

Design Goals

Input	Output		Supply		
VI	Vo	l _{out}	V _{cc}	V _{eemax}	V _{eemin}
-5.5V < V _{ee} < -4.5V	-3V	600mA	0V	-4.5V	-5.5V

Design Description

This design accurately steps down a voltage level and holds it stable at a fixed output voltage (low dropout regulator). The regulator takes a -4.5V to -5.5V input voltage and steps it down to a -3V rail that supplies current up to 600mA.

1

Design Notes

- Use the op amp in a linear operating region. Verify that the inputs of the op amp do not exceed the common-mode range of the device. Linear output swing is usually specified under the A_{OL} test conditions.
- 2. The common-mode voltage is equal to the inverting input voltage, set by the TLV431 reference of -1.24V.
- 3. Using a high-gain BJT reduces the output current requirement for the op amp.
- 4. The majority of the power loss is $|V_{ee} V_{out}| \times I_{out}$ and is dissipated in transistor T₁. A larger V_{ee} increases power loss and the temperature of T₁.
- 5. Other op amps can be used in place of the TLV9002, but can require adjustment of the feedback stabilization.
- 6. Positive feedback to the amplifier is used, because an inversion is performed by T₁.

Design Steps

The transfer function of the circuit is:

$$V_{out} = -1.24\text{V} \times \frac{R_1 + R_2}{R_2}$$

1. Based on the desired output voltage, in this case -3V, select a ratio of R_1 and R_2 that satisfies the above equation.

$$-3V = -1.24V \times \frac{R_1 + R_2}{R_2}$$
$$1.419 \times R_2 = R_1$$

Selecting standard resistors, select $1.02k\Omega$ and 715Ω .

2. For sizing the output capacitance, the product of C₂ and R_{esr} must generate a zero below 10kHz to verify stability. The ESR zero is located at:

$$F_{z(ESR)} = \frac{1}{2\pi R_{esr} C_2} = \frac{1}{2\pi (1\Omega) (47 \times 10^{-6} F)} = 3.38 \text{kHz}$$
