for internal initialization and that it is now ready to receive pixels.
- Configure GLBCE clock to normal mode. Enable the rest of VISS pipeline.

GLBCE has a minimum input restriction of 480x240 pixels. The input frame must be at least this size.

GLBCE LUTs must not be changed during the active frames. They can only be updated in vertical blanking. GLBCE\_LUT\_FI may be changed frame by frame depending on the GLBCE tuning method. Other LUTs (GLBCE\_REV\_PERCEPT\_LUT\_xx, GLBCE\_FWD\_PERCEPT\_LUT\_xx, and GLBCE\_WDR\_GAMMA\_LUT\_xx) are not expected to be updated dynamically except in very limited case.

#### 7.7.3.1.6.3.2 GLBCE Bypass

When the GLBCE is disabled (by VISS\_CNTL[0] GLBCE\_EN = 0), any access targeted to GLBCE registers or GLBCE statistics memory will respond with error status, and 'glbce\_cfg\_err' interrupt will be generated.

#### 7.7.3.1.7 VISS Stall Handling

VISS can handle momentarily stall condition created due to lack of enough band width. Streaming mode is described in the following sections.

##### 7.7.3.1.7.1 Stall Handling for Streaming Mode

Streaming stall handling is similar to memory to memory mode, except that final effect will be reflected in generating stall to the VPORT interface. Upon stall assertion, VISS expects no more than 2 VPORT pixel clock cycles.

#### 7.7.3.1.8 VISS Interrupts

The VISS submodules generate the interrupt events described in Section *VPAC Subsystem Interrupts*.

##### 7.7.3.1.8.1 Interrupts Merging

The configuration error interrupts are merged at VISS level. The following list describe the configuration error eventss and the corresponding merged interrupts.

- RAWFE\_CFG\_ERR\_INTR: Generated when configuration interface access the RFE end points, while frame processing is active. Merged interrupts from RFE:
  - lut1\_cfg\_err\_intr
  - lut2\_cfg\_err\_intr
  - lut3\_cfg\_err\_intr
  - wdr\_lut\_cfg\_err\_intr
  - dpc\_line\_cfg\_err\_intr
  - dpc\_lut\_cfg\_err\_intr
  - h3a\_lut\_cfg\_err\_intr
  - h3a\_line\_cfg\_err\_intr
- GLBCE\_CFG\_ERR\_INTR: Generated when the configuration interface access the GLBCE register region or statastics memory, while frame processing is active. Merged interrupts from GLBCE:
  - glbce\_statmem\_cfg\_err\_intr
  - glbce\_mmr\_cfg\_err\_intr
- FCFA\_CFG\_ERR\_INTR: Generated when the configuration interface access the CFA register region, or LUT or line memory, while frame processing is active. Merged interrupts from CFA:
  - lut\_cfg\_err\_intr
  - cfa\_mmr\_err\_intr
  - cfa\_pix\_err\_intr
- FCC\_OUTIF\_OVF\_ERR\_INTR: Generated when any of the FCC output interfaces overflows. Merged interrupts from CC:
  - overflow\_if\_y12\_intr
  - overflow\_if\_uv12\_intr
  - overflow\_if\_y8r8\_intr
  - overflow\_if\_c8g8\_intr

- overflow\_if\_s8b8\_intr
- FCC\_CFG\_ERR\_INTR: Generated when the configuration interface access FCC register region or its LUTs, while frame processing is active. Merged interrupts from FCC:
  - contrast0\_cfg\_err\_intr
  - contrast1\_cfg\_err\_intr
  - contrast2\_cfg\_err\_intr
  - lut\_12to80\_cfg\_err\_intr
  - lut\_12to81\_cfg\_err\_intr
  - lut\_12to82\_cfg\_err\_intr
- EE\_CFG\_ERR\_INTR: Configuration happened to EE regions causing corruption during frame processing. Merged EE sources are:
  - eelut\_cfg\_err\_intr
  - ee\_pix\_err\_intr
- EE\_SYNCOVF\_ERR\_INTR:
  - ee\_hz\_align12\_intr

#### 7.7.3.1.8.2 Handling of Configuration Error Interrupts

Table 7-89 give hints on handling configuration error interrupts.

**Table 7-89. VISS Configuration Error Interrupts Handling**

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
RAWFE		
PWL1_LUT, PWL2_LUT, PWL3_LUT	Config read access during active line OR write access during active frame.	Write '1' to corresponding bit in RAWFE_INT_STAT register.
WDR_LUT		
H3A_LUT		
H3A_ACCM		
H3A_LINE	Config read/write access during active frame at H3A boundary.	
DPC_LUT	Config read/write access during active frame.	
DPC_LINE	Config read access during active line OR write access during active frame.	
LSC Table	Config read/write access during active frame. Active frame in lsc case is VS at pwl to VE at lsc input delayed by 1 cycle.	
NSF4V		
NSF4V_LINE	Config read/write access when datapath is accessing the corresponding memory on the same cycle.	No register status in NSF4V.
GLBCE		
GLBCE non-shadowed registers	Config write access during active frame. Active frame window is from VS_IN to Filter done.	Write '1' to GLBCE_INT_STAT[0] MMR_CFG_ERR register bit.
GLBCE_STAT	Config read/write access during active frame. Active frame window is from VS_IN to Filter done.	Write '1' into GLBCE_INT_STAT[1] STATMEM_CFG_ERR register bit.
GLBCE_LINE	Not mapped to config.	N/A
CFA		
CFA FIR Filter registers	Config write access during active frame.	Write '1' to CFA_INT_STATUS[2] CFA_MMR_ERR register bit.
CFA_LUT	Config read/write access during active frame.	Write '1' into CFA_INT_STATUS[0] LUT_CFG_ERR register bit.
CFA_LINE	Config read/write access during active frame.	Write '1' to CFA_INT_STATUS[1] CFA_PIX_ERR register bit.
FCC		

**Table 7-89. VISS Configuration Error Interrupts Handling (continued)**

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
LUT_CONTRAST	Config access (read/write) occurs during active line when the LUT is enabled.	Write '1' to corresponding bit in FCC_FLEXCC_INT_STATUS register.
HISTOGRAM	Config access has occurred to the first location but not to the last location till the start of next frame implying that full histogram was not read.	
LUT_COLOR	Config access (read/write) occurs during active line when the LUT is enabled.	
CC_LINE	No error generation logic.	N/A
EE		
EE_LINE	Config accesses during active frame.	Write '1' to EE_INT_STATUS[1] EE_PIX_ERR register bit.
LUT	Config accesses during active frame.	Write '1' to EE_INT_STATUS[0] EELUT_CFG_ERR register bit.

#### 7.7.3.1.9 VISS Error Correcting Code (ECC) Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

One or more memories within VISS are ECC protected using an ECC Memory Wrapper which implements Single Error Correction and Double Error Detection (SECCDED).

The ECC wrapper provides Single Error Detection and Correction (SED/SEC). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC wrapper also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC wrapper also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

An ECC Aggregator at the VISS level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the host (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their ECC register set.

The following VISS memories are ECC protected:

- GLBCE statistics memory.
- RAWFE non pixel line buffer memories. See Section *VISS RAW Front-End (RAWFE)*, for more information.
- FCP non pixel line buffer memories

For more information on the ECC Aggregator operation, see Section *ECC Aggregator* in Chapter *Safety Modules*.

#### 7.7.3.1.10 VISS Programmer's Guide

##### 7.7.3.1.10.1 VISS Initialization Sequence

VISS initialization is part of any other HWA initialization on VPAC. Prior to starting HWA initialization through HTS, VISS must be configured in below order.

1. Configure RFE registers, GLBCE registers, NSF4V registers and FCP registers:
  - The VISS\_CNTL[0] GLBCE\_EN register bit needs to be set, in order to configure the GLBCE registers.
2. Select input / output stream properties inside LSE.
3. After reset and prior to enabling LSE, apply the following configuration:
  - a. Make sure VISS\_CNTL[0] GLBCE\_EN bit is '1'.
  - b. Enable IRQ for interrupt event 'glbce\_filtering\_done'.
  - c. Set VISS\_GLBCECONFIG[0] GLBCE\_PCLKFREE register bit to '1'.

- d. Wait for interrupt 'glbce\_filtering\_done'.
- e. Clear VISS\_GLBCECONFIG[0] GLBCE\_PCLKFREE register bit.
4. Enable LSE input and output buffer lines.
5. Enable pipeline and schedulers associated with VISS HTS configuration (pipeline enable must happen after enabling all attached schedulers).
6. Enabling HTS will trigger init sequence which will initialize LSE, RFE and FCP. This will also trigger head of pipe for NAVSS UDMA fetch (in case of memory to memory operation). Otherwise, VISS waits for streaming data from CSI RX.
7. After initializing VISS/VPAC, configure and enable CSI RX, CSI RX PHY and camera sensor in order.
8. Once streaming data starts, it will continue till the end of frame. Blanking (set in VISS\_LSE\_CFG[31-22] VP\_HBLNK\_CNT register field) must be configured more than VISS blanking needs (see *VISS Blanking Requirements*).
9. Once a complete frame is fully written into DDR, the HTS module comes back to init state and restart from step #6. For some usecase, LSE input/out enables after each frame might be considered as well (step #5).
10. After each 'frame\_done', if the configuration needs to be changed, it must be done within vertical blanking period for not shadowed registers (refer to Sections *VISS RAW Front-End (RAWFE)* and *VISS Flexible Color Processing (FCP) Module*, for more details).
11. At any stage, if there is a need to stop the streaming interface, the HTS must first be paused and then aborted, and then reset and re-configure the entire VISS as part of recovery from abort.

