

LMG365xR070 650V 70mΩ GaN FET With Integrated Driver and Protection

1 Features

- 650V 70mΩ GaN power FET with integrated gate driver
 - >200V/ns FET hold-off
 - Adjustable slew rates for optimization of switching performance and EMI mitigation
 - 10V/ns to 100V/ns turn-on slew rates
 - 10V/ns to full speed turn-off slew rates
 - Operates with supply pin and input logic pin voltage range from 9V to 26V
- Robust Protection
 - Cycle-by-cycle overcurrent and latched short-circuit protection with <300ns response
 - Withstands 720V surge while hard-switching
 - Self-protection from internal overtemperature and UVLO monitoring
- 9.8mm × 11.6mm TOLL package with thermal pad

2 Applications

- [Merchant network and server PSU](#)
- [Merchant telecom rectifiers](#)
- Solar inverters and industrial motor drives
- Uninterruptible power supplies

Simplified Block Diagram

3 Description

The LMG365xR070 GaN FET with integrated driver and protection is targeted at switch-mode power converters and enables designers to achieve new levels of power density and efficiency.

Adjustable gate driver strength allows the control of turn-on and maximum turn-off slew rates independently, which can be used to actively control EMI and optimize switching performance. Turn on slew rate can be varied from 10V/ns to 100V/ns, while the turn off slew rate can be limited from 10V/ns to a maximum based on the magnitude of load current. Protection features include under-voltage lockout (UVLO), cycle-by-cycle overcurrent limit, short-circuit and overtemperature protection. The LMG3651R070 provides a 5V LDO output on LDO5V pin that can be used to power external digital isolator. The LMG3656R070 includes the zero-voltage detection (ZVD) feature which provides a pulse output from the ZVD pin when zero-voltage switching is realized. The LMG3657R070 includes the zero-current detection (ZCD) feature that sets the ZCD pin high when the drain-to-source current is negative and transitions to low upon detecting the zero-crossing point.

Package Information

| PART NUMBER | PACKAGE ⁽¹⁾ | PACKAGE SIZE ⁽²⁾ |
|-------------|------------------------|-----------------------------|
| LMG365xR070 | KLA (TOLL, 9) | 9.8mm x 11.6mm |

- (1) For all available packages, see [Section 12](#).
 (2) The package size (length × width) is a nominal value and includes pins, where applicable.

Device Information

| PART NUMBER ⁽¹⁾ | Pin 7 |

6 Specifications

6.1 Absolute Maximum Ratings

Unless otherwise noted: voltages are respect to GND/SRC⁽¹⁾

| | | MIN | MAX | UNIT |
|----------------------------|---|------|--------------------|------|
| V _{DS} | Drain-source voltage, FET off | | 650 | V |
| V _{DS(surge)} | Drain-source voltage, surge condition, FET off | | 720 | V |
| V _{DS(tr)(surge)} | Drain-source transient ringing peak voltage, surge condition, FET off | | 800 | V |
| Pin voltage | VDD | -0.5 | 28 | V |
| | IN | -0.5 | 28 | V |
| | FLT/RDRV | -0.5 | 5.5 | V |
| I _D | Peak drain current, FET on | | TBD | A |
| I _{D(pulse)} | Pulse drain current, FET on, t _p < 10μs. | -34 | Internally Limited | A |
| T _J | Operating junction temperature | -40 | 175 | °C |
| T _{stg} | Storage temperature | -65 | 150 | °C |

- (1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

6.2 ESD Ratings

| | | | VALUE | UNIT |
|--------------------|-------------------------|---|-------|------|
| V _(ESD) | Electrostatic discharge | Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾ | ±2000 | V |
| | | Charged-device model (CDM), per ANSI/ESDA/JEDEC JS-002 ⁽²⁾ | ±500 | |

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

Unless otherwise noted: voltages are respect to GND/SRC

| | | MIN | NOM | MAX | UNIT |
|----------------|---|------|-----|------|------|
| Supply voltage | VDD | 9 | | 26 | V |
| Input voltage | IN | 0 | | 26 | V |
| I _D | Drain current, FET on | | | 10 | A |
| | Positive source current | | | 25 | mA |
| R ₁ | Resistance from external turn-on slew rate control resistor between FLT/RDRV to GND | 29.4 | | open | kΩ |
| R ₂ | Resistance and capacitance from external turn-off slew rate control series resistor and capacitor configuration between FLT/RDRV to GND | 2 | | open | kΩ |
| C ₂ | | 0 | | 680 | pF |

6.4 Thermal Information

| THERMAL METRIC ⁽¹⁾ | | KLA (TOLL) | | UNIT |
|-------------------------------|--|------------|--|------|
| | | 9 PINS | | |
| R _{θJC(bot)} | Junction-to-case (bottom) thermal resistance | 0.73 | | °C/W |

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

6.5 Electrical Characteristics

Unless otherwise noted: voltage, resistance, capacitance, and inductance are respect to GND/SRC; $-40^{\circ}\text{C} \leq T_J \leq 150^{\circ}\text{C}$; VDD = 12V; FLT/RDRV resistances R1 & R2 are open