#### 7.7.3.1.10.2 VISS Configuration Restrictions

Frame size restriction:

- If GLBCE is enabled in the VISS pipeline, the minimum frame required is 480x240 pixels.
- If GLBCE is disabled in the VISS pipeline, the minimum frame required is 64x16 pixels.
- Frame width and height has to be even.
- Histogram can only be enabled when the frame width is 256 pixels minimum.

LSE H3A channel enabling restriction:

- When the H3A output channel is enabled in LSE, at least one other output channel needs to be enabled.

#### 7.7.3.1.10.3 VISS Real-time Operating Requirements

SW needs to configure UTC/UDMA channel registers for write out buffers.

SW needs to reconfigure RAWFE LSE LUT, if needed, and any other non-shadowed registers during vertical blanking period only. Some control bits would be shadowed, which can be configured during a complete frame.

### 7.7.3.2 VISS Load Store Engine (LSE)

For more information on the VISS LSE module operation, see *LSE Integration* and *Load Store Engine (LSE)*.

### 7.7.3.3 VISS RAW Frond-End (RAWFE)

This section describes the Vision Imaging Sub-system (VISS) RAW Frond-End (RAWFE) module in the device.

#### 7.7.3.3.1 RAWFE Overview

The RAWFE is a set of raw pixel processing functions to enhance the RAW image signal received from the sensor. The key application of the RAWFE is in the ADAS space where in it is used for both analytics as well as visual use cases.

##### 7.7.3.3.1.1 RAWFE Supported Features

Each RAWFE module implements the following features:

- Support for any 2x2 RAW data pattern.
- • Support for 4x4 RGBIR CFA pattern (50% green, 25% IR, 12.5% red and 12.5% blue)
- Support for merge up to 3 separate exposures (non 4x4 RGBIR CFA pattern).
- PWL (piecewise linear) and LUT based de-companding at the front end of each exposure channel
- Support for WDR merge, including 2 exposure merge, 3 exposure merge and 2 exposure hybrid (12 bit and 16 bit) merge.
- Support for companding LUT from 24 bits down to 12 bits.
  - LUTs support higher precision in lower end.
- Support for LUT as well as adaptive Defect Pixel Correction.
- Support export of defective pixel coordination in adaptive defect pixel correction mode
- Support for table based lens shading correction.
- Support for 3A statistics
  - Statistics can be generated on independent exposures or merged data after tone map.

#### 7.7.3.3.2 RAWFE Functional Description

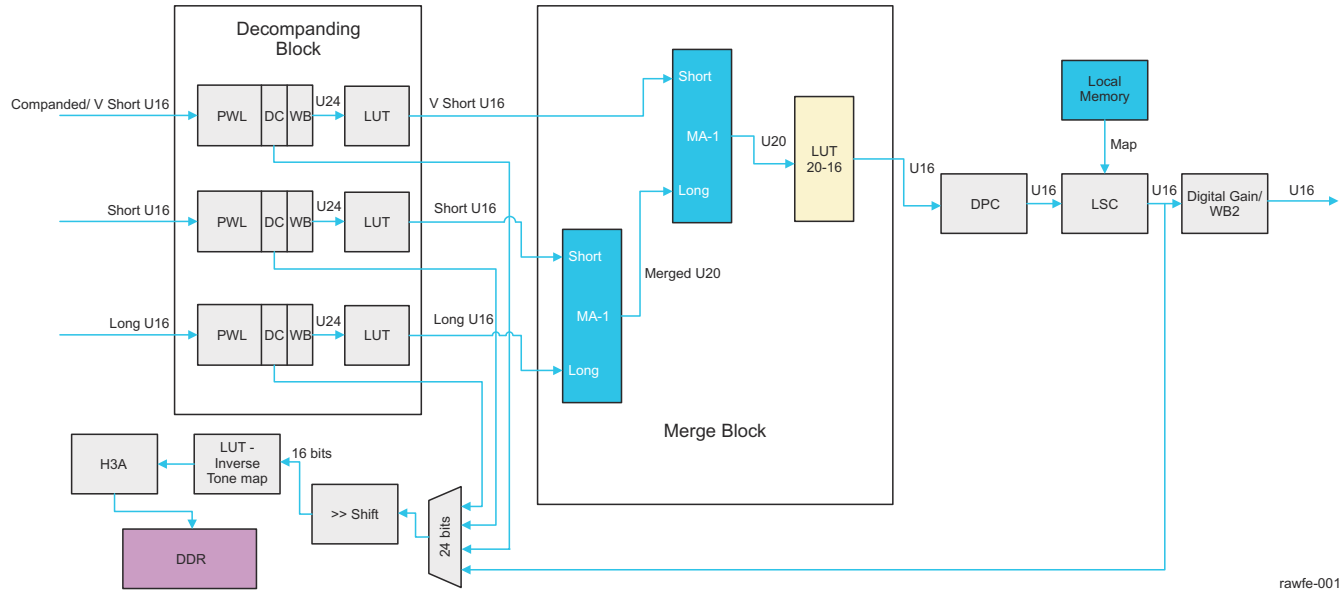

##### 7.7.3.3.2.1 RAWFE Functional Operation

The RAWFE processes captured image data from sensor and passes the data to the Flexible Color processing module (FCP) for demosaicing and color conversion.

[Figure 7-28](#) shows a high level conceptual block diagram of the RAWFE module.

The RAWFE consists of the following main components

- Decompanding block: This is used to decompand the sensor compressed raw to native bit depth. The same block can be used for tone mapping as well. The decompanding block can take sensor compressed RAW data and can decompand to up to 24 bits.
- WDR Merge: Each instance of the WDR merge block can take in 2 independent exposures (up to 16 bits) and generate up to 20 bit data.
- LSC Block: The block performs lens shading correction by applying gains stored in a look up memory.
- DPC: The block performs defect pixel correction using either LUT based memory or adaptive defect correction.
- H3A: The H3A block generates 2 different set of statistics, one for AWB and AE and the other for auto focus.
- In addition, when RGBIR sensor is used, H3A can be configured to select PCID output and generate statistics. H3A module is re-use HW IP from ISS6.5

**Figure 7-28. RAWFE Block Diagram**

#### 7.7.3.3.2 RAWFE ECC for RAMs

Table 7-90 lists the RAWFE ECC RAMs

**Table 7-90. Table 3: RAM ECC capabilities**

Module	# Rams	ECC
PWL LUT1	2	ECC, with single bit correction, including writeback.
PWL LUT2	2	ECC, with single bit correction, including writeback.
PWL LUT3	2	ECC, with single bit correction, including writeback.
WDR LUT	2	ECC, with single bit correction, including writeback.
H3A LUT	2	ECC, with single bit correction, including writeback.
DPC (line buffer)	4	No ecc
LSC LUT	1	ECC, with single bit correction, including writeback.
LSC GAIN	1	ECC, with single bit correction, including writeback.
H3A accum	1	No ecc
H3A line	1	No ecc

#### 7.7.3.3.3 RAWFE Interrupts

The following section lists the RAWFE interrupts

##### 7.7.3.3.3.1 RAWFE CPU Interrupts

Table 7-91 lists the interrupts generated by the RAWFE sub-modules.

**Table 7-91. RAWFE Interrupts**

Interrupt	Description
LUT1_CFG_ERR	Config access to LUT1 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LUT2_CFG_ERR	Config access to LUT2 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.

**Table 7-91. RAWFE Interrupts (continued)**

Interrupt	Description
LUT3_CFG_ERR	Config access to LUT3 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if cfg access occurs during active line. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
WDR_LUT_CFG_ERR	Config access to WDR LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_LUT_CFG_ERR	Config access to H3A LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_ACCM_CFG_ERR	Config access to H3A accum ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
H3A_LINE_CFG_ERR	Config access to H3A line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LUT_CFG_ERR	Config access to DPC LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LINE_CFG_ERR	Config access to DPC line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LSC_CFG_ERR	Config access to LSC ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame. Active frame in lsc case is VS at pwl to ve at lsc input delayed by 1 cycle.
H3A_AEW	h3a aew interrupt.
H3A_AF	h3a af interrupt
H3A	h3a interrupt
H3A_BUF_OVRFLOW_PULSE_INTR	Generated when an overflow occurs in the H3a output buffer

#### 7.7.3.3.2 RAWFE Debug Events

[Table 7-92](#) lists the RAWFE debug events. Debug events are used for hardware debug as well as performance measurement. They are not intended to be used as interrupts where the cpu needs to process them.