| $t_{\text{off}(\text{OC})}$ | Overcurrent fault FET turn-off time, FET on before overcurrent | From $I_D \geq I_{T(\text{OC})}$ to $V_{ds} > 10\text{V}$, $di/dt = 100\text{A}/\mu\text{s}$, in the fastest turn-off speed | | 370 | 480 | ns |
| $t_{\text{off}(\text{OC_ON})}$ | Overcurrent total on time, turn-on into overcurrent. | From $V_{ds} \leq 10\text{V}$ to $V_{ds} \geq 10\text{V}$, turning on at 110% of OC level, at 100 V/ns turn-on slew rate and fastest turn-off speed. | | 420 | 580 | ns |
| $t_{\text{off_cur}(\text{SC_ON})}$ | SC on time measured through drain current | From LS $I_{ds} > 50\text{A}$ to $I_{ds} < 50\text{A}$, at 100 V/ns turn-on slew rate in a half-bridge configuration. | 100 | | 500 | ns |
| $t_{\text{off_cur}(\text{SC})}$ | SC response time with source current measurement | From LS $V_{ds} > 9\text{V}$ to LS $I_{ds} < 50\text{A}$, at 100 V/ns turn-on slew rate in a half-bridge configuration. . | | | 300 | ns |
| | Latched-Fault reset time | Time required to hold both gate driver input low to clear latched-fault | 300 | 380 | 450 | μs |
| ZCD/ZVD | | | | | | |
| | ZCD delay | Current crossing zero (low to high) to ZCD output pulse $di/dt = 0.03\text{A}/\text{ns}$ | 12 | 25 | 50 | ns |
| | ZVD delay | In rising to ZVD output pulse. 100V/ns turn-on speed. | 13 | 20 | 50 | ns |
| t_{WD_ZVD} | ZVD pulse width | $V_{bus} = 10\text{V}$, $I_L = 5\text{A}$, measure ZVD pulse width | 90 | 120 | 170 | ns |

6.6 Switching Characteristics (continued)

Unless otherwise noted: voltage, resistance, capacitance, and inductance are respect to GND/SRC; $-40^{\circ}\text{C} \leq T_J \leq 150^{\circ}\text{C}$; $V_{DD} = 12\text{V}$; $\overline{\text{FLT}}/\text{RDRV}$ resistances R1 & R2 are open

| PARAMETER | | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|-----------|------------------|--|-----|-----|-----|------|
| | ZVD sensing time | Sensing time to fet turn on (100V/ns). IL=2A | | 11 | 25 | ns |

ADVANCE INFORMATION

7 Parameter Measurement Information

7.1 Switching Parameters

Figure 7-1 shows the circuit used to measure most switching parameters. The top device in this circuit is used to re-circulate the inductor current and functions in third-quadrant mode only. The bottom device is the active device that turns on to increase the inductor current to the desired test current. The bottom device is then turned off and on to create switching waveforms at a specific inductor current. Both the drain current (at the source) and the drain-source voltage is measured. Figure 7-2 shows the specific timing measurement. TI recommends to use the half-bridge as a double pulse tester. Excessive third-quadrant operation can overheat the top device.

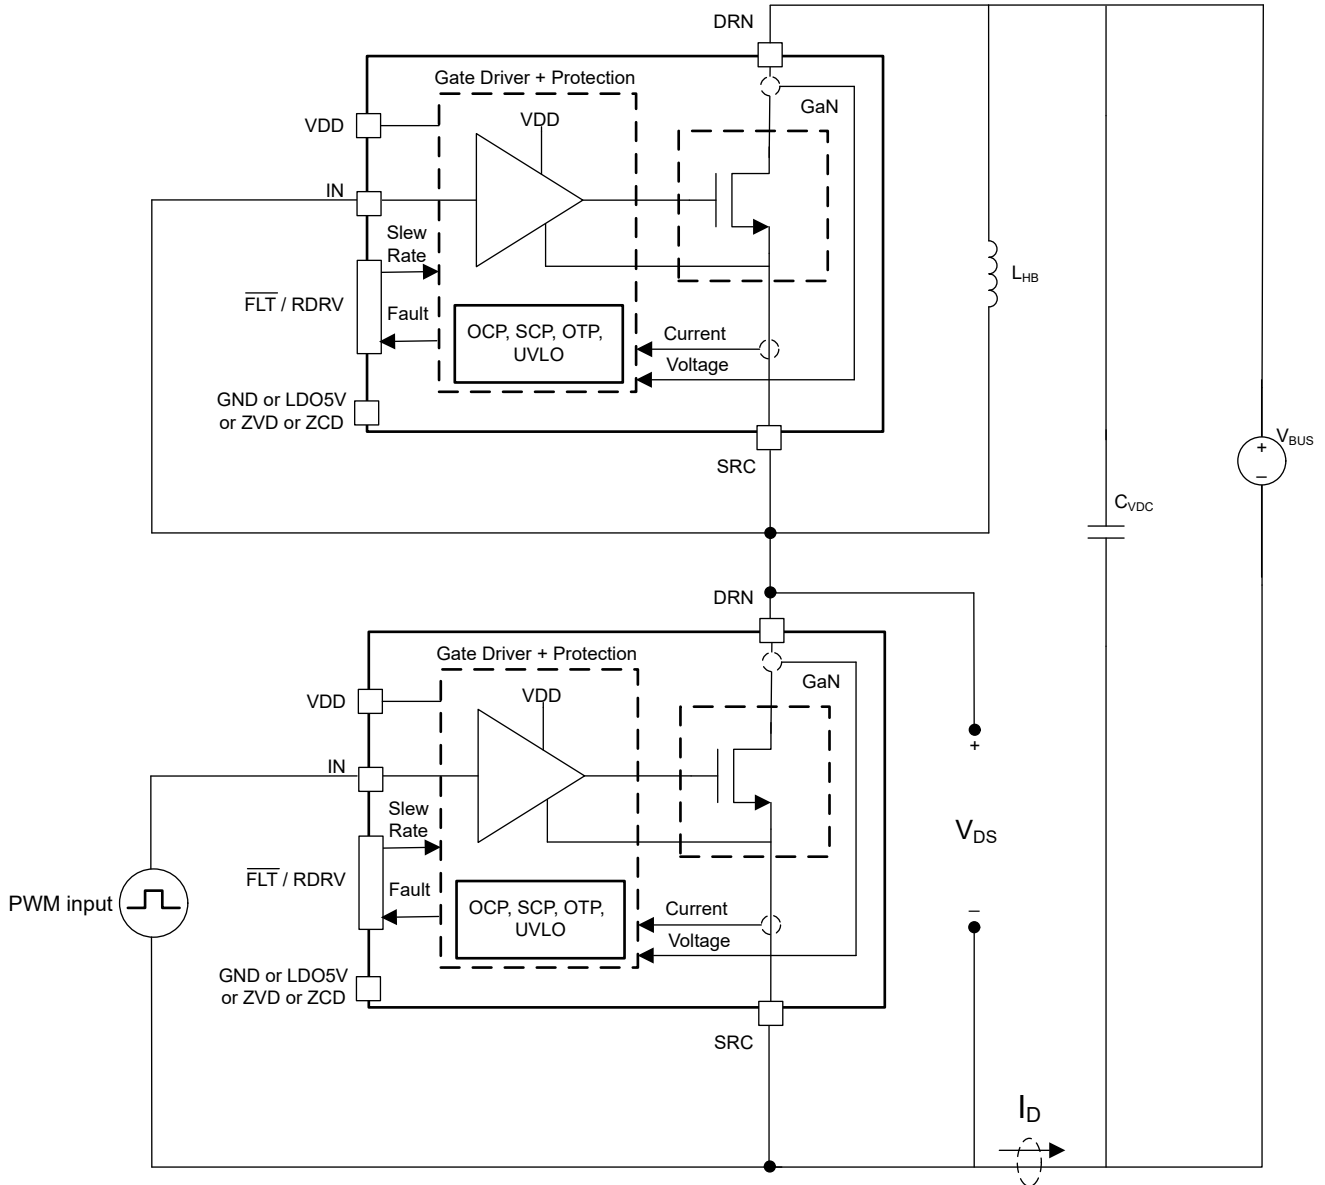

Figure 7-1. Circuit Used to Determine Switching Parameters

ADVANCE INFORMATION

Figure 7-2. Measurement to Determine Propagation Delays and Slew Rates

7.1.1 Turn-On Times

The turn-on transition has two timing components: turn-on delay time, and turn-on voltage fall time. The turn-on delay time is from when IN goes high to when the drain-source voltage falls 20% below the bus voltage. The turn-on voltage fall time is from when drain-source voltage falls 20% below the bus voltage to when the drain-source voltage falls 80% below the bus voltage. Note that the turn-on timing components are a function of the turn-on drive strength resistance RDRV_on connected to the $\overline{\text{FLT}}$ /RDRV pin.

7.1.2 Turn-Off Times

The turn-off transition has two timing components: turn-off delay time, and turn-off voltage rise time. The turn-off delay time is from when IN goes low to when the drain-source voltage rises to 20% of the bus voltage. The turn-off voltage rise time is from when the drain-source voltage rises from 20% of the bus voltage to when the drain-source voltage to 80% of the bus voltage. Note that the turn-off timing components are dependent on the L_{HB} load current, however LMG365xR070 also features the ability to limit turn-off drive strength. When the drain-to-source current is sufficiently high and the turn-off drive strength is limited, the timing components become dependent on the programming resistors RDRV_on, RDRV_off, and capacitance CDRV_off connected to the $\overline{\text{FLT}}$ /RDRV pin.

7.1.3 Drain-Source Turn-On and Turn-off Slew Rate

The drain-source turn-on and turn-off slew rate is measured on V_{DS} around the midpoint of the bus voltage, with units in volts per nanosecond. The resistors RDRV_on, RDRV_off, and capacitance CDRV_off connected to the $\overline{\text{FLT}}$ /RDRV pin is used to program the turn-on slew rate and limit the turn-off slew rate.

7.1.4 Zero-Voltage Detection Times (LMG3656R070 only)

Figure 7-3 defines the switching timings related to the zero-voltage detection (ZVD) block, and the device's drain-to-source voltage, IN pin signal, and ZVD output signals are demonstrated. When the device achieves zero-voltage switching (ZVS), the ZVD pin outputs a pulse-signal with width $T_{\text{WD_ZVD}}$, and the delay time in between IN pin's rising edge and ZVD pulse's rising edge is defined as $T_{\text{DL_ZVD}}$. A certain third quadrant conduction time is required to allow the device detecting a zero-voltage switching, and $T_{\text{3rd_ZVD}}$ indicates this timing. See the Section 8.3.8 section for more information about the ZVD timing parameters.