**Table 7-92. RAWFE Debug events**

Event	Description
VS_EVENT	ventricle start in the beginning of the rawfe pipeline
VE_EVENT	ventricle end at the end of the rawfe pipeline
HS_EVENT	horizontal start in the beginning of the rawfe pipeline
HE_EVENT	horizontal end at the end of the rawfe pipeline
LSE_SLAVE_STALL	rawfe is stalling lse target interface due to ext or mtc stall
LSE_MASTER_STALL	lse controller interface is stalled
LSE_INTERFACE_IDLE	within a frame lse is not sending data
X_Y_EVENT_MATCH	x-y pixel position has reached the start of rawfe pipeline
DPC_OTF_CORR_EVENT	dpc off corrected a pixel position
PIPE_ADV_EVENT	active pipeline advancement

#### 7.7.3.3.4 RAWFE Sub-Modules Details

The following sections describe in detail the sub-modules present within the RAWFE module.

##### 7.7.3.3.4.1 RAWFE Decompaning Block

The decompaning block is responsible for decompaning pwl (or LUT) compressed data back to its linear bit width. The decompaning block can generate up to 24 bits of data, however the data needs to be tone mapped down to 16 bits before additional processing can take place. There are 3 instances of the Decompaning block each implementing the same functionality.

The input interface of the decompaning block is 16 bits.

Figure 7-29 shows a high level block diagram of the decompaning block.

**Figure 7-29. RAWFE Decompaning Block Diagram**

##### 7.7.3.3.4.1.1 RAWFE Mask & Shift

The mask and shift block is used to mask out any control bits present in the data. The 'Mask' is a 16 bit configuration register which will perform a bit wise 'and' operation on the incoming data. (For example for sensor data with data in 12 bits and 4 bits of control information, the mask value would be programmed to 0xFFF). The Mask operation is followed by a shift operation. The 'Shift' field is a 3 bit configuration register which can perform a right shift (>>) from 0 to 7 bits.

##### 7.7.3.3.4.1.2 RAWFE Piece Wise Linear Operation

The PWL block is used to apply a piece-wise-linear gain on the incoming pixel data and is generally used to uncompress sensor compressed data. The knee points of the PWL curve should be programmed to correspond with the compression knee points used by the sensor configuration.

The PWL block supports an input size from 8 – 16 bits and can support an output up to 24 bits.

Figure 7-30 depicts a PWL curve applied on incoming data

**Figure 7-30. RAWFE PWL Curve implementation**

The PWL block implements the following equation assuming the input lies in the nth segment.

$$\text{Out\_Pixel} = ((X - \text{ThrX}_n) \times \text{Slope}) + \text{ThrY}_n \quad (2)$$

The figure below shows the PWL block architecture

**Figure 7-31. RAWFE PWL Block Diagram**

The Wdr\_clip parameter can be set to clip the output at the desired bit width (typically 20 bits).

#### 7.7.3.3.4.1.3 RAWFE Offset/WB-1 Block

This block is used for applying White balance correction in linear domain as well as for subtracting the DC offset using the signed 24 bit offsets. The functionality is similar to the WB2 block. Note, there is a tap out point to H3A after the offset application, but prior to the gain block. This allows the H3A to receive DC subtracted (but not WB corrected) data.

#### 7.7.3.3.4.1.4 RAWFE LUT Based compression

The LUT based compression is used for addressing multiple use cases.

- The primary function of the LUT is to take the PWL decompounded data (up to 24 bits and after DC subtraction) and compress it using an  $x^n$  curve to a bitwidth of 16 bits. This is required since the downstream path is only capable of supporting up to 16 bits of data.
- It can be used to decompand data when the compression curve cannot be addressed using 3 knee points or if the compression is true curve instead of PWL. In this scenario the DC subtraction IP is disabled and the LUT is used to implement both the decompression as well as the DC subtraction functionality.

The LUT compression is modified from the implementation in previous generation ISPs. The previous LUTs had 512 entries leading to a step size of  $2^{20}/512 = 2048$ . As such there were only 2 LUT points in the critical low range (0-4095) of the image. The LUT implementation is optimized for a 20-bit decompounded data and allows for a step size of 32 in the critical range (lower 12 bits) and a step size of 2048 in the successive ranges.

The Non Linear LUT implementation supports 3 zones for the input range

- For bitWidth < 12 bits, the LUT offers a linear range with a step size of 32. (Only the first 128 locations (plus 129th location for supporting interpolation) are utilized in this mode)
- For bitWidths between 13 and 20: This is the most common operating zone for the LUT. In this mode, the range between 0 and 4k is split in 128 locations with a step size of 32. Beyond 4k range, the step is variable and is set to 2k for the highest bit width of 20 and subsequently reduces by half as the bitwidth is reduced (E.g. 1k for 19 bits etc)
- For bitwidths between 21 and 24: In this operation zone, the first 128 locations are used with a varying step size based on bit width such that the step size is 64 for 21 bits of data and doubles with increase in bitWidth. (E.g. 128 for 22 bits etc). The remaining locations implement a varying step size between 4k (for 21 bits) and 32k (for 24 bits).
  - Example-1: Bitwidth=21 bits:
    - Range 0-8k-> Step size = 64;
    - Range 8k-  $2^{21}$  -> Step Size = 4096
  - Example-2: Bitwidth = 22 bits

- Range 0 -16k -> Step Size = 128
- Range 16k –  $2^{22}$  -> Step\_Size = 8192
- Example 3: Bitwidth = 24 bits
  - Range 0 – 64K -> Step Size = 512
  - Range 64K -  $2^{24}$  -> Step Size = 32k

The LUT logic provides a generic table which can support any bit width and can be used in different regions in the RAWFE as well as other modules.

The LUT3 supports shadowing for very short frame only. If the MMR shadow enable is set then the LUT2 is used on the LUT3 data.

#### 7.7.3.3.4.2 RAWFE WDR Merge Block

The merge block supports merging up to 3 exposures to generate a cumulative 20 bit frame.

The merge block is based on 2 instances of the Motion-Adaptive merge block, each of which is independently capable of supporting the merging of 2 exposures (10 – 16 bits each) to a combined bit width of up to 20 bits. In a more generic scenario the merge block should be designed and verified to support the following scenarios

- Merge 2 exposures of 10 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 20 bits
- Merge 2 exposures (12 bit and 16 bit) to 20 bits.
- Merge 2 exposures of 16 bit each to 20 bits.

Using two instances of the motion adaptive merge block provides the functionality to merge up to 3 independent exposures, each of 12 bits, to a combined bitwidth of 20 bits. The block also provides capability to only merge 2 exposures using a combination of mux and clipping blocks.

The merge block comprises of two instances of the motion adaptive merge (MA1/MA2) as well as an LUT based companding block and mux structures to enable different data flow. To keep the design complexity under control some restrictions are applied to the data connectivity on the merge blocks. A key restriction is that for the two exposure merge only the MA-2 block should be used and the MA-2 should be used along with MA-1 for 3 exposure merge. Further the position of the long and short exposures on each block are fixed. [Table 7-93](#) summarizes some of the possible combinations which can be realized using the logic. (Note, this is not an exhaustive list from a DV perspective).

The MA block when set to bypass/disabled mode, will pass the input stream marked as 'short' (refer to [Figure 7-28](#)) to the output.

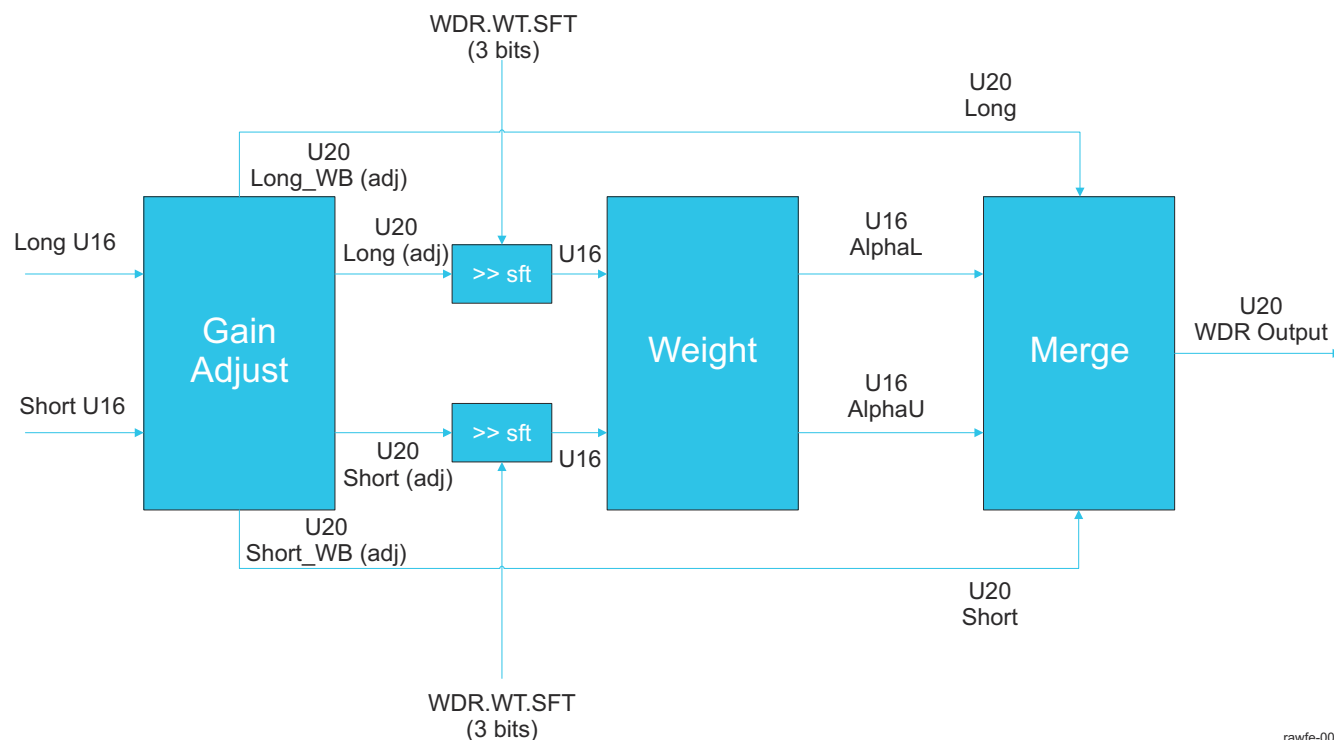

**Table 7-93. Figure 7:RAWFE Different merge modes**

Merge Mode	MA-1	MA-2	LUT
2 Exposures (12 bit) to 20 bit	Bypassed	Merge Long / Short	Use VS and Short Exposures
2 Exposures (12 bit) to 16 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures
2 Exposures (12 bit) to 16 bit with tone mapping	Bypassed	Merge Long /Short	Use VS and Short Exposures
2 Exposures (12 & 16) to 20 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures
3 Exposures (12 bit each) to 20 bit	Merge Long and Short	Merge VS / MA-1 output	Use all 3 exposures
Single exposure companded	Bypass	Bypass	Use VS exposure only

#### 7.7.3.3.4.2.1 RAWFE WDR Motion Adaptive Merge (MA1 / MA2)

This section provides the detailed description of the two instances of the motion adaptive merge.

[Figure 7-32](#) shows the high level block diagram of the MA merge block

**Figure 7-32. RAWFE WDR Motion Adaptive Merge**

The MA block receives two inputs each of which can be up to 16 bits. As mentioned earlier, the ordering of the long and the short exposure cannot be changed and should be positioned as it's depicted in the figure above. The MA block consists of 3 main sub-blocks, which are described in the following sub-sections.

#### 7.7.3.3.4.2.2 RAWFE Companding LUT

The companding LUT is used to perform a global tone mapping on the image and reduce the bit depth from 20 bits down to 16 bits. The LUT is implemented as a non uniformly spaced memory, with higher precision in the lower range of the image intensity. The LUT architecture is similar to that used for the decompanding LUT in the previous section.

#### 7.7.3.3.4.3 RAWFE Defective Pixel Correction (DPC) Block for 2x2 Bayer CFA

The defect pixel correction (DPC) block is responsible for correcting defective pixels present on the sensor as an artifact of the manufacturing process. The defect pixel detection can either be LUT based or on the fly (OTF – DPC). For LUT based DPC, the defect map is stored in a memory.

Figure 7-33 shows a high level block diagram of the DPC module. The DPC comprises of two different methods of performing the functionality, each of which is highlighted below. The LUT based defect correction mechanism requires the sensor to be calibrated and the defect positioned stored in memory, whereas the Adaptive DPC automatically detects defects and corrects them. If required the LUT DPC and adaptive DPC can be enabled together in sequence.

**Figure 7-33. RAWFE DPC Block Diagram**

### 7.7.3.3.4.3.1 RAWFE LUT Based DPC

LUT based defect pixel correction provides the highest level of accuracy since all defects can be identified perfectly without any false positives. The LUT based DPC mechanism however suffers from the limitation that the sensor has to be calibrated (each sample has to be individually calibrated) and that can add cost to the testing and qualification process. Some automotive grade sensor vendors provide the defect pixel locations already in an on chip memory and that can additionally be utilized to program the defect LUT without adding the cost. The LUT size for the DPC is constrained to 256 entries, since it is assume for a sensor of 2 -3 Mpix resolution, 256 entries are more than sufficient. Each entry in the LUT is 29 bits with 13 bits for x coordinate, 13 bits for Y coordinate and 3 bits for the method. [Figure 7-34](#) illustrates the organization of the LUT memory

rawfe-017

**Figure 7-34. RAWFE DPC LUT Memory Organization**

A sample table is provided below for 7 entries. The LUT is specified in left to right and top to down fashion (Raster Scan order). As such design only has to look at the current LUT pointer to be able to determine if the current location is a defect or not.

**Table 7-94. Figure 14: RAWFE Sample DPC Table**

10	1400	0	
236	1107	1	
236	1200	1	
488	10	1	
488	100	2	
800	138	3	
900	1000	1	
900	1100	3	

The method filed pertains to how the defect pixel is treated once it has been detected. Several possibilities arise including copying from one of the neighbors or using an average of the neighbors. The table below summarizes different methods that can be programmed for treating defect pixels.

**Table 7-95. Figure 15:RAWFE LUT DPC Method(s)**

Method Value	Functional equivalent
0	Replace with Black or white dot based on config
1	Dout = d4
2	Dout = d5
3	Dout = (d4 + d5)/2
4	Dout = (d2 + d7)/2
5	Dout = d2
6	Dout = d7
7	Dout = ((d2 + d7)/2 + (d4 + d5)/2)/2

The pixel arrangement and numbering convention is depicted in the image below with 'd0' being considered the center pixel.

Figure 7-35. RAWFE DPC Pixel numbering convention

When the DPC method is set to '0', the output is either a black or a white pixel (depending on a separate configuration register). With this method, the LUT dpc can be used in conjunction with OTF DPC in a way that the LUT programmed defects are almost always identified by the adaptive DPC. This can be used to accurately correct for all known defects and then using adaptive DPC to correct for temperature or other operating condition based defects. (Defect pixels are strongly correlated with analog gain).

#### 7.7.3.3.4.3.2 RAWFE On-The-Fly (OTF) DPC

The LUT based DPC suffers from the drawback that each sensor die has to be calibrated for defects. The calibration process adds cost to the sensor dies, as such the preferred DPC method relies on automatically detecting the defects based on thresholds.

The OTF DPC algorithm detects defective pixels by comparing the current pixel (d0 on the left of the figure below) against its 8 neighboring pixels with the same color (d1 ~ d8 on the left of the figure below). Let's use dmax and dmin to denote the maximum and minimum of d1 ~ d8 respectively. If the current pixel d0 is greater than the sum of dmax and a detection threshold T (i.e.,  $d0 > d_{max} + T$ ) as shown on the right of the figure below, then the current pixel is considered a defect and its value is replaced by dmax. Similarly, if  $d0 < d_{min} - T$ , then the current pixel is replaced by dmin.

Figure 7-36. RAWFE OTF DPC

The detection threshold T is made adaptive by calculating the local image intensity and using a programmable look-up-table. The local intensity is approximated by the average of the second largest and the second smallest pixel values among d1 ~ d8 (dmax2 and dmin2 respectively in the figure above). With this average value, the threshold T is obtained from the look-up-table with linear interpolation. The look-up-table contains the detection thresholds (U16) at the average values of 0, 512, 1024, 2048, 4096, 8192, 16384, 32768 and the corresponding slope values (S12Q8) for linear interpolation.

#### 7.7.3.3.4.4 RAWFE Lens Shading Correction (LSC) and Digital Gain (DG) Block

The lens shading module corrects for the lens fall off (loss of light) at the corners of the lens. [Figure 7-37](#) shows a sample image of this phenomenon and the corresponding result after treating with LSC operation.

**Figure 7-37. RAWFE Before and After LSC**

The image on the left shows a block at the center of the lens and a corresponding block at the edge of the lens. Both blocks are equally illuminated, as such should appear equally bright on the image. However, due to lens fall off, the block at the edge appears significantly darker than the block at the center. The image on the right shows the corresponding result after LSC gains have been applied.