Figure 7-3. ZVD Timing Specifications

8 Detailed Description

8.1 Overview

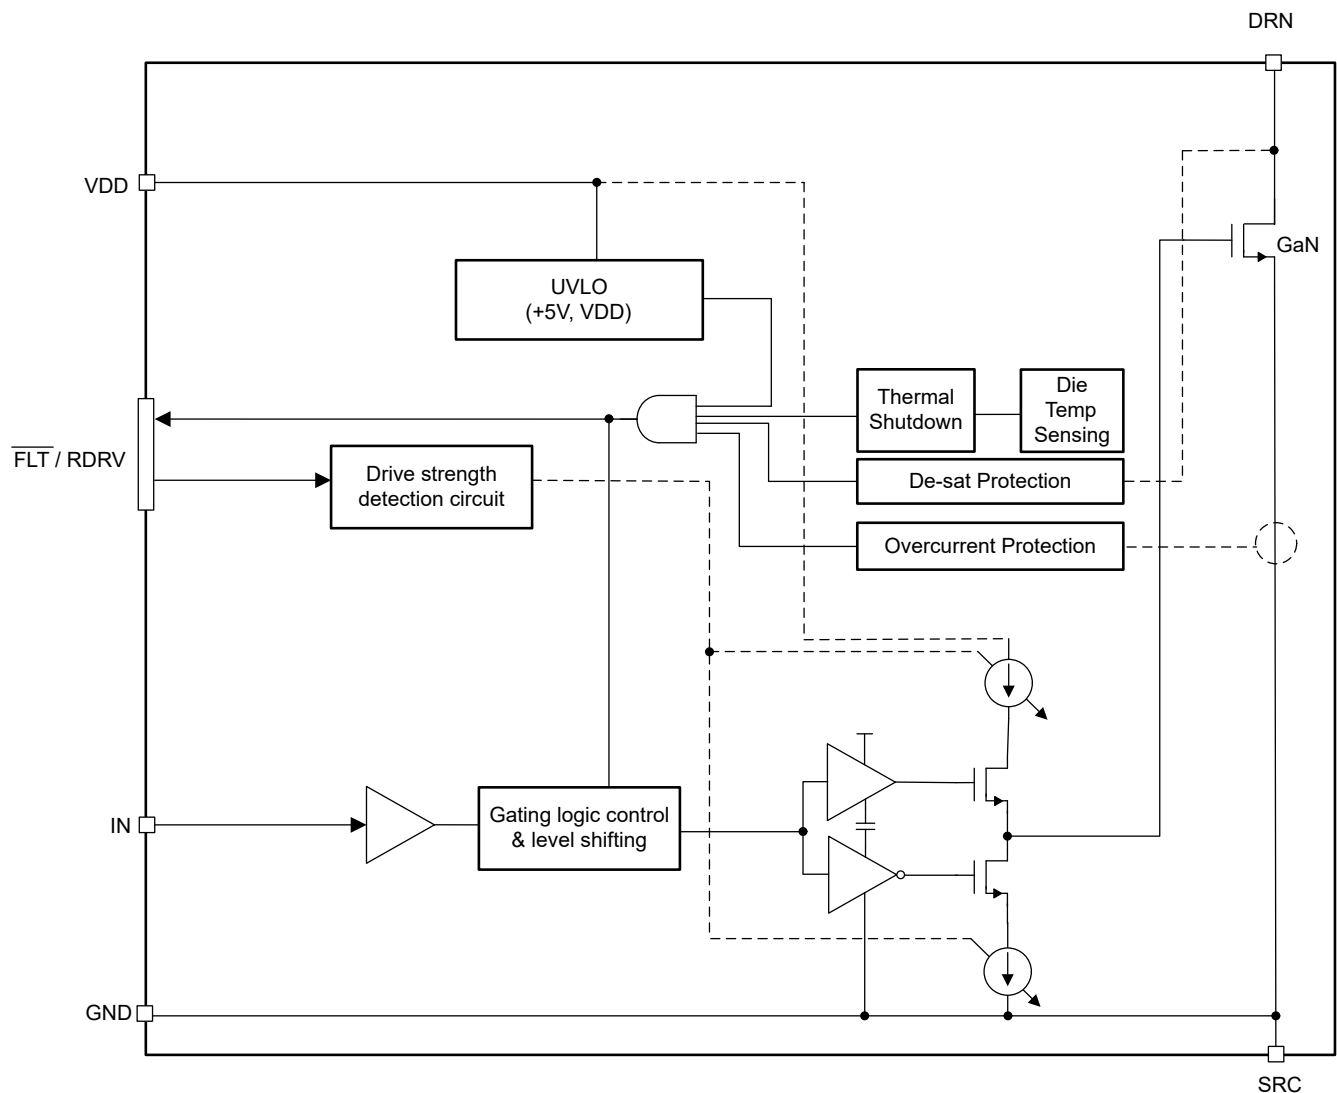

The LMG365xR070 is a high-performance power GaN device with integrated gate driver. The GaN device offers zero reverse recovery and ultra-low output capacitance, which enables high efficiency in bridge-based topologies.

The integrated driver ensures the device stays off for high drain slew rates. The integrated driver protects the GaN device from overcurrent, short-circuit, overtemperature, VDD undervoltage, and a high-impedance RDRV pin.