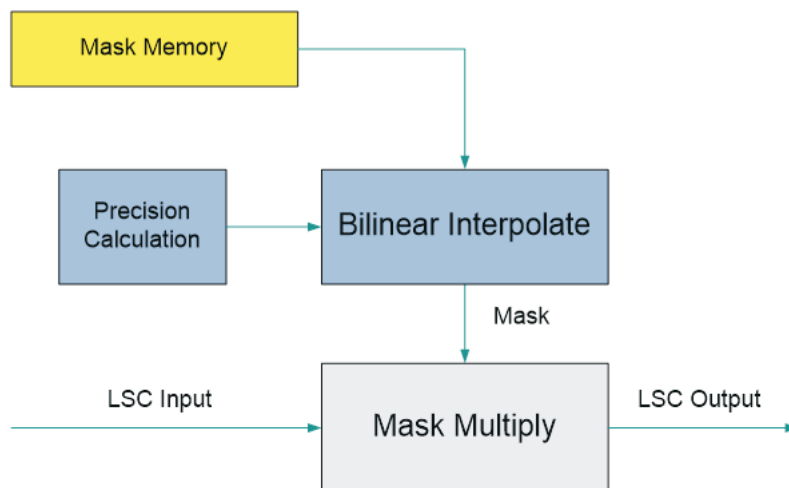

This block (2D-LSC) contains lens shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image is conceived to be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in internal MEMORY down-sampled, and is accessed and up-sampled by the LSC module to pixel resolution before being applied to the pixel data. The key difference from previous generation LSC is that the gain map is stored internally in the memory instead of relying on DRAM fetch.

The LSC module does not implement any Region of Interest (ROI) functionality and the LSC gain mask is applied on the entire image. Further, only an 8 bit gain is stored in the mask. The gain can be stored in different formats depending on the range. The 8 bits of gain can be used to represent different ranges based on the `lscfg.GAIN_FORMAT` register as per the table below

- 0 : U8Q8 -> 0 to 0.996
- 1 : U8Q8 +1 -> 1 to 1.996
- 2 : U8Q7 -> 0 to 1.992
- 3 : U8Q7 +1 -> 1 to 2.992
- 4 : U8Q6 -> 0 to 2.984
- 5 : U8Q6 +1 -> 1 to 3.984
- 6 : U8Q5 -> 0 to 6.968
- 7 : U8Q5 +1 -> 1 to 7.968

### Note

The offset field is removed from the implementation of the LUT and only the gain field is retained. This is different than previous implementations.

rawfe-021

**Figure 7-38. RAWFE LSC block diagram**

#### 7.7.3.3.4.4.1 RAWFE LSC Features Supported

- Gain map is MxN down-sampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {8,16,32,64,128 } independently.
- The size of the internal memory is based on a 2Mpix sensor with 16x32 downscaling ratio. As such the size is approximately 19 Kbytes-( 4758 locations with 4 Bytes/location) -> Each entry has gains for all 4 colors. This corresponds to a sensor resolution of 1928 x 1208
- Support 8-bit entry in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0 to shift the range up)

[Figure 7-37](#) illustrates the LSC active region and map up-scaling feature. (The maps are stored independently per color channel)

#### 7.7.3.3.4.4.2 RAWFE LSC Image Framing with Respect to Gain Map Samples

The gain maps are stored MxM downsampled, and needs to be upsampled by LSC hardware before being applied to the image. It is most straightforward for LSC hardware if the gain map grid is aligned with the input image grid. In other words, first pixel corresponds to a source gain map entry, rather than being upsampled through interpolation. [Figure 7-39](#) shows the LSC active region with respect to the gain map grid.

**Figure 7-39. RAWFE LSC active region with respect to gain map samples**

For an image frame size of  $W \times H$  (output and input are the same size), gain map being  $M \times N$  downsampled, it needs  $(\text{ceil}(W / M) + 1) \times (\text{ceil}(H / N) + 1) \times 4$  bytes of gain map data in internal memory. (NOTE:  $\text{ceil}()$  represents the ceiling function).

The LSC module is designed to work with Bayer CFA data, having R/Gr/Gb/B color pattern. For the purpose of functional description, we assume Red is the starting color, but any other starting color or other 2x2 color pattern can be used by placing color gains in the appropriate order.

Each 2x2 set of samples is stored together in a 32-bit word in internal memory. For R/Gr/Gb/B CFA data and 8x8 downsampled gains, the following order is assumed in the gain map, using conventional (X, Y) coordinate notation (X for horizontal offset and Y for vertical offset):

Line 0: R(0,0) Gr(1,0) Gb(0,1) B(1,1) R(8,0) Gr(9,0) Gb(8,1) B(9,1)...

Line 1: R(0,8) Gr(1,8) Gb(0,9) B(1,9) R(8,8) Gr(9,8) Gb(8,9) B(9,9)...

#### 7.7.3.3.4.5 RAWFE Gain & Offset Block

The gain block allow 2 primary functions

- Allow for digital gain to be applied if the image is too dark even after analog gain and exposure time have been set to the maximum
- Independent gain setting for each color channel in 13 bit format U13Q9 with 9 bits of fraction.
  - Allows a gain value from 0 to 31.996 in steps of 1/256.

The Gain block can be configured to apply an offset on top of the gain. This is to support the log compressed image mode, where in the traditional WB Gain becomes an offset.

#### 7.7.3.3.4.6 RAWFE H3A

##### 7.7.3.3.4.6.1 RAWFE H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting statistics about the raw image. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:

The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:

- Peak mode in a paxel: Accumulation of the maximum focus value (FV) of each line in a paxel
- Accumulation mode in a paxel

- Accumulation of horizontal and vertical focus value in a paxel
- Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
- Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
- Programmable width and height for the paxel/window
- Programmable red, green, and blue position within a  $2 \times 2$  matrix
- Separate horizontal start for paxel and filtering
- Programmable vertical and horizontal line increments within a paxel
- Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame on which to focus.
- Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.

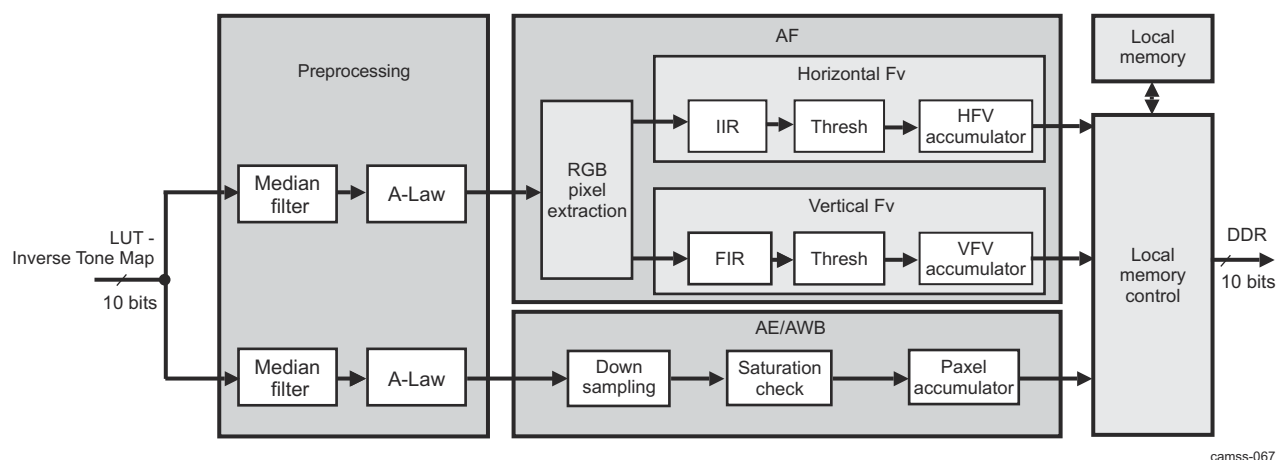

• Auto exposure and auto white balance (AE/AWB) engine:

The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulate clipped pixels along with all nonsaturated pixels in each window per color
- Accumulate the sum of squared pixels in each window per color
- Minimum and maximum pixel values in each window per color
- Support for up to 36 horizontal windows with sum + { sum\_sq or min+max } output
- Support for up to 56 horizontal windows with sum output
- Support for up to 128 vertical windows
- Programmable width and height for the windows. All windows in the frame are the same size.
- Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
- Programmable horizontal sampling points in a window
- Programmable vertical sampling points in a window
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 4096 pixels.

#### 7.7.3.3.4.6.2 RAWFE H3A Top-Level Block Diagram

The block diagram in [Figure 7-40](#) shows the process of the AF and AE/AWB data paths through the H3A module.

**Figure 7-40. RAWFE H3A Top-Level Block Diagram**

### 7.7.3.3.4.6.3 RAWFE H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the VISS\_RAWFE\_H3A\_LINE\_START register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 4096 pixels. After 4096 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 4096 clock cycles, then the active region ends immediately and the counter waits for the VISS\_RAWFE\_H3A\_LINE\_START register count to be reached again. For the vertical position the VISS\_RAWFE\_H3A\_LINE\_START[31:16] SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 7-41 shows the RAWFE H3A frame format settings.

Figure 7-41. RAWFE H3A Frame Format Settings

#### Note

(Frame width on VP) - (VISS\_RAWFE\_H3A\_LINE\_START[15:0] LINE\_START) must be less than or equal to 4096, because the H3A memory lines are limited to 4096 pixels.