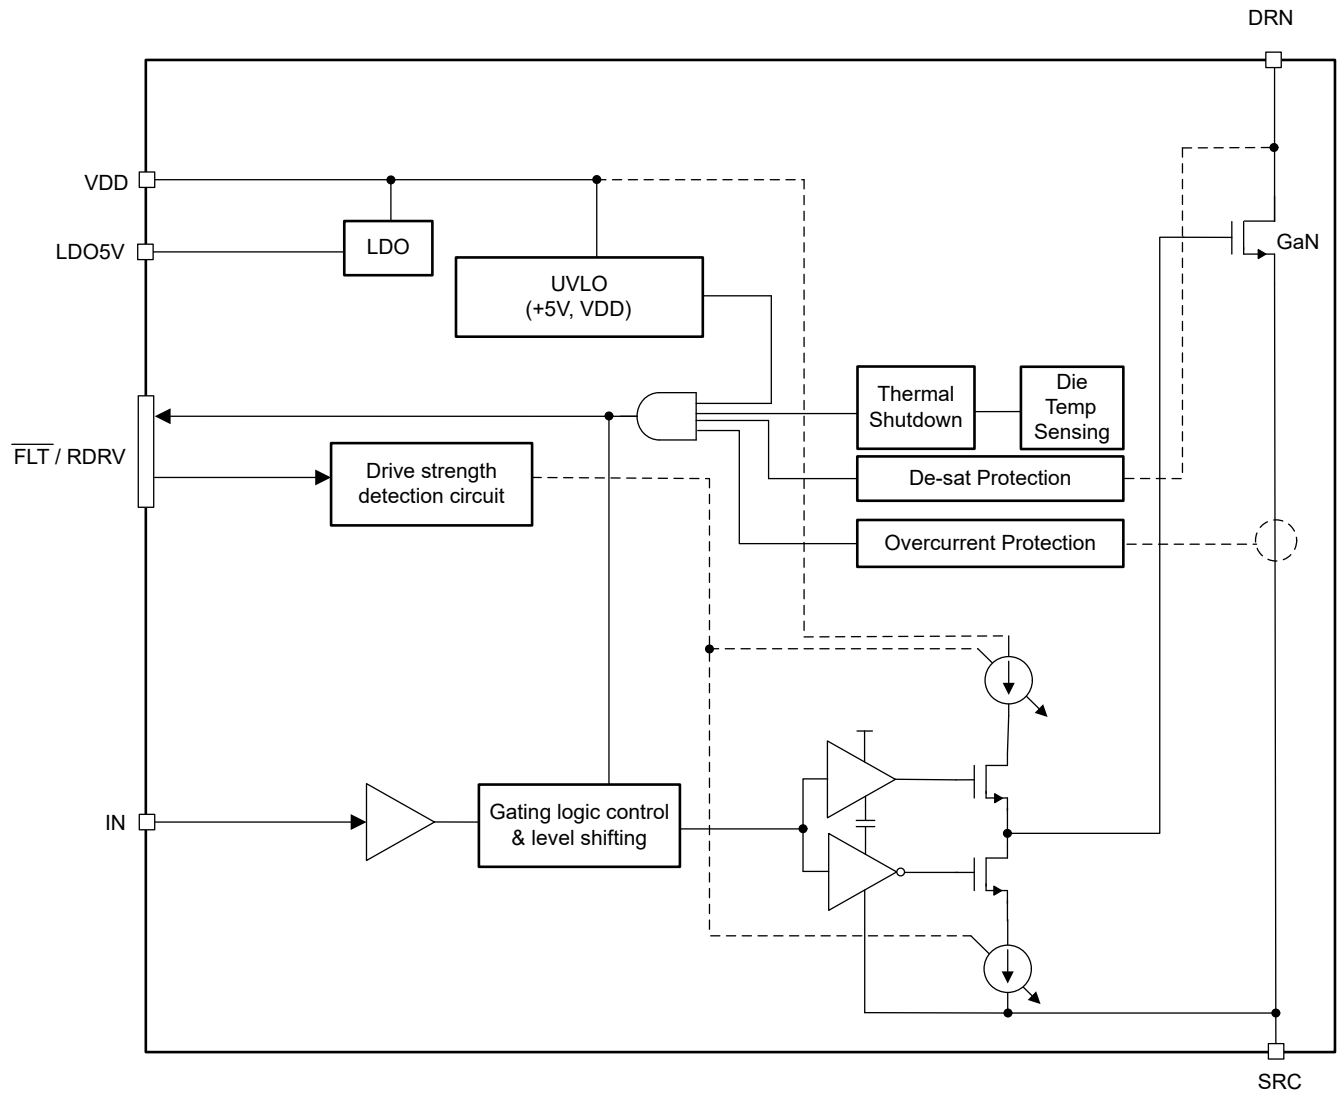

Unlike Si MOSFETs, GaN devices do not have a p-n junction from source to drain and thus have no reverse recovery charge. However, GaN devices still conduct from source to drain similar to a p-n junction body diode, but with higher voltage drop and higher conduction loss. Therefore, source-to-drain conduction time must be minimized while the LMG365xR070 GaN FET is turned off.

8.3 Feature Description

8.3.1 Drive Strength Adjustment

The LMG365xR070 allows users to adjust the drive strength of the device and obtain a desired slew rate, which provides flexibility when optimizing switching losses and minimizing EMI. The typical value of turn-on slew rate and the maximum value of turn-off slew rate can be independently controlled by connecting the resistors and capacitor as shown in the [Figure 8-1](#). The resistance and capacitance on $\overline{\text{FLT}}/\text{RDRV}$ pin is sensed once at power-up. To do so, the device forces a step-function from 0V to 1.2V on the external R1-R2-C2 network and measures the resulting current waveform. The DC measurement determines the turn-on slew rate setting, which is programmed by the resistance R1. The AC measurement dependent on R1-R2-C2 determines the turn-off slew rate setting, which is dependent on the magnitude of the drain-to-source current charging the output capacitance but can be limited to a maximum value programmed by the resistance R2 and capacitance C2, connected in parallel to R1. [Table 8-1](#) shows the recommended typical resistances and capacitance programming values at each slew rate setting.

The slew rate settings are determined one time at power up, then the $\overline{\text{FLT}}/\text{RDRV}$ pin is used as a push-pull 5V digital output for fault monitoring, as described in [Fault Reporting](#). If R2 and C2 are not used, the device turns-off at full-speed and the turn-off slew rate is strictly determined by the C_{oss} and the load current. If R1 is not used,

the device defaults to the 100V/ns slew rate setting. Using slower turn-on settings results in higher Eon losses, and slower turn-off settings results in higher Eoff losses.

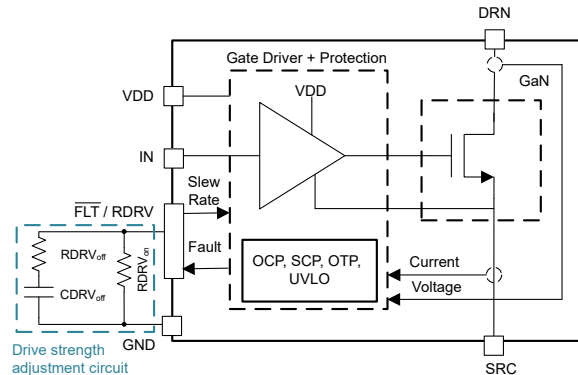

Figure 8-1. Drive Strength Adjustment Circuit

Table 8-1. Recommended Typical Programming Resistance (kΩ) and Capacitance (pF) for Adjusting Slew Rates

| TYPICAL TURN-ON SLEW RATE (V/ns) | MAXIMUM TURN-OFF SLEW RATE (V/ns) | | | | | | | | |
|----------------------------------|-----------------------------------|----|-----|------|-----|------|-----|-------------------------------|----|
| | R1 | 10 | | 20 | | 40 | | No limit ⁽¹⁾ | |
| | R1 | R2 | C2 | R2 | C2 | R2 | C2 | R2 | C2 |
| 10 | 29.4 | 2 | 680 | 4.87 | 270 | 9.09 | 150 | high impedance ⁽²⁾ | |
| 20 | 35.7 | 2 | 680 | 4.75 | 270 | 8.66 | 150 | | |
| 40 | 43.2 | 2 | 680 | 4.64 | 270 | 8.25 | 150 | | |
| 60 | 53.6 | 2 | 680 | 4.64 | 270 | 8.06 | 150 | | |
| 80 | 69.8 | 2 | 680 | 4.53 | 270 | 7.68 | 150 | | |
| 100 | > 400 ⁽²⁾ | 2 | 680 | 4.22 | 270 | 6.98 | 180 | | |

(1) Fully dependent on the magnitude of the drain-to-source current charging the output capacitance

(2) Open-circuit connection for programming resistances is acceptable

For example, setting R1 = 53.6kΩ, R2 = 4.64kΩ and C2 = 270pF results in turn-on slew rate of 60V/ns and turn-off slew rate is limited to a maximum of 20V/ns.

8.3.2 VDD Supply

VDD is the input supply for the internal circuits. Wide voltage ranges from 9V to 26V are supported on VDD pin.

8.3.3 Overcurrent and Short-Circuit Protection

There are two types of current faults which can be detected by the driver: overcurrent fault and short-circuit fault.

The overcurrent protection (OCP) circuit monitors drain current and compares that current signal with an internally set limit $I_{T(OC)}$. Upon detection of the overcurrent, the LMG365xR070 performs cycle-by-cycle protection as shown in Figure 8-2. In this mode, the GaN device is shut off when the drain current crosses the $I_{T(OC)}$ plus a delay $t_{off(OC)}$, but the overcurrent signal clears after the IN pin signal goes low. In the next cycle, the GaN device can turn on as normal. The cycle-by-cycle function can be used in cases where steady-state operation current is below the OCP level but transient response can still reach current limit, while the circuit operation cannot be paused. The cycle-by-cycle function also prevents the GaN device from overheating by overcurrent induced conduction losses.

The short-circuit protection is based on desaturation (de-sat) detection, which monitors the drain-source voltage V_{DS} and compares the voltage with an internally set limit $V_{T(Idsat)}$. If the OC occurs before the de-sat, the V_{DS} is below the threshold, then OC is triggered, else de-sat is triggered as shown in Figure 8-3. Saturation can be damaging for the GaN to continue to operate in that condition. Therefore, if a de-sat is detected, the GaN device is turned off with an intentionally slowed driver so that a lower overshoot voltage and ringing can be achieved

during the turn-off event. This fast response circuit helps protect the GaN device even under a hard short-circuit condition. In this protection, the GaN device is shut off and held off until the fault is reset by either holding the IN pin low for a period of time defined in the [Specifications](#) or removing power from VDD.

For safety considerations, OCP allows cycle-by-cycle operation while de-sat latches the device until reset. Both faults are reported on the $\overline{\text{FLT/RDRV}}$ pin.

Figure 8-2. Cycle-by-Cycle Overcurrent Protection Operation

Figure 8-3. Overcurrent Detection vs Desaturation Detection

8.3.4 Overtemperature Protection

The overtemperature protection holds off the GaN power FET if the LMG365xR070 temperature is above the overtemperature protection threshold. The overtemperature protection hysteresis avoids erratic thermal cycling.

An overtemperature fault is reported on the $\overline{\text{FLT}}/\text{RDRV}$ pin when the overtemperature protection is asserted. $\overline{\text{FLT}}/\text{RDRV}$ de-asserts and the device automatically returns to normal operation after the device temperature fall below the negative-going trip point.

8.3.5 UVLO Protection

The LMG365xR070 supports a wide range of V_{DD} voltages. However, when the V_{DD} voltage is below V_{DD} UVLO threshold, the GaN device stops switching and is held off. The V_{DD} UVLO voltage hysteresis prevents on-off chatter near the UVLO voltage trip point. The $\overline{\text{FLT}}/\text{RDRV}$ pin is pulled low as an indication of UVLO.

8.3.6 Fault Reporting

All faults are reported on the $\overline{\text{FLT}}/\text{RDRV}$ pin, which serves as both an input and output pin.

The $\overline{\text{FLT}}/\text{RDRV}$ is configured as an input only at the time of powerup to adjust the drive-strength, as described in [Drive Strength Adjustment](#).

The $\overline{\text{FLT}}/\text{RDRV}$ then used as an active low digital output, indicating the fault status thereafter. The pin is a push-pull 5V digital output which goes high when all faults have cleared, which means that there is additional quiescent current through R1 when the pin is forced high.

Depending on the input threshold levels for the external digital receiver connected to the fault pin, the 1.2V which is forced on this pin at power-up could be interpolated as either high or low. For this reason, it is recommended that the receiver has higher thresholds such as those common for CMOS-compatible inputs and not use TTL compatible inputs. If the input thresholds are lower, the 1.2V at power-up can be interpreted as a "high" and therefore showing that the device is not faulted when still powering up.

8.3.7 Auxiliary LDO (LMG3651R070 Only)

There is a 5V voltage regulator inside the part used to supply external loads, such as digital isolators for the high-side drive signal. The digital outputs of the part use this rail as their supply. No capacitor is required for stability, but transient response is poor if no external capacitor is provided. If the application uses this rail to supply external circuits, TI recommends to have a capacitor of at least 0.1 μF for improved transient response. A larger capacitor can be used for further transient response improvement. The decoupling capacitor used here must be a low-ESR ceramic type. Capacitances above 0.47 μF will slow down the start-up time of the LMG365xR070 due to the ramp-up time of the 5V rail.