### 7.7.3.3.4.6.4 RAWFE H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the VISS\_RAWFE\_H3A\_PCR[1] AF\_ALAW\_EN bit) and the AE/AWB engine (the VISS\_RAWFE\_H3A\_PCR[17] AEW\_ALAW\_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the VISS\_RAWFE\_H3A\_PCR[2] AF\_MED\_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The

horizontal median filter calculates the absolute difference between the current pixel (i) and pixel (i – 2), and between the current pixel (i) and pixel (i + 2). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel (i – 2) and pixel (i + 2) replaces pixel (i). The threshold of the horizontal median filter can be set in the VISS\_RAWFE\_H3A\_PCR[10:3] MED\_TH bit field.

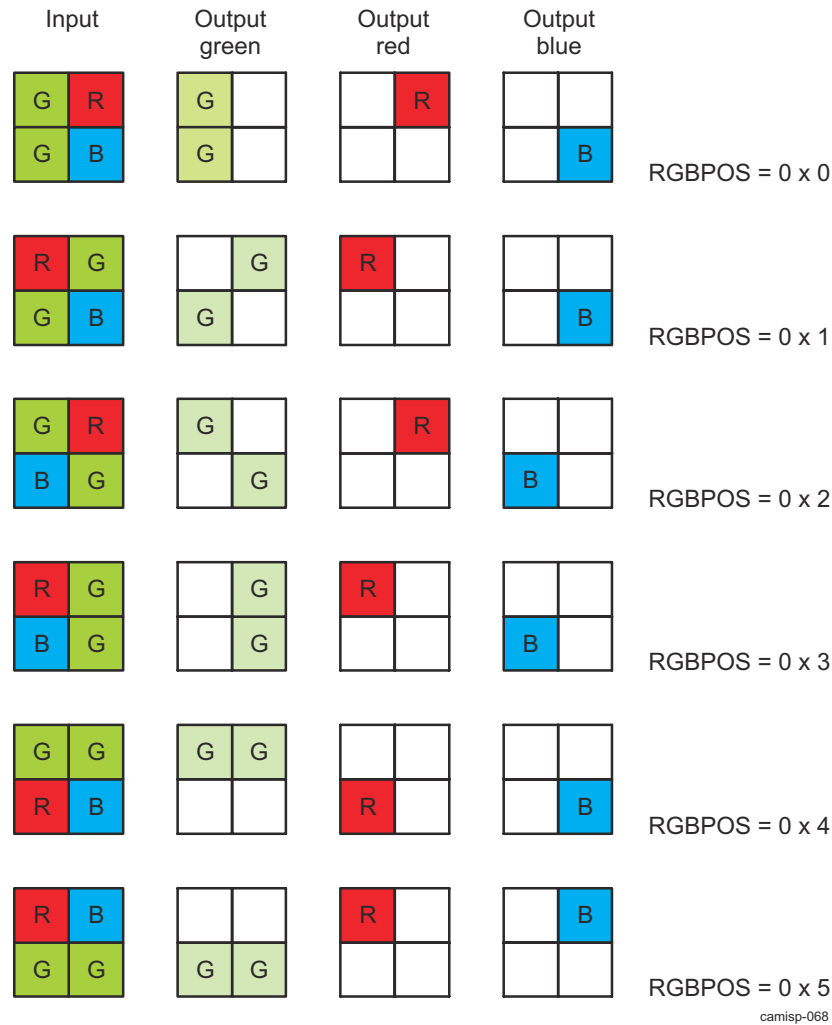

#### **7.7.3.3.4.6.5 RAWFE H3A Autofocus Engine**

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending of whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV<sup>2</sup> are produced. The FV and FV<sup>2</sup> values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

##### **7.7.3.3.4.6.5.1 RAWFE H3A Paxel Extraction**

From the paxel starting coordinate (the VISS\_RAWFE\_H3A\_AFPAXSTART[27:16] PAXSH and VISS\_RAWFE\_H3A\_AFPAXSTART[11:0] PAXSV bit fields) specifies the starting point of the paxel grid, with respect to first pixel of the input image frame.

The paxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if VISS\_RAWFE\_H3A\_PCR[20] AF\_VF\_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the VISS\_RAWFE\_H3A\_PCR[13:11] RGBPOS bit field to extract the correct colors from the input stream. [Figure 7-42](#) shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2 × 2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

**Figure 7-42. RAWFE H3A Red, Green, and Blue Pixel Extraction Examples**

Each paxel is VISS\_RAWFE\_H3A\_AFPAX1[23:16] PAXW × VISS\_RAWFE\_H3A\_AFPAX1[7:0] PAXH (width × height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every VISS\_RAWFE\_H3A\_AFPAX2[16:13] AFINCV lines. Vertical FV can skip columns, operating on one every VISS\_RAWFE\_H3A\_AFPAX2[20:17] AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) ≥ 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column VISS\_RAWFE\_H3A\_AFIIRSH[11:0] IIRSH.

Figure 7-43 shows the RAWFE H3A horizontal/vertical fv paxel configuration.

**Figure 7-43. RAWFE H3A Horizontal/Vertical FV Poxel Configuration**

**Note**

$(\text{VISS\_RAWFE\_H3A\_AFPAXSTART}[27:16] \text{ PAXSH}) + (\text{VISS\_RAWFE\_H3A\_AFPAX2}[5:0] \text{ PAXHC})$   
 $\times (\text{VISS\_RAWFE\_H3A\_AFPAX1}[23:16] \text{ PAXW}) \leq [(\text{Frame width on VP}) -$   
 $(\text{VISS\_RAWFE\_H3A\_LINE\_START}[15:0] \text{ LINE\_START})] \leq 4096$

Table 7-96 lists the bit fields that configure the size and number of pixels.

**Table 7-96. RAWFE H3A Poxel Register Field Descriptions**

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AFPAX1[23:16] PAXW	8	Poxel width (in pixels)
VISS_RAWFE_H3A_AFPAX1[7:0] PAXH	8	Poxel height (in lines)
VISS_RAWFE_H3A_AFPAX2[5:0] PAXHC	6	Poxel count for horizontal direction
VISS_RAWFE_H3A_AFPAX2[12:6] PAXVC	7	Poxel count for vertical direction
VISS_RAWFE_H3A_AFPAX2[16:13] AFINCV	4	Line increments in a poxel
VISS_RAWFE_H3A_AFPAX2[20:17] AFINCH	4	Column increments in a poxel
VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH	12	Poxel start position H
VISS_RAWFE_H3A_AFPAXSTART[11:0] PAXSV	12	Poxel start position V
VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the VISS\_RAWFE\_H3A\_ADVANCED[31:15] ID bit field, then VISS\_RAWFE\_H3A\_ADVANCED[0] AF\_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF poxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV\_1 and HFV\_2.

#### 7.7.3.3.4.6.5.2 RAWFE H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range –128 to 127 or –512 to 511.

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide

with 6 bits of decimal, S12Q6 (VISS\_RAWFE\_H3A\_AFCOEF010 to VISS\_RAWFE\_H3A\_AFCOEF0010 for SET0, and VISS\_RAWFE\_H3A\_AFCOEF110 to VISS\_RAWFE\_H3A\_AFCOEF1010 for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the VISS\_RAWFE\_H3A\_AFIIRSH[11:0] IIRSH bit field). The absolute values of the output (16 bits wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is  $m$  bits (signed) and the required output value is  $n$  bits, clipping transforms the input to between  $-2^1$  and  $2^1$ . Values lower than  $-2^1$  are set to  $-2^1$ , and values higher than  $2^1$  are set to  $2^1$ .

#### 7.7.3.3.4.6.5.3 RAWFE H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 7-96 lists the register fields that configure the size and number of paxels:

- In peak mode (VISS\_RAWFE\_H3A\_PCR[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode (VISS\_RAWFE\_H3A\_PCR[14] FVMODE = 0x0), all HFV<sub>n</sub> are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV<sub>n</sub> (HFV<sub>n\_peak</sub> for peak mode or HFV<sub>n\_sum</sub> for sum mode)
- HFV\_count<sub>n</sub>
- HFV\_sq<sub>n</sub> (HFV\_sq<sub>n\_peak</sub> for peak mode or HFV\_sq<sub>n\_sum</sub> for sum mode)