8.3.8 Zero-Voltage Detection (ZVD) (LMG3656R070 Only)

The zero-voltage switching (ZVS) converters are widely used to improve the power converter's efficiency. However, in those soft-switching topologies like LLC and triangular current mode (TCM) totem pole PFC, the device can lose ZVS depending on the load condition, inductor, magnetic parameters and control techniques, which affects the system efficiency. To insure ZVS, certain design margins or additional circuits are needed which sacrifices the converter performance and adds components.

To simplify the system design for soft-switching converters, LMG3656R070 part integrates a zero-voltage detection (ZVD) circuit that provides a digital feedback signal to indicate if the device has achieved ZVS in the current switching cycle. The circuit diagram is shown in Figure 8-4. When the IN pin signal goes high, the logic circuit checks if the device V_{DS} has reached below 0V to determine whether the device has achieved zero voltage switching in this switching cycle. Once a ZVS is identified, a pulse-output with a width of T_{WD_ZVD} will be sent out from the ZVD pin after a delay time of T_{DL_ZVD} as indicated in Figure 7-3. Note a certain third quadrant conduction time is required to allow the device detecting a zero-voltage switching, and T_{3rd_ZVD} is a function of the gate driver strength.

Figure 8-4. Circuit Diagram for Zero-Voltage Detection Circuit Block Diagram

The timings of the ZVD output corresponding to a continuous conduction mode Buck converter is shown in Figure 8-5, and the purpose is to demonstrate how ZVD function works in both hard-switching and soft-switching conditions. The load current going out of the switch node is defined as positive. In CCM buck operation, the high-side the hard-switching device while the low-side device can achieve zero-voltage switching with a proper dead-time settings. In the first switching cycle when low-side GaN IN pin rises, the switch-node voltage V_{DS} has dropped below zero and stays in third quadrant conduction for a period of T_1 . Since this third quadrant conduction time T_1 is larger than the detection time T_{3rd_ZVD} specified in electrical characteristic table, a zero-voltage switching is identified and the ZVD pin outputs a pulse signal to indicate that, and the pulse width of the ZVD pulse is also defined in the electrical characteristic table as T_{WD} . In the second switching cycle, the device is turned on earlier, and the third quadrant conduction time T_2 is less than T_{3rd_ZVD} . In this case, the ZVD signal stays low though the device has achieved ZVS. In the third switching cycle, the IN pin signal is advanced even earlier, and the device is in partial hard-switching. Accordingly, the ZVD output stays low in this case. Note the high side ZVD output stays low in this CCM buck operation as it always has hard-switching.

Figure 8-5. ZVD Function in a CCM Buck Converter

The ZVD function can facilitate the control in soft-switching topology, to illustrate it, the ZVD waveforms in a TCM totem pole PFC is shown in [Figure 8-6](#). In this diagram, the positive cycle is considered with $V_{IN} > 0.5 V_{OUT}$, and the load current going into the switch node is defined as positive. In the first switching cycle, the load current builds enough negative current, and the low-side device achieves ZVS with a clear third quadrant conduction time beyond T_{3rd_DET} . Therefore, the ZVD outputs a pulse signal and provide the ZVS information back. The ZVD pulses are missing in the next two switching cycles because the third quadrant conduction time becomes shorter in second cycle and the device actual loses ZVS in the third cycle.

Figure 8-6. ZVD Function in a TCM TP PFC Converter

8.3.9 Zero-Current Detection (ZCD) (LMG3657R070 Only)

GaN FET is usually used for high frequency soft-switching and the detection of FET current zero-crossing is needed for system control. LMG3657R070 integrates a zero current detection (ZCD) circuit that provides a digital feedback signal to indicate the when the drain-to-source current is positive. When the IN pin signal goes high, the ZCD circuit includes a blanking time t_{ZCD_Blank} , to prevent nuisance ZCD triggering during the turn-on transient. Following the blanking period, the ZCD circuit monitors the drain-to-source current. If the current is negative, a pulse-output with a width of t_{WD_ZVD} is set on the ZCD pin after detecting the zero-crossing point, with a delay time of t_{zc_Det} . If the current is positive, the pulse output is set on the ZCD pin immediately, as indicated in the timing diagrams below.

Figure 8-7. ZCD Timing Diagram When FET Turns ON Into Negative Current

Figure 8-8. ZCD Timing Diagram When FET Turns ON Into Positive Current

8.4 Device Functional Modes

The device has one mode of operation that applies when operated within the Recommended Operating Conditions.

9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

9.1 Application Information

The LMG365xR070 is a power IC targeting hard-switching and soft-switching applications operating up to 480V bus voltages. GaN devices offer zero reverse-recovery charge enabling high-frequency, hard-switching in applications like the totem-pole PFC. Low Q_{oss} of GaN devices also benefits soft-switching converters, such as the LLC and phase-shifted full-bridge configurations. As half-bridge configurations are the foundation of the two mentioned applications and many others, this section describes how to use the LMG365xR070 in a half-bridge configuration.

ADVANCE INFORMATION

9.2.1 Design Requirements

This design example is for a hard-switched boost converter which is representative of PFC applications. [Design Parameters](#) shows the system parameters for this design.

Table 9-1. Design Parameters

| PARAMETER | VALUE |
|--------------------------|--------|
| Input voltage | 200VDC |
| Output voltage | 400VDC |
| Input (inductor) current | 20A |
| Switching frequency | 100kHz |

9.2.2 Detailed Design Procedure

In high-voltage power converters, circuit design and PCB layout are essential for high-performance power converters. As designing a power converter is out of the scope of this document, this data sheet describes how to build well-behaved half-bridge configurations with the LMG365xR070.

9.2.2.1 Slew Rate Selection

The slew rate of LMG365xR070 can be adjusted between approximately 10 V/ns and 100V/ns by connecting drive strength adjustment circuit. Refer to [Drive Strength Adjustment](#) for the details.

The slew rate affects GaN device performance in terms of:

- Switching loss
- Voltage overshoot
- Noise coupling
- EMI emission

Generally, high slew rates provide low switching loss, but high slew rates can also create higher voltage overshoot, noise coupling, and EMI emissions. Following the design recommendations in this data sheet helps mitigate the challenges caused by a high slew rate. The LMG365xR070 offers circuit designers the flexibility to select the proper slew rate for the best performance of their applications.

9.2.2.2 Signal Level-Shifting

In half-bridges, high-voltage level shifters or digital isolators must be used to provide isolation for signal paths between the high-side device and control circuit. Using an isolator is optional for the low-side device. However, using an isolator equalizes the propagation delays between the high-side and low-side signal paths, and provides the ability to use different grounds for the GaN device and the controller. If an isolator is not used on the low-side device, the control ground and the power ground must be connected at the device and nowhere else on the board. For more information, see [Layout Guidelines](#). With fast-switching devices, common ground inductance can easily cause noise issues without the use of an isolator.

Choosing a digital isolator for level-shifting is important for improvement of noise immunity. As GaN device can easily create high dv/dt , $> 50V/ns$, in hard-switching applications, TI highly recommends to use isolators with high common-mode transient immunity (CMTI) and low barrier capacitance. Isolators with low CMTI can easily generate false signals, which could cause shoot-through. The barrier capacitance is part of the isolation capacitance between the signal ground and power ground, which is in direct proportion to the common mode current and EMI emission generated during the switching. Additionally, TI strongly encourages to select isolators which are not edge-triggered. In an edge-triggered isolator, a high dv/dt event can cause the isolator to flip states and cause circuit malfunction.

Generally, ON/OFF keyed isolators with default output low are preferred. Default low state ensures the system will not shoot-through when starting up or recovering from fault events. As a high CMTI event would only cause a very short (a few nanoseconds) false pulse, TI recommends a low pass filter, like 300Ω and 22pF R-C filter, to be placed at the driver input to filter out these false pulses.

9.3 Power Supply Recommendations

The LMG365xR070 only requires an unregulated VDD power supply from 9V to 26V. The low-side supply can be obtained from the local controller supply. The supply of the high-side device must come from an isolated supply or a bootstrap supply.

9.3.1 Using an Isolated Power Supply

Using an isolated power supply to power the high-side device has the advantage that it works regardless of continued power-stage switching or duty cycle. Using an isolated power supply can also power the high-side device before power-stage switching begins for a smooth start-up.

The isolated supply can be obtained with a push-pull converter, a flyback converter, a FlyBuck™ converter, or an isolated power module. When using an unregulated supply, the input of LMG365xR070 must not exceed the maximum supply voltage. A 26V TVS diode can be used to clamp the VDD voltage of LMG365xR070 for additional protection. Minimizing the inter-winding capacitance of the isolated power supply or transformer is necessary to reduce switching loss in hard-switched applications. Furthermore, capacitance across the isolated bias supply inject high currents into the signal-ground of the LMG365xR070 and can cause problematic ground-bounce transients. A common-mode choke can alleviate most of these issues.

9.3.2 Using a Bootstrap Diode

In half-bridge configuration, a floating supply is necessary for the high-side device. To obtain the best performance of LMG365xR070, TI highly recommends [Using an Isolated Power Supply](#). A bootstrap supply can be used with the recommendations of this section.

9.3.2.1 Diode Selection

The LMG365xR070 offers no reverse-recovery charge and very limited output charge. Hard-switching circuits using the LMG365xR070 also exhibit high voltage slew rates. A compatible bootstrap diode must not introduce high output charge and reverse-recovery charge.

A silicon carbide diode, like the GB01SLT06-214, can be used to avoid reverse-recovery effects. The SiC diode has an output charge of 3nC. Although there is additional loss from its output charge, it does not dominate the losses of the switching stage.

9.3.2.2 Managing the Bootstrap Voltage

In a synchronous buck or other converter where the low-side switch occasionally operates in third-quadrant, the bootstrap supply charges through a path that includes the third-quadrant voltage drop of the low-side LMG365xR070 during the dead time as shown in [Charging Path for Bootstrap Diode](#). This third-quadrant drop can be large, which can overcharge the bootstrap supply in certain conditions. The V_{DD} supply of LMG365xR070 must be kept below 28V.

Figure 9-7. Charging Path for Bootstrap Diode

As shown in [Suggested Bootstrap Regulation Circuit](#), the recommended bootstrap supply includes a bootstrap diode, a series resistor, and a 26V TVS or Zener diode in parallel with the V_{DD} bypass capacitor to prevent damaging the high-side LMG365xR070. The series resistor limits the charging current at start-up and when the low-side device is operating in third-quadrant mode. This resistor must be selected to allow sufficient current to power the LMG365xR070 at the desired operating frequency. At 100kHz operation, TI recommends a value of approximately 2Ω . At higher frequencies, this resistor value must be reduced or the resistor omitted entirely to ensure sufficient supply current.

Figure 9-8. Suggested Bootstrap Regulation Circuit

9.4 Layout

9.4.1 Layout Guidelines

The layout of the LMG365xR070 is critical to its performance and functionality. Because the half-bridge configuration is typically used with these GaN devices, layout recommendations are considered with this configuration. A four-layer or higher layer count board is required to reduce the parasitic inductances of the layout to achieve suitable performance. Critical layout guidelines are summarized below, and more details are further elaborated in the following sections.

10 Device and Documentation Support

TI offers an extensive line of development tools. Tools and software to evaluate the performance of the device, generate code, and develop solutions are listed below.

10.1 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

10.2 Support Resources

TI E2E™ [support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

10.3 Trademarks

FlyBuck™ and TI E2E™ are trademarks of Texas Instruments. All trademarks are the property of their respective owners.

10.4 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

10.5 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

11 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer:The information provided on this page represents TI's knowledge and belief as of the date that it is provided.