$n = 1$  or  $2$  for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on paxel rows
{
    rowpeak_n = 0;
    for (l=0; l<PAXW; l++) // Loop on values within a row
    {
        aIIRout_n = ABS(IIRout_n);
        if (aIIRout_n >= threshold_n)
        {
            hfval = aIIRout_n - threshold_n;
            HFV_count_n++;
        }
        else hfval = 0;
        if (hfval > rowpeak_n)
        {
            rowpeak_n = HFV_n;
        }
        HFV_n_sum += hfval;
        HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
    } // Finished looping on values in a row
    HFV_n_peak += rowpeak_n;
    HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}
```

- threshold<sub>n</sub> is VISS\_RAWFE\_H3A\_HVF\_THR[15:0] HTHR1 and VISS\_RAWFE\_H3A\_HVF\_THR[31:16] HTHR2, respectively.
- IIRout<sub>n</sub> is the IIRout<sub>1</sub> and IIRout<sub>2</sub> outputs, respectively.
- HFV\_count<sub>n</sub> and HFV\_sq<sub>n</sub> are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
  - HFV<sub>n</sub> = HFV<sub>n\_sum</sub>
  - HFV\_sq<sub>n</sub> = HFV\_sq<sub>n\_sum</sub>
- In peak mode:

- HFV\_n = HFV\_n\_peak
- HFV\_sq\_n = HFV\_sq\_n\_peak

#### 7.7.3.3.4.6.5.4 RAWFE H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1\_x, where x = 0 to 4, in the VISS\_RAWFE\_H3A\_VFV\_CFG1 and VISS\_RAWFE\_H3A\_VFV\_CFG2 registers for FIR 1, and VCOEF2\_x, where x = 0 to 4, in the VISS\_RAWFE\_H3A\_VFV\_CFG3 and VISS\_RAWFE\_H3A\_VFV\_CFG4 registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and takes an absolute value to produce a 16-bit unsigned value. This is then sent to threshold VISS\_RAWFE\_H3A\_VFV\_CFG2[31:16] VTHR1 for FIR 1, and VISS\_RAWFE\_H3A\_VFV\_CFG4[31:16] VTHR2 for FIR 2, and square logic to produce VFV\_n and VFV\_sq\_n.

#### 7.7.3.3.4.6.5.5 RAWFE H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

[Table 7-96](#) lists the bitfields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV\_n
- VFV\_count\_n
- VFV\_sq\_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;
if (aFIRout_n >= threshold_n)
{
    VFV_n = aFIRout_n - threshold_n
    VFV_count_n++;
}
else VFV_n = 0;
VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold\_n is VISS\_RAWFE\_H3A\_VFV\_CFG2[31:16] VTHR1 and VISS\_RAWFE\_H3A\_VFV\_CFG4[31:16] VTHR2, respectively.
- FIRout\_n is the FIRout\_1 and FIRout\_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

#### 7.7.3.3.4.6.6 RAWFE H3A AE/AWB Engine

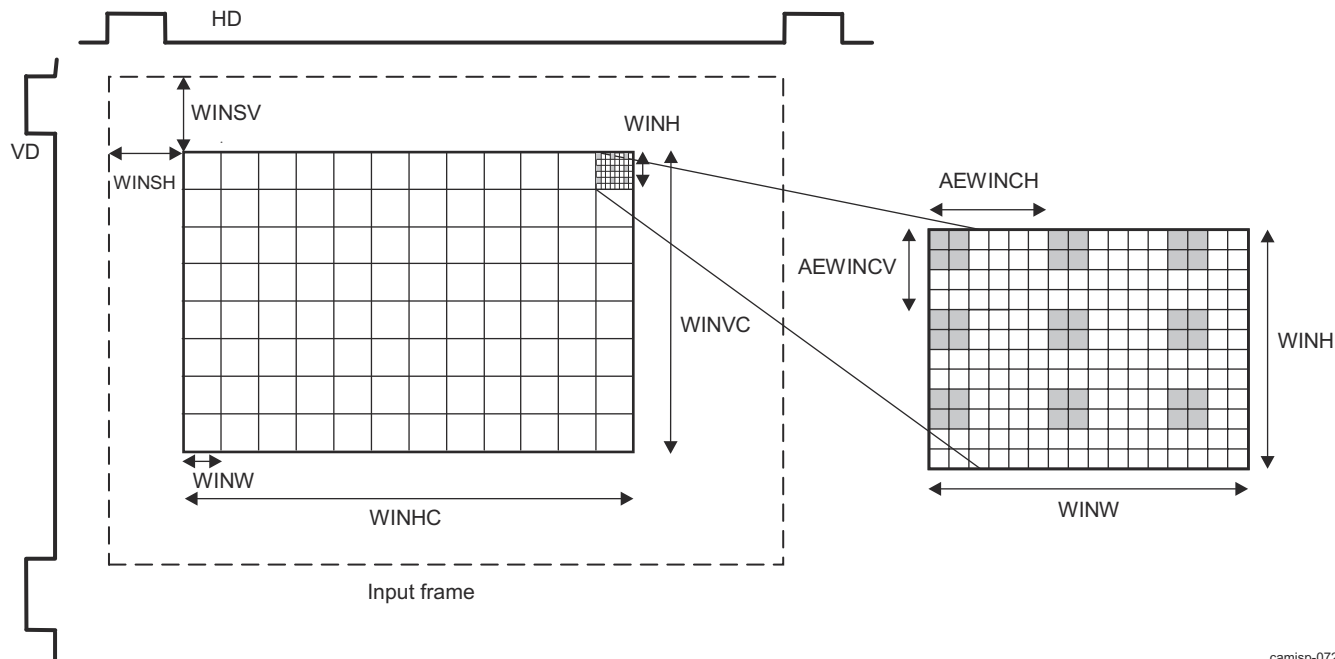

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2 × 2 blocks. For each subsampled 2 × 2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2 × 2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT bit field:

- Sum of square mode: VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT = 0x0
- Min/max mode: VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT = 0x1
- Sum-only mode: VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT = 0x2

#### 7.7.3.3.4.6.1 RAWFE H3A Sub\_sampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in Figure 7-44. Each window is further sampled down to a set of  $2 \times 2$  blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in Figure 7-44.

camisp-072

**Figure 7-44. RAWFE H3A AE/AWB Window Configurations**

Table 7-97 lists the bit fields that configure the window and block sizes, counts, and starting positions.

**Table 7-97. RAWFE H3A AE/AWB Window Register Field Descriptions**

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

#### 7.7.3.3.4.6.2 RAWFE H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the VISS\_RAWFE\_H3A\_AEWINBLK[27:16] WINSV bit field, and the height is specified in the VISS\_RAWFE\_H3A\_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 7-45 shows a black row of windows before rows of windows.

camisp-075

**Figure 7-45. RAWFE H3A Black Row of Windows Before Regular Rows of Windows**

Table 7-98 lists the bit fields that configure the window and block sizes, counts, and starting positions.

**Table 7-98. RAWFE H3A AE/AWB Window With Additional Black Row Register Field Descriptions**

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples
VISS_RAWFE_H3A_AEWINBLK[27:16] WINSV	12	Window start position H for single black line
VISS_RAWFE_H3A_AEWINBLK[6:0] WINH	7	Window height (in lines) for single black line

#### 7.7.3.3.4.6.3 RAWFE H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the VISS\_RAWFE\_H3A\_PCR[31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the  $2 \times 2$  block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

#### 7.7.3.3.4.6.4 RAWFE H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every  $2 \times 2$  pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a  $2 \times 2$  pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the  $2 \times 2$  pixel grid is associated with a color R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See [Section 7.7.3.3.4.6.4](#) for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the VISS\_RAWFE\_H3A\_AEWCFG[3:0] SUMSHFT bit field.

#### 7.7.3.3.4.6.7 RAWFE H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the VISS\_RAWFE\_H3A\_AFBUFST[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the VISS\_RAWFE\_H3A\_AFBUFST[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of pixels or windows. This requires that each horizontal row of pixels or windows starts and ends on a 32-byte boundary. If a horizontal row of pixels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the eighth consecutive window.

[Table 7-99](#) shows the packet formats for AF with vertical AF enabled.

**Table 7-99. RAWFE H3A AF Packet Format With Vertical AF Enabled**

Buffer Start Address (Byte Address)	31	16	15	0

#### 7.7.3.3.4.6.8 RAWFE H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine (ISR) does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the ISR does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and ISR execution.

The VISS\_RAWFE\_H3A\_PCR[15] BUSYAF and/or VISS\_RAWFE\_H3A\_PCR[18] BUSYAEAWB status bits are set when the start of frame occurs (if the VISS\_RAWFE\_H3A\_PCR[0] AF\_EN and/or VISS\_RAWFE\_H3A\_PCR[16] AEW\_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The VISS\_RAWFE\_H3A\_PCR[15] BUSYAF and/or VISS\_RAWFE\_H3A\_PCR[18] BUSYAEAWB status bits may be polled to determine the end of frame status.

#### 7.7.3.3.4.6.9 RAWFE H3A Interface Mux

The H3A logic also implements an LUT or Shift /clip block. The LUT logic is same as the decompanding LUT in the previous section(s) with some minor modifications. The input bit width to the LUT cannot exceed 16 and the LUT entry size is only 10 bits, since the H3A logic works on 10 bit data.

The logic also implements a shift and clipU10 functionality for converting data from up to 24 bits down to 10. The shift parameter has to be programmed to implement the desired shift value. The shift register programming must ensure that the output of the shift is not greater than 16bits when the LUT is enabled and it should not be greater than 10 bits when the LUT is disabled.

#### 7.7.3.3.4.6.10 RAWFE H3A interface to LSE

The H3A interface to LSE is VBUSP. It uses channel id to indicate data or control information. Please refer to LSE functional spec on control information mapping to channel id bits.

#### 7.7.3.3.4.6.11 RAWFE H3A Erratas

The following hardware restrictions apply and need to be taken care of by software:

1. When AF is enabled software can not use the first or last pixels in the window. Start at position 2 end at line -2.
2. When AEW is enabled software can not use the first pixel in a window. Start at position 2.
3.  $(PAXW+1) \% (AFINCH+1) \neq 1$  when VF enabled (PAXW and AFINCH are raw MMR parameters)

### 7.7.3.3.5 RAWFE Programmer's Guide

#### 7.7.3.3.5.1 RAWFE Core programming details

There are multiple use cases that can be enabled with this module, however broadly the use case are broken in to two categories, one for Companded Data sensors and the other for Separate Exposures sensors. The following fields should be programmed correctly for the IP to function

- PWL Core
- Set slopes and thresholds as per sensor settings only for Companded sensors
- Decompanding LUT
- This LUT is used for global tone map of decompounded data from 24 bits to 16 bits. (This is typically not used for separate exposures sensor)

- Merge Logic
- Program the merge block based on the exposure ratios of the incoming data.
- This block is typically not used for companded sensors.
- LUT after merge should be programmed to tone map from 20 bits down to 16 (Separate exposure sensors only)
- DPC/ LSC
- Set as per tuning parameters for both companded/separate exposures sensors
- H3A LUT and settings
- Use LUT if H3A input comes after LSC. Program LUT to apply inverse global curve.
- Use shift if data is coming from exposures directly.

#### 7.7.3.3.5.2 RAWFE Initialization Sequence

See [Section 7.7.2](#), *VPAC Subsystem* for details.

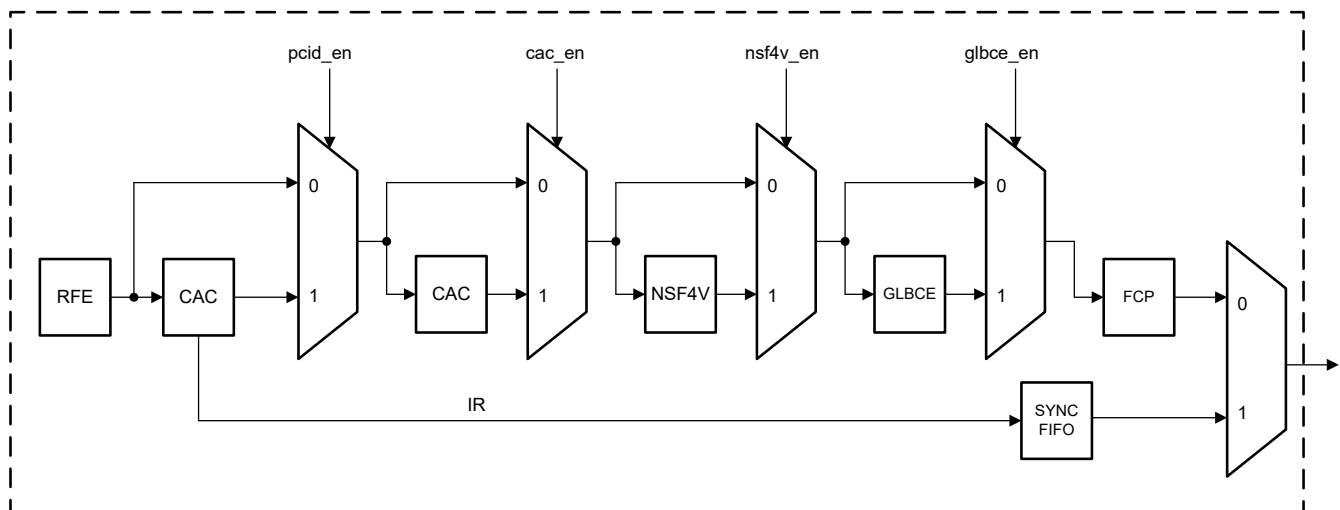

#### 7.7.3.3.5.3 RAWFE Real-time Operating Requirements

See [Section 7.7.2](#), *VPAC Subsystem* for details.

#### 7.7.3.3.6 Pattern Conversion and IR Demosaicing (PCID) Module

##### 7.7.3.3.6.1 Overview and Feature List

The PCID produces both Bayer and IR data concurrently from input RGBIR image. Bayer channel data is fed to rest of the VISS pipe line and IR channel output is directly written to memory using one of LSE channels. VPORT Delay SYNC\_FIFO supports programmable horizontal delay to match the delay with FCP output. [Figure 7-46](#) captures integration of PCID into VISS.

**Figure 7-46. PCID Integration in VISS**

##### 7.7.3.3.6.1.1 PCID Features Supported

- Performs pattern conversion on upto 16bits per pixel 4x4 RGBIR sensor data
  - Generates concurrent Bayer and full resolution IR output
  - Supports choice to interpolate the missing R/B pixel values at IR location to create Bayer output
- Can decontaminate Generated Bayer pattern of the IR signal
  - Supports programmable IR subtraction factor value in range [0, 2) for individual color channels
  - Supports spatial smoothening of the pixel level IR subtraction factors
- Supports 16-bit to upto 16-bit generic Gamma LUT on IR output
- Supports Constant Hue or Color difference method for pattern conversion and IR interpolation

### 7.7.3.3.6.1.2 Functional Operation

The PCID block integrates pattern conversion (re-mosaicing), IR up-sampling and IR subtraction functionality into a single block as illustrated in [Figure 7-27](#). The Pattern conversion and IR up-sampling block performs the task of interpolating missing pixel values, where it uses a two-stage process for re-mosaicing and IR demosaicing.

In the first step, missing green channel information in the input 4x4 RGBIR CFA (at the R, B and IR locations) is interpolated to obtain the green plane to full resolution. In the second step the missing R, B and IR values are interpolated to obtain the re-mosaiced 2x2 Bayer pattern and full resolution IR output. When interpolating the missing pixel values up-sampled green plane acts as a guide for interpolation along the local features such as edges and helps avoid the smoothening. The hardware allows user to choose between constant hue or constant color interpolation schemes along with configurable parameter values that allow precedence for preservation of particular image features during the interpolation process.

The key concerns when subtracting IR signal from the re-mosaiced Bayer pattern are that the level of IR contamination is function of DBF design, the IR contamination of the R, G and B pixels is variable, and subtraction of the IR signal from clipped/saturated pixels can lead to introduction of artifacts. The PCID module can calculate the subtraction factors for every pixel location and used by IR subtraction block for decontamination based on user defined parameters.

### 7.7.3.3.6.1.3 Calculation of pixel level IR subtraction factors

The PCID block enables subtraction of scaled IR signal value from generated 2x2 Bayer CFA pattern as

$$\begin{aligned} R' &= R - X_r * IR \\ G' &= G - X_g * IR \\ B' &= B - X_b * IR \end{aligned}$$

Where IR subtraction scales { $X_r$ ,  $X_g$  or  $X_b$ } used for a pixels are calculated in a two-step process involving the calculation of pixel level IR subtraction factors and optional spatial smoothening of the calculated IR subtraction factors to suppress noise and obtain smooth transitions.

To avoid subtraction of the IR signal from clipped/saturated pixels and in-turn introduction of color artifacts in the created Bayer pattern, HW allows user to define a cut-off value for R, G and B pixels over which the IR subtraction is disabled. Further to have smoother transition of the IR decontamination scales immediately below the cut-off value HW allows programming of the transition range over which the IR subtraction range gradually increases from no IR subtraction at the cut-off threshold to maximum programmed IR subtraction factor. To enable calculation of IR subtraction factor for Bayer output value at IR locations in the input CFA (where no R/G/B value is natively available) HW uses nearest maximum R/G/B pixel value for the location to calculate the IR subtraction factor based on this value especially if it is above cut-off or just below it within the transition range. For this user can configure the influence of the nearest maximum R/G/B pixel as function of the L1 distance with values in range [0,1]. When the maximum R/G/B pixel values in a neighborhood are in ranges close to the cut-off value the HW allows user to spatially smoothen the calculated IR subtraction factors in 5x5 region before performing IR subtraction.

**Figure 7-47. Calculated IR Subtraction Scale**

Figure 7-47 shows the calculated IR subtraction scale values with regard to the maximum neighborhood value as a function of user-defined cut-off threshold (T), transition range TBW and the desired maximum IR subtraction factor for the output Bayer channel.

The PCID block when outputting the interpolated IR image allows user to apply a tone curve on the output to compress the bitdepth from 16bit to 16/12/10/8 bits. The Tone curve can be defined using an IR remap LUT defined using 609 16bit knee points stored in 32bit containers.

### 7.7.3.4 VISS Spatial Noise Filter (NSF4V)

#### 7.7.3.4.1 NSF4V Introduction

##### 7.7.3.4.1.1 NSF4V Features

For a list of features supported by the NSF4V module, see Section *VPAC Features*.

Some additional NSF4V parameters include:

- Input image format: any 2x2 raw color pattern
- Frame Width: limited to 4096
- Throughput:
  - 1 pixel in/out per clock
- Back Pressure Mechanism:
  - Input clock gating
  - Vert line sync
    - 7 extra lines of clocks plus enough clocks to flush pipeline

##### 7.7.3.4.1.2 NSF4V Not Supported Features
